If `syntax = NULL` (the default) then the available syntax objects are consulted in turn, and selected if their extension component matches (as a regexp) the file name. Objects `SweaveSyntaxNoweb` (with `extension = "[rsRS]nw$"`) and `SweaveSyntaxLatex` (with `extension = "[rsRS]tex$"`) are supplied, but users or packages can supply others with names matching the pattern `SweaveSyntax.*`.

Further Sweave drivers are in, for example, packages **R2HTML**, **ascii**, **odfWeave** (archived) and **pgfSweave** (archived).

Non-Sweave vignettes may be built with `tools::buildVignette`.

### Examples

```
testfile <- system.file("Sweave", "Sweave-test-1.Rnw", package = "utils")

## enforce par(ask = FALSE)
options(device.ask.default = FALSE)

## create a LaTeX file - in the current working directory, getwd():
Sweave(testfile)

## This can be compiled to PDF by
## tools::texi2pdf("Sweave-test-1.tex")

## or outside R by
##
## R CMD texi2pdf Sweave-test-1.tex
## on Unix-alikes which sets the appropriate TEXINPUTS path.
```

```
##
## On Windows,
##      Rcmd texify --pdf Sweave-test-1.tex
## if MiKTeX is available.

## create an R source file from the code chunks
Stangle(testfile)
## which can be sourced, e.g.
source("Sweave-test-1.R")
```

|----------------|------------------------------|
| SweaveSyntConv | <i>Convert Sweave Syntax</i> |
|----------------|------------------------------|

---

## Description

This function converts the syntax of files in [Sweave](#) format to another Sweave syntax definition.

## Usage

```
SweaveSyntConv(file, syntax, output = NULL)
```

## Arguments

|                     |                                                                                                                                                                                                                                                                |
|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>file</code>   | Name of Sweave source file.                                                                                                                                                                                                                                    |
| <code>syntax</code> | An object of class <code>SweaveSyntax</code> or a character string with its name giving the target syntax to which the file is converted.                                                                                                                      |
| <code>output</code> | Name of output file, default is to remove the extension from the input file and to add the default extension of the target syntax. Any directory names in <code>file</code> are also removed such that the output is created in the current working directory. |

|     |                             |
|-----|-----------------------------|
| tar | <i>Create a Tar Archive</i> |
|-----|-----------------------------|

---

**Description**

Create a tar archive.

**Usage**

```
tar(tarfile, files = NULL,
    compression = c("none", "gzip", "bzip2", "xz"),
    compression_level = 6, tar = Sys.getenv("tar"),
    extra_flags = "")
```

**Arguments**

|                   |                                                                                                                                                                                                                                       |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| tarfile           | The pathname of the tar file: tilde expansion (see <a href="#">path.expand</a> ) will be performed. Alternatively, a <a href="#">connection</a> that can be used for binary writes.                                                   |
| files             | A character vector of filepaths to be archived: the default is to archive all files under the current directory.                                                                                                                      |
| compression       | character string giving the type of compression to be used (default none). Can be abbreviated.                                                                                                                                        |
| compression_level | integer: the level of compression. Only used for the internal method.                                                                                                                                                                 |
| tar               | character string: the path to the command to be used. If the command itself contains spaces it needs to be quoted (e.g., by <a href="#">shQuote</a> ) – but argument tar may also contain flags separated from the command by spaces. |
| extra_flags       | Any extra flags for an external tar.                                                                                                                                                                                                  |

**Details**

This is either a wrapper for a tar command or uses an internal implementation in R. The latter is used if tarfile is a connection or if the argument tar is "internal" or "" (the ‘factory-fresh’ default). Note that whereas Unix-alike versions of R set the environment variable TAR, its value is not the default for this function.

Argument extra\_flags is passed to an external tar and so is platform-dependent. Possibly useful values include ‘-h’ (follow symbolic links, also ‘-L’ on some platforms), ‘--acls’, ‘--exclude-backups’, ‘--exclude-vcs’ (and similar) and on Windows ‘--force-local’ (so drives can be included in filepaths: however, this is the default for the Rtools tar). For GNU tar, ‘--format=ustar’ forces a more portable format. (The default is set at compilation and will be shown at the end of the output from tar --help: for version 1.30 ‘out-of-the-box’ it is ‘--format=gnu’, but the manual says the intention is to change to ‘--format=posix’ which is the same as pax – it was never part of the POSIX standard for tar and should not be used.) For libarchive’s bsdtar, ‘--format=ustar’ is more portable than the default.

One issue which can cause an external command to fail is a command line too long for the system shell: as from R 3.5.0 this is worked around if the external command is detected to be GNU tar or libarchive tar (aka bsdtar).

Note that files = ' .' will usually not work with an external tar as that would expand the list of files after tarfile is created. (It does work with the default internal method.)

## Value

The return code from `system` or 0 for the internal version, invisibly.

## Portability

The ‘tar’ format no longer has an agreed standard! ‘Unix Standard Tar’ was part of POSIX 1003.1:1998 but has been removed in favour of `pax`, and in any case many common implementations diverged from the former standard.

Many R platforms use a version of GNU `tar` (including `Rtools` on Windows), but the behaviour seems to be changed with each version. macOS  $\geq$  10.6 and FreeBSD use `bsdtar` from the `libarchive` project (but for macOS, a version from 2010), and commercial Unixes will have their own versions. `bsdtar` is available for many other platforms: macOS up to at least 10.9 had GNU `tar` as `gnutar` and other platforms, e.g. Solaris, have it as `gtar`: on a Unix-alike `configure` will try `gnutar` and `gtar` before `tar`.

Known problems arise from

- The handling of file paths of more than 100 bytes. These were unsupported in early versions of `tar`, and supported in one way by POSIX `tar` and in another by GNU `tar` and yet another by the POSIX `pax` command which recent `tar` programs often support. The internal implementation warns on paths of more than 100 bytes, uses the ‘ustar’ way from the 1998 POSIX standard which supports up to 256 bytes (depending on the path: in particular the final component is limited to 100 bytes) if possible, otherwise the GNU way (which is widely supported, including by `untar`).

Most formats do not record the encoding of file paths.

- (File) links. `tar` was developed on an OS that used hard links, and physical files that were referred to more than once in the list of files to be included were included only once, the remaining instances being added as links. Later a means to include symbolic links was added. The internal implementation supports symbolic links (on OSes that support them), only. Of course, the question arises as to how links should be unpacked on OSes that do not support them: for regular files file copies can be used.

Names of links in the ‘ustar’ format are restricted to 100 bytes. There is an GNU extension for arbitrarily long link names, but `bsdtar` ignores it. The internal method uses the GNU extension, with a warning.

- Header fields, in particular the padding to be used when fields are not full or not used. POSIX did define the correct behaviour but commonly used implementations did (and still do) not comply.
- File sizes. The ‘ustar’ format is restricted to 8GB per (uncompressed) file.

For portability, avoid file paths of more than 100 bytes and all links (especially hard links and symbolic links to directories).

The internal implementation writes only the blocks of 512 bytes required (including trailing blocks of nuls), unlike GNU `tar` which by default pads with ‘nul’ to a multiple of 20 blocks (10KB). Implementations which pad differ on whether the block padding should occur before or after compression (or both): padding was designed for improved performance on physical tape drives.

The ‘ustar’ format records file modification times to a resolution of 1 second: on file systems with higher resolution it is conventional to discard fractional seconds.

## Compression

When an external `tar` command is used, compressing the tar archive requires that `tar` supports the ‘-z’, ‘-j’ or ‘-J’ flag, and may require the appropriate command (`gzip`, `bzip2` or `xz`) to be

available. For GNU `tar`, further compression programs can be specified by e.g. `extra_flags = "-I lz4"`. Some versions of `bsdtar` accept options such as `'--lz4'`, `'--lzop'` and `'--lrzip'` or an external compressor *via* `--use-compress-program lz4`: these could be supplied in `extra_flags`.

NetBSD prior to 8.0 used flag `'--xz'` rather than `'-J'`, so this should be used *via* `extra_flags = "--xz"` rather than `compression = "xz"`. The commands from OpenBSD and the Heirloom Toolchest are not documented to support `xz`.

The `tar` programs in commercial Unixen such as AIX and Solaris do not support compression.

### Note

For users of macOS (formerly OS X). Apple's HFS and HFS+ file systems have a legacy concept of 'resource forks' dating from classic Mac OS and rarely used nowadays. Apple's version of `tar` stores these as separate files in the tarball with names prefixed by `'._'`, and unpacks such files into resource forks (if possible): other ways of unpacking (including `untar` in R) unpack them as separate files.

When argument `tar` is set to the command `tar` on macOS, environment variable `COPYFILE_DISABLE=1` is set, which for the system version of `tar` prevents these separate files being included in the tarball.

[untar](#).

---

toLatex

*Converting R Objects to BibTeX or LaTeX*

---

### Description

These methods convert R objects to character vectors with BibTeX or LaTeX markup.

### Usage

```
toBibtex(object, ...)
toLatex(object, ...)
## S3 method for class 'Bibtex'
print(x, prefix = "", ...)
## S3 method for class 'Latex'
print(x, prefix = "", ...)
```

### Arguments

|                     |                                                                                                                      |
|---------------------|----------------------------------------------------------------------------------------------------------------------|
| <code>object</code> | object of a class for which a <code>toBibtex</code> or <code>toLatex</code> method exists.                           |
| <code>x</code>      | object of class <code>"Bibtex"</code> or <code>"Latex"</code> .                                                      |
| <code>prefix</code> | a character string which is printed at the beginning of each line, mostly used to insert whitespace for indentation. |
| <code>...</code>    | in the <code>print</code> methods, passed to <a href="#">writeLines</a> .                                            |

## Details

Objects of class "Bibtex" or "Latex" are simply character vectors where each element holds one line of the corresponding BibTeX or LaTeX file.

|----------------|--------------------------|
| txtProgressBar | <i>Text Progress Bar</i> |
|----------------|--------------------------|

---

## Description

Text progress bar in the R console.

## Usage

```
txtProgressBar(min = 0, max = 1, initial = 0, char = "=",
               width = NA, title, label, style = 1, file = "")

getTxtProgressBar(pb)
setTxtProgressBar(pb, value, title = NULL, label = NULL)
## S3 method for class 'txtProgressBar'
close(con, ...)
```

## Arguments

|                |                                                                                                                                                                           |
|----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| min, max       | (finite) numeric values for the extremes of the progress bar. Must have min < max.                                                                                        |
| initial, value | initial or new value for the progress bar. See ‘Details’ for what happens with invalid values.                                                                            |
| char           | the character (or character string) to form the progress bar.                                                                                                             |
| width          | the width of the progress bar, as a multiple of the width of char. If NA, the default, the number of characters is that which fits into <code>getOption("width")</code> . |
| style          | the ‘style’ of the bar – see ‘Details’.                                                                                                                                   |
| file           | an open connection object or "" which indicates the console: <code>stderr()</code> might be useful here.                                                                  |
| pb, con        | an object of class "txtProgressBar".                                                                                                                                      |
| title, label   | ignored, for compatibility with other progress bars.                                                                                                                      |
| ...            | for consistency with the generic.                                                                                                                                         |

## Details

`txtProgressBar` will display a progress bar on the R console (or a connection) via a text representation.

`setTxtProgressbar` will update the value. Missing (NA) and out-of-range values of `value` will be (silently) ignored. (Such values of `initial` cause the progress bar not to be displayed until a valid value is set.)

The progress bar should be closed when finished with: this outputs the final newline character.

`style = 1` and `style = 2` just shows a line of `char`. They differ in that `style = 2` redraws the line each time, which is useful if other code might be writing to the R console. `style = 3` marks the end of the range by `|` and gives a percentage to the right of the bar.

## Value

For `txtProgressBar` an object of class "txtProgressBar".

For `getTxtProgressBar` and `setTxtProgressBar`, a length-one numeric vector giving the previous value (invisibly for `setTxtProgressBar`).

## Note

Using `style 2` or `3` or reducing the value with `style = 1` uses `'\r'` to return to the left margin – the interpretation of carriage return is up to the terminal or console in which R is running, and this is liable to produce ugly output on a connection other than a terminal, including when `stdout()` is redirected to a file.

## See Also

`winProgressBar` (Windows only), `tkProgressBar` (Unix-alike platforms).

## Examples

```
# slow
testit <- function(x = sort(runif(20)), ...)
{
  pb <- txtProgressBar(...)
  for(i in c(0, x, 1)) {Sys.sleep(0.5); setTxtProgressBar(pb, i)}
  Sys.sleep(1)
  close(pb)
}
testit()
testit(runif(10))
testit(style = 3)
```

---

type.convert

*Convert Data to Appropriate Type*

---

## Description

Convert a data object to logical, integer, numeric, complex, character or factor as appropriate.

## Usage

```
type.convert(x, ...)
## Default S3 method:
type.convert(x, na.strings = "NA", as.is = FALSE, dec = ".",
             numerals = c("allow.loss", "warn.loss", "no.loss"), ...)
## S3 method for class 'data.frame'
type.convert(x, ...)
## S3 method for class 'list'
type.convert(x, ...)
```

## Arguments

|                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>          | a vector, matrix, array, data frame, or list.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>na.strings</code> | a vector of strings which are to be interpreted as <a href="#">NA</a> values. Blank fields are also considered to be missing values in logical, integer, numeric or complex vectors.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <code>as.is</code>      | whether convert to <a href="#">factors</a> . When false (as by default currently, but planned <b>to be changed!</b> ), convert character vectors to factors. See ‘Details’.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>dec</code>        | the character to be assumed for decimal points.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <code>numerals</code>   | string indicating how to convert numbers whose conversion to double precision would lose accuracy, typically when <code>x</code> has more digits than can be stored in a <a href="#">double</a> . Can be abbreviated. Possible values are<br><br><code>numerals = "allow.loss"</code> , <b>default:</b> the conversion happens with some accuracy loss. This was the behavior of R versions 3.0.3 and earlier, and the default from 3.1.1 onwards.<br><code>numerals = "warn.loss"</code> : a <a href="#">warning</a> about accuracy loss is signalled and the conversion happens as with <code>numerals = "allow.loss"</code> .<br><code>numerals = "no.loss"</code> : <code>x</code> is <i>not</i> converted to a number, but to a <a href="#">factor</a> or character, depending on <code>as.is</code> . This was the behavior of R version 3.1.0. |
| <code>...</code>        | arguments to be passed to or from methods.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

## Details

This helper function is used by [read.table](#). When the data object `x` is a data frame or list, the function is called recursively for each column or list element.

Given a vector, the function attempts to convert it to logical, integer, numeric or complex, and failing that converts a character vector to [factor](#) unless `as.is = TRUE`. The first type that can accept all the non-missing values is chosen.

Vectors which are entirely missing values are converted to logical, since `NA` is primarily logical.

Vectors containing just `F`, `T`, `FALSE`, `TRUE` and values from `na.strings` are converted to logical. Vectors containing optional whitespace followed by decimal constants representable as R integers or values from `na.strings` are converted to integer. Other vectors containing optional whitespace followed by other decimal or hexadecimal constants (see [NumericConstants](#)), or `NaN`, `Inf` or `infinity` (ignoring case) or values from `na.strings` are converted to numeric. Where converting inputs to numeric or complex would result in loss of accuracy they can optionally be returned as strings (for `as.is = TRUE`) or factors.

Since this is a helper function, the caller should always pass an appropriate value of `as.is`.

**Value**

An object like `x` but using another storage mode when appropriate.

**Author(s)**

R Core, with a contribution by Arni Magnusson

**See Also**

`read.table`, `class`, `storage.mode`.

**Examples**

```
## Numeric to integer
class(rivers)
x <- type.convert(rivers)
class(x)

## Convert many columns
auto <- type.convert(mtcars)
str(mtcars)
str(auto)

## Convert matrix
phones <- type.convert(WorldPhones)
storage.mode(WorldPhones)
storage.mode(phones)

## Factor or character
chr <- c("A", "B", "B", "A")
fac <- factor(c("A", "B", "B", "A"))
type.convert(chr)           # -> factor
type.convert(fac)           # -> factor
type.convert(chr, as.is = TRUE) # -> character
type.convert(fac, as.is = TRUE) # -> character
```

---

untar

*Extract or List Tar Archives*

---

**Description**

Extract files from or list the contents of a tar archive.

**Usage**

```
untar(tarfile, files = NULL, list = FALSE, exdir = ".",
      compressed = NA, extras = NULL, verbose = FALSE,
      restore_times = TRUE,
      support_old_tars = Sys.getenv("R_SUPPORT_OLD_TARS", FALSE),
      tar = Sys.getenv("TAR"))
```

## Arguments

|                               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>tarfile</code>          | The pathname of the tar file: tilde expansion (see <code>path.expand</code> ) will be performed. Alternatively, a <code>connection</code> that can be used for binary reads. For a <i>compressed</i> tarfile, and if a connection is to be used, that should be created by <code>gzfile(.)</code> (or <code>gzcon(.)</code> which currently only works for "gzip", whereas <code>gzfile()</code> works for all compressions available in <code>tar()</code> ).                                                                         |
| <code>files</code>            | A character vector of recorded filepaths to be extracted: the default is to extract all files.                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>list</code>             | If TRUE, list the files (the equivalent of <code>tar -tf</code> ). Otherwise extract the files (the equivalent of <code>tar -xf</code> ).                                                                                                                                                                                                                                                                                                                                                                                              |
| <code>exdir</code>            | The directory to extract files to (the equivalent of <code>tar -C</code> ). It will be created if necessary.                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>compressed</code>       | (Deprecated in favour of auto-detection, used only for an external <code>tar</code> command.) Logical or character string. Values "gzip", "bzip2" and "xz" select that form of compression (and may be abbreviated to the first letter). TRUE indicates gzip compression, FALSE no known compression, and NA (the default) indicates that the type is to be inferred from the file header.<br>The external command may ignore the selected compression type but detect a type automatically.                                           |
| <code>extras</code>           | NULL or a character string: further command-line flags such as '-p' to be passed to an external <code>tar</code> program.                                                                                                                                                                                                                                                                                                                                                                                                              |
| <code>verbose</code>          | logical: if true echo the command used for an external <code>tar</code> program.                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <code>restore_times</code>    | logical. If true (default) restore file modification times. If false, the equivalent of the '-m' flag. Times in tarballs are supposed to be in UTC, but tarballs have been submitted to CRAN with times in the future or far past: this argument allows such times to be discarded.<br>Note that file times in a tarball are stored with a resolution of 1 second, and can only be restored to the resolution supported by the file system (which on a FAT system is 2 seconds).                                                       |
| <code>support_old_tars</code> | logical. If false (the default), the external <code>tar</code> command is assumed to be able handle compressed tarfiles and if <code>compressed</code> does not specify it, to automatically detect the type of compression. (The major implementations have done so since 2009; for GNU <code>tar</code> since version 1.22.)<br>If true, the R code calls an appropriate decompressor and pipes the output to <code>tar</code> , for <code>compressed = NA</code> examining the tarfile header to determine the type of compression. |
| <code>tar</code>              | character string: the path to the command to be used or "internal". If the command itself contains spaces it needs to be quoted – but <code>tar</code> can also contain flags separated from the command by spaces.                                                                                                                                                                                                                                                                                                                    |

## Details

This is either a wrapper for a `tar` command or for an internal implementation written in R. The latter is used if `tarfile` is a connection or if the argument `tar` is "internal" or "" (except on Windows, when `tar.exe` is tried first).

Unless otherwise stated three types of compression of the tar file are supported: gzip, bzip2 and xz.

What options are supported will depend on the `tar` implementation used: the "internal" one is intended to provide support for most in a platform-independent way.

**GNU tar:** Modern GNU `tar` versions support compressed archives and since 1.15 are able to detect the type of compression automatically: version 1.22 added support for `xz` compression. On a Unix-alike, `configure` will set environment variable `TAR`, preferring GNU `tar` if found.

**bsdtar:** macOS 10.6 and later (and FreeBSD and some other OSes) have a `tar` from the libarchive project which detects all three forms of compression automatically (even if undocumented in macOS).

**NetBSD:** It is undocumented if NetBSD's `tar` can detect compression automatically: for versions before 8 the flag for `xz` compression was `--xz` not `-J`. So `support_old_tars = TRUE` is recommended (or use `bsdtar` if installed).

**OpenBSD:** OpenBSD's `tar` does not detect compression automatically. It has no support for `xz` beyond reporting that the file is `xz`-compressed. So `support_old_tars = TRUE` is recommended.

**Heirloom Toolchest:** This `tar` does automatically detect `gzip` and `bzip2` compression (undocumented) but has no support for `xz` compression.

**Older support:** Environment variable `R_GZIPCMD` gives the command to decompress `gzip` files, and `R_BZIPCMD` for `bzip2` files. (On Unix-alikes these are set at installation if found.) `xz` is used if available: if not decompression is expected to fail.

Arguments `compressed`, `extras` and `verbose` are only used when an external `tar` is used.

Some external `tar` commands will detect some of `lrzip`, `lzma`, `lz4`, `lzop` and `zstd` compression in addition to `gzip`, `bzip2` and `xz`. (For some external `tar` commands, compressed tarfiles can only be read if the appropriate utility program is available.) For GNU `tar`, further (de)compression programs can be specified by e.g. `extras = "-I lz4"`. For `bsdtar` this could be `extras = "--use-compress-program lz4"`. Most commands will detect (the nowadays rarely seen) `.tar.Z` archives compressed by `compress`.

The internal implementation restores symbolic links as links on a Unix-alike, and as file copies on Windows (which works only for existing files, not for directories), and hard links as links. If the linking operation fails (as it may on a FAT file system), a file copy is tried. Since it uses `gzfile` to read a file it can handle files compressed by any of the methods that function can handle: at least `compress`, `gzip`, `bzip2` and `xz` compression, and some types of `lzma` compression. It does not guard against restoring absolute file paths, as some `tar` implementations do. It will create the parent directories for directories or files in the archive if necessary. It handles the USTAR/POSIX, GNU and `pax` ways of handling file paths of more than 100 bytes, and the GNU way of handling link targets of more than 100 bytes.

You may see warnings from the internal implementation such as

```
unsupported entry type 'x'
```

This often indicates an invalid archive: entry types "A-Z" are allowed as extensions, but other types are reserved. The only thing you can do with such an archive is to find a `tar` program that handles it, and look carefully at the resulting files. There may also be the warning

```
using pax extended headers
```

This indicates that additional information may have been discarded, such as ACLs, encodings ...

The former standards only supported ASCII filenames (indeed, only alphanumeric plus period, underscore and hyphen). `untar` makes no attempt to map filenames to those acceptable on the

current system, and treats the filenames in the archive as applicable without any re-encoding in the current locale.

The internal implementation does not special-case ‘resource forks’ in macOS: that system’s `tar` command does. This may lead to unexpected files with names with prefix ‘`._`’.

Value

If `list = TRUE`, a character vector of (relative or absolute) paths of files contained in the tar archive.

Otherwise the return code from `system` with an external `tar` or `0L`, invisibly.

See Also

`tar`, `unzip`.

|       |                                     |
|-------|-------------------------------------|
| unzip | <i>Extract or List Zip Archives</i> |
|-------|-------------------------------------|

---

Description

Extract files from or list a zip archive.

Usage

```
unzip(zipfile, files = NULL, list = FALSE, overwrite = TRUE,
      junkpaths = FALSE, exdir = ".", unzip = "internal",
      setTimes = FALSE)
```

Arguments

|           |                                                                                                                                                                     |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| zipfile   | The pathname of the zip file: tilde expansion (see <code>path.expand</code> ) will be performed.                                                                    |
| files     | A character vector of recorded filepaths to be extracted: the default is to extract all files.                                                                      |
| list      | If <code>TRUE</code> , list the files and extract none. The equivalent of <code>unzip -l</code> .                                                                   |
| overwrite | If <code>TRUE</code> , overwrite existing files (the equivalent of <code>unzip -o</code> ), otherwise ignore such files (the equivalent of <code>unzip -n</code> ). |
| junkpaths | If <code>TRUE</code> , use only the basename of the stored filepath when extracting. The equivalent of <code>unzip -j</code> .                                      |
| exdir     | The directory to extract files to (the equivalent of <code>unzip -d</code> ). It will be created if necessary.                                                      |
| unzip     | The method to be used. An alternative is to use <code>getOption("unzip")</code> , which on a Unix-alike may be set to the path to a <code>unzip</code> program.     |
| setTimes  | logical. For the internal method only, should the file times be set based on the times in the zip file? (NB: this applies to included files, not to directories.)   |

**Value**

If `list = TRUE`, a data frame with columns `Name` (character) `Length` (the size of the uncompressed file, numeric) and `Date` (of class `"POSIXct"`).

Otherwise for the `"internal"` method, a character vector of the filepaths extracted to, invisibly.

**Note**

The default internal method is a minimal implementation, principally designed for Windows' users to be able to unpack Windows binary packages without external software. It does not (for example) support Unicode filenames as introduced in `zip 3.0`: for that use `unzip = "unzip"` with `unzip 6.00` or later. It does have some support for `bzip2` compression and `> 2GB` zip files (but not `>= 4GB` files pre-compression contained in a zip file: like many builds of `unzip` it may truncate these, in R's case with a warning if possible).

If `unzip` specifies a program, the format of the dates listed with `list = TRUE` is unknown (on Windows it can even depend on the current locale) and the return values could be `NA` or expressed in the wrong time zone or misinterpreted (the latter being far less likely as from `unzip 6.00`).

File times in zip files are stored in the style of MS-DOS, as local times to an accuracy of 2 seconds. This is not very useful when transferring zip files between machines (even across continents), so we chose not to restore them by default.

**Source**

The internal C code uses `zlib` and is in particular based on the contributed 'minizip' application in the `zlib` sources (from <https://zlib.net/>) by Gilles Vollant.

**See Also**

`unz` to read a single component from a zip file.

`zip` for packing, i.e., the "inverse" of `unzip()`; further `untar` and `tar`, the corresponding pair for (un)packing tar archives ("tarballs") such as R source packages.

---

update.packages

*Compare Installed Packages with CRAN-like Repositories*

---

**Description**

`old.packages` indicates packages which have a (suitable) later version on the repositories whereas `update.packages` offers to download and install such packages.

`new.packages` looks for (suitable) packages on the repositories that are not already installed, and optionally offers them for installation.

**Usage**

```
update.packages(lib.loc = NULL, repos = getOption("repos"),
               contriburl = contrib.url(repos, type),
               method, instlib = NULL,
               ask = TRUE, available = NULL,
               oldPkgs = NULL, ..., checkBuilt = FALSE,
               type = getOption("pkgType"))
```

```

old.packages(lib.loc = NULL, repos = getOption("repos"),
             contriburl = contrib.url(repos, type),
             instPkgs = installed.packages(lib.loc = lib.loc, ...),
             method, available = NULL, checkBuilt = FALSE, ...,
             type = getOption("pkgType"))

new.packages(lib.loc = NULL, repos = getOption("repos"),
             contriburl = contrib.url(repos, type),
             instPkgs = installed.packages(lib.loc = lib.loc, ...),
             method, available = NULL, ask = FALSE, ...,
             type = getOption("pkgType"))

```

### Arguments

|                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>lib.loc</code>    | character vector describing the location of R library trees to search through (and update packages therein), or <code>NULL</code> for all known trees (see <a href="#">.libPaths</a> ).                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <code>repos</code>      | character vector, the base URL(s) of the repositories to use, e.g., the URL of a CRAN mirror such as <code>"https://cloud.r-project.org"</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>contriburl</code> | URL(s) of the contrib sections of the repositories. Use this argument if your repository is incomplete. Overrides argument <code>repos</code> . Incompatible with <code>type = "both"</code> .                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <code>method</code>     | Download method, see <a href="#">download.file</a> . Unused if a non- <code>NULL</code> <code>available</code> is supplied.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <code>instlib</code>    | character string giving the library directory where to install the packages.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>ask</code>        | logical indicating whether to ask the user to select packages before they are downloaded and installed, or the character string <code>"graphics"</code> , which brings up a widget to allow the user to (de-)select from the list of packages which could be updated. The latter value only works on systems with a GUI version of <a href="#">select.list</a> , and is otherwise equivalent to <code>ask = TRUE</code> . <code>ask</code> does not control questions asked before installing packages from source via <code>type = "both"</code> (see option <code>"install.packages.compile.from.source"</code> ). |
| <code>available</code>  | an object as returned by <a href="#">available.packages</a> listing packages available at the repositories, or <code>NULL</code> which makes an internal call to <a href="#">available.packages</a> . Incompatible with <code>type = "both"</code> .                                                                                                                                                                                                                                                                                                                                                                 |
| <code>checkBuilt</code> | If <code>TRUE</code> , a package built under an earlier major.minor version of R (e.g., 3.4) is considered to be ‘old’.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <code>oldPkgs</code>    | if specified as non- <code>NULL</code> , <code>update.packages()</code> only considers these packages for updating. This may be a character vector of package names or a matrix as returned by <code>old.packages</code> .                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>instPkgs</code>   | by default all installed packages, <a href="#">installed.packages</a> ( <code>lib.loc = lib.loc</code> ). A subset can be specified; currently this must be in the same (character matrix) format as returned by <code>installed.packages()</code> .                                                                                                                                                                                                                                                                                                                                                                 |
| <code>...</code>        | Arguments such as <code>destdir</code> and <code>dependencies</code> to be passed to <a href="#">install.packages</a> and <code>ignore_repo_cache</code> , <code>max_repo_cache_age</code> and <code>noCache</code> to <a href="#">available.packages</a> or <a href="#">installed.packages</a> .                                                                                                                                                                                                                                                                                                                    |
| <code>type</code>       | character, indicating the type of package to download and install. See <a href="#">install.packages</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

## Details

`old.packages` compares the information from `available.packages` with that from `instPkgs` (computed by `installed.packages` by default) and reports installed packages that have newer versions on the repositories or, if `checkBuilt = TRUE`, that were built under an earlier minor version of R (for example built under 3.3.x when running R 3.4.0). (For binary package types there is no check that the version on the repository was built under the current minor version of R, but it is advertised as being suitable for this version.)

`new.packages` does the same comparison but reports uninstalled packages that are available at the repositories. If `ask != FALSE` it asks which packages should be installed in the first element of `lib.loc`.

The main function of the set is `update.packages`. First a list of all packages found in `lib.loc` is created and compared with those available at the repositories. If `ask = TRUE` (the default) packages with a newer version are reported and for each one the user can specify if it should be updated. If so the packages are downloaded from the repositories and installed in the respective library path (or `instlib` if specified).

For how the list of suitable available packages is determined see `available.packages`. `available = NULL` make a call to `available.packages(contriburl = contriburl, method = method)` and hence by default filters on R version, OS type and removes duplicates.

## Value

`update.packages` returns `NULL` invisibly.

For `old.packages`, `NULL` or a matrix with one row per package, row names the package names and column names "Package", "LibPath", "Installed" (the version), "Built" (the version built under), "ReposVer" and "Repository".

For `new.packages` a character vector of package names, *after* any selected *via* `ask` have been installed.

## Warning

Take care when using dependencies (passed to `install.packages`) with `update.packages`, for it is unclear where new dependencies should be installed. The current implementation will only allow it if all the packages to be updated are in a single library, when that library will be used.

---

|          |                           |
|----------|---------------------------|
| url.show | <i>Display a Text URL</i> |
|----------|---------------------------|

---

**Description**

Extension of [file.show](#) to display text files from a remote server.

**Usage**

```
url.show(url, title = url, file = tempfile(),
         delete.file = TRUE, method, ...)
```

**Arguments**

|             |                                                         |
|-------------|---------------------------------------------------------|
| url         | The URL to read from.                                   |
| title       | Title for the browser.                                  |
| file        | File to copy to.                                        |
| delete.file | Delete the file afterwards?                             |
| method      | File transfer method: see <a href="#">download.file</a> |
| ...         | Arguments to pass to <a href="#">file.show</a> .        |

**Note**

Since this is for text files, it will convert to CRLF line endings on Windows.

**See Also**

[url](#), [file.show](#), [download.file](#)

**Examples**

```
## Not run: url.show("https://www.stats.ox.ac.uk/pub/datasets/csb/ch3a.txt")
```

---

|           |                                         |
|-----------|-----------------------------------------|
| URLencode | <i>Encode or Decode a (partial) URL</i> |
|-----------|-----------------------------------------|

---

**Description**

Functions to percent-encode or decode characters in URLs.

**Usage**

```
URLencode(URL, reserved = FALSE, repeated = FALSE)
URLdecode(URL)
```

**Arguments**

|          |                                                                   |
|----------|-------------------------------------------------------------------|
| URL      | a character string.                                               |
| reserved | logical: should ‘reserved’ characters be encoded? See ‘Details’.  |
| repeated | logical: should apparently already-encoded URLs be encoded again? |

## Details

Characters in a URL other than the English alphanumeric characters and ‘\_ . ~’ should be encoded as % plus a two-digit hexadecimal representation, and any single-byte character can be so encoded. (Multi-byte characters are encoded byte-by-byte.) The standard refers to this as ‘percent-encoding’.

In addition, ‘! \$ & ' ( ) \* + , ; = : / ? @ # [ ]’ are reserved characters, and should be encoded unless used in their reserved sense, which is scheme specific. The default in `URLencode` is to leave them alone, which is appropriate for ‘file://’ URLs, but probably not for ‘http://’ ones.

An ‘apparently already-encoded URL’ is one containing %xx for two hexadecimal digits.

## Value

A character string.

## References

Internet STD 66 (formerly RFC 3986), <https://tools.ietf.org/html/std66>

## Examples

```
(y <- URLencode("a url with spaces and / and @"))
URLdecode(y)
(y <- URLencode("a url with spaces and / and @", reserved = TRUE))
URLdecode(y)

URLdecode(z <- "ab%20cd")
c(URLencode(z), URLencode(z, repeated = TRUE)) # first is usually wanted
```

---

utils-deprecated     *Deprecated Functions in Package* **utils**

---

## Description

These functions are provided for compatibility with older versions of R only, and may be defunct as soon as of the next release.

## See Also

---

View*Invoke a Data Viewer*

---

## Description

Invoke a spreadsheet-style data viewer on a matrix-like R object.

## Usage

```
View(x, title)
```

## Arguments

|                    |                                                                                               |
|--------------------|-----------------------------------------------------------------------------------------------|
| <code>x</code>     | an R object which can be coerced to a data frame with non-zero numbers of rows and columns.   |
| <code>title</code> | title for viewer window. Defaults to name of <code>x</code> prefixed by <code>Data :</code> . |

## Details

Object `x` is coerced (if possible) to a data frame, then columns are converted to character using `format.data.frame`. The object is then viewed in a spreadsheet-like data viewer, a read-only version of `data.entry`.

If there are row names on the data frame that are not `1:nrow`, they are displayed in a separate first column called `row.names`.

Objects with zero columns or zero rows are not accepted.

**On Unix-alikes**, the array of cells can be navigated by the cursor keys and Home, End, Page Up and Page Down (where supported by X11) as well as Enter and Tab.

**On Windows**, the array of cells can be navigated *via* the scrollbars and by the cursor keys, Home, End, Page Up and Page Down.

On Windows, the initial size of the data viewer window is taken from the default dimensions of a pager (see `Rconsole`), but adjusted downwards to show a whole number of rows and columns.

## Value

Invisible `NULL`. The function puts up a window and returns immediately: the window can be closed via its controls or menus.

## See Also

`edit.data.frame`, `data.entry`.

vignette

*View, List or Get R Source of Package Vignettes***Description**

View a specified package vignette, or list the available ones; display it rendered in a viewer, and get or edit its R source file.

**Usage**

```
vignette(topic, package = NULL, lib.loc = NULL, all = TRUE)

## S3 method for class 'vignette'
print(x, ...)
## S3 method for class 'vignette'
edit(name, ...)
```

**Arguments**

|                      |                                                                                                                                                                                 |
|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>topic</code>   | a character string giving the (base) name of the vignette to view. If omitted, all vignettes from all installed packages are listed.                                            |
| <code>package</code> | a character vector with the names of packages to search through, or <code>NULL</code> in which ‘all’ packages (as defined by argument <code>all</code> ) are searched.          |
| <code>lib.loc</code> | a character vector of directory names of R libraries, or <code>NULL</code> . The default value of <code>NULL</code> corresponds to all libraries currently known.               |
| <code>all</code>     | logical; if <code>TRUE</code> search all available packages in the library trees specified by <code>lib.loc</code> , and if <code>FALSE</code> , search only attached packages. |
| <code>x, name</code> | object of class <code>vignette</code> .                                                                                                                                         |
| <code>...</code>     | ignored by the <code>print</code> method, passed on to <code>file.edit</code> by the <code>edit</code> method.                                                                  |

**Details**

Function `vignette` returns an object of the same class, the `print` method opens a viewer for it.

On Unix-alikes, The program specified by the `pdfviewer` option is used for viewing PDF versions of vignettes.

If several vignettes have PDF/HTML versions with base name identical to `topic`, the first one found is used.

If no topics are given, all available vignettes are listed. The corresponding information is returned in an object of class `"packageIQR"`.

**See Also**

[browseVignettes](#) for an HTML-based vignette browser; [RShowDoc](#)(`<basename>`, `package = "<pkg>"`) displays a “rendered” vignette (pdf or html).

## Examples

```
## List vignettes from all *attached* packages
vignette(all = FALSE)

## List vignettes from all *installed* packages (can take a long time!):
vignette(all = TRUE)

## The grid intro vignette -- open it
## Not run: vignette("grid") # calling print()
## The same (conditional on existence of the vignette).
## Note that 'package = *' is much faster in the case of many installed packages:
if(!is.null(v1 <- vignette("grid", package="grid"))) {
  ## Not run: v1 # calling print(.)
  str(v1)
  ## Now let us have a closer look at the code

  ## Not run: edit(v1) # e.g., to send lines ...
}# if( has vignette "installed")
## A package can have more than one vignette (package grid has several):
vignette(package = "grid")
if(interactive()) {
  ## vignette("rotated")
  ## The same, but without searching for it:
  vignette("rotated", package = "grid")
}
```

---

warnErrList

---

*Collect and Summarize Errors From List*

---

## Description

Collect errors (class "error", typically from `tryCatch`) from a list `x` into a “summary warning”, by default produce a `warning` and keep that message as "warningMsg" attribute.

## Usage

```
warnErrList(x, warn = TRUE, errValue = NULL)
```

## Arguments

|                       |                                                                                                                                            |
|-----------------------|--------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>        | a <code>list</code> , typically from applying models to a list of data (sub)sets, e.g., using <code>tryCatch(*, error = identity)</code> . |
| <code>warn</code>     | logical indicating if <code>warning()</code> should be called.                                                                             |
| <code>errValue</code> | the value with which errors should be replaced.                                                                                            |

## Value

a `list` of the same length and names as the `x` argument, with the error components replaced by `errValue`, `NULL` by default, and summarized in the "warningMsg" attribute.

**See Also**

The `warnErrList()` utility has been used in `lmList()` and `nlsList()` in recommended package **nlme** forever.

**Examples**

```
## Regression for each Chick:
ChWtgrps <- split(ChickWeight, ChickWeight[, "Chick"])
sapply(ChWtgrps, nrow) # typically 12 obs.
nlis1 <- lapply(ChWtgrps, function(DAT) tryCatch(error = identity,
  lm(weight ~ (Time + I(Time^2)) * Diet, data = DAT)))
nl1 <- warnErrList(nlis1) #-> warning :
## 50 times the same error (as Diet has only one level in each group)
stopifnot(sapply(nl1, is.null)) ## all errors --> all replaced by NULL
nlis2 <- lapply(ChWtgrps, function(DAT) tryCatch(error = identity,
  lm(weight ~ Time + I(Time^2), data = DAT)))
nl2 <- warnErrList(nlis2)
stopifnot(identical(nl2, nlis2)) # because there was *no* error at all
nlis3 <- lapply(ChWtgrps, function(DAT) tryCatch(error = identity,
  lm(weight ~ poly(Time, 3), data = DAT)))
nl3 <- warnErrList(nlis3) # 1 error caught:
stopifnot(inherits(nlis3[[1]], "error")
  , identical(nl3[-1], nlis3[-1])
  , is.null(nl3[[1]]))
)

## With different error messages
if(requireNamespace("nlme")) { # almost always, as it is recommended
  data(Soybean, package="nlme")
  attr(Soybean, "formula") #-> weight ~ Time | Plot => split by "Plot":
  L <- lapply(split(Soybean, Soybean[, "Plot"]),
    function(DD) tryCatch(error = identity,
      nls(weight ~ SSlogis(Time, Asym, xmid, scal), data = DD)))
  Lw <- warnErrList(L)
} # if <nlme>
```

---

winDialog

---

*Dialog Boxes under Windows*

---

**Description**

On MS Windows only, put up a dialog box to communicate with the user. There are various types, either for the user to select from a set of buttons or to edit a string.

**Usage**

```
winDialog(type = c("ok", "okcancel", "yesno", "yesnocancel"),
  message)

winDialogString(message, default)
```

**Arguments**

|                      |                                                                                                      |
|----------------------|------------------------------------------------------------------------------------------------------|
| <code>type</code>    | character. The type of dialog box. It will have the buttons implied by its name.                     |
| <code>message</code> | character. The information field of the dialog box. Limited to 255 chars (by Windows, checked by R). |
| <code>default</code> | character. The default string.                                                                       |

**Value**

For `winDialog` a character string giving the name of the button pressed (in capitals) or `NULL` (invisibly) if the user had no choice.

For `winDialogString` a string giving the contents of the text box when `Ok` was pressed, or `NULL` if `Cancel` was pressed.

**Note**

The standard keyboard accelerators work with these dialog boxes: where appropriate `Return` accepts the default action, `Esc` cancels and the underlined initial letter (`Y` or `N`) can be used.

These functions are only available on Windows.

**See Also**

[winMenuAdd](#)  
[file.choose](#) to select a file  
 package `windlgs` in the package source distribution for ways to program dialogs in C in the `GraphApp` toolkit.

**Examples**

```
## Not run: winDialog("yesno", "Is it OK to delete file blah")
```

---

winextras

*Get Windows Version*

---

**Description**

Get the self-reported Microsoft Windows version number.

**Usage**

```
win.version()
```

**Details**

`win.version` is an auxiliary function for [sessionInfo](#) and [bug.report](#).

**Value**

A character string describing the version of Windows reported to be in use.

**Note**

This function is only available on Microsoft Windows.

The result is based on the Windows `GetVersionEx` API function, which for recent versions of Windows reports the compatibility version, and not necessarily the actual version (hence 8.1 and 10 may be reported as 8). If the API call reports 8, this function returns `>= 8`.

**Examples**

```
if(.Platform$OS.type == "windows")
  print(win.version())
```

---

|          |                                           |
|----------|-------------------------------------------|
| winMenus | <i>User Menus under MS Windows (Rgui)</i> |
|----------|-------------------------------------------|

---

**Description**

Enables users to add, delete and program menus for the `Rgui` in MS Windows.

**Usage**

```
winMenuAdd(menuname)
winMenuAddItem(menuname, itemname, action)
winMenuDel(menuname)
winMenuDelItem(menuname, itemname)
winMenuNames()
winMenuItems(menuname)
```

**Arguments**

|                       |                                                                                                |
|-----------------------|------------------------------------------------------------------------------------------------|
| <code>menuname</code> | a character string naming a menu.                                                              |
| <code>itemname</code> | a character string naming a menu item on an existing menu.                                     |
| <code>action</code>   | a character string describing the action when that menu is selected, or "enable" or "disable". |

**Details**

User menus are added to the right of existing menus, and items are added at the bottom of the menu.

By default the action character string is treated as R input, being echoed on the command line and parsed and executed as usual.

If the `menuname` parameter of `winMenuAddItem` does not already exist, it will be created automatically.

Normally new submenus and menu items are added to the main console menu. They may be added elsewhere using the following special names:

```
$ConsoleMain The console menu (the default)
$ConsolePopup The console popup menu
$Graph<n>Main The menu for graphics window <n>
$Graph<n>Popup The popup menu for graphics window <n>
```

Specifying an existing item in `winMenuAddItem` enables the action to be changed.

Submenus can be specified by separating the elements in `menuname` by slashes: as a consequence menu names may not contain slashes.

If the `action` is specified as `"none"` no action is taken: this can be useful to reserve items for future expansion.

The function `winMenuNames` can be used to find out what menus have been created by the user and returns a vector of the existing menu names.

The `winMenuItems` function will take the name of a menu and return the items that exist in that menu. The return value is a named vector where the names correspond to the names of the items and the values of the vector are the corresponding actions.

The `winMenuDel` function will delete a menu and all of its items and submenus. `winMenuDelItem` just deletes one menu item.

The total path to an item (menu string plus item string) cannot exceed 1000 bytes, and the menu string cannot exceed 500 bytes.

## Value

NULL, invisibly. If an error occurs, an informative error message will be given.

## Note

These functions are only available on Windows and only when using the `Rgui`, hence not in `ESS` nor `RStudio`.

## See Also

`winDialog`

## Examples

```
## Not run:
winMenuAdd("Testit")
winMenuAddItem("Testit", "one", "aaaa")
winMenuAddItem("Testit", "two", "bbbb")
winMenuAdd("Testit/extras")
winMenuAddItem("Testit", "-", "")
winMenuAddItem("Testit", "two", "disable")
winMenuAddItem("Testit", "three", "cccc")
winMenuAddItem("Testit/extras", "one more", "ddd")
winMenuAddItem("Testit/extras", "and another", "eee")
winMenuAdd("$ConsolePopup/Testit")
winMenuAddItem("$ConsolePopup/Testit", "six", "fff")
winMenuNames()
winMenuItems("Testit")

## End(Not run)
```

---

|                |                                       |
|----------------|---------------------------------------|
| winProgressBar | <i>Progress Bars under MS Windows</i> |
|----------------|---------------------------------------|

---

## Description

Put up a Windows progress bar widget, update and access it.

## Usage

```
winProgressBar(title = "R progress bar", label = "",
               min = 0, max = 1, initial = 0, width = 300)

getWinProgressBar(pb)
setWinProgressBar(pb, value, title = NULL, label = NULL)
## S3 method for class 'winProgressBar'
close(con, ...)
```

## Arguments

|                |                                                                                               |
|----------------|-----------------------------------------------------------------------------------------------|
| title, label   | character strings, giving the window title and the label on the dialog box respectively.      |
| min, max       | (finite) numeric values for the extremes of the progress bar.                                 |
| initial, value | initial or new value for the progress bar.                                                    |
| width          | the width of the progress bar in pixels: the dialog box will be 40 pixels wider (plus frame). |
| pb, con        | an object of class "winProgressBar".                                                          |
| ...            | for consistency with the generic.                                                             |

## Details

winProgressBar will display a progress bar centred on the screen. Space will be allocated for the label only if it is non-empty.

setWinProgressbar will update the value and for non-NULL values, the title and label (provided there was one when the widget was created). Missing (NA) and out-of-range values of value will be (silently) ignored.

The progress bar should be closed when finished with, but it will be garbage-collected once no R object refers to it.

## Value

For winProgressBar an object of class "winProgressBar".

For getWinProgressBar and setWinProgressBar, a length-one numeric vector giving the previous value (invisibly for setWinProgressBar).

## Note

These functions are only available on Windows.

See Also

On all platforms, [txtProgressBar](#), [tkProgressBar](#)

Examples

```
pb <- winProgressBar("test progress bar", "Some information in %",
                     0, 100, 50)

Sys.sleep(0.5)
u <- c(0, sort(runif(20, 0, 100)), 100)
for(i in u) {
  Sys.sleep(0.1)
  info <- sprintf("%d%% done", round(i))
  setWinProgressBar(pb, i, sprintf("test (%s)", info), info)
}
Sys.sleep(5)
close(pb)
```

---

|             |                    |
|-------------|--------------------|
| write.table | <i>Data Output</i> |
|-------------|--------------------|

---

Description

`write.table` prints its required argument `x` (after converting it to a data frame if it is not one nor a matrix) to a file or [connection](#).

Usage

```
write.table(x, file = "", append = FALSE, quote = TRUE, sep = " ",
            eol = "\n", na = "NA", dec = ".", row.names = TRUE,
            col.names = TRUE, qmethod = c("escape", "double"),
            fileEncoding = "")

write.csv(...)
write.csv2(...)
```

Arguments

- `x` the object to be written, preferably a matrix or data frame. If not, it is attempted to coerce `x` to a data frame.
- `file` either a character string naming a file or a [connection](#) open for writing. "" indicates output to the console.
- `append` logical. Only relevant if `file` is a character string. If `TRUE`, the output is appended to the file. If `FALSE`, any existing file of the name is destroyed.
- `quote` a logical value (`TRUE` or `FALSE`) or a numeric vector. If `TRUE`, any character or factor columns will be surrounded by double quotes. If a numeric vector, its elements are taken as the indices of columns to quote. In both cases, row and column names are quoted if they are written. If `FALSE`, nothing is quoted.
- `sep` the field separator string. Values within each row of `x` are separated by this string.

|                           |                                                                                                                                                                                                                                                                                                                                                                                                     |
|---------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>eol</code>          | the character(s) to print at the end of each line (row). For example, <code>eol = "\r\n"</code> will produce Windows' line endings on a Unix-alike OS, and <code>eol = "\r"</code> will produce files as expected by Excel:mac 2004.                                                                                                                                                                |
| <code>na</code>           | the string to use for missing values in the data.                                                                                                                                                                                                                                                                                                                                                   |
| <code>dec</code>          | the string to use for decimal points in numeric or complex columns: must be a single character.                                                                                                                                                                                                                                                                                                     |
| <code>row.names</code>    | either a logical value indicating whether the row names of <code>x</code> are to be written along with <code>x</code> , or a character vector of row names to be written.                                                                                                                                                                                                                           |
| <code>col.names</code>    | either a logical value indicating whether the column names of <code>x</code> are to be written along with <code>x</code> , or a character vector of column names to be written. See the section on 'CSV files' for the meaning of <code>col.names = NA</code> .                                                                                                                                     |
| <code>qmethod</code>      | a character string specifying how to deal with embedded double quote characters when quoting strings. Must be one of "escape" (default for <code>write.table</code> ), in which case the quote character is escaped in C style by a backslash, or "double" (default for <code>write.csv</code> and <code>write.csv2</code> ), in which case it is doubled. You can specify just the initial letter. |
| <code>fileEncoding</code> | character string: if non-empty declares the encoding to be used on a file (not a connection) so the character data can be re-encoded as they are written. See <a href="#">file</a> .                                                                                                                                                                                                                |
| <code>...</code>          | arguments to <code>write.table</code> : <code>append</code> , <code>col.names</code> , <code>sep</code> , <code>dec</code> and <code>qmethod</code> cannot be altered.                                                                                                                                                                                                                              |

## Details

If the table has no columns the rownames will be written only if `row.names = TRUE`, and *vice versa*.

Real and complex numbers are written to the maximal possible precision.

If a data frame has matrix-like columns these will be converted to multiple columns in the result (*via* [as.matrix](#)) and so a character `col.names` or a numeric `quote` should refer to the columns in the result, not the input. Such matrix-like columns are unquoted by default.

Any columns in a data frame which are lists or have a class (e.g., dates) will be converted by the appropriate `as.character` method: such columns are unquoted by default. On the other hand, any class information for a matrix is discarded and non-atomic (e.g., list) matrices are coerced to character.

Only columns which have been converted to character will be quoted if specified by `quote`.

The `dec` argument only applies to columns that are not subject to conversion to character because they have a class or are part of a matrix-like column (or matrix), in particular to columns protected by `I()`. Use `options("OutDec")` to control such conversions.

In almost all cases the conversion of numeric quantities is governed by the option "scipen" (see [options](#)), but with the internal equivalent of `digits = 15`. For finer control, use [format](#) to make a character matrix/data frame, and call `write.table` on that.

These functions check for a user interrupt every 1000 lines of output.

If `file` is a non-open connection, an attempt is made to open it and then close it after use.

To write a Unix-style file on Windows, use a binary connection e.g. `file = file("filename", "wb")`.

## CSV files

By default there is no column name for a column of row names. If `col.names = NA` and `row.names = TRUE` a blank column name is added, which is the convention used for CSV files to be read by spreadsheets. Note that such CSV files can be read in R by

```
read.csv(file = "<filename>", row.names = 1)
```

`write.csv` and `write.csv2` provide convenience wrappers for writing CSV files. They set `sep` and `dec` (see below), `qmethod = "double"`, and `col.names` to `NA` if `row.names = TRUE` (the default) and to `TRUE` otherwise.

`write.csv` uses `"."` for the decimal point and a comma for the separator.

`write.csv2` uses a comma for the decimal point and a semicolon for the separator, the Excel convention for CSV files in some Western European locales.

These wrappers are deliberately inflexible: they are designed to ensure that the correct conventions are used to write a valid file. Attempts to change `append`, `col.names`, `sep`, `dec` or `qmethod` are ignored, with a warning.

CSV files do not record an encoding, and this causes problems if they are not ASCII for many other applications. Windows Excel 2007/10 will open files (e.g., by the file association mechanism) correctly if they are ASCII or UTF-16 (use `fileEncoding = "UTF-16LE"`) or perhaps in the current Windows codepage (e.g., `"CP1252"`), but the 'Text Import Wizard' (from the 'Data' tab) allows far more choice of encodings. Excel:mac 2004/8 can *import* only 'Macintosh' (which seems to mean Mac Roman), 'Windows' (perhaps Latin-1) and 'PC-8' files. OpenOffice 3.x asks for the character set when opening the file.

There is an IETF RFC4180 (<https://tools.ietf.org/html/rfc4180>) for CSV files, which mandates comma as the separator and CRLF line endings. `write.csv` writes compliant files on Windows: use `eol = "\r\n"` on other platforms.

## Note

`write.table` can be slow for data frames with large numbers (hundreds or more) of columns: this is inevitable as each column could be of a different class and so must be handled separately. If they are all of the same class, consider using a matrix instead.

## See Also

The 'R Data Import/Export' manual.

`read.table`, `write`.

`write.matrix` in package **MASS**.

## Examples

```
## Not run:
## To write a CSV file for input to Excel one might use
x <- data.frame(a = I("a \" quote"), b = pi)
write.table(x, file = "foo.csv", sep = ",", col.names = NA,
            qmethod = "double")
## and to read this file back into R one needs
read.table("foo.csv", header = TRUE, sep = ",", row.names = 1)
## NB: you do need to specify a separator if qmethod = "double".

### Alternatively
```

```

write.csv(x, file = "foo.csv")
read.csv("foo.csv", row.names = 1)
## or without row names
write.csv(x, file = "foo.csv", row.names = FALSE)
read.csv("foo.csv")

## To write a file in Mac Roman for simple use in Mac Excel 2004/8
write.csv(x, file = "foo.csv", fileEncoding = "macroman")
## or for Windows Excel 2007/10
write.csv(x, file = "foo.csv", fileEncoding = "UTF-16LE")

## End(Not run)

```

---

zip

---

Create Zip Archives

---

## Description

A wrapper for an external zip command to create zip archives.

## Usage

```

zip(zipfile, files, flags = "-r9X", extras = "",
    zip = Sys.getenv("R_ZIPCMD", "zip"))

```

## Arguments

|         |                                                                                                     |
|---------|-----------------------------------------------------------------------------------------------------|
| zipfile | The pathname of the zip file: tilde expansion (see <a href="#">path.expand</a> ) will be performed. |
| files   | A character vector of recorded filepaths to be included.                                            |
| flags   | A character string of flags to be passed to the command: see ‘Details’.                             |
| extras  | An optional character vector: see ‘Details’.                                                        |
| zip     | A character string specifying the external command to be used.                                      |

## Details

On a Unix-alike, the default for `zip` will by default use the value of `R_ZIPCMD`, which is set in ‘etc/Renviron’ if an `unzip` command was found during configuration. On Windows, the default relies on a `zip` program (for example that from Rtools) being in the path.

The default for `flags` is that appropriate for zipping up a directory tree in a portable way: see the system-specific help for the `zip` command for other possibilities.

Argument `extras` can be used to specify `-x` or `-i` followed by a list of filepaths to exclude or include. Since `extras` will be treated as if passed to [system](#), if the filepaths contain spaces they must be quoted e.g. by [shQuote](#).

## Value

The status value returned by the external command, invisibly.

## See Also

[unzip](#), [unz](#); further, [tar](#) and [untar](#) for (un)packing tar archives.

## **Part II**

## Chapter 15

# The KernSmooth package

---

bkde

*Compute a Binned Kernel Density Estimate*

---

### Description

Returns x and y coordinates of the binned kernel density estimate of the probability density of the data.

### Usage

```
bkde(x, kernel = "normal", canonical = FALSE, bandwidth,  
      gridsize = 401L, range.x, truncate = TRUE)
```

### Arguments

|           |                                                                                                                                                                                                                                                                                                                                                                |
|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x         | numeric vector of observations from the distribution whose density is to be estimated. Missing values are not allowed.                                                                                                                                                                                                                                         |
| bandwidth | the kernel bandwidth smoothing parameter. Larger values of <code>bandwidth</code> make smoother estimates, smaller values of <code>bandwidth</code> make less smooth estimates. The default is a bandwidth computed from the variance of <code>x</code> , specifically the ‘oversmoothed bandwidth selector’ of Wand and Jones (1995, page 61).                |
| kernel    | character string which determines the smoothing kernel. <code>kernel</code> can be: "normal" - the Gaussian density function (the default). "box" - a rectangular box. "epanech" - the centred beta(2,2) density. "biweight" - the centred beta(3,3) density. "triweight" - the centred beta(4,4) density. This can be abbreviated to any unique abbreviation. |
| canonical | logical flag: if TRUE, canonically scaled kernels are used.                                                                                                                                                                                                                                                                                                    |
| gridsize  | the number of equally spaced points at which to estimate the density.                                                                                                                                                                                                                                                                                          |
| range.x   | vector containing the minimum and maximum values of <code>x</code> at which to compute the estimate. The default is the minimum and maximum data values, extended by the support of the kernel.                                                                                                                                                                |
| truncate  | logical flag: if TRUE, data with <code>x</code> values outside the range specified by <code>range.x</code> are ignored.                                                                                                                                                                                                                                        |

## Details

This is the binned approximation to the ordinary kernel density estimate. Linear binning is used to obtain the bin counts. For each  $x$  value in the sample, the kernel is centered on that  $x$  and the heights of the kernel at each datapoint are summed. This sum, after a normalization, is the corresponding  $y$  value in the output.

## Value

a list containing the following components:

|     |                                                                 |
|-----|-----------------------------------------------------------------|
| $x$ | vector of sorted $x$ values at which the estimate was computed. |
| $y$ | vector of density estimates at the corresponding $x$ .          |

## Background

Density estimation is a smoothing operation. Inevitably there is a trade-off between bias in the estimate and the estimate's variability: large bandwidths will produce smooth estimates that may hide local features of the density; small bandwidths may introduce spurious bumps into the estimate.

bkde2D

---

*Compute a 2D Binned Kernel Density Estimate*

---

## Description

Returns the set of grid points in each coordinate direction, and the matrix of density estimates over the mesh induced by the grid points. The kernel is the standard bivariate normal density.

## Usage

```
bkde2D(x, bandwidth, gridsize = c(51L, 51L), range.x, truncate = TRUE)
```

## Arguments

|                        |                                                                                                                                                                                                                                                                                                                                                                              |
|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>         | a two-column numeric matrix containing the observations from the distribution whose density is to be estimated. Missing values are not allowed.                                                                                                                                                                                                                              |
| <code>bandwidth</code> | numeric vector of length 2, containing the bandwidth to be used in each coordinate direction.                                                                                                                                                                                                                                                                                |
| <code>gridsize</code>  | vector containing the number of equally spaced points in each direction over which the density is to be estimated.                                                                                                                                                                                                                                                           |
| <code>range.x</code>   | a list containing two vectors, where each vector contains the minimum and maximum values of <code>x</code> at which to compute the estimate for each direction. The default minimum in each direction is minimum data value minus 1.5 times the bandwidth for that direction. The default maximum is the maximum data value plus 1.5 times the bandwidth for that direction. |
| <code>truncate</code>  | logical flag: if TRUE, data with <code>x</code> values outside the range specified by <code>range.x</code> are ignored.                                                                                                                                                                                                                                                      |

## Value

a list containing the following components:

|                   |                                                                                                            |
|-------------------|------------------------------------------------------------------------------------------------------------|
| <code>x1</code>   | vector of values of the grid points in the first coordinate direction at which the estimate was computed.  |
| <code>x2</code>   | vector of values of the grid points in the second coordinate direction at which the estimate was computed. |
| <code>fhat</code> | matrix of density estimates over the mesh induced by <code>x1</code> and <code>x2</code> .                 |

## Details

This is the binned approximation to the 2D kernel density estimate. Linear binning is used to obtain the bin counts and the Fast Fourier Transform is used to perform the discrete convolutions. For each `x1,x2` pair the bivariate Gaussian kernel is centered on that location and the heights of the kernel, scaled by the bandwidths, at each datapoint are summed. This sum, after a normalization, is the corresponding `fhat` value in the output.

contour(est$x1, est$x2, est$fhat)
persp(est$fhat)
```

bkfe

*Compute a Binned Kernel Functional Estimate***Description**

Returns an estimate of a binned approximation to the kernel estimate of the specified density functional. The kernel is the standard normal density.

**Usage**

```
bkfe(x, drv, bandwidth, gridsize = 401L, range.x, binned = FALSE,
      truncate = TRUE)
```

**Arguments**

|                        |                                                                                                                                                                                                 |
|------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>         | numeric vector of observations from the distribution whose density is to be estimated. Missing values are not allowed.                                                                          |
| <code>drv</code>       | order of derivative in the density functional. Must be a non-negative even integer.                                                                                                             |
| <code>bandwidth</code> | the kernel bandwidth smoothing parameter. Must be supplied.                                                                                                                                     |
| <code>gridsize</code>  | the number of equally-spaced points over which binning is performed.                                                                                                                            |
| <code>range.x</code>   | vector containing the minimum and maximum values of <code>x</code> at which to compute the estimate. The default is the minimum and maximum data values, extended by the support of the kernel. |
| <code>binned</code>    | logical flag: if <code>TRUE</code> , then <code>x</code> and <code>y</code> are taken to be grid counts rather than raw data.                                                                   |
| <code>truncate</code>  | logical flag: if <code>TRUE</code> , data with <code>x</code> values outside the range specified by <code>range.x</code> are ignored.                                                           |

**Details**

The density functional of order `drv` is the integral of the product of the density and its `drv`th derivative. The kernel estimates of such quantities are computed using a binned implementation, and the kernel is the standard normal density.

**Value**

the (scalar) estimated functional.

**Background**

Estimates of this type were proposed by Sheather and Jones (1991).

**References**

## Examples

```
data(geyser, package="MASS")
x <- geyser$duration
est <- bkfe(x, drv=4, bandwidth=0.3)
```

dpih

*Select a Histogram Bin Width*

## Description

Uses direct plug-in methodology to select the bin width of a histogram.

## Usage

```
dpih(x, scalest = "minim", level = 2L, gridsize = 401L,
     range.x = range(x), truncate = TRUE)
```

## Arguments

|                       |                                                                                                                                                                                                    |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>        | numeric vector containing the sample on which the histogram is to be constructed.                                                                                                                  |
| <code>scalest</code>  | estimate of scale.<br>"stdev" - standard deviation is used.<br>"iqr" - inter-quartile range divided by 1.349 is used.<br>"minim" - minimum of "stdev" and "iqr" is used.                           |
| <code>level</code>    | number of levels of functional estimation used in the plug-in rule.                                                                                                                                |
| <code>gridsize</code> | number of grid points used in the binned approximations to functional estimates.                                                                                                                   |
| <code>range.x</code>  | range over which functional estimates are obtained. The default is the minimum and maximum data values.                                                                                            |
| <code>truncate</code> | if <code>truncate</code> is <code>TRUE</code> then observations outside of the interval specified by <code>range.x</code> are omitted. Otherwise, they are used to weight the extreme grid points. |

## Details

The direct plug-in approach, where unknown functionals that appear in expressions for the asymptotically optimal bin width and bandwidths are replaced by kernel estimates, is used. The normal distribution is used to provide an initial estimate.

## Value

the selected bin width.

## Background

This method for selecting the bin width of a histogram is described in Wand (1995). It is an extension of the normal scale rule of Scott (1979) and uses plug-in ideas from bandwidth selection for kernel density estimation (e.g. Sheather and Jones, 1991).

*Select a Bandwidth for Kernel Density Estimation*

---

## Description

Use direct plug-in methodology to select the bandwidth of a kernel density estimate.

## Usage

```
dpik(x, scalest = "minim", level = 2L, kernel = "normal",
     canonical = FALSE, gridsize = 401L, range.x = range(x),
     truncate = TRUE)
```

## Arguments

|           |                                                                                                                                                                                                                                                                                                                                                   |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x         | numeric vector containing the sample on which the kernel density estimate is to be constructed.                                                                                                                                                                                                                                                   |
| scalest   | estimate of scale.<br>"stdev" - standard deviation is used.<br>"iqr" - inter-quartile range divided by 1.349 is used.<br>"minim" - minimum of "stdev" and "iqr" is used.                                                                                                                                                                          |
| level     | number of levels of functional estimation used in the plug-in rule.                                                                                                                                                                                                                                                                               |
| kernel    | character string which determines the smoothing kernel. kernel can be: "normal" - the Gaussian density function (the default). "box" - a rectangular box. "epanech" - the centred beta(2,2) density. "biweight" - the centred beta(3,3) density. "triweight" - the centred beta(4,4) density. This can be abbreviated to any unique abbreviation. |
| canonical | logical flag: if TRUE, canonically scaled kernels are used                                                                                                                                                                                                                                                                                        |
| gridsize  | the number of equally-spaced points over which binning is performed to obtain kernel functional approximation.                                                                                                                                                                                                                                    |

|                       |                                                                                                                                                          |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>range.x</code>  | vector containing the minimum and maximum values of <code>x</code> at which to compute the estimate. The default is the minimum and maximum data values. |
| <code>truncate</code> | logical flag: if <code>TRUE</code> , data with <code>x</code> values outside the range specified by <code>range.x</code> are ignored.                    |

### Details

The direct plug-in approach, where unknown functionals that appear in expressions for the asymptotically optimal bandwidths are replaced by kernel estimates, is used. The normal distribution is used to provide an initial estimate.

### Value

the selected bandwidth.

### Background

This method for selecting the bandwidth of a kernel density estimate was proposed by Sheather and Jones (1991) and is described in Section 3.6 of Wand and Jones (1995).

*Select a Bandwidth for Local Linear Regression*

---

### Description

Use direct plug-in methodology to select the bandwidth of a local linear Gaussian kernel regression estimate, as described by Ruppert, Sheather and Wand (1995).

### Usage

```
dpill(x, y, blockmax = 5, divisor = 20, trim = 0.01, proptrun = 0.05,
      gridsize = 401L, range.x, truncate = TRUE)
```

### Arguments

|                       |                                                                                                                                                                                                                                                                                                      |
|-----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>        | numeric vector of <code>x</code> data. Missing values are not accepted.                                                                                                                                                                                                                              |
| <code>y</code>        | numeric vector of <code>y</code> data. This must be same length as <code>x</code> , and missing values are not accepted.                                                                                                                                                                             |
| <code>blockmax</code> | the maximum number of blocks of the data for construction of an initial parametric estimate.                                                                                                                                                                                                         |
| <code>divisor</code>  | the value that the sample size is divided by to determine a lower limit on the number of blocks of the data for construction of an initial parametric estimate.                                                                                                                                      |
| <code>trim</code>     | the proportion of the sample trimmed from each end in the <code>x</code> direction before application of the plug-in methodology.                                                                                                                                                                    |
| <code>proptrun</code> | the proportion of the range of <code>x</code> at each end truncated in the functional estimates.                                                                                                                                                                                                     |
| <code>gridsize</code> | number of equally-spaced grid points over which the function is to be estimated.                                                                                                                                                                                                                     |
| <code>range.x</code>  | vector containing the minimum and maximum values of <code>x</code> at which to compute the estimate. For density estimation the default is the minimum and maximum data values with 5% of the range added to each end. For regression estimation the default is the minimum and maximum data values. |
| <code>truncate</code> | logical flag: if TRUE, data with <code>x</code> values outside the range specified by <code>range.x</code> are ignored.                                                                                                                                                                              |

### Details

The direct plug-in approach, where unknown functionals that appear in expressions for the asymptotically optimal bandwidths are replaced by kernel estimates, is used. The kernel is the standard normal density. Least squares quartic fits over blocks of data are used to obtain an initial estimate. Mallows's  $C_p$  is used to select the number of blocks.

### Value

the selected bandwidth.

### Warning

If there are severe irregularities (i.e. outliers, sparse regions) in the `x` values then the local polynomial smooths required for the bandwidth selection algorithm may become degenerate and the function will crash. Outliers in the `y` direction may lead to deterioration of the quality of the selected bandwidth.

```

locpoly

*Estimate Functions Using Local Polynomials***Description**

Estimates a probability density function, regression function or their derivatives using local polynomials. A fast binned implementation over an equally-spaced grid is used.

**Usage**

```
locpoly(x, y, drv = 0L, degree, kernel = "normal",
        bandwidth, gridsize = 401L, bwdisc = 25,
        range.x, binned = FALSE, truncate = TRUE)
```

**Arguments**

|                        |                                                                                                                                                                                                     |
|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>         | numeric vector of <code>x</code> data. Missing values are not accepted.                                                                                                                             |
| <code>bandwidth</code> | the kernel bandwidth smoothing parameter. It may be a single number or an array having length <code>gridsize</code> , representing a bandwidth that varies according to the location of estimation. |
| <code>y</code>         | vector of <code>y</code> data. This must be same length as <code>x</code> , and missing values are not accepted.                                                                                    |
| <code>drv</code>       | order of derivative to be estimated.                                                                                                                                                                |
| <code>degree</code>    | degree of local polynomial used. Its value must be greater than or equal to the value of <code>drv</code> . The default value is of degree is <code>drv + 1</code> .                                |
| <code>kernel</code>    | "normal" - the Gaussian density function. Currently ignored.                                                                                                                                        |
| <code>gridsize</code>  | number of equally-spaced grid points over which the function is to be estimated.                                                                                                                    |
| <code>bwdisc</code>    | number of logarithmically-equally-spaced bandwidths on which <code>bandwidth</code> is discretised, to speed up computation.                                                                        |
| <code>range.x</code>   | vector containing the minimum and maximum values of <code>x</code> at which to compute the estimate.                                                                                                |
| <code>binned</code>    | logical flag: if <code>TRUE</code> , then <code>x</code> and <code>y</code> are taken to be grid counts rather than raw data.                                                                       |
| <code>truncate</code>  | logical flag: if <code>TRUE</code> , data with <code>x</code> values outside the range specified by <code>range.x</code> are ignored.                                                               |

**Value**

if `y` is specified, a local polynomial regression estimate of  $E[Y|X]$  (or its derivative) is computed. If `y` is missing, a local polynomial estimate of the density of `x` (or its derivative) is computed.

a list containing the following components:

|                |                                                                                                             |
|----------------|-------------------------------------------------------------------------------------------------------------|
| <code>x</code> | vector of sorted <code>x</code> values at which the estimate was computed.                                  |
| <code>y</code> | vector of smoothed estimates for either the density or the regression at the corresponding <code>x</code> . |

**Details**

Local polynomial fitting with a kernel weight is used to estimate either a density, regression function or their derivatives. In the case of density estimation, the data are binned and the local fitting procedure is applied to the bin counts. In either case, binned approximations over an equally-spaced grid is used for fast computation. The bandwidth may be either scalar or a vector of length `gridsize`.

---

addterm

*Try All One-Term Additions to a Model*

---

## Description

Try fitting all models that differ from the current model by adding a single term from those supplied, maintaining marginality.

This function is generic; there exist methods for classes `lm` and `glm` and the default method will work for many other classes.

## Usage

```
addterm(object, ...)
```

```
## Default S3 method:
addterm(object, scope, scale = 0, test = c("none", "Chisq"),
        k = 2, sorted = FALSE, trace = FALSE, ...)
```

```
## S3 method for class 'lm'
addterm(object, scope, scale = 0, test = c("none", "Chisq", "F"),
        k = 2, sorted = FALSE, ...)
```

```
## S3 method for class 'glm'
addterm(object, scope, scale = 0, test = c("none", "Chisq", "F"),
        k = 2, sorted = FALSE, trace = FALSE, ...)
```

## Arguments

|                     |                                                                                                                                                                                                                                                                                                                                                             |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code> | An object fitted by some model-fitting function.                                                                                                                                                                                                                                                                                                            |
| <code>scope</code>  | a formula specifying a maximal model which should include the current one. All additional terms in the maximal model with all marginal terms in the original model are tried.                                                                                                                                                                               |
| <code>scale</code>  | used in the definition of the AIC statistic for selecting the models, currently only for <code>lm</code> , <code>aov</code> and <code>glm</code> models. Specifying <code>scale</code> asserts that the residual standard error or dispersion is known.                                                                                                     |
| <code>test</code>   | should the results include a test statistic relative to the original model? The F test is only appropriate for <code>lm</code> and <code>aov</code> models, and perhaps for some over-dispersed <code>glm</code> models. The Chisq test can be an exact test ( <code>lm</code> models with known scale) or a likelihood-ratio test depending on the method. |
| <code>k</code>      | the multiple of the number of degrees of freedom used for the penalty. Only <code>k=2</code> gives the genuine AIC: $k = \log(n)$ is sometimes referred to as BIC or SBC.                                                                                                                                                                                   |
| <code>sorted</code> | should the results be sorted on the value of AIC?                                                                                                                                                                                                                                                                                                           |
| <code>trace</code>  | if TRUE additional information may be given on the fits as they are tried.                                                                                                                                                                                                                                                                                  |
| <code>...</code>    | arguments passed to or from other methods.                                                                                                                                                                                                                                                                                                                  |

## Details

The definition of AIC is only up to an additive constant: when appropriate (l<sub>m</sub> models with specified scale) the constant is taken to be that used in Mallows' Cp statistic and the results are labelled accordingly.

## Value

A table of class "anova" containing at least columns for the change in degrees of freedom and AIC (or Cp) for the models. Some methods will give further information, for example sums of squares, deviances, log-likelihoods and test statistics.

Aids2

---

*Australian AIDS Survival Data*

---

## Description

Data on patients diagnosed with AIDS in Australia before 1 July 1991.

## Usage

```
Aids2
```

## Format

This data frame contains 2843 rows and the following columns:

`state` Grouped state of origin: "NSW" includes ACT and "other" is WA, SA, NT and TAS.  
`sex` Sex of patient.  
`diag` (Julian) date of diagnosis.  
`death` (Julian) date of death or end of observation.  
`status` "A" (alive) or "D" (dead) at end of observation.  
`T.categ` Reported transmission category.  
`age` Age (years) at diagnosis.

**Note**

This data set has been slightly jittered as a condition of its release, to ensure patient confidentiality.

**Source**

Dr P. J. Solomon and the Australian National Centre in HIV Epidemiology and Clinical Research.

`anorexia`*Anorexia Data on Weight Change*

---

**Description**

The `anorexia` data frame has 72 rows and 3 columns. Weight change data for young female anorexia patients.

**Usage**

```
anorexia
```

**Format**

This data frame contains the following columns:

`Treat` Factor of three levels: "Cont" (control), "CBT" (Cognitive Behavioural treatment) and "FT" (family treatment).

`Prewt` Weight of patient before study period, in lbs.

`Postwt` Weight of patient after study period, in lbs.

**Source**

---

`anova.negbin`*Likelihood Ratio Tests for Negative Binomial GLMs*

---

**Description**

Method function to perform sequential likelihood ratio tests for Negative Binomial generalized linear models.

**Usage**

```
## S3 method for class 'negbin'
anova(object, ..., test = "Chisq")
```

### Arguments

|                     |                                                                                                                                                                                                                                                       |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code> | Fitted model object of class <code>"negbin"</code> , inheriting from classes <code>"glm"</code> and <code>"lm"</code> , specifying a Negative Binomial fitted GLM. Typically the output of <code>glm.nb()</code> .                                    |
| <code>...</code>    | Zero or more additional fitted model objects of class <code>"negbin"</code> . They should form a nested sequence of models, but need not be specified in any particular order.                                                                        |
| <code>test</code>   | Argument to match the <code>test</code> argument of <code>anova.glm</code> . Ignored (with a warning if changed) if a sequence of two or more Negative Binomial fitted model objects is specified, but possibly used if only one object is specified. |

### Details

This function is a method for the generic function `anova()` for class `"negbin"`. It can be invoked by calling `anova(x)` for an object `x` of the appropriate class, or directly by calling `anova.negbin(x)` regardless of the class of the object.

### Note

If only one fitted model object is specified, a sequential analysis of deviance table is given for the fitted model. The `theta` parameter is kept fixed. If more than one fitted model object is specified they must all be of class `"negbin"` and likelihood ratio tests are done of each model within the next. In this case `theta` is assumed to have been re-estimated for each model.

### References

Venables, W. N. and Ripley, B. D. (2002) *Modern Applied Statistics with S*. Fourth edition. Springer.

### See Also

[glm.nb](#), [negative.binomial](#), [summary.negbin](#)

### Examples

```
m1 <- glm.nb(Days ~ Eth*Age*Lrn*Sex, quine, link = log)
m2 <- update(m1, . ~ . - Eth:Age:Lrn:Sex)
anova(m2, m1)
anova(m2)
```

---

area

*Adaptive Numerical Integration*

---

### Description

Integrate a function of one variable over a finite range using a recursive adaptive method. This function is mainly for demonstration purposes.

### Usage

```
area(f, a, b, ..., fa = f(a, ...), fb = f(b, ...),
     limit = 10, eps = 1e-05)
```

**Arguments**

|                    |                                                                                                |
|--------------------|------------------------------------------------------------------------------------------------|
| <code>f</code>     | The integrand as an S function object. The variable of integration must be the first argument. |
| <code>a</code>     | Lower limit of integration.                                                                    |
| <code>b</code>     | Upper limit of integration.                                                                    |
| <code>...</code>   | Additional arguments needed by the integrand.                                                  |
| <code>fa</code>    | Function value at the lower limit.                                                             |
| <code>fb</code>    | Function value at the upper limit.                                                             |
| <code>limit</code> | Limit on the depth to which recursion is allowed to go.                                        |
| <code>eps</code>   | Error tolerance to control the process.                                                        |

**Details**

The method divides the interval in two and compares the values given by Simpson's rule and the trapezium rule. If these are within `eps` of each other the Simpson's rule result is given, otherwise the process is applied separately to each half of the interval and the results added together.

**Value**

The integral from `a` to `b` of  $f(x)$ .

**References**

Venables, W. N. and Ripley, B. D. (1994) *Modern Applied Statistics with S-Plus*. Springer. pp. 105–110.

**Examples**

```
area(sin, 0, pi) # integrate the sin function from 0 to pi.
```

---

|          |                                                   |
|----------|---------------------------------------------------|
| bacteria | <i>Presence of Bacteria after Drug Treatments</i> |
|----------|---------------------------------------------------|

---

**Description**

Tests of the presence of the bacteria *H. influenzae* in children with otitis media in the Northern Territory of Australia.

**Usage**

```
bacteria
```

**Format**

This data frame has 220 rows and the following columns:

**y** presence or absence: a factor with levels `n` and `y`.

**ap** active/placebo: a factor with levels `a` and `p`.

**hilo** hi/low compliance: a factor with levels `hi` and `lo`.

**week** numeric: week of test.

**ID** subject ID: a factor.

**trt** a factor with levels `placebo`, `drug` and `drug+`, a re-coding of `ap` and `hilo`.

## Details

Dr A. Leach tested the effects of a drug on 50 children with a history of otitis media in the Northern Territory of Australia. The children were randomized to the drug or the a placebo, and also to receive active encouragement to comply with taking the drug.

The presence of *H. influenzae* was checked at weeks 0, 2, 4, 6 and 11: 30 of the checks were missing and are not included in this data frame.

```

---

bandwidth.nrd

*Bandwidth for density() via Normal Reference Distribution*

---

## Description

A well-supported rule-of-thumb for choosing the bandwidth of a Gaussian kernel density estimator.

## Usage

```
bandwidth.nrd(x)
```

**Arguments**

`x` A data vector.

**Value**

A bandwidth on a scale suitable for the `width` argument of `density`.

**References**

Venables, W. N. and Ripley, B. D. (2002) *Modern Applied Statistics with S*. Springer, equation (5.5) on page 130.

**Examples**

```
# The function is currently defined as
function(x)
{
  r <- quantile(x, c(0.25, 0.75))
  h <- (r[2] - r[1])/1.34
  4 * 1.06 * min(sqrt(var(x)), h) * length(x)^(-1/5)
}
```

---

bcv

*Biased Cross-Validation for Bandwidth Selection*

---

**Description**

Uses biased cross-validation to select the bandwidth of a Gaussian kernel density estimator.

**Usage**

```
bcv(x, nb = 1000, lower, upper)
```

**Arguments**

`x` a numeric vector

`nb` number of bins to use.

`lower, upper` Range over which to minimize. The default is almost always satisfactory.

**Value**

a bandwidth

beav1

---

*Body Temperature Series of Beaver 1*

---

**Description**

Reynolds (1994) describes a small part of a study of the long-term temperature dynamics of beaver *Castor canadensis* in north-central Wisconsin. Body temperature was measured by telemetry every 10 minutes for four females, but data from a one period of less than a day for each of two animals is used there.

**Usage**

```
beav1
```

**Format**

The `beav1` data frame has 114 rows and 4 columns. This data frame contains the following columns:

`day` Day of observation (in days since the beginning of 1990), December 12–13.

`time` Time of observation, in the form 0330 for 3.30am.

`temp` Measured body temperature in degrees Celsius.

`activ` Indicator of activity outside the retreat.

**Note**

The observation at 22:20 is missing.

**Source**

P. S. Reynolds (1994) Time-series analyses of beaver body temperatures. Chapter 11 of Lange, N., Ryan, L., Billard, L., Brillinger, D., Conquest, L. and Greenhouse, J. eds (1994) *Case Studies in Biometry*. New York: John Wiley and Sons.

Belgian-phones

*Belgium Phone Calls 1950-1973*

---

## Description

A list object with the annual numbers of telephone calls, in Belgium. The components are:

`year` last two digits of the year.

`calls` number of telephone calls made (in millions of calls).

## Usage

`phones`

## Source

P. J. Rousseeuw and A. M. Leroy (1987) *Robust Regression & Outlier Detection*. Wiley.

## References

---

biopsy*Biopsy Data on Breast Cancer Patients*

---

**Description**

This breast cancer database was obtained from the University of Wisconsin Hospitals, Madison from Dr. William H. Wolberg. He assessed biopsies of breast tumours for 699 patients up to 15 July 1992; each of nine attributes has been scored on a scale of 1 to 10, and the outcome is also known. There are 699 rows and 11 columns.

**Usage**

biopsy

**Format**

This data frame contains the following columns:

ID sample code number (not unique).  
V1 clump thickness.  
V2 uniformity of cell size.  
V3 uniformity of cell shape.  
V4 marginal adhesion.  
V5 single epithelial cell size.  
V6 bare nuclei (16 values are missing).  
V7 bland chromatin.  
V8 normal nucleoli.  
V9 mitoses.  
class "benign" or "malignant".

birthwt

*Risk Factors Associated with Low Infant Birth Weight*

---

## Description

The `birthwt` data frame has 189 rows and 10 columns. The data were collected at Baystate Medical Center, Springfield, Mass during 1986.

## Usage

```
birthwt
```

## Format

This data frame contains the following columns:

`low` indicator of birth weight less than 2.5 kg.  
`age` mother's age in years.  
`lwt` mother's weight in pounds at last menstrual period.  
`race` mother's race (1 = white, 2 = black, 3 = other).  
`smoke` smoking status during pregnancy.  
`ptl` number of previous premature labours.  
`ht` history of hypertension.  
`ui` presence of uterine irritability.  
`ftv` number of physician visits during the first trimester.  
`bwt` birth weight in grams.

## References

Venables, W. N. and Ripley, B. D. (2002) *Modern Applied Statistics with S*. Fourth edition. Springer.

## Examples

```
bwt <- with(birthwt, {
  race <- factor(race, labels = c("white", "black", "other"))
  ptd <- factor(ptl > 0)
  ftv <- factor(ftv)
  levels(ftv)[-1:2] <- "2+"
  data.frame(low = factor(low), age, lwt, race, smoke = (smoke > 0),
             ptd, ht = (ht > 0), ui = (ui > 0), ftv)
})
options(contrasts = c("contr.treatment", "contr.poly"))
glm(low ~ ., binomial, bwt)
```

---

 Boston

*Housing Values in Suburbs of Boston*

---

### Description

The `Boston` data frame has 506 rows and 14 columns.

### Usage

`Boston`

### Format

This data frame contains the following columns:

`crim` per capita crime rate by town.

`zn` proportion of residential land zoned for lots over 25,000 sq.ft.

`indus` proportion of non-retail business acres per town.

`chas` Charles River dummy variable (= 1 if tract bounds river; 0 otherwise).

`nox` nitrogen oxides concentration (parts per 10 million).

`rm` average number of rooms per dwelling.

`age` proportion of owner-occupied units built prior to 1940.

`dis` weighted mean of distances to five Boston employment centres.

`rad` index of accessibility to radial highways.

`tax` full-value property-tax rate per \$10,000.

`ptratio` pupil-teacher ratio by town.

`black`  $1000(Bk - 0.63)^2$  where  $Bk$  is the proportion of blacks by town.

`lstat` lower status of the population (percent).

`medv` median value of owner-occupied homes in \$1000s.

boxcox

*Box-Cox Transformations for Linear Models***Description**

Computes and optionally plots profile log-likelihoods for the parameter of the Box-Cox power transformation.

**Usage**

```
boxcox(object, ...)
```

```
## Default S3 method:
boxcox(object, lambda = seq(-2, 2, 1/10), plotit = TRUE,
        interp, eps = 1/50, xlab = expression(lambda),
        ylab = "log-Likelihood", ...)
```

```
## S3 method for class 'formula'
boxcox(object, lambda = seq(-2, 2, 1/10), plotit = TRUE,
        interp, eps = 1/50, xlab = expression(lambda),
        ylab = "log-Likelihood", ...)
```

```
## S3 method for class 'lm'
boxcox(object, lambda = seq(-2, 2, 1/10), plotit = TRUE,
        interp, eps = 1/50, xlab = expression(lambda),
        ylab = "log-Likelihood", ...)
```

**Arguments**

|                     |                                                                                                                                                         |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code> | a formula or fitted model object. Currently only <code>lm</code> and <code>aov</code> objects are handled.                                              |
| <code>lambda</code> | vector of values of <code>lambda</code> – default $(-2, 2)$ in steps of 0.1.                                                                            |
| <code>plotit</code> | logical which controls whether the result should be plotted.                                                                                            |
| <code>interp</code> | logical which controls whether spline interpolation is used. Default to <code>TRUE</code> if plotting with <code>lambda</code> of length less than 100. |
| <code>eps</code>    | Tolerance for <code>lambda = 0</code> ; defaults to 0.02.                                                                                               |
| <code>xlab</code>   | defaults to <code>"lambda"</code> .                                                                                                                     |
| <code>ylab</code>   | defaults to <code>"log-Likelihood"</code> .                                                                                                             |
| <code>...</code>    | additional parameters to be used in the model fitting.                                                                                                  |

**Value**

A list of the `lambda` vector and the computed profile log-likelihood vector, invisibly if the result is plotted.

**Side Effects**

If `plotit = TRUE` plots log-likelihood vs `lambda` and indicates a 95% confidence interval about the maximum observed value of `lambda`. If `interp = TRUE`, spline interpolation is used to give a smoother plot.

## Examples

```
boxcox(Volume ~ log(Height) + log(Girth), data = trees,
       lambda = seq(-0.25, 0.25, length = 10))

boxcox(Days+1 ~ Eth*Sex*Age*Lrn, data = quine,
       lambda = seq(-0.05, 0.45, len = 20))
```

---

cabbages

*Data from a cabbage field trial*

---

## Description

The cabbages data set has 60 observations and 4 variables

## Usage

```
cabbages
```

## Format

This data frame contains the following columns:

**Cult** Factor giving the cultivar of the cabbage, two levels: c39 and c52.

**Date** Factor specifying one of three planting dates: d16, d20 or d21.

**HeadWt** Weight of the cabbage head, presumably in kg.

**VitC** Ascorbic acid content, in undefined units.

caith

*Colours of Eyes and Hair of People in Caithness*

---

### Description

Data on the cross-classification of people in Caithness, Scotland, by eye and hair colour. The region of the UK is particularly interesting as there is a mixture of people of Nordic, Celtic and Anglo-Saxon origin.

### Usage

```
caith
```

### Format

A 4 by 5 table with rows the eye colours (blue, light, medium, dark) and columns the hair colours (fair, red, medium, dark, black).

par(mfcol=c(1,3))
plot(corresp(caith, nf=2)); title("symmetric")
plot(corresp(caith, nf=2), type="rows"); title("rows")
plot(corresp(caith, nf=2), type="col"); title("columns")
par(mfrow=c(1,1))
```

---

Cars93

*Data from 93 Cars on Sale in the USA in 1993*

---

### Description

The Cars93 data frame has 93 rows and 27 columns.

### Usage

```
Cars93
```

## Format

This data frame contains the following columns:

Manufacturer Manufacturer.

Model Model.

Type Type: a factor with levels "Small", "Sporty", "Compact", "Midsize", "Large" and "Van".

Min.Price Minimum Price (in \$1,000): price for a basic version.

Price Midrange Price (in \$1,000): average of Min.Price and Max.Price.

Max.Price Maximum Price (in \$1,000): price for "a premium version".

MPG.city City MPG (miles per US gallon by EPA rating).

MPG.highway Highway MPG.

AirBags Air Bags standard. Factor: none, driver only, or driver & passenger.

DriveTrain Drive train type: rear wheel, front wheel or 4WD; (factor).

Cylinders Number of cylinders (missing for Mazda RX-7, which has a rotary engine).

EngineSize Engine size (litres).

Horsepower Horsepower (maximum).

RPM RPM (revs per minute at maximum horsepower).

Rev.per.mile Engine revolutions per mile (in highest gear).

Man.trans.avail Is a manual transmission version available? (yes or no, Factor).

Fuel.tank.capacity Fuel tank capacity (US gallons).

Passengers Passenger capacity (persons)

Length Length (inches).

Wheelbase Wheelbase (inches).

Width Width (inches).

Turn.circle U-turn space (feet).

Rear.seat.room Rear seat room (inches) (missing for 2-seater vehicles).

Luggage.room Luggage capacity (cubic feet) (missing for vans).

Weight Weight (pounds).

Origin Of non-USA or USA company origins? (factor).

Make Combination of Manufacturer and Model (character).

## Details

Cars were selected at random from among 1993 passenger car models that were listed in both the *Consumer Reports* issue and the *PACE Buying Guide*. Pickup trucks and Sport/Utility vehicles were eliminated due to incomplete information in the *Consumer Reports* source. Duplicate models (e.g., Dodge Shadow and Plymouth Sundance) were listed at most once.

Further description can be found in Lock (1993).

cats

*Anatomical Data from Domestic Cats*

---

## Description

The heart and body weights of samples of male and female cats used for *digitalis* experiments. The cats were all adult, over 2 kg body weight.

## Usage

cats

## Format

This data frame contains the following columns:

Sex sex: Factor with levels "F" and "M".

Bwt body weight in kg.

Hwt heart weight in g.

---

cement

*Heat Evolved by Setting Cements*

---

## Description

Experiment on the heat evolved in the setting of each of 13 cements.

## Usage

cement

## Format

x1, x2, x3, x4 Proportions (%) of active ingredients.

y heat evolved in cal/gm.

**Details**

Thirteen samples of Portland cement were set. For each sample, the percentages of the four main chemical ingredients was accurately measured. While the cement was setting the amount of heat evolved was also measured.

**Source**

Woods, H., Steinour, H.H. and Starke, H.R. (1932) Effect of composition of Portland cement on heat evolved during hardening. *Industrial Engineering and Chemistry*, **24**, 1207–1214.

**References**

Hald, A. (1957) *Statistical Theory with Engineering Applications*. Wiley, New York.

**Examples**

```
lm(y ~ x1 + x2 + x3 + x4, cement)
```

---

chem

*Copper in Wholemeal Flour*

---

**Description**

A numeric vector of 24 determinations of copper in wholemeal flour, in parts per million.

**Usage**

```
chem
```

**Source**

Analytical Methods Committee (1989) Robust statistics – how not to reject outliers. *The Analyst* **114**, 1693–1702.

---

con2tr

*Convert Lists to Data Frames for use by lattice*

---

### Description

Convert lists to data frames for use by lattice.

### Usage

```
con2tr(obj)
```

### Arguments

obj                    A list of components x, y and z as passed to `contour`.

### Details

`con2tr` repeats the x and y components suitably to match the vector z.

### Value

A data frame suitable for passing to lattice (formerly trellis) functions.

### References

Venables, W. N. and Ripley, B. D. (2002) *Modern Applied Statistics with S*. Fourth edition. Springer.

---

confint-MASS

*Confidence Intervals for Model Parameters*

---

### Description

Computes confidence intervals for one or more parameters in a fitted model. Package **MASS** adds methods for `glm` and `nls` fits.

### Usage

```
## S3 method for class 'glm'
confint(object, parm, level = 0.95, trace = FALSE, ...)

## S3 method for class 'nls'
confint(object, parm, level = 0.95, ...)
```

## Arguments

|                     |                                                                                                                                                                       |
|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code> | a fitted model object. Methods currently exist for the classes "glm", "nls" and for profile objects from these classes.                                               |
| <code>parm</code>   | a specification of which parameters are to be given confidence intervals, either a vector of numbers or a vector of names. If missing, all parameters are considered. |
| <code>level</code>  | the confidence level required.                                                                                                                                        |
| <code>trace</code>  | logical. Should profiling be traced?                                                                                                                                  |
| <code>...</code>    | additional argument(s) for methods.                                                                                                                                   |

## Details

`confint` is a generic function in package `stats`.

These `confint` methods call the appropriate profile method, then find the confidence intervals by interpolation in the profile traces. If the profile object is already available it should be used as the main argument rather than the fitted model object itself.

## Value

A matrix (or vector) with columns giving lower and upper confidence limits for each parameter. These will be labelled as  $(1 - \text{level})/2$  and  $1 - (1 - \text{level})/2$  in % (by default 2.5% and 97.5%).

## References

Venables, W. N. and Ripley, B. D. (2002) *Modern Applied Statistics with S*. Fourth edition. Springer.

## See Also

`confint` (the generic and "lm" method), `profile`

## Examples

```
expn1 <- deriv(y ~ b0 + b1 * 2^(-x/th), c("b0", "b1", "th"),
               function(b0, b1, th, x) {})

wtloss.gr <- nls(Weight ~ expn1(b0, b1, th, Days),
               data = wtloss, start = c(b0=90, b1=95, th=120))

expn2 <- deriv(~b0 + b1*((w0 - b0)/b1)^(x/d0),
               c("b0", "b1", "d0"), function(b0, b1, d0, x, w0) {})

wtloss.init <- function(obj, w0) {
  p <- coef(obj)
  d0 <- - log((w0 - p["b0"])/p["b1"])/log(2) * p["th"]
  c(p[c("b0", "b1")], d0 = as.vector(d0))
}

out <- NULL
w0s <- c(110, 100, 90)
for(w0 in w0s) {
  fm <- nls(Weight ~ expn2(b0, b1, d0, Days, w0),
           wtloss, start = wtloss.init(wtloss.gr, w0))
  out <- rbind(out, c(coef(fm)["d0"], confint(fm, "d0")))
```

```

    }
    dimnames(out) <- list(paste(w0s, "kg:"), c("d0", "low", "high"))
    out

    ldose <- rep(0:5, 2)
    numdead <- c(1, 4, 9, 13, 18, 20, 0, 2, 6, 10, 12, 16)
    sex <- factor(rep(c("M", "F"), c(6, 6)))
    SF <- cbind(numdead, numalive = 20 - numdead)
    budworm.lg0 <- glm(SF ~ sex + ldose - 1, family = binomial)
    confint(budworm.lg0)
    confint(budworm.lg0, "ldose")

```

---

contr.sdif

---

*Successive Differences Contrast Coding*

---

## Description

A coding for factors based on successive differences.

## Usage

```
contr.sdif(n, contrasts = TRUE, sparse = FALSE)
```

## Arguments

|           |                                                                                                                          |
|-----------|--------------------------------------------------------------------------------------------------------------------------|
| n         | The number of levels required.                                                                                           |
| contrasts | logical: Should there be $n - 1$ columns orthogonal to the mean (the default) or $n$ columns spanning the space?         |
| sparse    | logical. If true and the result would be sparse (only true for <code>contrasts = FALSE</code> ), return a sparse matrix. |

## Details

The contrast coefficients are chosen so that the coded coefficients in a one-way layout are the differences between the means of the second and first levels, the third and second levels, and so on. This makes most sense for ordered factors, but does not assume that the levels are equally spaced.

## Value

If `contrasts` is `TRUE`, a matrix with  $n$  rows and  $n - 1$  columns, and the  $n$  by  $n$  identity matrix if `contrasts` is `FALSE`.

---

**Description**

Seven specimens were sent to 6 laboratories in 3 separate batches and each analysed for Analyte. Each analysis was duplicated.

**Usage**`coop`**Format**

This data frame contains the following columns:

`Lab` Laboratory, L1, L2, ..., L6.

`Spc` Specimen, S1, S2, ..., S7.

`Bat` Batch, B1, B2, B3 (nested within `Spc/Lab`),

`Conc` Concentration of Analyte in *g/kg*.

**Source**

`corresp`*Simple Correspondence Analysis*

---

**Description**

Find the principal canonical correlation and corresponding row- and column-scores from a correspondence analysis of a two-way contingency table.

**Usage**

```
corresp(x, ...)

## S3 method for class 'matrix'
corresp(x, nf = 1, ...)

## S3 method for class 'factor'
corresp(x, y, ...)

## S3 method for class 'data.frame'
corresp(x, ...)

## S3 method for class 'xtabs'
corresp(x, ...)

## S3 method for class 'formula'
corresp(formula, data, ...)
```

**Arguments**

|                         |                                                                                                                                                                                                                                                                                                                           |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x, formula</code> | The function is generic, accepting various forms of the principal argument for specifying a two-way frequency table. Currently accepted forms are matrices, data frames (coerced to frequency tables), objects of class " <code>xtabs</code> " and formulae of the form $\sim F1 + F2$ , where $F1$ and $F2$ are factors. |
| <code>nf</code>         | The number of factors to be computed. Note that although 1 is the most usual, one school of thought takes the first two singular vectors for a sort of biplot.                                                                                                                                                            |
| <code>y</code>          | a second factor for a cross-classification.                                                                                                                                                                                                                                                                               |
| <code>data</code>       | an optional data frame, list or environment against which to preferentially resolve variables in the formula.                                                                                                                                                                                                             |
| <code>...</code>        | If the principal argument is a formula, a data frame may be specified as well from which variables in the formula are preferentially satisfied.                                                                                                                                                                           |

**Details**

See Venables & Ripley (2002). The `plot` method produces a graphical representation of the table if `nf=1`, with the *areas* of circles representing the numbers of points. If `nf` is two or more the `biplot` method is called, which plots the second and third columns of the matrices  $A = D_r^{(-1/2)} U L$  and  $B = D_c^{(-1/2)} V L$  where the singular value decomposition is  $U L V$ . Thus the x-axis is the canonical correlation times the row and column scores. Although this is called a biplot, it does *not* have any useful inner product relationship between the row and column scores. Think of this as an equally-scaled plot with two unrelated sets of labels. The origin is marked on the plot with a cross. (For other versions of this plot see the book.)

**Value**

An list object of class "`correspondence`" for which `print`, `plot` and `biplot` methods are supplied. The main components are the canonical correlation(s) and the row and column scores.

 cov.rob

---

*Resistant Estimation of Multivariate Location and Scatter*

---

**Description**

Compute a multivariate location and scale estimate with a high breakdown point – this can be thought of as estimating the mean and covariance of the good part of the data. `cov.mve` and `cov.mcd` are compatibility wrappers.

**Usage**

```
cov.rob(x, cor = FALSE, quantile.used = floor((n + p + 1)/2),
        method = c("mve", "mcd", "classical"),
        nsamp = "best", seed)

cov.mve(...)
cov.mcd(...)
```

**Arguments**

|                            |                                                                                                                                                                                                                                                                                        |
|----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>             | a matrix or data frame.                                                                                                                                                                                                                                                                |
| <code>cor</code>           | should the returned result include a correlation matrix?                                                                                                                                                                                                                               |
| <code>quantile.used</code> | the minimum number of the data points regarded as good points.                                                                                                                                                                                                                         |
| <code>method</code>        | the method to be used – minimum volume ellipsoid, minimum covariance determinant or classical product-moment. Using <code>cov.mve</code> or <code>cov.mcd</code> forces <code>mve</code> or <code>mcd</code> respectively.                                                             |
| <code>nsamp</code>         | the number of samples or "best" or "exact" or "sample". The limit If "sample" the number chosen is $\min(5 \cdot p, 3000)$ , taken from Rousseeuw and Hubert (1997). If "best" exhaustive enumeration is done up to 5000 samples: if "exact" exhaustive enumeration will be attempted. |
| <code>seed</code>          | the seed to be used for random sampling: see <a href="#">RNGkind</a> . The current value of <code>.Random.seed</code> will be preserved if it is set.                                                                                                                                  |
| <code>...</code>           | arguments to <code>cov.rob</code> other than <code>method</code> .                                                                                                                                                                                                                     |

## Details

For method "mve", an approximate search is made of a subset of size `quantile.used` with an enclosing ellipsoid of smallest volume; in method "mcd" it is the volume of the Gaussian confidence ellipsoid, equivalently the determinant of the classical covariance matrix, that is minimized. The mean of the subset provides a first estimate of the location, and the rescaled covariance matrix a first estimate of scatter. The Mahalanobis distances of all the points from the location estimate for this covariance matrix are calculated, and those points within the 97.5% point under Gaussian assumptions are declared to be `good`. The final estimates are the mean and rescaled covariance of the `good` points.

The rescaling is by the appropriate percentile under Gaussian data; in addition the first covariance matrix has an *ad hoc* finite-sample correction given by Marazzi.

For method "mve" the search is made over ellipsoids determined by the covariance matrix of `p` of the data points. For method "mcd" an additional improvement step suggested by Rousseeuw and van Driessen (1999) is used, in which once a subset of size `quantile.used` is selected, an ellipsoid based on its covariance is tested (as this will have no larger a determinant, and may be smaller).

There is a hard limit on the allowed number of samples,  $2^{31} - 1$ . However, practical limits are likely to be much lower and one might check the number of samples used for exhaustive enumeration, `combn (NROW (x) , NCOL (x) + 1 )`, before attempting it.

## Value

A list with components

|                     |                                                                                                                         |
|---------------------|-------------------------------------------------------------------------------------------------------------------------|
| <code>center</code> | the final estimate of location.                                                                                         |
| <code>cov</code>    | the final estimate of scatter.                                                                                          |
| <code>cor</code>    | (only is <code>cor = TRUE</code> ) the estimate of the correlation matrix.                                              |
| <code>sing</code>   | message giving number of singular samples out of total                                                                  |
| <code>crit</code>   | the value of the criterion on log scale. For MCD this is the determinant, and for MVE it is proportional to the volume. |
| <code>best</code>   | the subset used. For MVE the best sample, for MCD the best set of size <code>quantile.used</code> .                     |
| <code>n.obs</code>  | total number of observations.                                                                                           |

cov.trob

*Covariance Estimation for Multivariate t Distribution***Description**

Estimates a covariance or correlation matrix assuming the data came from a multivariate t distribution: this provides some degree of robustness to outlier without giving a high breakdown point.

**Usage**

```
cov.trob(x, wt = rep(1, n), cor = FALSE, center = TRUE, nu = 5,
         maxit = 25, tol = 0.01)
```

**Arguments**

|                     |                                                                                                                                                                                                                                    |
|---------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>      | data matrix. Missing values (NAs) are not allowed.                                                                                                                                                                                 |
| <code>wt</code>     | A vector of weights for each case: these are treated as if the case <code>i</code> actually occurred <code>wt[i]</code> times.                                                                                                     |
| <code>cor</code>    | Flag to choose between returning the correlation ( <code>cor = TRUE</code> ) or covariance ( <code>cor = FALSE</code> ) matrix.                                                                                                    |
| <code>center</code> | a logical value or a numeric vector providing the location about which the covariance is to be taken. If <code>center = FALSE</code> , no centering is done; if <code>center = TRUE</code> the MLE of the location vector is used. |
| <code>nu</code>     | 'degrees of freedom' for the multivariate t distribution. Must exceed 2 (so that the covariance matrix is finite).                                                                                                                 |
| <code>maxit</code>  | Maximum number of iterations in fitting.                                                                                                                                                                                           |
| <code>tol</code>    | Convergence tolerance for fitting.                                                                                                                                                                                                 |

**Value**

A list with the following components

|                     |                                                                                 |
|---------------------|---------------------------------------------------------------------------------|
| <code>cov</code>    | the fitted covariance matrix.                                                   |
| <code>center</code> | the estimated or specified location vector.                                     |
| <code>wt</code>     | the specified weights: only returned if the <code>wt</code> argument was given. |
| <code>n.obs</code>  | the number of cases used in the fitting.                                        |
| <code>cor</code>    | the fitted correlation matrix: only returned if <code>cor = TRUE</code> .       |
| <code>call</code>   | The matched call.                                                               |
| <code>iter</code>   | The number of iterations used.                                                  |

## Description

A relative performance measure and characteristics of 209 CPUs.

## Usage

```
cpus
```

## Format

The components are:

`name` manufacturer and model.

`syct` cycle time in nanoseconds.

`mmin` minimum main memory in kilobytes.

`mmax` maximum main memory in kilobytes.

`cach` cache size in kilobytes.

`chmin` minimum number of channels.

`chmax` maximum number of channels.

`perf` published performance on a benchmark mix relative to an IBM 370/158-3.

`estperf` estimated performance (by Ein-Dor & Feldmesser).

crabs

*Morphological Measurements on Leptograpsus Crabs***Description**

The `crabs` data frame has 200 rows and 8 columns, describing 5 morphological measurements on 50 crabs each of two colour forms and both sexes, of the species *Leptograpsus variegatus* collected at Fremantle, W. Australia.

**Usage**

```
crabs
```

**Format**

This data frame contains the following columns:

`sp` species - "B" or "O" for blue or orange.

`sex` as it says.

`index` index 1 : 50 within each of the four groups.

`FL` frontal lobe size (mm).

`RW` rear width (mm).

`CL` carapace length (mm).

`CW` carapace width (mm).

`BD` body depth (mm).

Cushings

*Diagnostic Tests on Patients with Cushing's Syndrome***Description**

Cushing's syndrome is a hypertensive disorder associated with over-secretion of cortisol by the adrenal gland. The observations are urinary excretion rates of two steroid metabolites.

**Usage**

```
Cushings
```

**Format**

The Cushings data frame has 27 rows and 3 columns:

Tetrahydrocortisone urinary excretion rate (mg/24hr) of Tetrahydrocortisone.

Pregnanetriol urinary excretion rate (mg/24hr) of Pregnanetriol.

Type underlying type of syndrome, coded a (adenoma) , b (bilateral hyperplasia), c (carcinoma) or u for unknown.

---

denumerate

---

*Transform an Allowable Formula for 'loglm' into one for 'terms'*

---

## Description

[loglm](#) allows dimension numbers to be used in place of names in the formula. `denumerate` modifies such a formula into one that [terms](#) can process.

## Usage

```
denumerate(x)
```

## Arguments

`x` A formula conforming to the conventions of [loglm](#), that is, it may allow dimension numbers to stand in for names when specifying a log-linear model.

## Details

The model fitting function [loglm](#) fits log-linear models to frequency data using iterative proportional scaling. To specify the model the user must nominate the margins in the data that remain fixed under the log-linear model. It is convenient to allow the user to use dimension numbers, 1, 2, 3, ... for the first, second, third, ..., margins in a similar way to variable names. As the model formula has to be parsed by [terms](#), which treats 1 in a special way and requires parseable variable names, these formulae have to be modified by giving genuine names for these margin, or dimension numbers. `denumerate` replaces these numbers with names of a special form, namely `n` is replaced by `.vn`. This allows [terms](#) to parse the formula in the usual way.

## Value

A linear model formula like that presented, except that where dimension numbers, say `n`, have been used to specify fixed margins these are replaced by names of the form `.vn` which may be processed by [terms](#).

## See Also

[renumerate](#)

## Examples

```
denumerate(~(1+2+3)^3 + a/b)
## which gives ~ (.v1 + .v2 + .v3)^3 + a/b
```

---

dose.p

---

*Predict Doses for Binomial Assay model*

---

**Description**

Calibrate binomial assays, generalizing the calculation of LD50.

**Usage**

```
dose.p(obj, cf = 1:2, p = 0.5)
```

**Arguments**

|     |                                                                                        |
|-----|----------------------------------------------------------------------------------------|
| obj | A fitted model object of class inheriting from "glm".                                  |
| cf  | The terms in the coefficient vector giving the intercept and coefficient of (log-)dose |
| p   | Probabilities at which to predict the dose needed.                                     |

**Value**

An object of class "glm.dose" giving the prediction (attribute "p" and standard error (attribute "SE") at each response probability.

**References**

Venables, W. N. and Ripley, B. D. (2002) *Modern Applied Statistics with S*. Springer.

**Examples**

```
ldose <- rep(0:5, 2)
numdead <- c(1, 4, 9, 13, 18, 20, 0, 2, 6, 10, 12, 16)
sex <- factor(rep(c("M", "F"), c(6, 6)))
SF <- cbind(numdead, numalive = 20 - numdead)
budworm.lg0 <- glm(SF ~ sex + ldose - 1, family = binomial)

dose.p(budworm.lg0, cf = c(1,3), p = 1:3/4)
dose.p(update(budworm.lg0, family = binomial(link=probit)),
        cf = c(1,3), p = 1:3/4)
```

---

drivers

---

*Deaths of Car Drivers in Great Britain 1969-84*

---

**Description**

A regular time series giving the monthly totals of car drivers in Great Britain killed or seriously injured Jan 1969 to Dec 1984. Compulsory wearing of seat belts was introduced on 31 Jan 1983

**Usage**

```
drivers
```

---

dropterm

---

*Try All One-Term Deletions from a Model*

---

## Description

Try fitting all models that differ from the current model by dropping a single term, maintaining marginality.

This function is generic; there exist methods for classes `lm` and `glm` and the default method will work for many other classes.

## Usage

```
dropterm (object, ...)

## Default S3 method:
dropterm(object, scope, scale = 0, test = c("none", "Chisq"),
         k = 2, sorted = FALSE, trace = FALSE, ...)

## S3 method for class 'lm'
dropterm(object, scope, scale = 0, test = c("none", "Chisq", "F"),
         k = 2, sorted = FALSE, ...)

## S3 method for class 'glm'
dropterm(object, scope, scale = 0, test = c("none", "Chisq", "F"),
         k = 2, sorted = FALSE, trace = FALSE, ...)
```

## Arguments

|                     |                                                                                                                                                                                                                                                                                                                                                            |
|---------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code> | A object fitted by some model-fitting function.                                                                                                                                                                                                                                                                                                            |
| <code>scope</code>  | a formula giving terms which might be dropped. By default, the model formula. Only terms that can be dropped and maintain marginality are actually tried.                                                                                                                                                                                                  |
| <code>scale</code>  | used in the definition of the AIC statistic for selecting the models, currently only for <code>lm</code> , <code>ao</code> and <code>glm</code> models. Specifying <code>scale</code> asserts that the residual standard error or dispersion is known.                                                                                                     |
| <code>test</code>   | should the results include a test statistic relative to the original model? The F test is only appropriate for <code>lm</code> and <code>ao</code> models, and perhaps for some over-dispersed <code>glm</code> models. The Chisq test can be an exact test ( <code>lm</code> models with known scale) or a likelihood-ratio test depending on the method. |
| <code>k</code>      | the multiple of the number of degrees of freedom used for the penalty. Only <code>k = 2</code> gives the genuine AIC: <code>k = log(n)</code> is sometimes referred to as BIC or SBC.                                                                                                                                                                      |

|        |                                                                            |
|--------|----------------------------------------------------------------------------|
| sorted | should the results be sorted on the value of AIC?                          |
| trace  | if TRUE additional information may be given on the fits as they are tried. |
| ...    | arguments passed to or from other methods.                                 |

**Details**

The definition of AIC is only up to an additive constant: when appropriate (lm models with specified scale) the constant is taken to be that used in Mallows' Cp statistic and the results are labelled accordingly.

**Value**

A table of class "anova" containing at least columns for the change in degrees of freedom and AIC (or Cp) for the models. Some methods will give further information, for example sums of squares, deviances, log-likelihoods and test statistics.

```

---

 epil

---

*Seizure Counts for Epileptics*

---

**Description**

Thall and Vail (1990) give a data set on two-week seizure counts for 59 epileptics. The number of seizures was recorded for a baseline period of 8 weeks, and then patients were randomly assigned to a treatment group or a control group. Counts were then recorded for four successive two-week periods. The subject's age is the only covariate.

**Usage**

epil

### Format

This data frame has 236 rows and the following 9 columns:

`y` the count for the 2-week period.  
`trt` treatment, "placebo" or "progabide".  
`base` the counts in the baseline 8-week period.  
`age` subject's age, in years.  
`V4` 0/1 indicator variable of period 4.  
`subject` subject number, 1 to 59.  
`period` period, 1 to 4.  
`lbase` log-counts for the baseline period, centred to have zero mean.  
`lage` log-ages, centred to have zero mean.

### Source

            family = poisson, data = epil3), cor = FALSE)
## IGNORE_RDIFF_END

summary(glmmPQL(y ~ lbase*trt + lage + V4,
                random = ~ 1 | subject,
                family = poisson, data = epil))
summary(glmmPQL(y ~ pred, random = ~1 | subject,
                family = poisson, data = epil3))
```

---

eqsplot

---

*Plots with Geometrically Equal Scales*

---

**Description**

Version of a scatterplot with scales chosen to be equal on both axes, that is 1cm represents the same units on each

**Usage**

```
eqsplot(x, y, ratio = 1, tol = 0.04, uin, ...)
```

**Arguments**

|                    |                                                                                                                                                                                                         |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>     | vector of x values, or a 2-column matrix, or a list with components <code>x</code> and <code>y</code>                                                                                                   |
| <code>y</code>     | vector of y values                                                                                                                                                                                      |
| <code>ratio</code> | desired ratio of units on the axes. Units on the y axis are drawn at <code>ratio</code> times the size of units on the x axis. Ignored if <code>uin</code> is specified and of length 2.                |
| <code>tol</code>   | proportion of white space at the margins of plot                                                                                                                                                        |
| <code>uin</code>   | desired values for the units-per-inch parameter. If of length 1, the desired units per inch on the x axis.                                                                                              |
| <code>...</code>   | further arguments for <code>plot</code> and graphical parameters. Note that <code>par(xaxs="i", yaxs="i")</code> is enforced, and <code>xlim</code> and <code>ylim</code> will be adjusted accordingly. |

**Details**

Limits for the x and y axes are chosen so that they include the data. One of the sets of limits is then stretched from the midpoint to make the units in the ratio given by `ratio`. Finally both are stretched by  $1 + \text{tol}$  to move points away from the axes, and the points plotted.

**Value**

invisibly, the values of `uin` used for the plot.

**Side Effects**

performs the plot.

**Note**

Arguments `ratio` and `uin` were suggested by Bill Dunlap.

farms

*Ecological Factors in Farm Management***Description**

The `farms` data frame has 20 rows and 4 columns. The rows are farms on the Dutch island of Terschelling and the columns are factors describing the management of grassland.

**Usage**

```
farms
```

**Format**

This data frame contains the following columns:

`Mois` Five levels of soil moisture – level 3 does not occur at these 20 farms.

`Manag` Grassland management type (SF = standard, BF = biological, HF = hobby farming, NM = nature conservation).

`Use` Grassland use (U1 = hay production, U2 = intermediate, U3 = grazing).

`Manure` Manure usage – classes C0 to C4.

fgl

*Measurements of Forensic Glass Fragments***Description**

The `fgl` data frame has 214 rows and 10 columns. It was collected by B. German on fragments of glass collected in forensic work.

**Usage**

```
fgl
```

**Format**

This data frame contains the following columns:

RI refractive index; more precisely the refractive index is 1.518xxxx.

The next 8 measurements are percentages by weight of oxides.

Na sodium.

Mg manganese.

Al aluminium.

Si silicon.

K potassium.

Ca calcium.

Ba barium.

Fe iron.

`type` The fragments were originally classed into seven types, one of which was absent in this dataset. The categories which occur are window float glass (`WinF`: 70), window non-float glass (`WinNF`: 76), vehicle window glass (`Veh`: 17), containers (`Con`: 13), tableware (`Tabl`: 9) and vehicle headlamps (`Head`: 29).

fitdistr

*Maximum-likelihood Fitting of Univariate Distributions***Description**

Maximum-likelihood fitting of univariate distributions, allowing parameters to be held fixed if desired.

**Usage**

```
fitdistr(x, densfun, start, ...)
```

## Arguments

|                      |                                                                                                                                                                                                                                                                                                                                                 |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>       | A numeric vector of length at least one containing only <a href="#">finite</a> values.                                                                                                                                                                                                                                                          |
| <code>densfun</code> | Either a character string or a function returning a density evaluated at its first argument.<br>Distributions "beta", "cauchy", "chi-squared", "exponential", "gamma", "geometric", "log-normal", "lognormal", "logistic", "negative binomial", "normal", "Poisson", "t" and "weibull" are recognised, case being ignored.                      |
| <code>start</code>   | A named list giving the parameters to be optimized with initial values. This can be omitted for some of the named distributions and must be for others (see <a href="#">Details</a> ).                                                                                                                                                          |
| <code>...</code>     | Additional parameters, either for <code>densfun</code> or for <code>optim</code> . In particular, it can be used to specify bounds via <code>lower</code> or <code>upper</code> or both. If arguments of <code>densfun</code> (or the density function corresponding to a character-string specification) are included they will be held fixed. |

## Details

For the Normal, log-Normal, geometric, exponential and Poisson distributions the closed-form MLEs (and exact standard errors) are used, and `start` should not be supplied.

For all other distributions, direct optimization of the log-likelihood is performed using [optim](#). The estimated standard errors are taken from the observed information matrix, calculated by a numerical approximation. For one-dimensional problems the Nelder-Mead method is used and for multi-dimensional problems the BFGS method, unless arguments named `lower` or `upper` are supplied (when `L-BFGS-B` is used) or `method` is supplied explicitly.

For the "t" named distribution the density is taken to be the location-scale family with location `m` and scale `s`.

For the following named distributions, reasonable starting values will be computed if `start` is omitted or only partially specified: "cauchy", "gamma", "logistic", "negative binomial" (parametrized by `mu` and `size`), "t" and "weibull". Note that these starting values may not be good enough if the fit is poor: in particular they are not resistant to outliers unless the fitted distribution is long-tailed.

There are [print](#), [coef](#), [vcov](#) and [logLik](#) methods for class "fitdistr".

## Value

An object of class "fitdistr", a list with four components,

|                       |                                               |
|-----------------------|-----------------------------------------------|
| <code>estimate</code> | the parameter estimates,                      |
| <code>sd</code>       | the estimated standard errors,                |
| <code>vcov</code>     | the estimated variance-covariance matrix, and |
| <code>loglik</code>   | the log-likelihood.                           |

## Note

Numerical optimization cannot work miracles: please note the comments in [optim](#) on scaling data. If the fitted parameters are far away from one, consider re-fitting specifying the control parameter `parscale`.

fractions

*Rational Approximation***Description**

Find rational approximations to the components of a real numeric object using a standard continued fraction method.

**Usage**

```
fractions(x, cycles = 10, max.denominator = 2000, ...)
```

**Arguments**

|                              |                                                                                                                                             |
|------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>               | Any object of mode numeric. Missing values are now allowed.                                                                                 |
| <code>cycles</code>          | The maximum number of steps to be used in the continued fraction approximation process.                                                     |
| <code>max.denominator</code> | An early termination criterion. If any partial denominator exceeds <code>max.denominator</code> the continued fraction stops at that point. |
| <code>...</code>             | arguments passed to or from other methods.                                                                                                  |

**Details**

Each component is first expanded in a continued fraction of the form

$$x = \text{floor}(x) + 1 / (p_1 + 1 / (p_2 + \dots))$$

where  $p_1, p_2, \dots$  are positive integers, terminating either at `cycles` terms or when a  $p_j > \text{max.denominator}$ . The continued fraction is then re-arranged to retrieve the numerator and denominator as integers.

The numerators and denominators are then combined into a character vector that becomes the "fracs" attribute and used in printed representations.

Arithmetic operations on "fractions" objects have full floating point accuracy, but the character representation printed out may not.

**Value**

An object of class "fractions". A structure with `.Data` component the same as the input numeric `x`, but with the rational approximations held as a character vector attribute, "fracs". Arithmetic operations on "fractions" objects are possible.

**Examples**

```
X <- matrix(runif(25), 5, 5)
zapsmall(solve(X, X/5)) # print near-zeroes as zero
fractions(solve(X, X/5))
fractions(solve(X, X/5)) + 1
```

GAGurine

*Level of GAG in Urine of Children***Description**

Data were collected on the concentration of a chemical GAG in the urine of 314 children aged from zero to seventeen years. The aim of the study was to produce a chart to help a paediatrician to assess if a child's GAG concentration is 'normal'.

**Usage**

```
GAGurine
```

**Format**

This data frame contains the following columns:

Age age of child in years.

GAG concentration of GAG (the units have been lost).

**Source**

Mrs Susan Prosser, Paediatrics Department, University of Oxford, via Department of Statistics Consulting Service.

**References**

galaxies

*Velocities for 82 Galaxies***Description**

A numeric vector of velocities in km/sec of 82 galaxies from 6 well-separated conic sections of an unfilled survey of the Corona Borealis region. Multimodality in such surveys is evidence for voids and superclusters in the far universe.

**Usage**

```
galaxies
```

**Note**

There is an 83rd measurement of 5607 km/sec in the Postman *et al.* paper which is omitted in Roeder (1990) and from the dataset here.

There is also a typo: this dataset has 78th observation 26690 which should be 26960.

---

|             |                                                                            |
|-------------|----------------------------------------------------------------------------|
| gamma.shape | <i>Estimate the Shape Parameter of the Gamma Distribution in a GLM Fit</i> |
|-------------|----------------------------------------------------------------------------|

---

**Description**

Find the maximum likelihood estimate of the shape parameter of the gamma distribution after fitting a Gamma generalized linear model.

**Usage**

```
## S3 method for class 'glm'
gamma.shape(object, it.lim = 10,
            eps.max = .Machine$double.eps^0.25, verbose = FALSE, ...)
```

**Arguments**

|         |                                                                                                           |
|---------|-----------------------------------------------------------------------------------------------------------|
| object  | Fitted model object from a Gamma family or quasi family with <code>variance = "mu^2"</code> .             |
| it.lim  | Upper limit on the number of iterations.                                                                  |
| eps.max | Maximum discrepancy between approximations for the iteration process to continue.                         |
| verbose | If TRUE, causes successive iterations to be printed out. The initial estimate is taken from the deviance. |
| ...     | further arguments passed to or from other methods.                                                        |

**Details**

A glm fit for a Gamma family correctly calculates the maximum likelihood estimate of the mean parameters but provides only a crude estimate of the dispersion parameter. This function takes the results of the glm fit and solves the maximum likelihood equation for the reciprocal of the dispersion parameter, which is usually called the shape (or exponent) parameter.

**Value**

List of two components

|       |                                                                                                |
|-------|------------------------------------------------------------------------------------------------|
| alpha | the maximum likelihood estimate                                                                |
| SE    | the approximate standard error, the square-root of the reciprocal of the observed information. |

gehan

*Remission Times of Leukaemia Patients*

---

## Description

A data frame from a trial of 42 leukaemia patients. Some were treated with the drug *6-mercaptopurine* and the rest are controls. The trial was designed as matched pairs, both withdrawn from the trial when either came out of remission.

## Usage

gehan

## Format

This data frame contains the following columns:

`pair` label for pair.

`time` remission time in weeks.

`cens` censoring, 0/1.

`treat` treatment, control or 6-MP.

## Source

summary(gehan.cox)
```

---

genotype

*Rat Genotype Data*

---

## Description

Data from a foster feeding experiment with rat mothers and litters of four different genotypes: A, B, I and J. Rat litters were separated from their natural mothers at birth and given to foster mothers to rear.

## Usage

```
genotype
```

## Format

The data frame has the following components:

`Litter` genotype of the litter.

`Mother` genotype of the foster mother.

`Wt` Litter average weight gain of the litter, in grams at age 28 days. (The source states that the within-litter variability is negligible.)

geyser

*Old Faithful Geyser Data*

---

## Description

A version of the eruptions data from the ‘Old Faithful’ geyser in Yellowstone National Park, Wyoming. This version comes from Azzalini and Bowman (1990) and is of continuous measurement from August 1 to August 15, 1985.

Some nocturnal duration measurements were coded as 2, 3 or 4 minutes, having originally been described as ‘short’, ‘medium’ or ‘long’.

## Usage

```
geyser
```

## Format

A data frame with 299 observations on 2 variables.

|          |         |                                |
|----------|---------|--------------------------------|
| duration | numeric | Eruption time in mins          |
| waiting  | numeric | Waiting time for this eruption |

## Note

The `waiting` time was incorrectly described as the time to the next eruption in the original files, and corrected for **MASS** version 7.3-30.

gilgais*Line Transect of Soil in Gilgai Territory*

---

**Description**

This dataset was collected on a line transect survey in gilgai territory in New South Wales, Australia. Gilgais are natural gentle depressions in otherwise flat land, and sometimes seem to be regularly distributed. The data collection was stimulated by the question: are these patterns reflected in soil properties? At each of 365 sampling locations on a linear grid of 4 meters spacing, samples were taken at depths 0-10 cm, 30-40 cm and 80-90 cm below the surface. pH, electrical conductivity and chloride content were measured on a 1:5 soil:water extract from each sample.

**Usage**

gilgais

**Format**

This data frame contains the following columns:

pH00 pH at depth 0–10 cm.  
pH30 pH at depth 30–40 cm.  
pH80 pH at depth 80–90 cm.  
e00 electrical conductivity in mS/cm (0–10 cm).  
e30 electrical conductivity in mS/cm (30–40 cm).  
e80 electrical conductivity in mS/cm (80–90 cm).  
c00 chloride content in ppm (0–10 cm).  
c30 chloride content in ppm (30–40 cm).  
c80 chloride content in ppm (80–90 cm).

ginv

*Generalized Inverse of a Matrix***Description**

Calculates the Moore-Penrose generalized inverse of a matrix X.

**Usage**

```
ginv(X, tol = sqrt(.Machine$double.eps))
```

**Arguments**

X                      Matrix for which the Moore-Penrose inverse is required.  
tol                     A relative tolerance to detect zero singular values.

**Value**

A MP generalized inverse matrix for X.

**References**

Venables, W. N. and Ripley, B. D. (1999) *Modern Applied Statistics with S-PLUS*. Third Edition. Springer. p.100.

**See Also**

[solve](#), [svd](#), [eigen](#)

glm.convert

*Change a Negative Binomial fit to a GLM fit***Description**

This function modifies an output object from `glm.nb()` to one that looks like the output from `glm()` with a negative binomial family. This allows it to be updated keeping the theta parameter fixed.

**Usage**

```
glm.convert(object)
```

**Arguments**

object                An object of class "negbin", typically the output from `glm.nb()`.

**Details**

Convenience function needed to effect some low level changes to the structure of the fitted model object.

**Value**

An object of class "glm" with negative binomial family. The theta parameter is then fixed at its present estimate.

**See Also**

[glm.nb](#), [negative.binomial](#), [glm](#)

**Examples**

```
quine.nbl <- glm.nb(Days ~ Sex/(Age + Eth*Lrn), data = quine)
quine.nbA <- glm.convert(quine.nbl)
quine.nbB <- update(quine.nbl, . ~ . + Sex:Age:Lrn)
anova(quine.nbA, quine.nbB)
```

---

|        |                                                         |
|--------|---------------------------------------------------------|
| glm.nb | <i>Fit a Negative Binomial Generalized Linear Model</i> |
|--------|---------------------------------------------------------|

---

**Description**

A modification of the system function [glm\(\)](#) to include estimation of the additional parameter, `theta`, for a Negative Binomial generalized linear model.

**Usage**

```
glm.nb(formula, data, weights, subset, na.action,
       start = NULL, etastart, mustart,
       control = glm.control(...), method = "glm.fit",
       model = TRUE, x = FALSE, y = TRUE, contrasts = NULL, ...,
       init.theta, link = log)
```

**Arguments**

`formula`, `data`, `weights`, `subset`, `na.action`, `start`, `etastart`, `mustart`, `control`, `method`,  
arguments for the [glm\(\)](#) function. Note that these exclude family and offset (but [offset\(\)](#) can be used).

`init.theta` Optional initial value for the theta parameter. If omitted a moment estimator after an initial fit using a Poisson GLM is used.

`link` The link function. Currently must be one of `log`, `sqrt` or `identity`.

**Details**

An alternating iteration process is used. For given `theta` the GLM is fitted using the same process as used by [glm\(\)](#). For fixed means the `theta` parameter is estimated using score and information iterations. The two are alternated until convergence of both. (The number of alternations and the number of iterations when estimating `theta` are controlled by the `maxit` parameter of [glm.control\(\)](#).)

Setting `trace > 0` traces the alternating iteration process. Setting `trace > 1` traces the [glm](#) fit, and setting `trace > 2` traces the estimation of `theta`.

**Value**

A fitted model object of class `negbin` inheriting from `glm` and `lm`. The object is like the output of `glm` but contains three additional components, namely `theta` for the ML estimate of  $\theta$ , `SE.theta` for its approximate standard error (using observed rather than expected information), and `twologlik` for twice the log-likelihood function.

**References**

**See Also**

`glm`, `negative.binomial`, `anova.negbin`, `summary.negbin`, `theta.md`

There is a `simulate` method.

**Examples**

```
quine.nb1 <- glm.nb(Days ~ Sex/(Age + Eth*Lrn), data = quine)
quine.nb2 <- update(quine.nb1, . ~ . + Sex:Age:Lrn)
quine.nb3 <- update(quine.nb2, Days ~ .^4)
anova(quine.nb1, quine.nb2, quine.nb3)
```

---

glmmPQL

*Fit Generalized Linear Mixed Models via PQL*

---

**Description**

Fit a GLMM model with multivariate normal random effects, using Penalized Quasi-Likelihood.

**Usage**

```
glmmPQL(fixed, random, family, data, correlation, weights,
        control, niter = 10, verbose = TRUE, ...)
```

**Arguments**

|                          |                                                                                                                                                                                        |
|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>fixed</code>       | a two-sided linear formula giving fixed-effects part of the model.                                                                                                                     |
| <code>random</code>      | a formula or list of formulae describing the random effects.                                                                                                                           |
| <code>family</code>      | a GLM family.                                                                                                                                                                          |
| <code>data</code>        | an optional data frame, list or environment used as the first place to find variables in the formulae, <code>weights</code> and if present in <code>...</code> , <code>subset</code> . |
| <code>correlation</code> | an optional correlation structure.                                                                                                                                                     |
| <code>weights</code>     | optional case weights as in <code>glm</code> .                                                                                                                                         |
| <code>control</code>     | an optional argument to be passed to <code>lme</code> .                                                                                                                                |
| <code>niter</code>       | maximum number of iterations.                                                                                                                                                          |
| <code>verbose</code>     | logical: print out record of iterations?                                                                                                                                               |
| <code>...</code>         | Further arguments for <code>lme</code> .                                                                                                                                               |

## Details

glmmPQL works by repeated calls to [lme](#), so package nlme will be loaded at first use if necessary.

## Value

A object of class "lme": see [lmeObject](#).

hills

---

*Record Times in Scottish Hill Races*

---

## Description

The record times in 1984 for 35 Scottish hill races.

## Usage

```
hills
```

## Format

The components are:

`dist` distance in miles (on the map).

`climb` total height gained during the route, in feet.

`time` record time in minutes.

## Source

A.C. Atkinson (1986) Comment: Aspects of diagnostic regression analysis. *Statistical Science* **1**, 397–402.

[A.C. Atkinson (1988) Transformations unmasked. *Technometrics* **30**, 311–318 “corrects” the time for Knock Hill from 78.65 to 18.65. It is unclear if this based on the original records.]

hist.scott

*Plot a Histogram with Automatic Bin Width Selection*

---

## Description

Plot a histogram with automatic bin width selection, using the Scott or Freedman–Diaconis formulae.

## Usage

```
hist.scott(x, prob = TRUE, xlab = deparse(substitute(x)), ...)
hist.FD(x, prob = TRUE, xlab = deparse(substitute(x)), ...)
```

## Arguments

|           |                                                           |
|-----------|-----------------------------------------------------------|
| x         | A data vector                                             |
| prob      | Should the plot have unit area, so be a density estimate? |
| xlab, ... | Further arguments to hist.                                |

## Value

For the `nclass.*` functions, the suggested number of classes.

## Side Effects

Plot a histogram.

housing

*Frequency Table from a Copenhagen Housing Conditions Survey***Description**

The housing data frame has 72 rows and 5 variables.

**Usage**

```
housing
```

**Format**

Sat Satisfaction of householders with their present housing circumstances, (High, Medium or Low, ordered factor).

Infl Perceived degree of influence householders have on the management of the property (High, Medium, Low).

Type Type of rental accommodation, (Tower, Atrium, Apartment, Terrace).

Cont Contact residents are afforded with other residents, (Low, High).

Freq Frequencies: the numbers of residents in each class.

huber

*Huber M-estimator of Location with MAD Scale*

---

## Description

Finds the Huber M-estimator of location with MAD scale.

## Usage

```
huber(y, k = 1.5, tol = 1e-06)
```

**Arguments**

|                  |                                                  |
|------------------|--------------------------------------------------|
| <code>y</code>   | vector of data values                            |
| <code>k</code>   | Winsorizes at <code>k</code> standard deviations |
| <code>tol</code> | convergence tolerance                            |

**Value**

|                                       |                    |
|---------------------------------------|--------------------|
| list of location and scale parameters |                    |
| <code>mu</code>                       | location estimate  |
| <code>s</code>                        | MAD scale estimate |

immer

*Yields from a Barley Field Trial*

---

**Description**

The `immer` data frame has 30 rows and 4 columns. Five varieties of barley were grown in six locations in each of 1931 and 1932.

**Usage**

```
immer
```

**Format**

This data frame contains the following columns:

`Loc` The location.

`Var` The variety of barley ("manchuria", "svansota", "velvet", "trebi" and "peatland").

`Y1` Yield in 1931.

`Y2` Yield in 1932.

**Source**

Immer, F.R., Hayes, H.D. and LeRoy Powers (1934) Statistical determination of barley varietal adaptation. *Journal of the American Society for Agronomy* **26**, 403–419.

## Examples

```
immer.aov <- aov(cbind(Y1,Y2) ~ Loc + Var, data = immer)
summary(immer.aov)

immer.aov <- aov((Y1+Y2)/2 ~ Var + Loc, data = immer)
summary(immer.aov)
model.tables(immer.aov, type = "means", se = TRUE, cterms = "Var")
```

---

Insurance

*Numbers of Car Insurance claims*

---

## Description

The data given in data frame `Insurance` consist of the numbers of policyholders of an insurance company who were exposed to risk, and the numbers of car insurance claims made by those policyholders in the third quarter of 1973.

## Usage

```
Insurance
```

## Format

This data frame contains the following columns:

`District` factor: district of residence of policyholder (1 to 4): 4 is major cities.

`Group` an ordered factor: group of car with levels <1 litre, 1–1.5 litre, 1.5–2 litre, >2 litre.

`Age` an ordered factor: the age of the insured in 4 groups labelled <25, 25–29, 30–35, >35.

`HOLDERS` numbers of policyholders.

`Claims` numbers of claims

## References

Venables, W. N. and Ripley, B. D. (1999) *Modern Applied Statistics with S-PLUS*. Third Edition. Springer.

## Examples

```
## main-effects fit as Poisson GLM with offset
glm(Claims ~ District + Group + Age + offset(log(Holders)),
     data = Insurance, family = poisson)

# same via loglm
loglm(Claims ~ District + Group + Age + offset(log(Holders)),
      data = Insurance)
```

isoMDS

*Kruskal's Non-metric Multidimensional Scaling*

## Description

One form of non-metric multidimensional scaling

## Usage

```
isoMDS(d, y = cmdscale(d, k), k = 2, maxit = 50, trace = TRUE,
      tol = 1e-3, p = 2)
```

```
Shepard(d, x, p = 2)
```

## Arguments

|       |                                                                                                                                                                                                                                                        |
|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| d     | distance structure of the form returned by <code>dist</code> , or a full, symmetric matrix. Data are assumed to be dissimilarities or relative distances, but must be positive except for self-distance. Both missing and infinite values are allowed. |
| y     | An initial configuration. If none is supplied, <code>cmdscale</code> is used to provide the classical solution, unless there are missing or infinite dissimilarities.                                                                                  |
| k     | The desired dimension for the solution, passed to <code>cmdscale</code> .                                                                                                                                                                              |
| maxit | The maximum number of iterations.                                                                                                                                                                                                                      |
| trace | Logical for tracing optimization. Default <code>TRUE</code> .                                                                                                                                                                                          |
| tol   | convergence tolerance.                                                                                                                                                                                                                                 |
| p     | Power for Minkowski distance in the configuration space.                                                                                                                                                                                               |
| x     | A final configuration.                                                                                                                                                                                                                                 |

## Details

This chooses a  $k$ -dimensional (default  $k = 2$ ) configuration to minimize the stress, the square root of the ratio of the sum of squared differences between the input distances and those of the configuration to the sum of configuration distances squared. However, the input distances are allowed a monotonic transformation.

An iterative algorithm is used, which will usually converge in around 10 iterations. As this is necessarily an  $O(n^2)$  calculation, it is slow for large datasets. Further, since for the default  $p = 2$  the configuration is only determined up to rotations and reflections (by convention the centroid is at the origin), the result can vary considerably from machine to machine.

**Value**

Two components:

|                     |                                                |
|---------------------|------------------------------------------------|
| <code>points</code> | A k-column vector of the fitted configuration. |
| <code>stress</code> | The final stress achieved (in percent).        |

**Side Effects**

If `trace` is true, the initial stress and the current stress are printed out every 5 iterations.

---

kde2d

---

*Two-Dimensional Kernel Density Estimation*

---

**Description**

Two-dimensional kernel density estimation with an axis-aligned bivariate normal kernel, evaluated on a square grid.

**Usage**

```
kde2d(x, y, h, n = 25, lims = c(range(x), range(y)))
```

**Arguments**

|                   |                                                                                                                                                                                     |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>    | x coordinate of data                                                                                                                                                                |
| <code>y</code>    | y coordinate of data                                                                                                                                                                |
| <code>h</code>    | vector of bandwidths for x and y directions. Defaults to normal reference bandwidth (see <a href="#">bandwidth.nrd</a> ). A scalar value will be taken to apply to both directions. |
| <code>n</code>    | Number of grid points in each direction. Can be scalar or a length-2 integer vector.                                                                                                |
| <code>lims</code> | The limits of the rectangle covered by the grid as <code>c(xl, xu, yl, yu)</code> .                                                                                                 |

**Value**

A list of three components.

`x`, `y`            The x and y coordinates of the grid points, vectors of length `n`.

`z`                An `n[1]` by `n[2]` matrix of the estimated density: rows correspond to the value of `x`, columns to the value of `y`.

 lda

*Linear Discriminant Analysis*

---

**Description**

Linear discriminant analysis.

**Usage**

```
lda(x, ...)

## S3 method for class 'formula'
lda(formula, data, ..., subset, na.action)

## Default S3 method:
```

```
lda(x, grouping, prior = proportions, tol = 1.0e-4,
    method, CV = FALSE, nu, ...)

## S3 method for class 'data.frame'
lda(x, ...)

## S3 method for class 'matrix'
lda(x, grouping, ..., subset, na.action)
```

### Arguments

|                        |                                                                                                                                                                                                                                                                                         |
|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>formula</code>   | A formula of the form <code>groups ~ x1 + x2 + . . .</code> . That is, the response is the grouping factor and the right hand side specifies the (non-factor) discriminators.                                                                                                           |
| <code>data</code>      | An optional data frame, list or environment from which variables specified in <code>formula</code> are preferentially to be taken.                                                                                                                                                      |
| <code>x</code>         | (required if no formula is given as the principal argument.) a matrix or data frame or Matrix containing the explanatory variables.                                                                                                                                                     |
| <code>grouping</code>  | (required if no formula principal argument is given.) a factor specifying the class for each observation.                                                                                                                                                                               |
| <code>prior</code>     | the prior probabilities of class membership. If unspecified, the class proportions for the training set are used. If present, the probabilities should be specified in the order of the factor levels.                                                                                  |
| <code>tol</code>       | A tolerance to decide if a matrix is singular; it will reject variables and linear combinations of unit-variance variables whose variance is less than <code>tol^2</code> .                                                                                                             |
| <code>subset</code>    | An index vector specifying the cases to be used in the training sample. (NOTE: If given, this argument must be named.)                                                                                                                                                                  |
| <code>na.action</code> | A function to specify the action to be taken if NAs are found. The default action is for the procedure to fail. An alternative is <code>na.omit</code> , which leads to rejection of cases with missing values on any required variable. (NOTE: If given, this argument must be named.) |
| <code>method</code>    | "moment" for standard estimators of the mean and variance, "mle" for MLEs, "mve" to use <code>cov.mve</code> , or "t" for robust estimates based on a <i>t</i> distribution.                                                                                                            |
| <code>CV</code>        | If true, returns results (classes and posterior probabilities) for leave-one-out cross-validation. Note that if the prior is estimated, the proportions in the whole dataset are used.                                                                                                  |
| <code>nu</code>        | degrees of freedom for <code>method = "t"</code> .                                                                                                                                                                                                                                      |
| <code>. . .</code>     | arguments passed to or from other methods.                                                                                                                                                                                                                                              |

### Details

The function tries hard to detect if the within-class covariance matrix is singular. If any variable has within-group variance less than `tol^2` it will stop and report the variable as constant. This could result from poor scaling of the problem, but is more likely to result from constant variables.

Specifying the `prior` will affect the classification unless over-ridden in `predict.lda`. Unlike in most statistical packages, it will also affect the rotation of the linear discriminants within their space, as a weighted between-groups covariance matrix is used. Thus the first few linear discriminants emphasize the differences between groups with the weights given by the prior, which may differ from their prevalence in the dataset.

If one or more groups is missing in the supplied data, they are dropped with a warning, but the classifications produced are with respect to the original set of levels.

**Value**

If `CV = TRUE` the return value is a list with components `class`, the MAP classification (a factor), and `posterior`, posterior probabilities for the classes.

Otherwise it is an object of class `"lda"` containing the following components:

|                      |                                                                                                                                                                                    |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>prior</code>   | the prior probabilities used.                                                                                                                                                      |
| <code>means</code>   | the group means.                                                                                                                                                                   |
| <code>scaling</code> | a matrix which transforms observations to discriminant functions, normalized so that within groups covariance matrix is spherical.                                                 |
| <code>svd</code>     | the singular values, which give the ratio of the between- and within-group standard deviations on the linear discriminant variables. Their squares are the canonical F-statistics. |
| <code>N</code>       | The number of observations used.                                                                                                                                                   |
| <code>call</code>    | The (matched) function call.                                                                                                                                                       |

**Note**

This function may be called giving either a formula and optional data frame, or a matrix and grouping factor as the first two arguments. All other arguments are optional, but `subset=` and `na.action=`, if required, must be fully named.

If a formula is given as the principal argument the object may be modified using `update()` in the usual way.

```

ldahist

*Histograms or Density Plots of Multiple Groups***Description**

Plot histograms or density plots of data on a single Fisher linear discriminant.

**Usage**

```
ldahist(data, g, nbins = 25, h, x0 = - h/1000, breaks,
        xlim = range(breaks), ymax = 0, width,
        type = c("histogram", "density", "both"),
        sep = (type != "density"),
        col = 5, xlab = deparse(substitute(data)), bty = "n", ...)
```

**Arguments**

|        |                                                                                                             |
|--------|-------------------------------------------------------------------------------------------------------------|
| data   | vector of data. Missing values (NAs) are allowed and omitted.                                               |
| g      | factor or vector giving groups, of the same length as data.                                                 |
| nbins  | Suggested number of bins to cover the whole range of the data.                                              |
| h      | The bin width (takes precedence over nbins).                                                                |
| x0     | Shift for the bins - the breaks are at $x_0 + h * (\dots, -1, 0, 1, \dots)$                                 |
| breaks | The set of breakpoints to be used. (Usually omitted, takes precedence over h and nbins).                    |
| xlim   | The limits for the x-axis.                                                                                  |
| ymax   | The upper limit for the y-axis.                                                                             |
| width  | Bandwidth for density estimates. If missing, the Sheather-Jones selector is used for each group separately. |
| type   | Type of plot.                                                                                               |
| sep    | Whether there is a separate plot for each group, or one combined plot.                                      |
| col    | The colour number for the bar fill.                                                                         |
| xlab   | label for the plot x-axis. By default, this will be the name of data.                                       |
| bty    | The box type for the plot - defaults to none.                                                               |
| ...    | additional arguments to polygon.                                                                            |

**Side Effects**

Histogram and/or density plots are plotted on the current device.

leuk

---

*Survival Times and White Blood Counts for Leukaemia Patients*

---

**Description**

A data frame of data from 33 leukaemia patients.

**Usage**

leuk

**Format**

A data frame with columns:

wbc white blood count.

ag a test result, "present" or "absent".

time survival time in weeks.

**Details**

Survival times are given for 33 patients who died from acute myelogenous leukaemia. Also measured was the patient's white blood cell count at the time of diagnosis. The patients were also factored into 2 groups according to the presence or absence of a morphologic characteristic of white blood cells. Patients termed AG positive were identified by the presence of Auer rods and/or significant granulation of the leukaemic cells in the bone marrow at the time of diagnosis.

**Examples**

```
library(survival)
plot(survfit(Surv(time) ~ ag, data = leuk), lty = 2:3, col = 2:3)

# now Cox models
leuk.cox <- coxph(Surv(time) ~ ag + log(wbc), leuk)
summary(leuk.cox)
```

lm.gls

*Fit Linear Models by Generalized Least Squares***Description**

Fit linear models by Generalized Least Squares

**Usage**

```
lm.gls(formula, data, W, subset, na.action, inverse = FALSE,
        method = "qr", model = FALSE, x = FALSE, y = FALSE,
        contrasts = NULL, ...)
```

**Arguments**

|           |                                                                                                                                                                  |
|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| formula   | a formula expression as for regression models, of the form <code>response ~ predictors</code> . See the documentation of <code>formula</code> for other details. |
| data      | an optional data frame, list or environment in which to interpret the variables occurring in <code>formula</code> .                                              |
| W         | a weight matrix.                                                                                                                                                 |
| subset    | expression saying which subset of the rows of the data should be used in the fit. All observations are included by default.                                      |
| na.action | a function to filter missing data.                                                                                                                               |
| inverse   | logical: if true <code>W</code> specifies the inverse of the weight matrix: this is appropriate if a variance matrix is used.                                    |
| method    | method to be used by <code>lm.fit</code> .                                                                                                                       |
| model     | should the model frame be returned?                                                                                                                              |
| x         | should the design matrix be returned?                                                                                                                            |
| y         | should the response be returned?                                                                                                                                 |
| contrasts | a list of contrasts to be used for some or all of                                                                                                                |
| ...       | additional arguments to <code>lm.fit</code> .                                                                                                                    |

**Details**

The problem is transformed to uncorrelated form and passed to `lm.fit`.

**Value**

An object of class `"lm.gls"`, which is similar to an `"lm"` object. There is no `"weights"` component, and only a few `"lm"` methods will work correctly. As from version 7.1-22 the residuals and fitted values refer to the untransformed problem.

|----------|-------------------------|
| lm.ridge | <i>Ridge Regression</i> |
|----------|-------------------------|

---

**Description**

Fit a linear model by ridge regression.

**Usage**

```
lm.ridge(formula, data, subset, na.action, lambda = 0, model = FALSE,
         x = FALSE, y = FALSE, contrasts = NULL, ...)
```

**Arguments**

|           |                                                                                                                                                                                                            |
|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| formula   | a formula expression as for regression models, of the form <code>response ~ predictors</code> . See the documentation of <code>formula</code> for other details. <a href="#">offset</a> terms are allowed. |
| data      | an optional data frame, list or environment in which to interpret the variables occurring in <code>formula</code> .                                                                                        |
| subset    | expression saying which subset of the rows of the data should be used in the fit. All observations are included by default.                                                                                |
| na.action | a function to filter missing data.                                                                                                                                                                         |
| lambda    | A scalar or vector of ridge constants.                                                                                                                                                                     |
| model     | should the model frame be returned? Not implemented.                                                                                                                                                       |
| x         | should the design matrix be returned? Not implemented.                                                                                                                                                     |
| y         | should the response be returned? Not implemented.                                                                                                                                                          |
| contrasts | a list of contrasts to be used for some or all of factor terms in the formula. See the <code>contrasts.arg</code> of <a href="#">model.matrix.default</a> .                                                |
| ...       | additional arguments to <a href="#">lm.fit</a> .                                                                                                                                                           |

**Details**

If an intercept is present in the model, its coefficient is not penalized. (If you want to penalize an intercept, put in your own constant term and remove the intercept.)

**Value**

A list with components

|        |                                                                                                                                                                           |
|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| coef   | matrix of coefficients, one row for each value of <code>lambda</code> . Note that these are not on the original scale and are for use by the <a href="#">coef</a> method. |
| scales | scalings used on the X matrix.                                                                                                                                            |
| Inter  | was intercept included?                                                                                                                                                   |
| lambda | vector of <code>lambda</code> values                                                                                                                                      |
| ym     | mean of y                                                                                                                                                                 |
| xm     | column means of x matrix                                                                                                                                                  |
| GCV    | vector of GCV values                                                                                                                                                      |
| kHKB   | HKB estimate of the ridge constant.                                                                                                                                       |
| kLW    | L-W estimate of the ridge constant.                                                                                                                                       |

*Fit Log-Linear Models by Iterative Proportional Scaling*

---

## Description

This function provides a front-end to the standard function, `loglin`, to allow log-linear models to be specified and fitted in a manner similar to that of other fitting functions, such as `glm`.

## Usage

```
loglm(formula, data, subset, na.action, ...)
```

## Arguments

|           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| formula   | <p>A linear model formula specifying the log-linear model.</p> <p>If the left-hand side is empty, the <code>data</code> argument is required and must be a (complete) array of frequencies. In this case the variables on the right-hand side may be the names of the <code>dimnames</code> attribute of the frequency array, or may be the positive integers: 1, 2, 3, ... used as alternative names for the 1st, 2nd, 3rd, ... dimension (classifying factor). If the left-hand side is not empty it specifies a vector of frequencies. In this case the <code>data</code> argument, if present, must be a data frame from which the left-hand side vector and the classifying factors on the right-hand side are (preferentially) obtained. The usual abbreviation of a <code>.</code> to stand for ‘all other variables in the data frame’ is allowed. Any non-factors on the right-hand side of the formula are coerced to factor.</p> |
| data      | <p>Numeric array or data frame (or list or environment). In the first case it specifies the array of frequencies; in the second it provides the data frame from which the variables occurring in the formula are preferentially obtained in the usual way.</p> <p>This argument may be the result of a call to <a href="#">xtabs</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| subset    | <p>Specifies a subset of the rows in the data frame to be used. The default is to take all rows.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| na.action | <p>Specifies a method for handling missing observations. The default is to fail if missing values are present.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| ...       | <p>May supply other arguments to the function <a href="#">loglm1</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

## Details

If the left-hand side of the formula is empty the `data` argument supplies the frequency array and the right-hand side of the formula is used to construct the list of fixed faces as required by `loglin`. Structural zeros may be specified by giving a `start` argument with those entries set to zero, as described in the help information for `loglin`.

If the left-hand side is not empty, all variables on the right-hand side are regarded as classifying factors and an array of frequencies is constructed. If some cells in the complete array are not specified they are treated as structural zeros. The right-hand side of the formula is again used to construct the list of faces on which the observed and fitted totals must agree, as required by `loglin`. Hence terms such as `a:b`, `a*b` and `a/b` are all equivalent.

## Value

An object of class "loglm" conveying the results of the fitted log-linear model. Methods exist for the generic functions `print`, `summary`, `deviance`, `fitted`, `coef`, `resid`, `anova` and `update`, which perform the expected tasks. Only log-likelihood ratio tests are allowed using `anova`.

The deviance is simply an alternative name for the log-likelihood ratio statistic for testing the current model within a saturated model, in accordance with standard usage in generalized linear models.

## Warning

If structural zeros are present, the calculation of degrees of freedom may not be correct. `loglin` itself takes no action to allow for structural zeros. `loglm` deducts one degree of freedom for each structural zero, but cannot make allowance for gains in error degrees of freedom due to loss of dimension in the model space. (This would require checking the rank of the model matrix, but since iterative proportional scaling methods are developed largely to avoid constructing the model matrix explicitly, the computation is at least difficult.)

When structural zeros (or zero fitted values) are present the estimated coefficients will not be available due to infinite estimates. The deviances will normally continue to be correct, though.

c(deviance(fm), deviance(gm))        # deviances agree
## [1] 1368.7 1368.7
c(fm$df, gm$df)                      # resid df do not!
c(fm$df, gm$df.residual)             # resid df do not!
## [1] 127 128
# The loglm residual degrees of freedom is wrong because of
# a non-detectable redundancy in the model matrix.

```

logtrans

*Estimate log Transformation Parameter***Description**

Find and optionally plot the marginal (profile) likelihood for alpha for a transformation model of the form  $\log(y + \alpha) \sim x_1 + x_2 + \dots$ .

**Usage**

```

logtrans(object, ...)

## Default S3 method:
logtrans(object, ..., alpha = seq(0.5, 6, by = 0.25) - min(y),
         plotit = TRUE, interp =, xlab = "alpha",
         ylab = "log Likelihood")

## S3 method for class 'formula'
logtrans(object, data, ...)

## S3 method for class 'lm'
logtrans(object, ...)

```

**Arguments**

**object** Fitted linear model object, or formula defining the untransformed model that is  $y \sim x_1 + x_2 + \dots$ . The function is generic.

|        |                                                                                                                                                                                          |
|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ...    | If object is a formula, this argument may specify a data frame as for <code>lm</code> .                                                                                                  |
| alpha  | Set of values for the transformation parameter, <code>alpha</code> .                                                                                                                     |
| plotit | Should plotting be done?                                                                                                                                                                 |
| interp | Should the marginal log-likelihood be interpolated with a spline approximation? (Default is <code>TRUE</code> if plotting is to be done and the number of real points is less than 100.) |
| xlab   | as for <code>plot</code> .                                                                                                                                                               |
| ylab   | as for <code>plot</code> .                                                                                                                                                               |
| data   | optional data argument for <code>lm</code> fit.                                                                                                                                          |

Value

List with components `x` (for `alpha`) and `y` (for the marginal log-likelihood values).

Side Effects

A plot of the marginal log-likelihood is produced, if requested, together with an approximate mle and 95% confidence interval.

|-----|-----------------------------|
| lqs | <i>Resistant Regression</i> |
|-----|-----------------------------|

---

Description

Fit a regression to the *good* points in the dataset, thereby achieving a regression estimator with a high breakdown point. `lmsreg` and `ltsreg` are compatibility wrappers.

Usage

```
lqs(x, ...)

## S3 method for class 'formula'
lqs(formula, data, ...,
    method = c("lts", "lqs", "lms", "S", "model.frame"),
    subset, na.action, model = TRUE,
    x.ret = FALSE, y.ret = FALSE, contrasts = NULL)
```

```
## Default S3 method:
lqs(x, y, intercept = TRUE, method = c("lts", "lqs", "lms", "S"),
    quantile, control = lqs.control(...), k0 = 1.548, seed, ...)

lmsreg(...)
ltsreg(...)
```

## Arguments

|                                  |                                                                                                                                                                                                                                                                                                                            |
|----------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>formula</code>             | a formula of the form $y \sim x_1 + x_2 + \dots$                                                                                                                                                                                                                                                                           |
| <code>data</code>                | an optional data frame, list or environment from which variables specified in <code>formula</code> are preferentially to be taken.                                                                                                                                                                                         |
| <code>subset</code>              | an index vector specifying the cases to be used in fitting. (NOTE: If given, this argument must be named exactly.)                                                                                                                                                                                                         |
| <code>na.action</code>           | function to specify the action to be taken if NAs are found. The default action is for the procedure to fail. Alternatives include <code>na.omit</code> and <code>na.exclude</code> , which lead to omission of cases with missing values on any required variable. (NOTE: If given, this argument must be named exactly.) |
| <code>model, x.ret, y.ret</code> | logical. If TRUE the model frame, the model matrix and the response are returned, respectively.                                                                                                                                                                                                                            |
| <code>contrasts</code>           | an optional list. See the <code>contrasts.arg</code> of <code>model.matrix.default</code> .                                                                                                                                                                                                                                |
| <code>x</code>                   | a matrix or data frame containing the explanatory variables.                                                                                                                                                                                                                                                               |
| <code>y</code>                   | the response: a vector of length the number of rows of <code>x</code> .                                                                                                                                                                                                                                                    |
| <code>intercept</code>           | should the model include an intercept?                                                                                                                                                                                                                                                                                     |
| <code>method</code>              | the method to be used. <code>model.frame</code> returns the model frame: for the others see the Details section. Using <code>lmsreg</code> or <code>ltsreg</code> forces "lms" and "lts" respectively.                                                                                                                     |
| <code>quantile</code>            | the quantile to be used: see Details. This is over-ridden if <code>method = "lms"</code> .                                                                                                                                                                                                                                 |
| <code>control</code>             | additional control items: see Details.                                                                                                                                                                                                                                                                                     |
| <code>k0</code>                  | the cutoff / tuning constant used for $\chi()$ and $\psi()$ functions when <code>method = "S"</code> , currently corresponding to Tukey's 'biweight'.                                                                                                                                                                      |
| <code>seed</code>                | the seed to be used for random sampling: see <code>.Random.seed</code> . The current value of <code>.Random.seed</code> will be preserved if it is set..                                                                                                                                                                   |
| <code>...</code>                 | arguments to be passed to <code>lqs.default</code> or <code>lqs.control</code> , see <code>control</code> above and Details.                                                                                                                                                                                               |

## Details

Suppose there are  $n$  data points and  $p$  regressors, including any intercept.

The first three methods minimize some function of the sorted squared residuals. For methods "lqs" and "lms" is the quantile squared residual, and for "lts" it is the sum of the quantile smallest squared residuals. "lqs" and "lms" differ in the defaults for `quantile`, which are `floor((n+p+1)/2)` and `floor((n+1)/2)` respectively. For "lts" the default is `floor(n/2) + floor((p+1)/2)`.

The "S" estimation method solves for the scale  $s$  such that the average of a function  $\chi$  of the residuals divided by  $s$  is equal to a given constant.

The `control` argument is a list with components

`psamp`: the size of each sample. Defaults to `p`.  
`nsamp`: the number of samples or "best" (the default) or "exact" or "sample". If "sample" the number chosen is  $\min(5 \cdot p, 3000)$ , taken from Rousseeuw and Hubert (1997). If "best" exhaustive enumeration is done up to 5000 samples; if "exact" exhaustive enumeration will be attempted however many samples are needed.  
`adjust`: should the intercept be optimized for each sample? Defaults to `TRUE`.

### Value

An object of class "lqs". This is a list with components

|                            |                                                                                                                                                                                                                                                        |
|----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>crit</code>          | the value of the criterion for the best solution found, in the case of <code>method == "S"</code> before IWLS refinement.                                                                                                                              |
| <code>sing</code>          | character. A message about the number of samples which resulted in singular fits.                                                                                                                                                                      |
| <code>coefficients</code>  | of the fitted linear model                                                                                                                                                                                                                             |
| <code>bestone</code>       | the indices of those points fitted by the best sample found (prior to adjustment of the intercept, if requested).                                                                                                                                      |
| <code>fitted.values</code> | the fitted values.                                                                                                                                                                                                                                     |
| <code>residuals</code>     | the residuals.                                                                                                                                                                                                                                         |
| <code>scale</code>         | estimate(s) of the scale of the error. The first is based on the fit criterion. The second (not present for <code>method == "S"</code> ) is based on the variance of those residuals whose absolute value is less than 2.5 times the initial estimate. |

### Note

There seems no reason other than historical to use the `lms` and `lqs` options. LMS estimation is of low efficiency (converging at rate  $n^{-1/3}$ ) whereas LTS has the same asymptotic efficiency as an M estimator with trimming at the quartiles (Marazzi, 1993, p.201). LQS and LTS have the same maximal breakdown value of  $(\text{floor}((n-p)/2) + 1)/n$  attained if  $\text{floor}((n+p)/2) \leq \text{quantile} \leq \text{floor}((n+p+1)/2)$ . The only drawback mentioned of LTS is greater computation, as a sort was thought to be required (Marazzi, 1993, p.201) but this is not true as a partial sort can be used (and is used in this implementation).

Adjusting the intercept for each trial fit does need the residuals to be sorted, and may be significant extra computation if  $n$  is large and  $p$  small.

Opinions differ over the choice of `psamp`. Rousseeuw and Hubert (1997) only consider  $p$ ; Marazzi (1993) recommends  $p+1$  and suggests that more samples are better than adjustment for a given computational limit.

The computations are exact for a model with just an intercept and adjustment, and for LQS for a model with an intercept plus one regressor and exhaustive search with adjustment. For all other cases the minimization is only known to be approximate.

mca

---

## Multiple Correspondence Analysis

---

### Description

Computes a multiple correspondence analysis of a set of factors.

### Usage

```
mca(df, nf = 2, abbrev = FALSE)
```

### Arguments

|        |                                                                                                                                                                                                         |
|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| df     | A data frame containing only factors                                                                                                                                                                    |
| nf     | The number of dimensions for the MCA. Rarely 3 might be useful.                                                                                                                                         |
| abbrev | Should the vertex names be abbreviated? By default these are of the form ‘factor.level’ but if <code>abbrev = TRUE</code> they are just ‘level’ which will suffice if the factors have distinct levels. |

### Value

An object of class "mca", with components

|      |                                                                                            |
|------|--------------------------------------------------------------------------------------------|
| rs   | The coordinates of the rows, in <code>nf</code> dimensions.                                |
| cs   | The coordinates of the column vertices, one for each level of each factor.                 |
| fs   | Weights for each row, used to interpolate additional factors in <code>predict.mca</code> . |
| p    | The number of factors                                                                      |
| d    | The singular values for the <code>nf</code> dimensions.                                    |
| call | The matched call.                                                                          |

michelson

*Michelson's Speed of Light Data*

---

### Description

Measurements of the speed of light in air, made between 5th June and 2nd July, 1879. The data consists of five experiments, each consisting of 20 consecutive runs. The response is the speed of light in km/s, less 299000. The currently accepted value, on this scale of measurement, is 734.5.

### Usage

```
michelson
```

### Format

The data frame contains the following components:

`Expt` The experiment number, from 1 to 5.

`Run` The run number within each experiment.

`Speed` Speed-of-light measurement.

### Source

minn38

*Minnesota High School Graduates of 1938*

---

### Description

The Minnesota high school graduates of 1938 were classified according to four factors, described below. The `minn38` data frame has 168 rows and 5 columns.

### Usage

```
minn38
```

### Format

This data frame contains the following columns:

`hs` high school rank: "L", "M" and "U" for lower, middle and upper third.

`phs` post high school status: Enrolled in college, ("C"), enrolled in non-collegiate school, ("N"), employed full-time, ("E") and other, ("O").

`fol` father's occupational level, (seven levels, "F1", "F2", ..., "F7").

`sex` sex: factor with levels "F" or "M".

`f` frequency.

---

motors

*Accelerated Life Testing of Motorettes*

---

### Description

The `motors` data frame has 40 rows and 3 columns. It describes an accelerated life test at each of four temperatures of 10 motorettes, and has rather discrete times.

### Usage

```
motors
```

### Format

This data frame contains the following columns:

`temp` the temperature (degrees C) of the test.

`time` the time in hours to failure or censoring at 8064 hours (= 336 days).

`cens` an indicator variable for death.

muscle

*Effect of Calcium Chloride on Muscle Contraction in Rat Hearts*

## Description

The purpose of this experiment was to assess the influence of calcium in solution on the contraction of heart muscle in rats. The left auricle of 21 rat hearts was isolated and on several occasions a constant-length strip of tissue was electrically stimulated and dipped into various concentrations of calcium chloride solution, after which the shortening of the strip was accurately measured as the response.

## Usage

```
muscle
```

## Format

This data frame contains the following columns:

Strip which heart muscle strip was used?

Conc concentration of calcium chloride solution, in multiples of 2.2 mM.

Length the change in length (shortening) of the strip, (allegedly) in mm.

  panel.xyplot(x, Muscle$logLength[subscripts], ...)
  llines(spline(x, y))
})

```

mvnorm

*Simulate from a Multivariate Normal Distribution***Description**

Produces one or more samples from the specified multivariate normal distribution.

**Usage**

```
mvnorm(n = 1, mu, Sigma, tol = 1e-6, empirical = FALSE, EISPACK = FALSE)
```

**Arguments**

|                        |                                                                                                                           |
|------------------------|---------------------------------------------------------------------------------------------------------------------------|
| <code>n</code>         | the number of samples required.                                                                                           |
| <code>mu</code>        | a vector giving the means of the variables.                                                                               |
| <code>Sigma</code>     | a positive-definite symmetric matrix specifying the covariance matrix of the variables.                                   |
| <code>tol</code>       | tolerance (relative to largest variance) for numerical lack of positive-definiteness in <code>Sigma</code> .              |
| <code>empirical</code> | logical. If true, <code>mu</code> and <code>Sigma</code> specify the empirical not population mean and covariance matrix. |
| <code>EISPACK</code>   | logical: values other than <code>FALSE</code> are an error.                                                               |

**Details**

The matrix decomposition is done via `eigen`; although a Choleski decomposition might be faster, the eigendecomposition is stabler.

**Value**

If `n = 1` a vector of the same length as `mu`, otherwise an `n` by `length(mu)` matrix with one sample in each row.

**Side Effects**

Causes creation of the dataset `.Random.seed` if it does not already exist, otherwise its value is updated.

negative.binomial    *Family function for Negative Binomial GLMs*

---

## Description

Specifies the information required to fit a Negative Binomial generalized linear model, with known `theta` parameter, using `glm()`.

## Usage

```
negative.binomial(theta = stop("'theta' must be specified"), link = "log")
```

## Arguments

|                    |                                                                                                                                                                                                                  |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>theta</code> | The known value of the additional parameter, <code>theta</code> .                                                                                                                                                |
| <code>link</code>  | The link function, as a character string, name or one-element character vector specifying one of <code>log</code> , <code>sqrt</code> or <code>identity</code> , or an object of class <code>"link-glm"</code> . |

## Value

An object of class `"family"`, a list of functions and expressions needed by `glm()` to fit a Negative Binomial generalized linear model.

newcomb

*Newcomb's Measurements of the Passage Time of Light***Description**

A numeric vector giving the 'Third Series' of measurements of the passage time of light recorded by Newcomb in 1882. The given values divided by 1000 plus 24.8 give the time in millionths of a second for light to traverse a known distance. The 'true' value is now considered to be 33.02.

The dataset is given in the order in Staudte and Sheather. Stigler (1977, Table 5) gives the dataset as

```
28 26 33 24 34 -44 27 16 40 -2 29 22 24 21 25 30 23 29 31 19
24 20 36 32 36 28 25 21 28 29 37 25 28 26 30 32 36 26 30 22
36 23 27 27 28 27 31 27 26 33 26 32 32 24 39 28 24 25 32 25
29 27 28 29 16 23
```

However, order is not relevant to its use as an example of robust estimation. (Thanks to Anthony Unwin for bringing this difference to our attention.)

**Usage**

nlschools

*Eighth-Grade Pupils in the Netherlands***Description**

Snijders and Bosker (1999) use as a running example a study of 2287 eighth-grade pupils (aged about 11) in 132 classes in 131 schools in the Netherlands. Only the variables used in our examples are supplied.

**Usage**

nlschools

## Format

This data frame contains 2287 rows and the following columns:

`lang` language test score.

`IQ` verbal IQ.

`class` class ID.

`GS` class size: number of eighth-grade pupils recorded in the class (there may be others: see `COMB`, and some may have been omitted with missing values).

`SES` social-economic status of pupil's family.

`COMB` were the pupils taught in a multi-grade class (0/1)? Classes which contained pupils from grades 7 and 8 are coded 1, but only eighth-graders were tested.

npk

---

*Classical N, P, K Factorial Experiment*

---

## Description

A classical N, P, K (nitrogen, phosphate, potassium) factorial experiment on the growth of peas conducted on 6 blocks. Each half of a fractional factorial design confounding the NPK interaction was used on 3 of the plots.

## Usage

```
npk
```

**Format**

The npk data frame has 24 rows and 5 columns:

block which block (label 1 to 6).

N indicator (0/1) for the application of nitrogen.

P indicator (0/1) for the application of phosphate.

K indicator (0/1) for the application of potassium.

yield Yield of peas, in pounds/plot (the plots were (1/70) acre).

**Note**

This dataset is also contained in R 3.0.2 and later.

Null

Null Spaces of Matrices

---

**Description**

Given a matrix, `M`, find a matrix `N` giving a basis for the (left) null space. That is `crossprod(N, M) = t(N) %*% M` is an all-zero matrix and `N` has the maximum number of linearly independent columns.

**Usage**

```
Null(M)
```

**Arguments**

`M` Input matrix. A vector is coerced to a 1-column matrix.

**Details**

For a basis for the (right) null space  $\{x : Mx = 0\}$ , use `Null(t(M))`.

**Value**

The matrix `N` with the basis for the (left) null space, or a matrix with zero columns if the matrix `M` is square and of maximal rank.

**References**

oats

*Data from an Oats Field Trial*

---

## Description

The yield of oats from a split-plot field trial using three varieties and four levels of manurial treatment. The experiment was laid out in 6 blocks of 3 main plots, each split into 4 sub-plots. The varieties were applied to the main plots and the manurial treatments to the sub-plots.

## Usage

```
oats
```

## Format

This data frame contains the following columns:

B Blocks, levels I, II, III, IV, V and VI.

V Varieties, 3 levels.

N Nitrogen (manurial) treatment, levels 0.0cwt, 0.2cwt, 0.4cwt and 0.6cwt, showing the application in cwt/acre.

Y Yields in 1/4lbs per sub-plot, each of area 1/80 acre.

|     |                                                          |
|-----|----------------------------------------------------------|
| OME | <i>Tests of Auditory Perception in Children with OME</i> |
|-----|----------------------------------------------------------|

---

**Description**

Experiments were performed on children on their ability to differentiate a signal in broad-band noise. The noise was played from a pair of speakers and a signal was added to just one channel; the subject had to turn his/her head to the channel with the added signal. The signal was either coherent (the amplitude of the noise was increased for a period) or incoherent (independent noise was added for the same period to form the same increase in power).

The threshold used in the original analysis was the stimulus loudness needs to get 75% correct responses. Some of the children had suffered from otitis media with effusion (OME).

**Usage**

OME

**Format**

- The OME data frame has 1129 rows and 7 columns:
- ID Subject ID (1 to 99, with some IDs missing). A few subjects were measured at different ages.
- OME "low" or "high" or "N/A" (at ages other than 30 and 60 months).
- Age Age of the subject (months).
- Loud Loudness of stimulus, in decibels.
- Noise Whether the signal in the stimulus was "coherent" or "incoherent".
- Correct Number of correct responses from Trials trials.
- Trials Number of trials performed.

**Background**

The experiment was to study otitis media with effusion (OME), a very common childhood condition where the middle ear space, which is normally air-filled, becomes congested by a fluid. There is a concomitant fluctuating, conductive hearing loss which can result in various language, cognitive and social deficits. The term ‘binaural hearing’ is used to describe the listening conditions in which the brain is processing information from both ears at the same time. The brain computes differences in the intensity and/or timing of signals arriving at each ear which contributes to sound localisation and also to our ability to hear in background noise.

Some years ago, it was found that children of 7–8 years with a history of significant OME had significantly worse binaural hearing than children without such a history, despite having equivalent sensitivity. The question remained as to whether it was the timing, the duration, or the degree of

severity of the otitis media episodes during critical periods, which affected later binaural hearing. In an attempt to begin to answer this question, 95 children were monitored for the presence of effusion every month since birth. On the basis of OME experience in their first two years, the test population was split into one group of high OME prevalence and one of low prevalence.

**Description**

The subjective assessment, on a 0 to 20 integer scale, of 54 classical painters. The painters were assessed on four characteristics: composition, drawing, colour and expression. The data is due to the Eighteenth century art critic, de Piles.

**Usage**

```
painters
```

**Format**

The row names of the data frame are the painters. The components are:

Composition Composition score.

Drawing Drawing score.

Colour Colour score.

Expression Expression score.

School The school to which a painter belongs, as indicated by a factor level code as follows:  
 "A": Renaissance; "B": Mannerist; "C": Seicento; "D": Venetian; "E": Lombard; "F":  
 Sixteenth Century; "G": Seventeenth Century; "H": French.

---

pairs.lda

---

*Produce Pairwise Scatterplots from an 'lda' Fit*

---

**Description**

Pairwise scatterplot of the data on the linear discriminants.

**Usage**

```
## S3 method for class 'lda'
pairs(x, labels = colnames(x), panel = panel.lda,
      dimen, abbrev = FALSE, ..., cex=0.7, type = c("std", "trellis"))
```

**Arguments**

|                     |                                                                                                                                                   |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>      | Object of class "lda".                                                                                                                            |
| <code>labels</code> | vector of character strings for labelling the variables.                                                                                          |
| <code>panel</code>  | panel function to plot the data in each panel.                                                                                                    |
| <code>dimen</code>  | The number of linear discriminants to be used for the plot; if this exceeds the number determined by <code>x</code> the smaller value is used.    |
| <code>abbrev</code> | whether the group labels are abbreviated on the plots. If <code>abbrev &gt; 0</code> this gives <code>minlength</code> in the call to abbreviate. |
| <code>...</code>    | additional arguments for <code>pairs.default</code> .                                                                                             |
| <code>cex</code>    | graphics parameter <code>cex</code> for labels on plots.                                                                                          |
| <code>type</code>   | type of plot. The default is in the style of <code>pairs.default</code> ; the style "trellis" uses the Trellis function <code>splom</code> .      |

**Details**

This function is a method for the generic function `pairs()` for class "lda". It can be invoked by calling `pairs(x)` for an object `x` of the appropriate class, or directly by calling `pairs.lda(x)` regardless of the class of the object.

parcoord

*Parallel Coordinates Plot*

---

**Description**

Parallel coordinates plot

**Usage**

```
parcoord(x, col = 1, lty = 1, var.label = FALSE, ...)
```

**Arguments**

|                        |                                                                                     |
|------------------------|-------------------------------------------------------------------------------------|
| <code>x</code>         | a matrix or data frame who columns represent variables. Missing values are allowed. |
| <code>col</code>       | A vector of colours, recycled as necessary for each observation.                    |
| <code>lty</code>       | A vector of line types, recycled as necessary for each observation.                 |
| <code>var.label</code> | If TRUE, each variable's axis is labelled with maximum and minimum values.          |
| <code>...</code>       | Further graphics parameters which are passed to <code>matplot</code> .              |

**Side Effects**

a parallel coordinates plots is drawn.

**Examples**

```
parcoord(state.x77[, c(7, 4, 6, 2, 5, 3)])

ir <- rbind(iris3[, , 1], iris3[, , 2], iris3[, , 3])
parcoord(log(ir)[, c(3, 4, 2, 1)], col = 1 + (0:149)%/%50)
```

---

petrol

---

*N. L. Prater's Petrol Refinery Data*

---

**Description**

The yield of a petroleum refining process with four covariates. The crude oil appears to come from only 10 distinct samples.

These data were originally used by Prater (1956) to build an estimation equation for the yield of the refining process of crude oil to gasoline.

**Usage**

```
petrol
```

**Format**

The variables are as follows

No crude oil sample identification label. (Factor.)

SG specific gravity, degrees API. (Constant within sample.)

VP vapour pressure in pounds per square inch. (Constant within sample.)

V10 volatility of crude; ASTM 10% point. (Constant within sample.)

EP desired volatility of gasoline. (The end point. Varies within sample.)

Y yield as a percentage of crude.

**Source**

N. H. Prater (1956) Estimate gasoline yields from crudes. *Petroleum Refiner* **35**, 236–238.

This dataset is also given in D. J. Hand, F. Daly, K. McConway, D. Lunn and E. Ostrowski (eds) (1994) *A Handbook of Small Data Sets*. Chapman & Hall.

Pima.tr

*Diabetes in Pima Indian Women*

---

## Description

A population of women who were at least 21 years old, of Pima Indian heritage and living near Phoenix, Arizona, was tested for diabetes according to World Health Organization criteria. The data were collected by the US National Institute of Diabetes and Digestive and Kidney Diseases. We used the 532 complete records after dropping the (mainly missing) data on serum insulin.

## Usage

```
Pima.tr
Pima.tr2
Pima.te
```

## Format

These data frames contains the following columns:

```
npreg number of pregnancies.
glu plasma glucose concentration in an oral glucose tolerance test.
bp diastolic blood pressure (mm Hg).
skin triceps skin fold thickness (mm).
bmi body mass index (weight in kg/(height in m)2).
ped diabetes pedigree function.
age age in years.
type Yes or No, for diabetic according to WHO criteria.
```

## Details

The training set `Pima.tr` contains a randomly selected set of 200 subjects, and `Pima.te` contains the remaining 332 subjects. `Pima.tr2` contains `Pima.tr` plus 100 subjects with missing values in the explanatory variables.

|----------|------------------------------------|

---

## Description

Plots a set of data on one, two or more linear discriminants.

## Usage

```
## S3 method for class 'lda'
plot(x, panel = panel.lda, ..., cex = 0.7, dimen,
      abbrev = FALSE, xlab = "LD1", ylab = "LD2")
```

## Arguments

|        |                                                                                                                                   |
|--------|-----------------------------------------------------------------------------------------------------------------------------------|
| x      | An object of class "lda".                                                                                                         |
| panel  | the panel function used to plot the data.                                                                                         |
| ...    | additional arguments to pairs, ldahist or eqscplot.                                                                               |
| cex    | graphics parameter cex for labels on plots.                                                                                       |
| dimen  | The number of linear discriminants to be used for the plot; if this exceeds the number determined by x the smaller value is used. |
| abbrev | whether the group labels are abbreviated on the plots. If abbrev > 0 this gives minlength in the call to abbreviate.              |
| xlab   | label for the x axis                                                                                                              |
| ylab   | label for the y axis                                                                                                              |

## Details

This function is a method for the generic function `plot()` for class "lda". It can be invoked by calling `plot(x)` for an object x of the appropriate class, or directly by calling `plot.lda(x)` regardless of the class of the object.

The behaviour is determined by the value of `dimen`. For `dimen > 2`, a `pairs` plot is used. For `dimen = 2`, an equiscaled scatter plot is drawn. For `dimen = 1`, a set of histograms or density plots are drawn. Use argument `type` to match "histogram" or "density" or "both".

## S3 method for class 'profile'
plot(x, ...)
## S3 method for class 'profile'
pairs(x, colours = 2:3, ...)
```

**Arguments**

|         |                                                                             |
|---------|-----------------------------------------------------------------------------|
| x       | an object inheriting from class "profile".                                  |
| colours | Colours to be used for the mean curves conditional on x and y respectively. |
| ...     | arguments passed to or from other methods.                                  |

## Details

This is the main `plot` method for objects created by `profile.glm`. It can also be called on objects created by `profile.nls`, but they have a specific method, `plot.profile.nls`.

The `pairs` method shows, for each pair of parameters  $x$  and  $y$ , two curves intersecting at the maximum likelihood estimate, which give the loci of the points at which the tangents to the contours of the bivariate profile likelihood become vertical and horizontal, respectively. In the case of an exactly bivariate normal profile likelihood, these two curves would be straight lines giving the conditional means of  $y|x$  and  $x|y$ , and the contours would be exactly elliptical.

## Author(s)

Originally, D. M. Bates and W. N. Venables. (For S in 1996.)

## See Also

`profile.glm`, `profile.nls`.

## Examples

```
## see ?profile.glm for an example using glm fits.

## a version of example(profile.nls) from R >= 2.8.0
fml <- nls(demand ~ SSasymptOrig(Time, A, lrc), data = BOD)
pr1 <- profile(fml, alpha = 0.1)
MASS::plot.profile(pr1)
pairs(pr1) # a little odd since the parameters are highly correlated

## an example from ?nls
x <- -(1:100)/10
y <- 100 + 10 * exp(x / 2) + rnorm(x)/10
nlmod <- nls(y ~ Const + A * exp(B * x), start=list(Const=100, A=10, B=1))
pairs(profile(nlmod))
```

---

polr

*Ordered Logistic or Probit Regression*

---

## Description

Fits a logistic or probit regression model to an ordered factor response. The default logistic case is *proportional odds logistic regression*, after which the function is named.

## Usage

```
polr(formula, data, weights, start, ..., subset, na.action,
      contrasts = NULL, Hess = FALSE, model = TRUE,
      method = c("logistic", "probit", "loglog", "cloglog", "cauchit"))
```

## Arguments

|                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>formula</code>   | a formula expression as for regression models, of the form <code>response ~ predictors</code> . The response should be a factor (preferably an ordered factor), which will be interpreted as an ordinal response, with levels ordered as in the factor. The model must have an intercept: attempts to remove one will lead to a warning and be ignored. An offset may be used. See the documentation of <a href="#">formula</a> for other details. |
| <code>data</code>      | an optional data frame, list or environment in which to interpret the variables occurring in <code>formula</code> .                                                                                                                                                                                                                                                                                                                                |
| <code>weights</code>   | optional case weights in fitting. Default to 1.                                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>start</code>     | initial values for the parameters. This is in the format <code>c(coefficients, zeta)</code> : see the Values section.                                                                                                                                                                                                                                                                                                                              |
| <code>...</code>       | additional arguments to be passed to <a href="#">optim</a> , most often a <code>control</code> argument.                                                                                                                                                                                                                                                                                                                                           |
| <code>subset</code>    | expression saying which subset of the rows of the data should be used in the fit. All observations are included by default.                                                                                                                                                                                                                                                                                                                        |
| <code>na.action</code> | a function to filter missing data.                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <code>contrasts</code> | a list of contrasts to be used for some or all of the factors appearing as variables in the model formula.                                                                                                                                                                                                                                                                                                                                         |
| <code>Hess</code>      | logical for whether the Hessian (the observed information matrix) should be returned. Use this if you intend to call <code>summary</code> or <code>vcov</code> on the fit.                                                                                                                                                                                                                                                                         |
| <code>model</code>     | logical for whether the model matrix should be returned.                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>method</code>    | logistic or probit or (complementary) log-log or <code>cauchit</code> (corresponding to a Cauchy latent variable).                                                                                                                                                                                                                                                                                                                                 |

## Details

This model is what Agresti (2002) calls a *cumulative link* model. The basic interpretation is as a *coarsened* version of a latent variable  $Y_i$  which has a logistic or normal or extreme-value or Cauchy distribution with scale parameter one and a linear model for the mean. The ordered factor which is observed is which bin  $Y_i$  falls into with breakpoints

$$\zeta_0 = -\infty < \zeta_1 < \dots < \zeta_K = \infty$$

This leads to the model

$$\text{logit}P(Y \leq k|x) = \zeta_k - \eta$$

with *logit* replaced by *probit* for a normal latent variable, and  $\eta$  being the linear predictor, a linear function of the explanatory variables (with no intercept). Note that it is quite common for other software to use the opposite sign for  $\eta$  (and hence the coefficients `beta`).

In the logistic case, the left-hand side of the last display is the log odds of category  $k$  or less, and since these are log odds which differ only by a constant for different  $k$ , the odds are proportional. Hence the term *proportional odds logistic regression*.

The log-log and complementary log-log links are the increasing functions  $F^{-1}(p) = -\log(-\log(p))$  and  $F^{-1}(p) = \log(-\log(1 - p))$ ; some call the first the ‘negative log-log’ link. These correspond to a latent variable with the extreme-value distribution for the maximum and minimum respectively.

A *proportional hazards* model for grouped survival times can be obtained by using the complementary log-log link with grouping ordered by increasing times.

[predict](#), [summary](#), [vcov](#), [anova](#), [model.frame](#) and an `extractAIC` method for use with [stepAIC](#) (and [step](#)). There are also [profile](#) and [confint](#) methods.

**Value**

A object of class "polr". This has components

|                            |                                                                                                                                    |
|----------------------------|------------------------------------------------------------------------------------------------------------------------------------|
| <code>coefficients</code>  | the coefficients of the linear predictor, which has no intercept.                                                                  |
| <code>zeta</code>          | the intercepts for the class boundaries.                                                                                           |
| <code>deviance</code>      | the residual deviance.                                                                                                             |
| <code>fitted.values</code> | a matrix, with a column for each level of the response.                                                                            |
| <code>lev</code>           | the names of the response levels.                                                                                                  |
| <code>terms</code>         | the <code>terms</code> structure describing the model.                                                                             |
| <code>df.residual</code>   | the number of residual degrees of freedoms, calculated using the weights.                                                          |
| <code>edf</code>           | the (effective) number of degrees of freedom used by the model                                                                     |
| <code>n, nobs</code>       | the (effective) number of observations, calculated using the weights. ( <code>nobs</code> is for use by <a href="#">stepAIC</a> ). |
| <code>call</code>          | the matched call.                                                                                                                  |
| <code>method</code>        | the matched method used.                                                                                                           |
| <code>convergence</code>   | the convergence code returned by <code>optim</code> .                                                                              |
| <code>niter</code>         | the number of function and gradient evaluations used by <code>optim</code> .                                                       |
| <code>lp</code>            | the linear predictor (including any offset).                                                                                       |
| <code>Hessian</code>       | (if <code>Hess</code> is true). Note that this is a numerical approximation derived from the optimization proces.                  |
| <code>model</code>         | (if <code>model</code> is true).                                                                                                   |

**Note**

The [vcov](#) method uses the approximate Hessian: for reliable results the model matrix should be sensibly scaled with all columns having range the order of one.

Prior to version 7.3-32, `method = "cloglog"` confusingly gave the log-log link, implicitly assuming the first response level was the 'best'.

|-----------------|----------------------------------------|
| predict.glmmPQL | <i>Predict Method for glmmPQL Fits</i> |
|-----------------|----------------------------------------|

---

## Description

Obtains predictions from a fitted generalized linear model with random effects.

## Usage

```
## S3 method for class 'glmmPQL'
predict(object, newdata = NULL, type = c("link", "response"),
        level, na.action = na.pass, ...)
```

## Arguments

|           |                                                                                                                                                                                                                                                                                                                               |
|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object    | a fitted object of class inheriting from "glmmPQL".                                                                                                                                                                                                                                                                           |
| newdata   | optionally, a data frame in which to look for variables with which to predict.                                                                                                                                                                                                                                                |
| type      | the type of prediction required. The default is on the scale of the linear predictors; the alternative "response" is on the scale of the response variable. Thus for a default binomial model the default predictions are of log-odds (probabilities on logit scale) and type = "response" gives the predicted probabilities. |
| level     | an optional integer vector giving the level(s) of grouping to be used in obtaining the predictions. Level values increase from outermost to innermost grouping, with level zero corresponding to the population predictions. Defaults to the highest or innermost level of grouping.                                          |
| na.action | function determining what should be done with missing values in newdata. The default is to predict NA.                                                                                                                                                                                                                        |
| ...       | further arguments passed to or from other methods.                                                                                                                                                                                                                                                                            |

## Value

If level is a single integer, a vector otherwise a data frame.

## See Also

## Examples

```
fit <- glmmPQL(y ~ trt + I(week > 2), random = ~1 | ID,
              family = binomial, data = bacteria)
predict(fit, bacteria, level = 0, type="response")
predict(fit, bacteria, level = 1, type="response")
```

---

predict.lda

*Classify Multivariate Observations by Linear Discrimination*

---

## Description

Classify multivariate observations in conjunction with `lda`, and also project data onto the linear discriminants.

## Usage

```
## S3 method for class 'lda'
predict(object, newdata, prior = object$prior, dimen,
        method = c("plug-in", "predictive", "debiased"), ...)
```

## Arguments

|                      |                                                                                                                                                                                                                                                                                                                                          |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code>  | object of class "lda"                                                                                                                                                                                                                                                                                                                    |
| <code>newdata</code> | data frame of cases to be classified or, if <code>object</code> has a formula, a data frame with columns of the same names as the variables used. A vector will be interpreted as a row vector. If <code>newdata</code> is missing, an attempt will be made to retrieve the data used to fit the <code>lda</code> object.                |
| <code>prior</code>   | The prior probabilities of the classes, by default the proportions in the training set or what was set in the call to <code>lda</code> .                                                                                                                                                                                                 |
| <code>dimen</code>   | the dimension of the space to be used. If this is less than <code>min(p, ng-1)</code> , only the first <code>dimen</code> discriminant components are used (except for <code>method="predictive"</code> ), and only those dimensions are returned in <code>x</code> .                                                                    |
| <code>method</code>  | This determines how the parameter estimation is handled. With "plug-in" (the default) the usual unbiased parameter estimates are used and assumed to be correct. With "debiased" an unbiased estimator of the log posterior probabilities is used, and with "predictive" the parameter estimates are integrated out using a vague prior. |
| <code>...</code>     | arguments based from or to other methods                                                                                                                                                                                                                                                                                                 |

## Details

This function is a method for the generic function `predict()` for class "lda". It can be invoked by calling `predict(x)` for an object `x` of the appropriate class, or directly by calling `predict.lda(x)` regardless of the class of the object.

Missing values in `newdata` are handled by returning `NA` if the linear discriminants cannot be evaluated. If `newdata` is omitted and the `na.action` of the fit omitted cases, these will be omitted on the prediction.

This version centres the linear discriminants so that the weighted mean (weighted by `prior`) of the group centroids is at the origin.

**Value**

a list with components

|           |                                                                             |
|-----------|-----------------------------------------------------------------------------|
| class     | The MAP classification (a factor)                                           |
| posterior | posterior probabilities for the classes                                     |
| x         | the scores of test cases on up to <code>dimen</code> discriminant variables |

predict.mca

*Predict Method for Class 'mca'*

---

**Description**

Used to compute coordinates for additional rows or additional factors in a multiple correspondence analysis.

**Usage**

```
## S3 method for class 'mca'
predict(object, newdata, type = c("row", "factor"), ...)
```

**Arguments**

|                      |                                                                                                                                                                           |
|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code>  | An object of class <code>"mca"</code> , usually the result of a call to <code>mca</code> .                                                                                |
| <code>newdata</code> | A data frame containing <i>either</i> additional rows of the factors used to fit <code>object</code> <i>or</i> additional factors for the cases used in the original fit. |
| <code>type</code>    | Are predictions required for further rows or for new factors?                                                                                                             |
| <code>...</code>     | Additional arguments from <code>predict</code> : unused.                                                                                                                  |

**Value**

If `type = "row"`, the coordinates for the additional rows.

If `type = "factor"`, the coordinates of the column vertices for the levels of the new factors.

```

---

profile.glm

*Method for Profiling glm Objects*

---

**Description**

Investigates the profile log-likelihood function for a fitted model of class "glm".

**Usage**

```
## S3 method for class 'glm'
profile(fitted, which = 1:p, alpha = 0.01, maxsteps = 10,
       del = zmax/5, trace = FALSE, ...)
```

**Arguments**

|          |                                                                                                                                             |
|----------|---------------------------------------------------------------------------------------------------------------------------------------------|
| fitted   | the original fitted model object.                                                                                                           |
| which    | the original model parameters which should be profiled. This can be a numeric or character vector. By default, all parameters are profiled. |
| alpha    | highest significance level allowed for the profile t-statistics.                                                                            |
| maxsteps | maximum number of points to be used for profiling each parameter.                                                                           |
| del      | suggested change on the scale of the profile t-statistics. Default value chosen to allow profiling at about 10 parameter values.            |
| trace    | logical: should the progress of profiling be reported?                                                                                      |
| ...      | further arguments passed to or from other methods.                                                                                          |

**Details**

The profile t-statistic is defined as the square root of change in sum-of-squares divided by residual standard error with an appropriate sign.

**Value**

A list of classes "profile.glm" and "profile" with an element for each parameter being profiled. The elements are data-frames with two variables

`par.vals`            a matrix of parameter values for each fitted model.  
`tau`                 the profile t-statistics.

**Author(s)**

Originally, D. M. Bates and W. N. Venables. (For S in 1996.)

**Usage**

```
qda(x, ...)

## S3 method for class 'formula'
qda(formula, data, ..., subset, na.action)

## Default S3 method:
qda(x, grouping, prior = proportions,
    method, CV = FALSE, nu, ...)

## S3 method for class 'data.frame'
qda(x, ...)
```

```
## S3 method for class 'matrix'
qda(x, grouping, ..., subset, na.action)
```

### Arguments

|                        |                                                                                                                                                                                                                                                                                         |
|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>formula</code>   | A formula of the form <code>groups ~ x1 + x2 + . . .</code> . That is, the response is the grouping factor and the right hand side specifies the (non-factor) discriminators.                                                                                                           |
| <code>data</code>      | An optional data frame, list or environment from which variables specified in <code>formula</code> are preferentially to be taken.                                                                                                                                                      |
| <code>x</code>         | (required if no formula is given as the principal argument.) a matrix or data frame or Matrix containing the explanatory variables.                                                                                                                                                     |
| <code>grouping</code>  | (required if no formula principal argument is given.) a factor specifying the class for each observation.                                                                                                                                                                               |
| <code>prior</code>     | the prior probabilities of class membership. If unspecified, the class proportions for the training set are used. If specified, the probabilities should be specified in the order of the factor levels.                                                                                |
| <code>subset</code>    | An index vector specifying the cases to be used in the training sample. (NOTE: If given, this argument must be named.)                                                                                                                                                                  |
| <code>na.action</code> | A function to specify the action to be taken if NAs are found. The default action is for the procedure to fail. An alternative is <code>na.omit</code> , which leads to rejection of cases with missing values on any required variable. (NOTE: If given, this argument must be named.) |
| <code>method</code>    | "moment" for standard estimators of the mean and variance, "mle" for MLEs, "mve" to use <code>cov.mve</code> , or "t" for robust estimates based on a t distribution.                                                                                                                   |
| <code>CV</code>        | If true, returns results (classes and posterior probabilities) for leave-out-out cross-validation. Note that if the prior is estimated, the proportions in the whole dataset are used.                                                                                                  |
| <code>nu</code>        | degrees of freedom for <code>method = "t"</code> .                                                                                                                                                                                                                                      |
| <code>...</code>       | arguments passed to or from other methods.                                                                                                                                                                                                                                              |

### Details

Uses a QR decomposition which will give an error message if the within-group variance is singular for any group.

### Value

an object of class "qda" containing the following components:

|                      |                                                                                                                                                             |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>prior</code>   | the prior probabilities used.                                                                                                                               |
| <code>means</code>   | the group means.                                                                                                                                            |
| <code>scaling</code> | for each group <code>i</code> , <code>scaling[, , i]</code> is an array which transforms observations so that within-groups covariance matrix is spherical. |
| <code>ldet</code>    | a vector of half log determinants of the dispersion matrix.                                                                                                 |
| <code>lev</code>     | the levels of the grouping factor.                                                                                                                          |
| <code>terms</code>   | (if formula is a formula) an object of mode expression and class term summarizing the formula.                                                              |

`call` the (matched) function call.

unless `CV=TRUE`, when the return value is a list with components:

`class` The MAP classification (a factor)  
`posterior` posterior probabilities for the classes

train <- rbind(iris3[tr,,1], iris3[tr,,2], iris3[tr,,3])
test <- rbind(iris3[-tr,,1], iris3[-tr,,2], iris3[-tr,,3])
cl <- factor(c(rep("s",25), rep("c",25), rep("v",25)))
z <- qda(train, cl)
predict(z, test)$class
```

---

quine

*Absenteeism from School in Rural New South Wales*

---

## Description

The quine data frame has 146 rows and 5 columns. Children from Walgett, New South Wales, Australia, were classified by Culture, Age, Sex and Learner status and the number of days absent from school in a particular school year was recorded.

## Usage

quine

## Format

This data frame contains the following columns:

`Eth` ethnic background: Aboriginal or Not, ("A" or "N").  
`Sex` sex: factor with levels ("F" or "M").  
`Age` age group: Primary ("F0"), or forms "F1", "F2" or "F3".  
`Lrn` learner status: factor with levels Average or Slow learner, ("AL" or "SL").  
`Days` days absent from school in the year.

Rabbit

---

*Blood Pressure in Rabbits*

---

## Description

Five rabbits were studied on two occasions, after treatment with saline (control) and after treatment with the 5 –  $HT_3$  antagonist MDL 72222. After each treatment ascending doses of phenylbiguanide were injected intravenously at 10 minute intervals and the responses of mean blood pressure measured. The goal was to test whether the cardiogenic chemoreflex elicited by phenylbiguanide depends on the activation of 5 –  $HT_3$  receptors.

## Usage

Rabbit

## Format

This data frame contains 60 rows and the following variables:

`BPchange` change in blood pressure relative to the start of the experiment.

`Dose` dose of Phenylbiguanide in micrograms.

`Run` label of run ("C1" to "C5", then "M1" to "M5").

`Treatment` placebo or the 5 –  $HT_3$  antagonist MDL 72222.

`Animal` label of animal used ("R1" to "R5").

---

rational*Rational Approximation*

---

### Description

Find rational approximations to the components of a real numeric object using a standard continued fraction method.

### Usage

```
rational(x, cycles = 10, max.denominator = 2000, ...)
```

### Arguments

|                              |                                                                                                                                             |
|------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>               | Any object of mode numeric. Missing values are now allowed.                                                                                 |
| <code>cycles</code>          | The maximum number of steps to be used in the continued fraction approximation process.                                                     |
| <code>max.denominator</code> | An early termination criterion. If any partial denominator exceeds <code>max.denominator</code> the continued fraction stops at that point. |
| <code>...</code>             | arguments passed to or from other methods.                                                                                                  |

### Details

Each component is first expanded in a continued fraction of the form

$$x = \text{floor}(x) + 1 / (p_1 + 1 / (p_2 + \dots))$$

where  $p_1, p_2, \dots$  are positive integers, terminating either at `cycles` terms or when a  $p_j > \text{max.denominator}$ . The continued fraction is then re-arranged to retrieve the numerator and denominator as integers and the ratio returned as the value.

### Value

A numeric object with the same attributes as `x` but with entries rational approximations to the values. This effectively rounds relative to the size of the object and replaces very small entries by zero.

### See Also

[fractions](#)

### Examples

```
X <- matrix(runif(25), 5, 5)
zapsmall(solve(X, X/5)) # print near-zeroes as zero
rational(solve(X, X/5))
```

---

renumerate

---

*Convert a Formula Transformed by 'denumerate'*

---

### Description

`denumerate` converts a formula written using the conventions of `loglm` into one that `terms` is able to process. `renumerate` converts it back again to a form like the original.

### Usage

```
renumerate(x)
```

### Arguments

`x`                      A formula, normally as modified by `denumerate`.

### Details

This is an inverse function to `denumerate`. It is only needed since `terms` returns an expanded form of the original formula where the non-marginal terms are exposed. This expanded form is mapped back into a form corresponding to the one that the user originally supplied.

### Value

A formula where all variables with names of the form `.vn`, where `n` is an integer, converted to numbers, `n`, as allowed by the formula conventions of `loglm`.

### See Also

`denumerate`

### Examples

```
denumerate(~(1+2+3)^3 + a/b)
## ~ (.v1 + .v2 + .v3)^3 + a/b
renumerate(.Last.value)
## ~ (1 + 2 + 3)^3 + a/b
```

---

rlm

---

*Robust Fitting of Linear Models*

---

### Description

Fit a linear model by robust regression using an M estimator.

**Usage**

```

rlm(x, ...)

## S3 method for class 'formula'
rlm(formula, data, weights, ..., subset, na.action,
     method = c("M", "MM", "model.frame"),
     wt.method = c("inv.var", "case"),
     model = TRUE, x.ret = TRUE, y.ret = FALSE, contrasts = NULL)

## Default S3 method:
rlm(x, y, weights, ..., w = rep(1, nrow(x)),
     init = "ls", psi = psi.huber,
     scale.est = c("MAD", "Huber", "proposal 2"), k2 = 1.345,
     method = c("M", "MM"), wt.method = c("inv.var", "case"),
     maxit = 20, acc = 1e-4, test.vec = "resid", lqs.control = NULL)

psi.huber(u, k = 1.345, deriv = 0)
psi.hampel(u, a = 2, b = 4, c = 8, deriv = 0)
psi.bisquare(u, c = 4.685, deriv = 0)

```

**Arguments**

|           |                                                                                                                                                                                                                                                                                                                                   |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| formula   | a formula of the form $y \sim x_1 + x_2 + \dots$                                                                                                                                                                                                                                                                                  |
| data      | an optional data frame, list or environment from which variables specified in formula are preferentially to be taken.                                                                                                                                                                                                             |
| weights   | a vector of prior weights for each case.                                                                                                                                                                                                                                                                                          |
| subset    | An index vector specifying the cases to be used in fitting.                                                                                                                                                                                                                                                                       |
| na.action | A function to specify the action to be taken if NAs are found. The ‘factory-fresh’ default action in R is <code>na.omit</code> , and can be changed by <code>options(na.action=)</code> .                                                                                                                                         |
| x         | a matrix or data frame containing the explanatory variables.                                                                                                                                                                                                                                                                      |
| y         | the response: a vector of length the number of rows of x.                                                                                                                                                                                                                                                                         |
| method    | currently either M-estimation or MM-estimation or (for the formula method only) find the model frame. MM-estimation is M-estimation with Tukey’s bi-weight initialized by a specific S-estimator. See the ‘Details’ section.                                                                                                      |
| wt.method | are the weights case weights (giving the relative importance of case, so a weight of 2 means there are two of these) or the inverse of the variances, so a weight of two means this error is half as variable?                                                                                                                    |
| model     | should the model frame be returned in the object?                                                                                                                                                                                                                                                                                 |
| x.ret     | should the model matrix be returned in the object?                                                                                                                                                                                                                                                                                |
| y.ret     | should the response be returned in the object?                                                                                                                                                                                                                                                                                    |
| contrasts | optional contrast specifications: see <code>lm</code> .                                                                                                                                                                                                                                                                           |
| w         | (optional) initial down-weighting for each case.                                                                                                                                                                                                                                                                                  |
| init      | (optional) initial values for the coefficients OR a method to find initial values OR the result of a fit with a <code>coef</code> component. Known methods are "ls" (the default) for an initial least-squares fit using weights <code>w*weights</code> , and "lts" for an unweighted least-trimmed squares fit with 200 samples. |

|                          |                                                                                                                                                                                                                                                                                                                       |
|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>psi</code>         | the <code>psi</code> function is specified by this argument. It must give (possibly by name) a function <code>g(x, ..., deriv)</code> that for <code>deriv=0</code> returns <code>psi(x)/x</code> and for <code>deriv=1</code> returns <code>psi'(x)</code> . Tuning constants will be passed in via <code>...</code> |
| <code>scale.est</code>   | method of scale estimation: re-scaled MAD of the residuals (default) or Huber's proposal 2 (which can be selected by either <code>"Huber"</code> or <code>"proposal 2"</code> ).                                                                                                                                      |
| <code>k2</code>          | tuning constant used for Huber proposal 2 scale estimation.                                                                                                                                                                                                                                                           |
| <code>maxit</code>       | the limit on the number of IWLS iterations.                                                                                                                                                                                                                                                                           |
| <code>acc</code>         | the accuracy for the stopping criterion.                                                                                                                                                                                                                                                                              |
| <code>test.vec</code>    | the stopping criterion is based on changes in this vector.                                                                                                                                                                                                                                                            |
| <code>...</code>         | additional arguments to be passed to <code>rlm.default</code> or to the <code>psi</code> function.                                                                                                                                                                                                                    |
| <code>lqs.control</code> | An optional list of control values for <code>lqs</code> .                                                                                                                                                                                                                                                             |
| <code>u</code>           | numeric vector of evaluation points.                                                                                                                                                                                                                                                                                  |
| <code>k, a, b, c</code>  | tuning constants.                                                                                                                                                                                                                                                                                                     |
| <code>deriv</code>       | 0 or 1: compute values of the <code>psi</code> function or of its first derivative.                                                                                                                                                                                                                                   |

### Details

Fitting is done by iterated re-weighted least squares (IWLS).

`Psi` functions are supplied for the Huber, Hampel and Tukey bisquare proposals as `psi.huber`, `psi.hampel` and `psi.bisquare`. Huber's corresponds to a convex optimization problem and gives a unique solution (up to collinearity). The other two will have multiple local minima, and a good starting point is desirable.

Selecting `method = "MM"` selects a specific set of options which ensures that the estimator has a high breakdown point. The initial set of coefficients and the final scale are selected by an S-estimator with  $k_0 = 1.548$ ; this gives (for  $n \gg p$ ) breakdown point 0.5. The final estimator is an M-estimator with Tukey's biweight and fixed scale that will inherit this breakdown point provided  $c > k_0$ ; this is true for the default value of  $c$  that corresponds to 95% relative efficiency at the normal. Case weights are not supported for `method = "MM"`.

### Value

An object of class `"rlm"` inheriting from `"lm"`. Note that the `df.residual` component is deliberately set to NA to avoid inappropriate estimation of the residual scale from the residual mean square by `"lm"` methods.

The additional components not in an `lm` object are

|                        |                                                                       |
|------------------------|-----------------------------------------------------------------------|
| <code>s</code>         | the robust scale estimate used                                        |
| <code>w</code>         | the weights used in the IWLS process                                  |
| <code>psi</code>       | the <code>psi</code> function with parameters substituted             |
| <code>conv</code>      | the convergence criteria at each iteration                            |
| <code>converged</code> | did the IWLS converge?                                                |
| <code>wresid</code>    | a working residual, weighted for <code>"inv.var"</code> weights only. |

### Note

Prior to version 7.3-52, offset terms in `formula` were omitted from fitted and predicted values.

rlm(stack.loss ~ ., stackloss, psi = psi.bisquare)
```

---

rms.curv

*Relative Curvature Measures for Non-Linear Regression*

---

## Description

Calculates the root mean square parameter effects and intrinsic relative curvatures,  $c^\theta$  and  $c^t$ , for a fitted nonlinear regression, as defined in Bates & Watts, section 7.3, p. 253ff

## Usage

```
rms.curv(obj)
```

## Arguments

`obj` Fitted model object of class "nls". The model must be fitted using the default algorithm.

## Details

The method of section 7.3.1 of Bates & Watts is implemented. The function `deriv3` should be used generate a model function with first derivative (gradient) matrix and second derivative (Hessian) array attributes. This function should then be used to fit the nonlinear regression model.

A print method, `print.rms.curv`, prints the `pc` and `ic` components only, suitably annotated.

If either `pc` or `ic` exceeds some threshold (0.3 has been suggested) the curvature is unacceptably high for the planar assumption.

## Value

A list of class `rms.curv` with components `pc` and `ic` for parameter effects and intrinsic relative curvatures multiplied by  $\sqrt{F}$ , `ct` and `ci` for  $c^\theta$  and  $c^t$  (unmultiplied), and `C` the C-array as used in section 7.3.1 of Bates & Watts.

```
# The treated sample from the Puromycin data
mmcurve <- deriv3(~ Vm * conc/(K + conc), c("Vm", "K"),
                  function(Vm, K, conc) NULL)
Treated <- Puromycin[Puromycin$state == "treated", ]
(Purfit1 <- nls(rate ~ mmcurve(Vm, K, conc), data = Treated,
                start = list(Vm=200, K=0.1)))
rms.curv(Purfit1)
##Parameter effects: c^theta x sqrt(F) = 0.2121
##                  Intrinsic: c^iota x sqrt(F) = 0.092
```

---

rnegbin

---

*Simulate Negative Binomial Variates*

---

## Description

Function to generate random outcomes from a Negative Binomial distribution, with mean  $\mu$  and variance  $\mu + \mu^2/\theta$ .

## Usage

```
rnegbin(n, mu = n, theta = stop("'theta' must be specified"))
```

## Arguments

|       |                                                                                                                                                                                                  |
|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| n     | If a scalar, the number of sample values required. If a vector, <code>length(n)</code> is the number required and <code>n</code> is used as the mean vector if <code>mu</code> is not specified. |
| mu    | The vector of means. Short vectors are recycled.                                                                                                                                                 |
| theta | Vector of values of the <code>theta</code> parameter. Short vectors are recycled.                                                                                                                |

## Details

The function uses the representation of the Negative Binomial distribution as a continuous mixture of Poisson distributions with Gamma distributed means. Unlike `rnbinom` the index can be arbitrary.

## Value

Vector of random Negative Binomial variate values.

## Side Effects

Changes `.Random.seed` in the usual way.

**Examples**

```
# Negative Binomials with means fitted(fm) and theta = 4.5
fm <- glm.nb(Days ~ ., data = quine)
dummy <- rnegbin(fitted(fm), theta = 4.5)
```

---

|------|------------------------------------------|
| road | <i>Road Accident Deaths in US States</i> |
|------|------------------------------------------|

---

**Description**

A data frame with the annual deaths in road accidents for half the US states.

**Usage**

```
road
```

**Format**

Columns are:

state name.

deaths number of deaths.

drivers number of drivers (in 10,000s).

popden population density in people per square mile.

rural length of rural roads, in 1000s of miles.

temp average daily maximum temperature in January.

fuel fuel consumption in 10,000,000 US gallons per year.

**Description**

The data give the numbers of rotifers falling out of suspension for different fluid densities. There are two species, `pm` *Polyartha major* and `kc`, *Keratella cochlearis* and for each species the number falling out and the total number are given.

**Usage**

```
rotifer
```

**Format**

density specific density of fluid.  
 pm.y number falling out for *P. major*.  
 pm.total total number of *P. major*.  
 kc.y number falling out for *K. cochlearis*.  
 kc.tot total number of *K. cochlearis*.

sammon

---

*Sammon's Non-Linear Mapping*

---

**Description**

One form of non-metric multidimensional scaling.

**Usage**

```

sammon(d, y = cmdscale(d, k), k = 2, niter = 100, trace = TRUE,
       magic = 0.2, tol = 1e-4)

```

**Arguments**

|       |                                                                                                                                                                                                                                             |
|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| d     | distance structure of the form returned by <code>dist</code> , or a full, symmetric matrix. Data are assumed to be dissimilarities or relative distances, but must be positive except for self-distance. This can contain missing values.   |
| y     | An initial configuration. If none is supplied, <code>cmdscale</code> is used to provide the classical solution. (If there are missing values in <code>d</code> , an initial configuration must be provided.) This must not have duplicates. |
| k     | The dimension of the configuration.                                                                                                                                                                                                         |
| niter | The maximum number of iterations.                                                                                                                                                                                                           |
| trace | Logical for tracing optimization. Default <code>TRUE</code> .                                                                                                                                                                               |
| magic | initial value of the step size constant in diagonal Newton method.                                                                                                                                                                          |
| tol   | Tolerance for stopping, in units of stress.                                                                                                                                                                                                 |

**Details**

This chooses a two-dimensional configuration to minimize the stress, the sum of squared differences between the input distances and those of the configuration, weighted by the distances, the whole sum being divided by the sum of input distances to make the stress scale-free.

An iterative algorithm is used, which will usually converge in around 50 iterations. As this is necessarily an  $O(n^2)$  calculation, it is slow for large datasets. Further, since the configuration is only determined up to rotations and reflections (by convention the centroid is at the origin), the result can vary considerably from machine to machine. In this release the algorithm has been modified by adding a step-length search (`magic`) to ensure that it always goes downhill.

**Value**

Two components:

|        |                                                  |
|--------|--------------------------------------------------|
| points | A two-column vector of the fitted configuration. |
| stress | The final stress achieved.                       |

**Side Effects**

If `trace` is true, the initial stress and the current stress are printed out every 10 iterations.

ships

*Ships Damage Data*

---

## Description

Data frame giving the number of damage incidents and aggregate months of service by ship type, year of construction, and period of operation.

## Usage

```
ships
```

## Format

`type` type: "A" to "E".

`year` year of construction: 1960–64, 65–69, 70–74, 75–79 (coded as "60", "65", "70", "75").

`period` period of operation : 1960–74, 75–79.

`service` aggregate months of service.

`incidents` number of damage incidents.

shuttle

*Space Shuttle Autolander Problem*

---

**Description**

The `shuttle` data frame has 256 rows and 7 columns. The first six columns are categorical variables giving example conditions; the seventh is the decision. The first 253 rows are the training set, the last 3 the test conditions.

**Usage**

```
shuttle
```

**Format**

This data frame contains the following factor columns:

`stability` stable positioning or not (`stab` / `xstab`).

`error` size of error (`MM` / `SS` / `LX` / `XL`).

`sign` sign of error, positive or negative (`pp` / `nn`).

`wind` wind sign (`head` / `tail`).

`magn` wind strength (`Light` / `Medium` / `Strong` / `Out of Range`).

`vis` visibility (`yes` / `no`).

`use` use the autolander or not. (`auto` / `noauto`.)

snails

*Snail Mortality Data*

---

### Description

Groups of 20 snails were held for periods of 1, 2, 3 or 4 weeks in carefully controlled conditions of temperature and relative humidity. There were two species of snail, A and B, and the experiment was designed as a 4 by 3 by 4 by 2 completely randomized design. At the end of the exposure time the snails were tested to see if they had survived; the process itself is fatal for the animals. The object of the exercise was to model the probability of survival in terms of the stimulus variables, and in particular to test for differences between species.

The data are unusual in that in most cases fatalities during the experiment were fairly small.

### Usage

```
snails
```

### Format

The data frame contains the following components:

Species snail species A (1) or B (2).

Exposure exposure in weeks.

Rel.Hum relative humidity (4 levels).

Temp temperature, in degrees Celsius (3 levels).

Deaths number of deaths.

N number of snails exposed.

---

stepAIC*Choose a model by AIC in a Stepwise Algorithm*

---

**Description**

Performs stepwise model selection by AIC.

**Usage**

```
stepAIC(object, scope, scale = 0,  
        direction = c("both", "backward", "forward"),  
        trace = 1, keep = NULL, steps = 1000, use.start = FALSE,  
        k = 2, ...)
```

**Arguments**

object an object representing a model of an appropriate class. This is used as the initial model in the stepwise search.

scope defines the range of models examined in the stepwise search. This should be either a single formula, or a list containing components upper and lower, both formulae. See the details for how to specify the formulae and how they are used.

|           |                                                                                                                                                                                                                                                                |
|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| scale     | used in the definition of the AIC statistic for selecting the models, currently only for <code>lm</code> and <code>aoV</code> models (see <code>extractAIC</code> for details).                                                                                |
| direction | the mode of stepwise search, can be one of "both", "backward", or "forward", with a default of "both". If the <code>scope</code> argument is missing the default for <code>direction</code> is "backward".                                                     |
| trace     | if positive, information is printed during the running of <code>stepAIC</code> . Larger values may give more information on the fitting process.                                                                                                               |
| keep      | a filter function whose input is a fitted model object and the associated AIC statistic, and whose output is arbitrary. Typically <code>keep</code> will select a subset of the components of the object and return them. The default is not to keep anything. |
| steps     | the maximum number of steps to be considered. The default is 1000 (essentially as many as required). It is typically used to stop the process early.                                                                                                           |
| use.start | if true the updated fits are done starting at the linear predictor for the currently selected model. This may speed up the iterative calculations for <code>glm</code> (and other fits), but it can also slow them down. <b>Not used in R.</b>                 |
| k         | the multiple of the number of degrees of freedom used for the penalty. Only $k = 2$ gives the genuine AIC: $k = \log(n)$ is sometimes referred to as BIC or SBC.                                                                                               |
| ...       | any additional arguments to <code>extractAIC</code> . (None are currently used.)                                                                                                                                                                               |

### Details

The set of models searched is determined by the `scope` argument. The right-hand-side of its `lower` component is always included in the model, and right-hand-side of the model is included in the upper component. If `scope` is a single formula, it specifies the upper component, and the lower model is empty. If `scope` is missing, the initial model is used as the upper model.

Models specified by `scope` can be templates to update `object` as used by `update.formula`.

There is a potential problem in using `glm` fits with a variable `scale`, as in that case the deviance is not simply related to the maximized log-likelihood. The `glm` method for `extractAIC` makes the appropriate adjustment for a gaussian family, but may need to be amended for other cases. (The `binomial` and `poisson` families have fixed `scale` by default and do not correspond to a particular maximum-likelihood problem for variable `scale`.)

Where a conventional deviance exists (e.g. for `lm`, `aoV` and `glm` fits) this is quoted in the analysis of variance table: it is the *unscaled* deviance.

### Value

the stepwise-selected model is returned, with up to two additional components. There is an "anova" component corresponding to the steps taken in the search, as well as a "keep" component if the `keep=` argument was supplied in the call. The "Resid. Dev" column of the analysis of deviance table refers to a constant minus twice the maximized log likelihood: it will be a deviance only in cases where a saturated model is well-defined (thus excluding `lm`, `aoV` and `survreg` fits, for example).

### Note

The model fitting must apply the models to the same dataset. This may be a problem if there are missing values and an `na.action` other than `na.fail` is used (as is the default in R). We suggest you remove the missing values first.

---

stormer

*The Stormer Viscometer Data*

---

## Description

The stormer viscometer measures the viscosity of a fluid by measuring the time taken for an inner cylinder in the mechanism to perform a fixed number of revolutions in response to an actuating weight. The viscometer is calibrated by measuring the time taken with varying weights while the mechanism is suspended in fluids of accurately known viscosity. The data comes from such a calibration, and theoretical considerations suggest a nonlinear relationship between time, weight and viscosity, of the form  $\text{Time} = (B1 * \text{Viscosity}) / (\text{Weight} - B2) + E$  where  $B1$  and  $B2$  are unknown parameters to be estimated, and  $E$  is error.

## Usage

```
stormer
```

**Format**

The data frame contains the following components:

Viscosity viscosity of fluid.

Wt actuating weight.

Time time taken.

**Source**

E. J. Williams (1959) *Regression Analysis*. Wiley.

**References**

Venables, W. N. and Ripley, B. D. (2002) *Modern Applied Statistics with S*. Fourth edition. Springer.

---

studres

*Extract Studentized Residuals from a Linear Model*

---

**Description**

The Studentized residuals. Like standardized residuals, these are normalized to unit variance, but the Studentized version is fitted ignoring the current data point. (They are sometimes called jack-knifed residuals).

**Usage**

```
studres(object)
```

**Arguments**

object            any object representing a linear model.

**Value**

The vector of appropriately transformed residuals.

summary.loglm*Summary Method Function for Objects of Class 'loglm'*

---

## Description

Returns a summary list for log-linear models fitted by iterative proportional scaling using `loglm`.

## Usage

```
## S3 method for class 'loglm'
summary(object, fitted = FALSE, ...)
```

## Arguments

|                     |                                                                                                                                                      |
|---------------------|------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code> | a fitted <code>loglm</code> model object.                                                                                                            |
| <code>fitted</code> | if <code>TRUE</code> return observed and expected frequencies in the result. Using <code>fitted = TRUE</code> may necessitate re-fitting the object. |
| <code>...</code>    | arguments to be passed to or from other methods.                                                                                                     |

## Details

This function is a method for the generic function `summary()` for class `"loglm"`. It can be invoked by calling `summary(x)` for an object `x` of the appropriate class, or directly by calling `summary.loglm(x)` regardless of the class of the object.

## Value

a list is returned for use by `print.summary.loglm`. This has components

|                      |                                                                                                                  |
|----------------------|------------------------------------------------------------------------------------------------------------------|
| <code>formula</code> | the formula used to produce <code>object</code>                                                                  |
| <code>tests</code>   | the table of test statistics (likelihood ratio, Pearson) for the fit.                                            |
| <code>oe</code>      | if <code>fitted = TRUE</code> , an array of the observed and expected frequencies, otherwise <code>NULL</code> . |

|                |                                                              |
|----------------|--------------------------------------------------------------|
| summary.negbin | <i>Summary Method Function for Objects of Class 'negbin'</i> |
|----------------|--------------------------------------------------------------|

---

## Description

Identical to `summary.glm`, but with three lines of additional output: the ML estimate of theta, its standard error, and twice the log-likelihood function.

## Usage

```
## S3 method for class 'negbin'
summary(object, dispersion = 1, correlation = FALSE, ...)
```

## Arguments

|                          |                                                                                                                                                       |
|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code>      | fitted model object of class <code>negbin</code> inheriting from <code>glm</code> and <code>lm</code> . Typically the output of <code>glm.nb</code> . |
| <code>dispersion</code>  | as for <code>summary.glm</code> , with a default of 1.                                                                                                |
| <code>correlation</code> | as for <code>summary.glm</code> .                                                                                                                     |
| <code>...</code>         | arguments passed to or from other methods.                                                                                                            |

## Details

`summary.glm` is used to produce the majority of the output and supply the result. This function is a method for the generic function `summary()` for class "negbin". It can be invoked by calling `summary(x)` for an object `x` of the appropriate class, or directly by calling `summary.negbin(x)` regardless of the class of the object.

## Value

As for `summary.glm`; the additional lines of output are not included in the resultant object.

## Side Effects

A summary table is produced as for `summary.glm`, with the additional information described above.

## References

Venables, W. N. and Ripley, B. D. (2002) *Modern Applied Statistics with S*. Fourth edition. Springer.

summary.rlm

*Summary Method for Robust Linear Models***Description**

summary method for objects of class "rlm"

**Usage**

```
## S3 method for class 'rlm'
summary(object, method = c("XtX", "XtWX"), correlation = FALSE, ...)
```

**Arguments**

|             |                                                                                                                                                                                                                                   |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object      | the fitted model. This is assumed to be the result of some fit that produces an object inheriting from the class <code>rlm</code> , in the sense that the components returned by the <code>rlm</code> function will be available. |
| method      | Should the weighted (by the IWLS weights) or unweighted cross-products matrix be used?                                                                                                                                            |
| correlation | logical. Should correlations be computed (and printed)?                                                                                                                                                                           |
| ...         | arguments passed to or from other methods.                                                                                                                                                                                        |

**Details**

This function is a method for the generic function `summary()` for class "rlm". It can be invoked by calling `summary(x)` for an object `x` of the appropriate class, or directly by calling `summary.rlm(x)` regardless of the class of the object.

**Value**

If printing takes place, only a null value is returned. Otherwise, a list is returned with the following components. Printing always takes place if this function is invoked automatically as a method for the `summary` function.

|              |                                                                                                                                                                           |
|--------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| correlation  | The computed correlation coefficient matrix for the coefficients in the model.                                                                                            |
| cov.unscaled | The unscaled covariance matrix; i.e, a matrix such that multiplying it by an estimate of the error variance produces an estimated covariance matrix for the coefficients. |
| sigma        | The scale estimate.                                                                                                                                                       |
| stddev       | A scale estimate used for the standard errors.                                                                                                                            |
| df           | The number of degrees of freedom for the model and for residuals.                                                                                                         |
| coefficients | A matrix with three columns, containing the coefficients, their standard errors and the corresponding t statistic.                                                        |
| terms        | The terms object used in fitting this model.                                                                                                                              |

survey

*Student Survey Data***Description**

This data frame contains the responses of 237 Statistics I students at the University of Adelaide to a number of questions.

**Usage**

```
survey
```

**Format**

The components of the data frame are:

**Sex** The sex of the student. (Factor with levels "Male" and "Female".)

**Wr.Hnd** span (distance from tip of thumb to tip of little finger of spread hand) of writing hand, in centimetres.

**NW.Hnd** span of non-writing hand.

**W.Hnd** writing hand of student. (Factor, with levels "Left" and "Right".)

**Fold** "Fold your arms! Which is on top" (Factor, with levels "R on L", "L on R", "Neither".)

**Pulse** pulse rate of student (beats per minute).

**Clap** 'Clap your hands! Which hand is on top?' (Factor, with levels "Right", "Left", "Neither".)

**Exer** how often the student exercises. (Factor, with levels "Freq" (frequently), "Some", "None".)

**Smoke** how much the student smokes. (Factor, levels "Heavy", "Regul" (regularly), "Occas" (occasionally), "Never".)

**Height** height of the student in centimetres.

**M.I** whether the student expressed height in imperial (feet/inches) or metric (centimetres/metres) units. (Factor, levels "Metric", "Imperial".)

**Age** age of the student in years.

synth.tr

*Synthetic Classification Problem***Description**

The `synth.tr` data frame has 250 rows and 3 columns. The `synth.te` data frame has 100 rows and 3 columns. It is intended that `synth.tr` be used from training and `synth.te` for testing.

**Usage**

```
synth.tr
synth.te
```

**Format**

These data frames contains the following columns:

```
xs x-coordinate
ys y-coordinate
yc class, coded as 0 or 1.
```

**Source**

Ripley, B.D. (1994) Neural networks and related methods for classification (with discussion). *Journal of the Royal Statistical Society series B* **56**, 409–456.

theta.md

*Estimate theta of the Negative Binomial***Description**

Given the estimated mean vector, estimate `theta` of the Negative Binomial Distribution.

**Usage**

```
theta.md(y, mu, dfr, weights, limit = 20, eps = .Machine$double.eps^0.25)

theta.ml(y, mu, n, weights, limit = 10, eps = .Machine$double.eps^0.25,
         trace = FALSE)

theta.mm(y, mu, dfr, weights, limit = 10, eps = .Machine$double.eps^0.25)
```

## Arguments

|                      |                                                                                                                                                           |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>y</code>       | Vector of observed values from the Negative Binomial.                                                                                                     |
| <code>mu</code>      | Estimated mean vector.                                                                                                                                    |
| <code>n</code>       | Number of data points (defaults to the sum of <code>weights</code> )                                                                                      |
| <code>dfr</code>     | Residual degrees of freedom (assuming <code>theta</code> known). For a weighted fit this is the sum of the weights minus the number of fitted parameters. |
| <code>weights</code> | Case weights. If missing, taken as 1.                                                                                                                     |
| <code>limit</code>   | Limit on the number of iterations.                                                                                                                        |
| <code>eps</code>     | Tolerance to determine convergence.                                                                                                                       |
| <code>trace</code>   | logical: should iteration progress be printed?                                                                                                            |

## Details

`theta.md` estimates by equating the deviance to the residual degrees of freedom, an analogue of a moment estimator.

`theta.ml` uses maximum likelihood.

`theta.mm` calculates the moment estimator of `theta` by equating the Pearson chi-square  $\sum (y - \mu)^2 / (\mu + \mu^2 / \theta)$  to the residual degrees of freedom.

## Value

The required estimate of `theta`, as a scalar. For `theta.ml`, the standard error is given as attribute "SE".

## See Also

## Examples

```
quine.nb <- glm.nb(Days ~ .^2, data = quine)
theta.md(quine$Days, fitted(quine.nb), dfr = df.residual(quine.nb))
theta.ml(quine$Days, fitted(quine.nb))
theta.mm(quine$Days, fitted(quine.nb), dfr = df.residual(quine.nb))

## weighted example
yeast <- data.frame(cbind(numbers = 0:5, fr = c(213, 128, 37, 18, 3, 1)))
fit <- glm.nb(numbers ~ 1, weights = fr, data = yeast)
summary(fit)
mu <- fitted(fit)
theta.md(yeast$numbers, mu, dfr = 399, weights = yeast$fr)
theta.ml(yeast$numbers, mu, limit = 15, weights = yeast$fr)
theta.mm(yeast$numbers, mu, dfr = 399, weights = yeast$fr)
```

---

topo

*Spatial Topographic Data*

---

### Description

The `topo` data frame has 52 rows and 3 columns, of topographic heights within a 310 feet square.

### Usage

```
topo
```

### Format

This data frame contains the following columns:

`x` x coordinates (units of 50 feet)

`y` y coordinates (units of 50 feet)

`z` heights (feet)

Traffic

*Effect of Swedish Speed Limits on Accidents*

---

### Description

An experiment was performed in Sweden in 1961–2 to assess the effect of a speed limit on the motorway accident rate. The experiment was conducted on 92 days in each year, matched so that day `j` in 1962 was comparable to day `j` in 1961. On some days the speed limit was in effect and enforced, while on other days there was no speed limit and cars tended to be driven faster. The speed limit days tended to be in contiguous blocks.

### Usage

```
Traffic
```

### Format

This data frame contains the following columns:

`year` 1961 or 1962.

`day` of year.

`limit` was there a speed limit?

`y` traffic accident count for that day.

```

## Arguments

|        |                                                                                                                                                                                                                                                                                                                                                                            |
|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| data   | numeric vector of data for histogram. Missing values (NAs) are allowed and omitted.                                                                                                                                                                                                                                                                                        |
| nbins  | The suggested number of bins. Either a positive integer, or a character string naming a rule: "Scott" or "Freedman-Diaconis" or "FD". (Case is ignored.)                                                                                                                                                                                                                   |
| h      | The bin width, a strictly positive number (takes precedence over nbins).                                                                                                                                                                                                                                                                                                   |
| x0     | Shift for the bins - the breaks are at $x_0 + h * (\dots, -1, 0, 1, \dots)$                                                                                                                                                                                                                                                                                                |
| breaks | The set of breakpoints to be used. (Usually omitted, takes precedence over h and nbins).                                                                                                                                                                                                                                                                                   |
| prob   | If true (the default) plot a true histogram. The vertical axis has a <i>relative frequency density</i> scale, so the product of the dimensions of any panel gives the relative frequency. Hence the total area under the histogram is 1 and it is directly comparable with most other estimates of the probability density function. If false plot the counts in the bins. |
| xlim   | The limits for the x-axis.                                                                                                                                                                                                                                                                                                                                                 |
| ymax   | The upper limit for the y-axis.                                                                                                                                                                                                                                                                                                                                            |
| col    | The colour for the bar fill: the default is colour 5 in the default R palette.                                                                                                                                                                                                                                                                                             |
| xlab   | label for the plot x-axis. By default, this will be the name of data.                                                                                                                                                                                                                                                                                                      |
| bty    | The box type for the plot - defaults to none.                                                                                                                                                                                                                                                                                                                              |
| ...    | additional arguments to <a href="#">rect</a> or <a href="#">plot</a> .                                                                                                                                                                                                                                                                                                     |

**Details**

This plots a true histogram, a density estimate of total area 1. If `breaks` is specified, those break-points are used. Otherwise if `h` is specified, a regular grid of bins is used with width `h`. If neither `breaks` nor `h` is specified, `nbins` is used to select a suitable `h`.

**Side Effects**

A histogram is plotted on the current device.

 ucv

*Unbiased Cross-Validation for Bandwidth Selection*

---

**Description**

Uses unbiased cross-validation to select the bandwidth of a Gaussian kernel density estimator.

**Usage**

```
ucv(x, nb = 1000, lower, upper)
```

**Arguments**

|                           |                                                                          |
|---------------------------|--------------------------------------------------------------------------|
| <code>x</code>            | a numeric vector                                                         |
| <code>nb</code>           | number of bins to use.                                                   |
| <code>lower, upper</code> | Range over which to minimize. The default is almost always satisfactory. |

**Value**

a bandwidth.

UScereal

*Nutritional and Marketing Information on US Cereals***Description**

The UScereal data frame has 65 rows and 11 columns. The data come from the 1993 ASA Statistical Graphics Exposition, and are taken from the mandatory F&DA food label. The data have been normalized here to a portion of one American cup.

**Usage**

UScereal

**Format**

This data frame contains the following columns:

mfr Manufacturer, represented by its first initial: G=General Mills, K=Kelloggs, N=Nabisco, P=Post, Q=Quaker Oats, R=Ralston Purina.

calories number of calories in one portion.

protein grams of protein in one portion.

fat grams of fat in one portion.

sodium milligrams of sodium in one portion.

fibre grams of dietary fibre in one portion.

carbo grams of complex carbohydrates in one portion.

sugars grams of sugars in one portion.

shelf display shelf (1, 2, or 3, counting from the floor).

potassium grams of potassium.

vitamins vitamins and minerals (none, enriched, or 100%).

**Source**

The original data are available at <http://lib.stat.cmu.edu/datasets/1993.expo/>.

UScrime

*The Effect of Punishment Regimes on Crime Rates***Description**

Criminologists are interested in the effect of punishment regimes on crime rates. This has been studied using aggregate data on 47 states of the USA for 1960 given in this data frame. The variables seem to have been re-scaled to convenient numbers.

**Usage**

UScrime

**Format**

This data frame contains the following columns:

M percentage of males aged 14–24.  
 So indicator variable for a Southern state.  
 Ed mean years of schooling.  
 Po1 police expenditure in 1960.  
 Po2 police expenditure in 1959.  
 LF labour force participation rate.  
 M.F number of males per 1000 females.  
 Pop state population.  
 NW number of non-whites per 1000 people.  
 U1 unemployment rate of urban males 14–24.  
 U2 unemployment rate of urban males 35–39.  
 GDP gross domestic product per head.  
 Ineq income inequality.  
 Prob probability of imprisonment.  
 Time average time served in state prisons.  
 y rate of crimes in a particular category per head of population.

---

 VA

---

*Veteran's Administration Lung Cancer Trial*

---

### Description

Veteran's Administration lung cancer trial from Kalbfleisch & Prentice.

### Usage

VA

### Format

A data frame with columns:

`stime` survival or follow-up time in days.

`status` dead or censored.

`treat` treatment: standard or test.

`age` patient's age in years.

`Karn` Karnofsky score of patient's performance on a scale of 0 to 100.

`diag.time` times since diagnosis in months at entry to trial.

`cell` one of four cell types.

`prior` prior therapy?

---

 waders

---

*Counts of Waders at 15 Sites in South Africa*

---

### Description

The `waders` data frame has 15 rows and 19 columns. The entries are counts of waders in summer.

### Usage

`waders`

**Format**

This data frame contains the following columns (species)

S1 Oystercatcher  
 S2 White-fronted Plover  
 S3 Kitt Lutz's Plover  
 S4 Three-banded Plover  
 S5 Grey Plover  
 S6 Ringed Plover  
 S7 Bar-tailed Godwit  
 S8 Whimbrel  
 S9 Marsh Sandpiper  
 S10 Greenshank  
 S11 Common Sandpiper  
 S12 Turnstone  
 S13 Knot  
 S14 Sanderling  
 S15 Little Stint  
 S16 Curlew Sandpiper  
 S17 Ruff  
 S18 Avocet  
 S19 Black-winged Stilt

The rows are the sites:

A = Namibia North coast  
 B = Namibia North wetland  
 C = Namibia South coast  
 D = Namibia South wetland  
 E = Cape North coast  
 F = Cape North wetland  
 G = Cape West coast  
 H = Cape West wetland  
 I = Cape South coast  
 J = Cape South wetland  
 K = Cape East coast  
 L = Cape East wetland  
 M = Transkei coast  
 N = Natal coast  
 O = Natal wetland

**Examples**

```
plot(corresp(waders, nf=2))
```

whiteside

*House Insulation: Whiteside's Data***Description**

Mr Derek Whiteside of the UK Building Research Station recorded the weekly gas consumption and average external temperature at his own house in south-east England for two heating seasons, one of 26 weeks before, and one of 30 weeks after cavity-wall insulation was installed. The object of the exercise was to assess the effect of the insulation on gas consumption.

**Usage**

whiteside

**Format**

The whiteside data frame has 56 rows and 3 columns.:

Insul A factor, before or after insulation.

Temp Purportedly the average outside temperature in degrees Celsius. (These values is far too low for any 56-week period in the 1960s in South-East England. It might be the weekly average of daily minima.)

Gas The weekly gas consumption in 1000s of cubic feet.

**Source**

A data set collected in the 1960s by Mr Derek Whiteside of the UK Building Research Station. Reported by

Hand, D. J., Daly, F., McConway, K., Lunn, D. and Ostrowski, E. eds (1993) *A Handbook of Small Data Sets*. Chapman & Hall, p. 69.

**References**

Venables, W. N. and Ripley, B. D. (2002) *Modern Applied Statistics with S*. Fourth edition. Springer.

**Examples**

```
require(lattice)
xyplot(Gas ~ Temp | Insul, whiteside, panel =
  function(x, y, ...) {
    panel.xyplot(x, y, ...)
    panel.lmline(x, y, ...)
  }, xlab = "Average external temperature (deg. C)",
  ylab = "Gas consumption (1000 cubic feet)", aspect = "xy",
  strip = function(...) strip.default(..., style = 1))

gasB <- lm(Gas ~ Temp, whiteside, subset = Insul=="Before")
gasA <- update(gasB, subset = Insul=="After")
summary(gasB)
summary(gasA)
gasBA <- lm(Gas ~ Insul/Temp - 1, whiteside)
summary(gasBA)
```

```
gasQ <- lm(Gas ~ Insul/(Temp + I(Temp^2)) - 1, whiteside)
coef(summary(gasQ))

gasPR <- lm(Gas ~ Insul + Temp, whiteside)
anova(gasPR, gasBA)
options(contrasts = c("contr.treatment", "contr.poly"))
gasBA1 <- lm(Gas ~ Insul*Temp, whiteside)
coef(summary(gasBA1))
```

width.SJ

*Bandwidth Selection by Pilot Estimation of Derivatives***Description**

Uses the method of Sheather & Jones (1991) to select the bandwidth of a Gaussian kernel density estimator.

**Usage**

```
width.SJ(x, nb = 1000, lower, upper, method = c("ste", "dpi"))
```

**Arguments**

|              |                                                                  |
|--------------|------------------------------------------------------------------|
| x            | a numeric vector                                                 |
| nb           | number of bins to use.                                           |
| upper, lower | range over which to search for solution if method = "ste".       |
| method       | Either "ste" ("solve-the-equation") or "dpi" ("direct plug-in"). |

**Value**

a bandwidth.

**Note**

A faster version for large n (thousands) is available in  $R \geq 3.4.0$  as part of [bw.SJ](#): quadruple its value for comparability with this version.

width.SJ(galaxies)
```

---

write.matrix

---

*Write a Matrix or Data Frame*

---

**Description**

Writes a matrix or data frame to a file or the console, using column labels and a layout respecting columns.

**Usage**

```
write.matrix(x, file = "", sep = " ", blocksize)
```

**Arguments**

|                        |                                                                                                                                                                       |
|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>         | matrix or data frame.                                                                                                                                                 |
| <code>file</code>      | name of output file. The default ("") is the console.                                                                                                                 |
| <code>sep</code>       | The separator between columns.                                                                                                                                        |
| <code>blocksize</code> | If supplied and positive, the output is written in blocks of <code>blocksize</code> rows. Choose as large as possible consistent with the amount of memory available. |

**Details**

If `x` is a matrix, supplying `blocksize` is more memory-efficient and enables larger matrices to be written, but each block of rows might be formatted slightly differently.

If `x` is a data frame, the conversion to a matrix may negate the memory saving.

**Side Effects**

A formatted file is produced, with column headings (if `x` has them) and columns of data.

wtloss

---

*Weight Loss Data from an Obese Patient*

---

**Description**

The data frame gives the weight, in kilograms, of an obese patient at 52 time points over an 8 month period of a weight rehabilitation programme.

**Usage**

```
wtloss
```

**Format**

This data frame contains the following columns:

`Days` time in days since the start of the programme.

`Weight` weight in kilograms of the patient.

**Source**

Dr T. Davies, Adelaide.

**References**

Venables, W. N. and Ripley, B. D. (2002) *Modern Applied Statistics with S*. Fourth edition. Springer.

**Examples**

```
## IGNORE_RDIFF_BEGIN
wtloss.fm <- nls(Weight ~ b0 + b1*2^(-Days/th),
  data = wtloss, start = list(b0=90, b1=95, th=120))
wtloss.fm
## IGNORE_RDIFF_END
plot(wtloss)
with(wtloss, lines(Days, fitted(wtloss.fm)))
```

## Chapter 17

# The `Matrix` package

---

`abIndex-class`

*Class "abIndex" of Abstract Index Vectors*

---

### Description

The `"abIndex"` [class](#), short for “Abstract Index Vector”, is used for dealing with large index vectors more efficiently, than using integer (or [numeric](#)) vectors of the kind `2:1000000` or `c(0:1e5, 1000:1e6)`.

Note that the current implementation details are subject to change, and if you consider working with these classes, please contact the package maintainers (`packageDescription("Matrix")$Maintainer`).

### Objects from the Class

Objects can be created by calls of the form `new("abIndex", ...)`, but more easily and typically either by `as(x, "abIndex")` where `x` is an integer (valued) vector, or directly by `abIseq()` and combination `c(...)` of such.

### Slots

**kind:** a [character](#) string, one of `("int32", "double", "rleDiff")`, denoting the internal structure of the `abIndex` object.

**x:** Object of class `"numLike"`; is used (i.e., not of length 0) only iff the object is *not* compressed, i.e., currently exactly when `kind != "rleDiff"`.

**rleD:** object of class `"rleDiff"`, used for compression via [rle](#).

### Methods

**as.numeric, as.integer, as.vector** `signature(x = "abIndex"): ...`

**[** `signature(x = "abIndex", i = "index", j = "ANY", drop = "ANY"): ...`

**coerce** `signature(from = "numeric", to = "abIndex"): ...`

**coerce** `signature(from = "abIndex", to = "numeric"): ...`

**coerce** `signature(from = "abIndex", to = "integer"): ...`

**length** `signature(x = "abIndex"): ...`

**Ops** signature(e1 = "numeric", e2 = "abIndex"): These and the following arithmetic and logic operations are **not yet implemented**; see [Ops](#) for a list of these (S4) group methods.

**Ops** signature(e1 = "abIndex", e2 = "abIndex"): ...

**Ops** signature(e1 = "abIndex", e2 = "numeric"): ...

**Summary** signature(x = "abIndex"): ...

**show** ("abIndex"): simple [show](#) method, building on `show(<rlDiff>)`.

**is.na** ("abIndex"): works analogously to regular vectors.

**is.finite, is.infinite** ("abIndex"): ditto.

## Note

This is currently experimental and not yet used for our own code. Please contact us (`packageDescription("Matrix")$Maintainer`), if you plan to make use of this class.

Partly builds on ideas and code from Jens Oehlschlaegel, as implemented (around 2008, in the GPL'ed part of) package **ff**.

## See Also

[rle](#) (base) which is used here; [numeric](#)

## Examples

```
showClass("abIndex")
ii <- c(-3:40, 20:70)
str(ai <- as(ii, "abIndex"))# note
ai # -> show() method

stopifnot(identical(-3:20,
                    as(abIseq1(-3,20), "vector")))
```

---

abIseq

*Sequence Generation of "abIndex", Abstract Index Vectors*

---

## Description

Generation of abstract index vectors, i.e., objects of class "[abIndex](#)".

`abIseq()` is designed to work entirely like [seq](#), but producing "abIndex" vectors.

`abIseq1()` is its basic building block, where `abIseq1(n,m)` corresponds to `n:m`.

`c(x, ...)` will return an "abIndex" vector, when `x` is one.

## Usage

```
abIseq1(from = 1, to = 1)
abIseq (from = 1, to = 1, by = ((to - from)/(length.out - 1)),
        length.out = NULL, along.with = NULL)

## S3 method for class 'abIndex'
c(...)
```

**Arguments**

|                         |                                                                                                                                                                                     |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>from, to</code>   | the starting and (maximal) end value of the sequence.                                                                                                                               |
| <code>by</code>         | number: increment of the sequence.                                                                                                                                                  |
| <code>length.out</code> | desired length of the sequence. A non-negative number, which for <code>seq</code> and <code>seq.int</code> will be rounded up if fractional.                                        |
| <code>along.with</code> | take the length from the length of this argument.                                                                                                                                   |
| <code>...</code>        | in general an arbitrary number of R objects; here, when the first is an <code>"abIndex"</code> vector, these arguments will be concatenated to a new <code>"abIndex"</code> object. |

**Value**

An abstract index vector, i.e., object of class `"abIndex"`.

**See Also**

the class `abIndex` documentation; `rep2abI()` for another constructor; `rle` (**base**).

**Examples**

```
stopifnot(identical(-3:20,
                    as(abIseq1(-3,20), "vector")))

try( ## (arithmetic) not yet implemented
abIseq(1, 50, by = 3)
)
```

---

all-methods

---

*"Matrix" Methods for Functions all() and any()*

---

**Description**

The basic R functions `all` and `any` now have methods for `Matrix` objects and should behave as for `matrix` ones.

**Methods**

```
all signature(x = "Matrix", ..., na.rm = FALSE): ...
any signature(x = "Matrix", ..., na.rm = FALSE): ...
all signature(x = "ldenseMatrix", ..., na.rm = FALSE): ...
all signature(x = "lsparseMatrix", ..., na.rm = FALSE): ...
```

### Examples

```
M <- Matrix(1:12 + 0, 3, 4)
all(M >= 1) # TRUE
any(M < 0) # FALSE
MN <- M; MN[2,3] <- NA; MN
all(MN >= 0) # NA
any(MN < 0) # NA
any(MN < 0, na.rm = TRUE) # -> FALSE
```

---

all.equal-methods    *Matrix Package Methods for Function all.equal()*

---

### Description

Methods for function `all.equal()` (from R package **base**) are defined for all `Matrix` classes.

### Methods

**target = "Matrix", current = "Matrix" \**  
**target = "ANY", current = "Matrix" \**  
**target = "Matrix", current = "ANY"** these three methods are simply using `all.equal.numeric` directly and work via `as.vector()`.  
 There are more methods, notably also for `"sparseVector"`'s, see `showMethods("all.equal")`.

### Examples

```
showMethods("all.equal")

(A <- spMatrix(3,3, i= c(1:3,2:1), j=c(3:1,1:2), x = 1:5))
ex <- expand(lu. <- lu(A))
stopifnot( all.equal(as(A[lu.@p + 1L, lu.@q + 1L], "CsparseMatrix"),
                    lu.@L %*% lu.@U),
           with(ex, all.equal(as(P %*% A %*% Q, "CsparseMatrix"),
                               L %*% U)),
           with(ex, all.equal(as(A, "CsparseMatrix"),
                               t(P) %*% L %*% U %*% t(Q))))
```

---

atomicVector-class    *Virtual Class "atomicVector" of Atomic Vectors*

---

### Description

The `class` `"atomicVector"` is a *virtual* class containing all atomic vector classes of base R, as also implicitly defined via `is.atomic`.

### Objects from the Class

A virtual Class: No objects may be created from it.

## Methods

In the **Matrix** package, the "atomicVector" is used in signatures where typically “old-style” "matrix" objects can be used and can be substituted by simple vectors.

## Extends

The atomic classes "logical", "integer", "double", "numeric", "complex", "raw" and "character" are extended directly. Note that "numeric" already contains "integer" and "double", but we want all of them to be direct subclasses of "atomicVector".

## Author(s)

Martin Maechler

## See Also

`is.atomic`, `integer`, `numeric`, `complex`, etc.

## Examples

```
showClass("atomicVector")
```

---

band

---

*Extract bands of a matrix*

---

## Description

Returns a new matrix formed by extracting the lower triangle (`tril`) or the upper triangle (`triu`) or a general band relative to the diagonal (`band`), and setting other elements to zero. The general forms of these functions include integer arguments to specify how many diagonal bands above or below the main diagonal are not set to zero.

## Usage

```
band(x, k1, k2, ...)
tril(x, k = 0, ...)
triu(x, k = 0, ...)
```

## Arguments

|                        |                                                                                                                                                                                                                                                                                                    |
|------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>         | a matrix-like object                                                                                                                                                                                                                                                                               |
| <code>k, k1, k2</code> | integers specifying the diagonal bands that will not be set to zero. These are given relative to the main diagonal, which is <code>k=0</code> . A negative value of <code>k</code> indicates a diagonal below the main diagonal and a positive value indicates a diagonal above the main diagonal. |
| <code>...</code>       | Optional arguments used by specific methods. (None used at present.)                                                                                                                                                                                                                               |

## Value

An object of an appropriate matrix class. The class of the value of `tril` or `triu` inherits from `triangularMatrix` when appropriate. Note that the result is of class `sparseMatrix` only if `x` is.

## Methods

**x = "CsparseMatrix"** method for compressed, sparse, column-oriented matrices.

**x = "TsparseMatrix"** method for sparse matrices in triplet format.

**x = "RsparseMatrix"** method for compressed, sparse, row-oriented matrices.

**x = "ddenseMatrix"** method for dense numeric matrices, including packed numeric matrices.

## See Also

[bandSparse](#) for the *construction* of a banded sparse matrix directly from its non-zero diagonals.

## Examples

```
## A random sparse matrix :
set.seed(7)
m <- matrix(0, 5, 5)
m[sample(length(m), size = 14)] <- rep(1:9, length=14)
(mm <- as(m, "CsparseMatrix"))

tril(mm)          # lower triangle
tril(mm, -1)      # strict lower triangle
triu(mm, 1)       # strict upper triangle
band(mm, -1, 2)   # general band
(m5 <- Matrix(rnorm(25), nc = 5))
tril(m5)          # lower triangle
tril(m5, -1)      # strict lower triangle
triu(m5, 1)       # strict upper triangle
band(m5, -1, 2)   # general band
(m65 <- Matrix(rnorm(30), nc = 5)) # not square
triu(m65)         # result in not dtrMatrix unless square
(sm5 <- crossprod(m65)) # symmetric
  band(sm5, -1, 1) # symmetric band preserves symmetry property
as(band(sm5, -1, 1), "sparseMatrix") # often preferable
```

---

bandSparse

---

Construct Sparse Banded Matrix from (Sup-/Super-) Diagonals

---

## Description

Construct a sparse banded matrix by specifying its non-zero sup- and super-diagonals.

## Usage

```
bandSparse(n, m = n, k, diagonals, symmetric = FALSE,
           repr = "C", giveCsparse = (repr == "C"))
```

**Arguments**

|                          |                                                                                                                                                                                                                                                                                                                                                                                                                   |
|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>n, m</code>        | the matrix dimension $(n, m) = (nrow, ncol)$ .                                                                                                                                                                                                                                                                                                                                                                    |
| <code>k</code>           | integer vector of “diagonal numbers”, with identical meaning as in <code>band(*, k)</code> , i.e., relative to the main diagonal, which is $k=0$ .                                                                                                                                                                                                                                                                |
| <code>diagonals</code>   | optional list of sub-/super- diagonals; if missing, the result will be a pattern matrix, i.e., inheriting from class <code>nMatrix</code> .<br>diagonals can also be $n' \times d$ matrix, where $d < \text{length}(k)$ and $n' \geq \min(n, m)$ . In that case, the sub-/super- diagonals are taken from the columns of diagonals, where only the first several rows will be used (typically) for off-diagonals. |
| <code>symmetric</code>   | logical; if true the result will be symmetric (inheriting from class <code>symmetricMatrix</code> ) and only the upper or lower triangle must be specified (via <code>k</code> and <code>diagonals</code> ).                                                                                                                                                                                                      |
| <code>repr</code>        | character string, one of "C", "T", or "R", specifying the sparse representation to be used for the result, i.e., one from the super classes <code>CsparseMatrix</code> , <code>TsparseMatrix</code> , or <code>RsparseMatrix</code> .                                                                                                                                                                             |
| <code>giveCsparse</code> | <b>(deprecated, replaced with repr)</b> : logical indicating if the result should be a <code>CsparseMatrix</code> or a <code>TsparseMatrix</code> , where the default was TRUE, and now is determined from <code>repr</code> ; very often Csparse matrices are more efficient subsequently, but not always.                                                                                                       |

**Value**

a sparse matrix (of class `CsparseMatrix`) of dimension  $n \times m$  with diagonal “bands” as specified.

**See Also**

`band`, for extraction of matrix bands; `bdiag`, `diag`, `sparseMatrix`, `Matrix`.

**Examples**

```
diags <- list(1:30, 10*(1:20), 100*(1:20))
s1 <- bandSparse(13, k = -c(0:2, 6), diag = c(diags, diags[2]), symm=TRUE)
s1
s2 <- bandSparse(13, k = c(0:2, 6), diag = c(diags, diags[2]), symm=TRUE)
stopifnot(identical(s1, t(s2)), is(s1, "dsCMatrix"))

## a pattern Matrix of *full* (sub-)diagonals:
bk <- c(0:4, 7, 9)
(s3 <- bandSparse(30, k = bk, symm = TRUE))

## If you want a pattern matrix, but with "sparse"-diagonals,
## you currently need to go via logical sparse:
lLis <- lapply(list(rpois(20, 2), rpois(20, 1), rpois(20, 3))[c(1:3, 2:3, 3:2)],
              as.logical)
(s4 <- bandSparse(20, k = bk, symm = TRUE, diag = lLis))
(s4. <- as(drop0(s4), "nsparsMatrix"))

n <- 1e4
bk <- c(0:5, 7, 11)
bMat <- matrix(1:8, n, 8, byrow=TRUE)
bLis <- as.data.frame(bMat)
```

```

B <- bandSparse(n, k = bk, diag = bLis)
Bs <- bandSparse(n, k = bk, diag = bLis, symmetric=TRUE)
B [1:15, 1:30]
Bs[1:15, 1:30]
## can use a list *or* a matrix for specifying the diagonals:
stopifnot(identical(B, bandSparse(n, k = bk, diag = bMat)),
  identical(Bs, bandSparse(n, k = bk, diag = bMat, symmetric=TRUE))
    , inherits(B, "dtCMatrix") # triangular!
)

```

bdiag

*Construct a Block Diagonal Matrix***Description**

Build a block diagonal matrix given several building block matrices.

**Usage**

```

bdiag(...)
.bdiag(lst)

```

**Arguments**

... individual matrices or a [list](#) of matrices.  
 lst non-empty [list](#) of matrices.

**Details**

For non-trivial argument list, `bdiag()` calls `.bdiag()`. The latter maybe useful to programmers.

**Value**

A *sparse* matrix obtained by combining the arguments into a block diagonal matrix.

The value of `bdiag()` inheris from class [CsparseMatrix](#), whereas `.bdiag()` returns a [TsparseMatrix](#).

**Note**

This function has been written and is efficient for the case of relatively few block matrices which are typically sparse themselves.

It is currently *inefficient* for the case of many small dense block matrices. For the case of *many* dense  $k \times k$  matrices, the `bdiag_m()` function in the ‘Examples’ is an order of magnitude faster.

**Author(s)**

Martin Maechler, built on a version posted by Berton Gunter to R-help; earlier versions have been posted by other authors, notably Scott Chasalow to S-news. Doug Bates’s faster implementation builds on [TsparseMatrix](#) objects.

## See Also

[Diagonal](#) for constructing matrices of class [diagonalMatrix](#), or [kronecker](#) which also works for "Matrix" inheriting matrices.

[bandSparse](#) constructs a *banded* sparse matrix from its non-zero sub-/super - diagonals.

Note that other CRAN R packages have own versions of `bdiag()` which return traditional matrices.

## Examples

```
bdiag(matrix(1:4, 2), diag(3))
## combine "Matrix" class and traditional matrices:
bdiag(Diagonal(2), matrix(1:3, 3,4), diag(3:2))

mlist <- list(1, 2:3, diag(x=5:3), 27, cbind(1,3:6), 100:101)
bdiag(mlist)
stopifnot(identical(bdiag(mlist),
                      bdiag(lapply(mlist, as.matrix))))

ml <- c(as(matrix((1:24)%% 11 == 0, 6,4),"nMatrix"),
        rep(list(Diagonal(2, x=TRUE)), 3))
mln <- c(ml, Diagonal(x = 1:3))
stopifnot(is(bdiag(ml), "lsparseMatrix"),
          is(bdiag(mln), "dsparseMatrix") )

## random (diagonal-)block-triangular matrices:
rblockTri <- function(nb, max.ni, lambda = 3) {
  .bdiag(replicate(nb, {
    n <- sample.int(max.ni, 1)
    tril(Matrix(rpois(n*n, lambda=lambda), n,n)) }))
}

(T4 <- rblockTri(4, 10, lambda = 1))
image(T1 <- rblockTri(12, 20))

##' Fast version of Matrix :: .bdiag() -- for the case of *many* (k x k) matrices:
##' @param lmat list(<mat1>, <mat2>, ....., <mat_N>) where each mat_j is a k x k 'matrix'
##' @return a sparse (N*k x N*k) matrix of class \code{"\linkS4class{dgCMatrix}"}.
bdiag_m <- function(lmat) {
  ## Copyright (C) 2016 Martin Maechler, ETH Zurich
  if(!length(lmat)) return(new("dgCMatrix"))
  stopifnot(is.list(lmat), is.matrix(lmat[[1]]),
            (k <- (d <- dim(lmat[[1]]))[1]) == d[2], # k x k
            all(vapply(lmat, dim, integer(2)) == k)) # all of them
  N <- length(lmat)
  if(N * k > .Machine$integer.max)
    stop("resulting matrix too large; would be M x M, with M=", N*k)
  M <- as.integer(N * k)
  ## result: an M x M matrix
  new("dgCMatrix", Dim = c(M,M),
      ## 'i :' maybe there's a faster way (w/o matrix indexing), but elegant?
      i = as.vector(matrix(0L:(M-1L), nrow=k)[, rep(seq_len(N), each=k)]),
      p = k * 0L:M,
      x = as.double(unlist(lmat, recursive=FALSE, use.names=FALSE)))
}
```

```
l12 <- replicate(12, matrix(rpois(16, lambda = 6.4), 4,4), simplify=FALSE)
dim(T12 <- bdiag_m(l12))# 48 x 48
T12[1:20, 1:20]
```

---

BunchKaufman-methods

### *Bunch-Kaufman Decomposition Methods*

---

## Description

The Bunch-Kaufman Decomposition of a square symmetric matrix  $A$  is  $A = PLDL'P'$  where  $P$  is a permutation matrix,  $L$  is *unit*-lower triangular and  $D$  is *block*-diagonal with blocks of dimension  $1 \times 1$  or  $2 \times 2$ .

This is generalization of a pivoting  $LDL'$  Cholesky decomposition.

## Usage

```
## S4 method for signature 'dsyMatrix'
BunchKaufman(x, ...)
## S4 method for signature 'dspMatrix'
BunchKaufman(x, ...)
## S4 method for signature 'matrix'
BunchKaufman(x, uplo = NULL, ...)
```

## Arguments

|                   |                                                                                                                                                                                                                                                                                                            |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>    | a symmetric square matrix.                                                                                                                                                                                                                                                                                 |
| <code>uplo</code> | optional string, "U" or "L" indicating which "triangle" half of <code>x</code> should determine the result. The default is "U" unless <code>x</code> has a <code>uplo</code> slot which is the case for those inheriting from class <code>symmetricMatrix</code> , where <code>x@uplo</code> will be used. |
| <code>...</code>  | potentially further arguments passed to methods.                                                                                                                                                                                                                                                           |

## Details

FIXME: We really need an `expand()` method in order to *work* with the result!

## Value

an object of class `BunchKaufman`, which can also be used as a (triangular) matrix directly. Somewhat amazingly, it inherits its `uplo` slot from `x`.

## Methods

Currently, only methods for **dense** numeric symmetric matrices are implemented. To compute the Bunch-Kaufman decomposition, the methods use either one of two Lapack routines:

```
x = "dspMatrix" routine dsptrf(); whereas
x = "dsyMatrix" , and
x = "matrix" use dsytrf().
```

## References

The original LAPACK source code, including documentation; <https://www.netlib.org/lapack/double/dsytrf.f> and <https://www.netlib.org/lapack/double/dsptrf.f>

## See Also

The resulting class, [BunchKaufman](#). Related decompositions are the LU, [lu](#), and the Cholesky, [chol](#) (and for *sparse* matrices, [Cholesky](#)).

## Examples

```
data(CAex)
dim(CAex)
isSymmetric(CAex) # TRUE
CAs <- as(CAex, "symmetricMatrix")
if(FALSE) # no method defined yet for *sparse* :
  bk. <- BunchKaufman(CAs)
## does apply to *dense* symmetric matrices:
bkCA <- BunchKaufman(as(CAs, "denseMatrix"))
bkCA

image(bkCA) # shows how sparse it is, too
str(R.CA <- as(bkCA, "sparseMatrix"))
## an upper triangular 72x72 matrix with only 144 non-zero entries
```

---

CAex

*Albers' example Matrix with "Difficult" Eigen Factorization*

---

## Description

An example of a sparse matrix for which [eigen\(\)](#) seemed to be difficult, an unscaled version of this has been posted to the web, accompanying an E-mail to R-help (<https://stat.ethz.ch/mailman/listinfo/r-help>), by Casper J Albers, Open University, UK.

## Usage

```
data(CAex)
```

## Format

This is a  $72 \times 72$  symmetric matrix with 216 non-zero entries in five bands, stored as sparse matrix of class [dgCMatrix](#).

## Details

Historical note (2006-03-30): In earlier versions of R, [eigen](#)(CAex) fell into an infinite loop whereas [eigen](#)(CAex, EISPACK=TRUE) had been okay.

## Examples

```
data(CAex)
str(CAex) # of class "dgCMatrix"

image(CAex) # -> it's a simple band matrix with 5 bands
## and the eigen values are basically 1 (42 times) and 0 (30 x):
zapsmall(ev <- eigen(CAex, only.values=TRUE)$values)
## i.e., the matrix is symmetric, hence
sCA <- as(CAex, "symmetricMatrix")
## and
stopifnot(class(sCA) == "dsCMatrix",
           as(sCA, "matrix") == as(CAex, "matrix"))
```

---

cBind

---

*Versions of 'cbind' and 'rbind' recursively built on cbind2/rbind2*

---

## Description

The base functions `cbind` and `rbind` are defined for an arbitrary number of arguments and hence have the first formal argument `...`. For that reason, in the past S4 methods could easily be defined for binding together matrices inheriting from `Matrix`.

For that reason, `cbind2` and `rbind2` have been provided for binding together *two* matrices, and we have defined methods for these and the `'Matrix'`-matrices.

Before R version 3.2.0 (April 2015), we have needed a substitute for *S4-enabled* versions of `cbind` and `rbind`, and provided `cBind` and `rBind` with identical syntax and semantic in order to bind together multiple matrices (`"matrix"` or `"Matrix"` and vectors. With R version 3.2.0 and newer, `cBind` and `rBind` are *deprecated* and produce a deprecation warning (via `.Deprecated`), and your code should start using `cbind()` and `rbind()` instead.

## Usage

```
cBind(..., deparse.level = 1)
rBind(..., deparse.level = 1)
```

## Arguments

`...` matrix-like R objects to be bound together, see `cbind` and `rbind`.  
`deparse.level` integer determining under which circumstances column and row names are built from the actual arguments' 'expression', see `cbind`.

## Details

The implementation of these is *recursive*, calling `cbind2` or `rbind2` respectively, where these have methods defined and so should dispatch appropriately.

## Value

typically a 'matrix-like' object of a similar `class` as the first argument in `...`

Note that sometimes by default, the result is a `sparseMatrix` if one of the arguments is (even in the case where this is not efficient). In other cases, the result is chosen to be sparse when there are more zero entries than non-zero ones (as the default `sparse` in `Matrix()`).

**Author(s)**

Martin Maechler

**See Also**[cbind2](#), [cbind](#), Documentation in base R's **methods** package .**Examples**

```
(a <- matrix(c(2:1,1:2), 2,2))
D <- Diagonal(2)
if(getRversion() < "3.2.0") {
  M1 <- cbind(0, rBind(a, 7))
  print(M1) # remains traditional matrix

  M2 <- cBind(4, a, D, -1, D, 0) # a sparse Matrix
  print(M2)

} else { ## newer versions of R do not need cBind / rBind:

  M1 <- cbind(0, suppressWarnings(rBind(a, 7)))
  print(M1) # remains traditional matrix

  M2 <- suppressWarnings(cBind(4, a, D, -1, D, 0)) # a sparse Matrix
  print(M2)

  stopifnot(identical(M1, cbind(0, rbind(a, 7))),
             identical(M2, cbind(4, a, D, -1, D, 0)))
}# R >= 3.2.0
```

CHMfactor-class

*CHOLMOD-based Cholesky Factorizations***Description**

The virtual class "CHMfactor" is a class of CHOLMOD-based Cholesky factorizations of symmetric, sparse, compressed, column-oriented matrices. Such a factorization is simplicial (virtual class "CHMsimpl") or supernodal (virtual class "CHMsuper"). Objects that inherit from these classes are either numeric factorizations (classes "dCHMsimpl" and "dCHMsuper") or symbolic factorizations (classes "nCHMsimpl" and "nCHMsuper").

**Usage**

```
isLDL(x)

## S4 method for signature 'CHMfactor'
update(object, parent, mult = 0, ...)
.updateCHMfactor(object, parent, mult)

## and many more methods, notably,
##   solve(a, b, system = c("A", "LDLt", "LD", "DLt", "L", "Lt", "D", "P", "Pt"), ...)
##   ----- see below
```

## Arguments

|                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|---------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x, object, a</code> | a "CHMfactor" object (almost always the result of <code>Cholesky()</code> ).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>parent</code>       | a "dsCMatrix" or "dgCMatrix" matrix object with the same nonzero pattern as the matrix that generated object. If <code>parent</code> is symmetric, of class "dsCMatrix", then object should be a decomposition of a matrix with the same nonzero pattern as <code>parent</code> . If <code>parent</code> is not symmetric then object should be the decomposition of a matrix with the same nonzero pattern as <code>tcrossprod(parent)</code> .<br>Since Matrix version 1.0-8, other "sparseMatrix" matrices are coerced to <code>dsparseMatrix</code> and <code>CsparseMatrix</code> if needed. |
| <code>mult</code>         | a numeric scalar (default 0). <code>mult</code> times the identity matrix is (implicitly) added to <code>parent</code> or <code>tcrossprod(parent)</code> before updating the decomposition object.                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>...</code>          | potentially further arguments to the methods.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

## Objects from the Class

Objects can be created by calls of the form `new("dCHMsuper", ...)` but are more commonly created via `Cholesky()`, applied to `dsCMatrix` or `lsCMatrix` objects.

For an introduction, it may be helpful to look at the `expand()` method and examples below.

## Slots

of "CHMfactor" and all classes inheriting from it:

**perm:** An integer vector giving the 0-based permutation of the rows and columns chosen to reduce fill-in and for post-ordering.

**colcount:** Object of class "integer" ....

**type:** Object of class "integer" ....

Slots of the non virtual classes "[dl]CHM(superlsimpl)":

**p:** Object of class "integer" of pointers, one for each column, to the initial (zero-based) index of elements in the column. Only present in classes that contain "CHMsimpl".

**i:** Object of class "integer" of length `nnzero` (number of non-zero elements). These are the row numbers for each non-zero element in the matrix. Only present in classes that contain "CHMsimpl".

**x:** For the "d\*" classes: "numeric" - the non-zero elements of the matrix.

## Methods

**isLDL** (`x`) returns a **logical** indicating if `x` is an  $LDL'$  decomposition or (when `FALSE`) an  $LL'$  one.

**coerce** signature(`from` = "CHMfactor", `to` = "sparseMatrix") (or equivalently, `to` = "Matrix" or `to` = "triangularMatrix")

`as(*, "sparseMatrix")` returns the lower triangular factor  $L$  from the  $LL'$  form of the Cholesky factorization. Note that (currently) the factor from the  $LL'$  form is always returned, even if the "CHMfactor" object represents an  $LDL'$  decomposition. Furthermore, this is the factor after any fill-reducing permutation has been applied. See the `expand` method for obtaining both the permutation matrix,  $P$ , and the lower Cholesky factor,  $L$ .

**coerce** signature (from = "CHMfactor", to = "pMatrix") returns the permutation matrix  $P$ , representing the fill-reducing permutation used in the decomposition.

**expand** signature (x = "CHMfactor") returns a list with components  $P$ , the matrix representing the fill-reducing permutation, and  $L$ , the lower triangular Cholesky factor. The original positive-definite matrix  $A$  corresponds to the product  $A = P'LL'P$ . Because of fill-in during the decomposition the product may apparently have more non-zeros than the original matrix, even after applying `drop0` to it. However, the extra "non-zeros" should be very small in magnitude.

**image** signature (x = "CHMfactor") : Plot the image of the lower triangular factor,  $L$ , from the decomposition. This method is equivalent to `image(as(x, "sparseMatrix"))` so the comments in the above description of the `coerce` method apply here too.

**solve** signature (a = "CHMfactor", b = "ddenseMatrix"), system = \*:

The `solve` methods for a "CHMfactor" object take an optional third argument `system` whose value can be one of the character strings "A", "LDLt", "LD", "DLt", "L", "Lt", "D", "P" or "Pt". This argument describes the system to be solved. The default, "A", is to solve  $Ax = b$  for  $x$  where  $A$  is the sparse, positive-definite matrix that was factored to produce  $a$ . Analogously, `system = "L"` returns the solution  $x$ , of  $Lx = b$ . Similarly, for all system codes but "P" and "Pt" where, e.g., `x <- solve(a, b, system = "P")` is equivalent to `x <- P %*% b`.

See also [solve-methods](#).

**determinant** signature (x = "CHMfactor", logarithm = "logical") returns the determinant (or the logarithm of the determinant, if `logarithm = TRUE`, the default) of the factor  $L$  from the  $LL'$  decomposition (even if the decomposition represented by  $x$  is of the  $LDL'$  form (!)). This is the square root of the determinant (half the logarithm of the determinant when `logarithm = TRUE`) of the positive-definite matrix that was decomposed.

**update** signature (object = "CHMfactor"), parent. The `update` method requires an additional argument `parent`, which is either a "dsCMatrix" object, say  $A$ , (with the same structure of nonzeros as the matrix that was decomposed to produce `object`) or a general "dgCMatrix", say  $M$ , where  $A := MM'$  ( $= \text{tcrossprod}(\text{parent})$ ) is used for  $A$ . Further it provides an optional argument `mult`, a numeric scalar. This method updates the numeric values in `object` to the decomposition of  $A + mI$  where  $A$  is the matrix above (either the `parent` or  $MM'$ ) and  $m$  is the scalar `mult`. Because only the numeric values are updated this method should be faster than creating and decomposing  $A + mI$ . It is not uncommon to want, say, the determinant of  $A + mI$  for many different values of  $m$ . This method would be the preferred approach in such cases.

## Examples

```
## An example for the expand() method
n <- 1000; m <- 200; nnz <- 2000
set.seed(1)
M1 <- spMatrix(n, m,
               i = sample(n, nnz, replace = TRUE),
               j = sample(m, nnz, replace = TRUE),
               x = round(rnorm(nnz), 1))
XX <- crossprod(M1) ## = M1'M1 = M M' where M <- t(M1)
CX <- Cholesky(XX)
isLDL(CX)
```

```

str(CX) ## a "dCHMsimpl" object
r <- expand(CX)
L.P <- with(r, crossprod(L,P)) ## == L'P
PLLP <- crossprod(L.P)          ## == (L'P)' L'P == P'LL'P = XX = M M'
b <- sample(m)
stopifnot(all.equal(PLLP, XX),
           all(as.vector(solve(CX, b, system="P" )) == r$P %**% b),
           all(as.vector(solve(CX, b, system="Pt")) == t(r$P) %**% b) )

u1 <- update(CX, XX, mult=pi)
u2 <- update(CX, t(M1), mult=pi) # with the original M, where XX = M M'
stopifnot(all.equal(u1,u2, tol=1e-14))

chol

*Choleski Decomposition - 'Matrix' S4 Generic and Methods*

## Description

Compute the Choleski factorization of a real symmetric positive-definite square matrix.

## Usage

```

chol(x, ...)
## S4 method for signature 'dsCMatrix'
chol(x, pivot = FALSE, ...)
## S4 method for signature 'dsparsedMatrix'
chol(x, pivot = FALSE, cache = TRUE, ...)

```

## Arguments

|                    |                                                                                                                                                                    |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>     | a (sparse or dense) square matrix, here inheriting from class <code>Matrix</code> ; if <code>x</code> is not positive definite, an error is signalled.             |
| <code>pivot</code> | logical indicating if pivoting is to be used. Currently, this is <i>not</i> made use of for dense matrices.                                                        |
| <code>cache</code> | logical indicating if the result should be cached in <code>x@factors</code> ; note that this argument is experimental and only available for some sparse matrices. |
| <code>...</code>   | potentially further arguments passed to methods.                                                                                                                   |

## Details

Note that these Cholesky factorizations are typically *cached* with `x` currently, and these caches are available in `x@factors`, which may be useful for the sparse case when `pivot = TRUE`, where the permutation can be retrieved; see also the examples.

However, this should not be considered part of the API and made use of. Rather consider `Cholesky()` in such situations, since `chol(x, pivot=TRUE)` uses the same algorithm (but not the same return value!) as `Cholesky(x, LDL=FALSE)` and `chol(x)` corresponds to `Cholesky(x, perm=FALSE, LDL=FALSE)`.

**Value**

a matrix of class `Cholesky`, i.e., upper triangular:  $R$  such that  $R'R = x$  (if `pivot=FALSE`) or  $P'R'RP = x$  (if `pivot=TRUE` and  $P$  is the corresponding permutation matrix).

**Methods**

Use `showMethods(chol)` to see all; some are worth mentioning here:

**chol** signature (`x = "dgeMatrix"`): works via `"dpoMatrix"`, see class `dpoMatrix`.

**chol** signature (`x = "dpoMatrix"`): Returns (and stores) the Cholesky decomposition of `x`, via LAPACK routines `dlacpy` and `dpotrf`.

**chol** signature (`x = "dppMatrix"`): Returns (and stores) the Cholesky decomposition via LAPACK routine `dpptf`.

**chol** signature (`x = "dsCMatrix", pivot = "logical"`): Returns (and stores) the Cholesky decomposition of `x`. If `pivot` is true, the Approximate Minimal Degree (AMD) algorithm is used to create a reordering of the rows and columns of `x` so as to reduce fill-in.

**See Also**

The default from `base`, `chol`; for more flexibility (but not returning a matrix!) `Cholesky`.

**Examples**

```
showMethods(chol, inherited = FALSE) # show different methods

sy2 <- new("dsyMatrix", Dim = as.integer(c(2,2)), x = c(14, NA, 32, 77))
(c2 <- chol(sy2))#-> "Cholesky" matrix
stopifnot(all.equal(c2, chol(as(sy2, "dpoMatrix")), tolerance= 1e-13))
str(c2)

## An example where chol() can't work
(sy3 <- new("dsyMatrix", Dim = as.integer(c(2,2)), x = c(14, -1, 2, -7)))
try(chol(sy3)) # error, since it is not positive definite

## A sparse example --- exemplifying 'pivot'
(mm <- toeplitz(as(c(10, 0, 1, 0, 3), "sparseVector")))) # 5 x 5
(R <- chol(mm)) ## default: pivot = FALSE
R2 <- chol(mm, pivot=FALSE)
stopifnot( identical(R, R2), all.equal(crossprod(R), mm) )
(R. <- chol(mm, pivot=TRUE))# nice band structure,
## but of course crossprod(R.) is *NOT* equal to mm
## --> see Cholesky() and its examples, for the pivot structure & factorization
stopifnot(all.equal(sqrt(det(mm)), det(R)),
          all.equal(prod(diag(R)), det(R)),
          all.equal(prod(diag(R.)), det(R)))

## a second, even sparser example:
```

```

(M2 <- toeplitz(as(c(1,.5, rep(0,12), -.1), "sparseVector")))
c2 <- chol(M2)
C2 <- chol(M2, pivot=TRUE)
## For the experts, check the caching of the factorizations:
ff <- M2@factors[["spdCholesky"]]
FF <- M2@factors[["sPdCholesky"]]
L1 <- as(ff, "Matrix") # pivot=FALSE: no perm.
L2 <- as(FF, "Matrix"); P2 <- as(FF, "pMatrix")
stopifnot(identical(t(L1), c2),
           all.equal(t(L2), C2, tolerance=0), #-- why not identical()?
           all.equal(M2, tcrossprod(L1)),      # M = LL'
           all.equal(M2, crossprod(crossprod(L2, P2))) # M = P'L L'P
           )

```

---

chol2inv-methods      *Inverse from Choleski or QR Decomposition – Matrix Methods*

---

## Description

Invert a symmetric, positive definite square matrix from its Choleski decomposition. Equivalently, compute  $(X'X)^{-1}$  from the ( $R$  part) of the QR decomposition of  $X$ .  
 Even more generally, given an upper triangular matrix  $R$ , compute  $(R'R)^{-1}$ .

## Methods

- x = "ANY"** the default method from **base**, see `chol2inv`, for traditional matrices.
- x = "dtrMatrix"** method for the numeric triangular matrices, built on the same LAPACK DPOTRI function as the base method.
- x = "denseMatrix"** if  $x$  is coercable to a `triangularMatrix`, call the "dtrMatrix" method above.
- x = "sparseMatrix"** if  $x$  is coercable to a `triangularMatrix`, use `solve()` currently.

## See Also

`chol` (for `Matrix` objects); further, `chol2inv` (from the **base** package), `solve`.

## Examples

```

(M <- Matrix(cbind(1, 1:3, c(1,3,7))))
(cM <- chol(M)) # a "Cholesky" object, inheriting from "dtrMatrix"
chol2inv(cM) %**% M # the identity
stopifnot(all(chol2inv(cM) %**% M - Diagonal(nrow(M))) < 1e-10)

```

## Description

Computes the Cholesky (aka “Choleski”) decomposition of a sparse, symmetric, positive-definite matrix. However, typically `chol()` should rather be used unless you are interested in the different kinds of sparse Cholesky decompositions.

## Usage

```
Cholesky(A, perm = TRUE, LDL = !super, super = FALSE, Imult = 0, ...)
```

## Arguments

|                    |                                                                                                                                                                                                                                                                                                                                                                               |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>A</code>     | sparse symmetric matrix. No missing values or IEEE special values are allowed.                                                                                                                                                                                                                                                                                                |
| <code>perm</code>  | logical scalar indicating if a fill-reducing permutation should be computed and applied to the rows and columns of <code>A</code> . Default is <code>TRUE</code> .                                                                                                                                                                                                            |
| <code>LDL</code>   | logical scalar indicating if the decomposition should be computed as <code>LDL'</code> where <code>L</code> is a unit lower triangular matrix. The alternative is <code>LL'</code> where <code>L</code> is lower triangular with arbitrary diagonal elements. Default is <code>TRUE</code> . Setting it to <code>NA</code> leaves the choice to a CHOLMOD-internal heuristic. |
| <code>super</code> | logical scalar indicating if a supernodal decomposition should be created. The alternative is a simplicial decomposition. Default is <code>FALSE</code> . Setting it to <code>NA</code> leaves the choice to a CHOLMOD-internal heuristic.                                                                                                                                    |
| <code>Imult</code> | numeric scalar which defaults to zero. The matrix that is decomposed is $A + m \cdot I$ where $m$ is the value of <code>Imult</code> and <code>I</code> is the identity matrix of order <code>ncol(A)</code> .                                                                                                                                                                |
| <code>...</code>   | further arguments passed to or from other methods.                                                                                                                                                                                                                                                                                                                            |

## Details

This is a generic function with special methods for different types of matrices. Use `showMethods("Cholesky")` to list all the methods for the `Cholesky` generic.

The method for class `dsCMatrix` of sparse matrices — the only one available currently — is based on functions from the CHOLMOD library.

Again: If you just want the Cholesky decomposition of a matrix in a straightforward way, you should probably rather use `chol()`.

Note that if `perm=TRUE` (default), the decomposition is

$$A = P' \tilde{L} D \tilde{L}' P = P' L L' P,$$

where  $L$  can be extracted by `as(*, "Matrix")`,  $P$  by `as(*, "pMatrix")` and both by `expand(*)`, see the class `CHMfactor` documentation.

Note that consequently, you cannot easily get the “traditional” cholesky factor  $R$ , from this decomposition, as

$$R' R = A = P' L L' P = P' \tilde{R} \tilde{R} P = (\tilde{R} P)' (\tilde{R} P),$$

but  $\tilde{R} P$  is *not* triangular even though  $\tilde{R}$  is.

## Value

an object inheriting from either `"CHMsuper"`, or `"CHMsimpl"`, depending on the `super` argument; both classes extend `"CHMfactor"` which extends `"MatrixFactorization"`.

In other words, the result of `Cholesky()` is *not* a matrix, and if you want one, you should probably rather use `chol()`, see Details.

## See Also

Class definitions `CHMfactor` and `dsCMatrix` and function `expand`. Note the extra `solve(*, system = .)` options in `CHMfactor`.

Note that `chol()` returns matrices (inheriting from `"Matrix"`) whereas `Cholesky()` returns a `"CHMfactor"` object, and hence a typical user will rather use `chol(A)`.

## Examples

```
data(KNex)
mtm <- with(KNex, crossprod(mm))
str(mtm@factors) # empty list()
(C1 <- Cholesky(mtm)) # uses show(<MatrixFactorization>)
str(mtm@factors) # 'SPDCholesky' (simpl)
(Cm <- Cholesky(mtm, super = TRUE))
c(C1 = isLDL(C1), Cm = isLDL(Cm))
str(mtm@factors) # 'SPDCholesky' *and* 'SPdCholesky'
str(cml <- as(C1, "sparseMatrix"))
str(cmat <- as(Cm, "sparseMatrix")) # hmm: super is *less* sparse here
cml[1:20, 1:20]

b <- matrix(c(rep(0, 711), 1), nc = 1)
## solve(Cm, b) by default solves Ax = b, where A = Cm'Cm (= mtm)!
## hence, the identical() check *should* work, but fails on some GOTObas:
x <- solve(Cm, b)
stopifnot(identical(x, solve(Cm, b, system = "A")),
           all.equal(x, solve(mtm, b)))

Cn <- Cholesky(mtm, perm = FALSE) # no permutation -- much worse:
sizes <- c(simple = object.size(C1),
           super = object.size(Cm),
           noPerm = object.size(Cn))
## simple is 100, super= 137, noPerm= 812 :
noquote(cbind(format(100 * sizes / sizes[1], digits=4)))

## Visualize the sparseness:
dq <- function(ch) paste('"' , ch, '"' , sep="") ## dQuote(<UTF-8>) gives bad plots
image(mtm, main=paste("crossprod(mm) : Sparse", dq(class(mtm))))
image(cml, main= paste("as(Cholesky(crossprod(mm)), \"sparseMatrix\") : ",
```

```

dq(class(cm1)))

## Smaller example, with same matrix as in help(chol) :
(mm <- Matrix(toeplitz(c(10, 0, 1, 0, 3)), sparse = TRUE)) # 5 x 5
(opts <- expand.grid(perm = c(TRUE,FALSE), LDL = c(TRUE,FALSE), super = c(FALSE,TRUE)))
rr <- lapply(seq_len(nrow(opts)), function(i)
  do.call(Cholesky, c(list(A = mm), opts[i,])))
nn <- do.call(expand.grid, c(attr(opts, "out.attr")$dimnames,
  stringsAsFactors=FALSE,KEEP.OUT.ATTRS=FALSE))
names(rr) <- apply(nn, 1, function(r)
  paste(sub("(=.) .*", "\\1", r), collapse=","))
str(rr, max=1)

str(re <- lapply(rr, expand), max=2) ## each has a 'P' and a 'L' matrix

R0 <- chol(mm, pivot=FALSE)
R1 <- chol(mm, pivot=TRUE )
stopifnot(all.equal(t(R1), re[[1]]$L),
  all.equal(t(R0), re[[2]]$L),
  identical(as(1:5, "pMatrix"), re[[2]]$P), # no pivoting
TRUE)

# Version of the underlying SuiteSparse library by Tim Davis :
.SuiteSparse_version()

```

Cholesky-class

*Cholesky and Bunch-Kaufman Decompositions*

## Description

The "Cholesky" class is the class of Cholesky decompositions of positive-semidefinite, real dense matrices. The "BunchKaufman" class is the class of Bunch-Kaufman decompositions of symmetric, real matrices. The "pCholesky" and "pBunchKaufman" classes are their *packed* storage versions.

## Objects from the Class

Objects can be created by calls of the form `new("Cholesky",...)` or `new("BunchKaufman",...)`, etc, or rather by calls of the form `chol(pm)` or `BunchKaufman(pm)` where `pm` inherits from the "`dpoMatrix`" or "`dsyMatrix`" class or as a side-effect of other functions applied to "`dpoMatrix`" objects (see `dpoMatrix`).

## Slots

A Cholesky decomposition extends class `MatrixFactorization` but is basically a triangular matrix extending the "`dtrMatrix`" class.

**uplo:** inherited from the "`dtrMatrix`" class.

**diag:** inherited from the "`dtrMatrix`" class.

**x:** inherited from the "`dtrMatrix`" class.

**Description**

Form row and column sums and means for objects, for `sparseMatrix` the result may optionally be sparse (`sparseVector`), too. Row or column names are kept respectively as for **base** matrices and `colSums` methods, when the result is `numeric` vector.

**Usage**

```
colSums(x, na.rm = FALSE, dims = 1, ...)
rowSums(x, na.rm = FALSE, dims = 1, ...)
colMeans(x, na.rm = FALSE, dims = 1, ...)
rowMeans(x, na.rm = FALSE, dims = 1, ...)

## S4 method for signature 'CsparseMatrix'
colSums(x, na.rm = FALSE,
        dims = 1, sparseResult = FALSE)
## S4 method for signature 'CsparseMatrix'
rowSums(x, na.rm = FALSE,
        dims = 1, sparseResult = FALSE)
## S4 method for signature 'CsparseMatrix'
colMeans(x, na.rm = FALSE,
         dims = 1, sparseResult = FALSE)
## S4 method for signature 'CsparseMatrix'
rowMeans(x, na.rm = FALSE,
         dims = 1, sparseResult = FALSE)
```

**Arguments**

|                           |                                                                                                                                                                                                      |
|---------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>            | a Matrix, i.e., inheriting from <code>Matrix</code> .                                                                                                                                                |
| <code>na.rm</code>        | logical. Should missing values (including NaN) be omitted from the calculations?                                                                                                                     |
| <code>dims</code>         | completely ignored by the <code>Matrix</code> methods.                                                                                                                                               |
| <code>...</code>          | potentially further arguments, for method <-> generic compatibility.                                                                                                                                 |
| <code>sparseResult</code> | logical indicating if the result should be sparse, i.e., inheriting from class <code>sparseVector</code> . Only applicable when <code>x</code> is inheriting from a <code>sparseMatrix</code> class. |

**Value**

returns a numeric vector if `sparseResult` is `FALSE` as per default. Otherwise, returns a `sparseVector`.

`dimnames(x)` are only kept (as `names(v)`) when the resulting `v` is `numeric`, since `sparseVectors` do not have names.

**See Also**

`colSums` and the `sparseVector` classes.

## Examples

```
(M <- bdiag(Diagonal(2), matrix(1:3, 3,4), diag(3:2))) # 7 x 8
colSums(M)
d <- Diagonal(10, c(0,0,10,0,2,rep(0,5)))
MM <- kronecker(d, M)
dim(MM) # 70 80
length(MM@x) # 160, but many are '0' ; drop those:
MM <- drop0(MM)
length(MM@x) # 32
cm <- colSums(MM)
(scm <- colSums(MM, sparseResult = TRUE))
stopifnot(is(scm, "sparseVector"),
           identical(cm, as.numeric(scm)))
rowSums(MM, sparseResult = TRUE) # 14 of 70 are not zero
colMeans(MM, sparseResult = TRUE) # 16 of 80 are not zero
## Since we have no 'NA's, these two are equivalent :
stopifnot(identical(rowMeans(MM, sparseResult = TRUE),
                    rowMeans(MM, sparseResult = TRUE, na.rm = TRUE)),
           rowMeans(Diagonal(16)) == 1/16,
           colSums(Diagonal(7)) == 1)

## dimnames(x) --> names( <value> ) :
dimnames(M) <- list(paste0("r", 1:7), paste0("V",1:8))
M
colSums(M)
rowMeans(M)
## Assertions :
stopifnot(all.equal(colSums(M),
                    setNames(c(1,1,6,6,6,6,3,2), colnames(M))),
          all.equal(rowMeans(M), structure(c(1,1,4,8,12,3,2) / 8,
                                           .Names = paste0("r", 1:7))))
```

---

compMatrix-class      *Class "compMatrix" of Composite (Factorizable) Matrices*

---

## Description

Virtual class of *composite* matrices; i.e., matrices that can be *factorized*, typically as a product of simpler matrices.

## Objects from the Class

A virtual Class: No objects may be created from it.

## Slots

**factors:** Object of class "list" - a list of factorizations of the matrix. Note that this is typically empty, i.e., `list()`, initially and is *updated **automagically*** whenever a matrix factorization is computed.

**Dim, Dimnames:** inherited from the [Matrix](#) class, see there.

## Extends

Class "Matrix", directly.

## Methods

**dimnames<-** signature(x = "compMatrix", value = "list"): set the dimnames to a [list](#) of length 2, see [dimnames<-](#). The factors slot is currently reset to empty, as the factorization dimnames would have to be adapted, too.

## See Also

The matrix factorization classes "[MatrixFactorization](#)" and their generators, [lu\(\)](#), [qr\(\)](#), [chol\(\)](#) and [Cholesky\(\)](#), [BunchKaufman\(\)](#), [Schur\(\)](#).

---

|         |                                                                            |
|---------|----------------------------------------------------------------------------|
| condest | <i>Compute Approximate CONDition number and 1-Norm of (Large) Matrices</i> |
|---------|----------------------------------------------------------------------------|

---

## Description

“Estimate”, i.e. compute approximately the CONDition number of a (potentially large, often sparse) matrix A. It works by apply a fast *randomized* approximation of the 1-norm, `norm(A, "1")`, through `onenormest()`.

## Usage

```
condest(A, t = min(n, 5), normA = norm(A, "1"),
        silent = FALSE, quiet = TRUE)

onenormest(A, t = min(n, 5), A.x, At.x, n,
           silent = FALSE, quiet = silent,
           iter.max = 10, eps = 4 * .Machine$double.eps)
```

## Arguments

|           |                                                                                                                                       |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------|
| A         | a square matrix, optional for <code>onenormest()</code> , where instead of A, A.x and At.x can be specified, see there.               |
| t         | number of columns to use in the iterations.                                                                                           |
| normA     | number; (an estimate of) the 1-norm of A, by default <code>norm(A, "1")</code> ; may be replaced by an estimate.                      |
| silent    | logical indicating if warning and (by default) convergence messages should be displayed.                                              |
| quiet     | logical indicating if convergence messages should be displayed.                                                                       |
| A.x, At.x | when A is missing, these two must be given as functions which compute <code>A %% x</code> , or <code>t(A) %% x</code> , respectively. |
| n         | <code>== nrow(A)</code> , only needed when A is not specified.                                                                        |
| iter.max  | maximal number of iterations for the 1-norm estimator.                                                                                |
| eps       | the relative change that is deemed irrelevant.                                                                                        |

## Details

`condest()` calls `lu(A)`, and subsequently `onenormest(A.x = , At.x =)` to compute an approximate norm of the *inverse* of  $A$ ,  $A^{-1}$ , in a way which keeps using sparse matrices efficiently when  $A$  is sparse.

Note that `onenormest()` uses random vectors and hence *both* functions' results are random, i.e., depend on the random seed, see, e.g., `set.seed()`.

## Value

Both functions return a `list`; `condest()` with components,

|                  |                                                                                                                                                                                                       |
|------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>est</code> | a number $> 0$ , the estimated (1-norm) condition number $\hat{\kappa}$ ; when $r := \text{rcond}(A)$ , $1/\hat{\kappa} \approx r$ .                                                                  |
| <code>v</code>   | the maximal $Ax$ column, scaled to $\text{norm}(v) = 1$ . Consequently, $\text{norm}(Av) = \text{norm}(A)/\text{est}$ ; when <code>est</code> is large, <code>v</code> is an approximate null vector. |

The function `onenormest()` returns a list with components,

|                   |                                                                                                                                              |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------|
| <code>est</code>  | a number $> 0$ , the estimated <code>norm(A, "1")</code> .                                                                                   |
| <code>v</code>    | 0-1 integer vector length <code>n</code> , with an 1 at the index <code>j</code> with maximal column <code>A[, j]</code> in <code>A</code> . |
| <code>w</code>    | numeric vector, the largest $Ax$ found.                                                                                                      |
| <code>iter</code> | the number of iterations used.                                                                                                               |

## Author(s)

This is based on octave's `condest()` and `onenormest()` implementations with original author Jason Riedy, U Berkeley; translation to R and adaption by Martin Maechler.

```

---

CsparseMatrix-class

*Class "CsparseMatrix" of Sparse Matrices in Column-compressed Form*

---

## Description

The "CsparseMatrix" class is the virtual class of all sparse matrices coded in sorted compressed column-oriented form. Since it is a virtual class, no objects may be created from it. See `showClass("CsparseMatrix")` for its subclasses.

## Slots

**i:** Object of class "integer" of length `nnzero` (number of non-zero elements). These are the *0-based* row numbers for each non-zero element in the matrix, i.e., `i` must be in `0:(nrow(.)-1)`.

**p:** integer vector for providing pointers, one for each column, to the initial (zero-based) index of elements in the column. `.@p` is of length `ncol(.) + 1`, with `p[1] == 0` and `p[length(p)] == nnzero`, such that in fact, `diff(.@p)` are the number of non-zero elements for each column.

In other words, `m@p[1:ncol(m)]` contains the indices of those elements in `m@x` that are the first elements in the respective column of `m`.

**Dim, Dimnames:** inherited from the superclass, see the `sparseMatrix` class.

## Extends

Class "sparseMatrix", directly. Class "Matrix", by class "sparseMatrix".

## Methods

matrix products `%*%`, `crossprod()` and `tcrossprod()`, several `solve` methods, and other matrix methods available:

`signature(e1 = "CsparseMatrix", e2 = "numeric"): ...`

**Aritht** `signature(e1 = "numeric", e2 = "CsparseMatrix"): ...`

**Math** `signature(x = "CsparseMatrix"): ...`

**band** `signature(x = "CsparseMatrix"): ...`

- `signature(e1 = "CsparseMatrix", e2 = "numeric"): ...`

- `signature(e1 = "numeric", e2 = "CsparseMatrix"): ...`

+ `signature(e1 = "CsparseMatrix", e2 = "numeric"): ...`

+ `signature(e1 = "numeric", e2 = "CsparseMatrix"): ...`

**coerce** `signature(from = "CsparseMatrix", to = "TsparseMatrix"): ...`

```

coerce signature(from = "CsparseMatrix",to = "denseMatrix"): ...
coerce signature(from = "CsparseMatrix",to = "matrix"): ...
coerce signature(from = "CsparseMatrix",to = "lsparseMatrix"): ...
coerce signature(from = "CsparseMatrix",to = "nsparseMatrix"): ...
coerce signature(from = "TsparseMatrix",to = "CsparseMatrix"): ...
coerce signature(from = "denseMatrix",to = "CsparseMatrix"): ...
diag signature(x = "CsparseMatrix"): ...
gamma signature(x = "CsparseMatrix"): ...
lgamma signature(x = "CsparseMatrix"): ...
log signature(x = "CsparseMatrix"): ...
t signature(x = "CsparseMatrix"): ...
tril signature(x = "CsparseMatrix"): ...
triu signature(x = "CsparseMatrix"): ...

```

### Note

All classes extending `CsparseMatrix` have a common validity (see `validObject`) check function. That function additionally checks the `i` slot for each column to contain increasing row numbers.

In earlier versions of **Matrix** ( $\leq 0.999375-16$ ), `validObject` automatically re-sorted the entries when necessary, and hence `new()` calls with somewhat permuted `i` and `x` slots worked, as `new(...)` (with slot arguments) automatically checks the validity.

Now, you have to use `sparseMatrix` to achieve the same functionality or know how to use `.validateCsparse()` to do so.

### See Also

`colSums`, `kronecker`, and other such methods with own help pages.

Further, the super class of `CsparseMatrix`, `sparseMatrix`, and, e.g., class `dgCMatrix` for the links to other classes.

### Examples

```

getClass("CsparseMatrix")

## The common validity check function (based on C code):
getValidity(getClass("CsparseMatrix"))

```

---

ddenseMatrix-class *Virtual Class "ddenseMatrix" of Numeric Dense Matrices*

---

### Description

This is the virtual class of all dense numeric (i.e., **double**, hence “*ddense*”) S4 matrices.

Its most important subclass is the `dgeMatrix` class.

**Extends**

Class "dMatrix" directly; class "Matrix", by the above.

**Slots**

the same slots at its subclass [dgeMatrix](#), see there.

**Methods**

Most methods are implemented via `as(*, "dgeMatrix")` and are mainly used as “fallbacks” when the subclass doesn’t need its own specialized method.

Use `showMethods(class = "ddenseMatrix", where = "package:Matrix")` for an overview.

**See Also**

The virtual classes [Matrix](#), [dMatrix](#), and [dsparseMatrix](#).

**Examples**

```
showClass("ddenseMatrix")

showMethods(class = "ddenseMatrix", where = "package:Matrix")
```

---

|                 |                                                       |
|-----------------|-------------------------------------------------------|
| ddiMatrix-class | <i>Class "ddiMatrix" of Diagonal Numeric Matrices</i> |
|-----------------|-------------------------------------------------------|

---

**Description**

The class "ddiMatrix" of numerical diagonal matrices.

Note that diagonal matrices now extend `sparseMatrix`, whereas they did extend dense matrices earlier.

**Objects from the Class**

Objects can be created by calls of the form `new("ddiMatrix", ...)` but typically rather via [Diagonal](#).

**Slots**

**x:** numeric vector. For an  $n \times n$  matrix, the x slot is of length  $n$  or 0, depending on the diag slot:  
**diag:** "character" string, either "U" or "N" where "U" denotes unit-diagonal, i.e., identity matrices.

**Dim,Dimnames:** matrix dimension and `dimnames`, see the [Matrix](#) class description.

**Extends**

Class "[diagonalMatrix](#)", directly. Class "[dMatrix](#)", directly. Class "[sparseMatrix](#)", indirectly, see `showClass("ddiMatrix")`.

**Methods**

```
%*% signature(x = "ddiMatrix", y = "ddiMatrix"): ...
```

**See Also**

Class [diagonalMatrix](#) and function [Diagonal](#).

**Examples**

```
(d2 <- Diagonal(x = c(10,1)))
str(d2)
## slightly larger in internal size:
str(as(d2, "sparseMatrix"))

M <- Matrix(cbind(1,2:4))
M %*% d2 #> `fast' multiplication

chol(d2) # trivial
stopifnot(is(cd2 <- chol(d2), "ddiMatrix"),
  all.equal(cd2@x, c(sqrt(10),1)))
```

---

denseMatrix-class    *Virtual Class "denseMatrix" of All Dense Matrices*

---

**Description**

This is the virtual class of all dense (S4) matrices. It is the direct superclass of [ddenseMatrix](#), [ldenseMatrix](#)

**Extends**

class "Matrix" directly.

**Slots**

exactly those of its superclass "[Matrix](#)".

**Methods**

Use [showMethods](#)(class = "denseMatrix", where = "package:Matrix") for an overview of methods.

Extraction ("[" ) methods, see [\[-methods](#).

**See Also**

[colSums](#), [kronecker](#), and other such methods with own help pages.

Its superclass [Matrix](#), and main subclasses, [ddenseMatrix](#) and [sparseMatrix](#).

**Examples**

```
showClass("denseMatrix")
```

---

dgCMatrix-class      *Compressed, sparse, column-oriented numeric matrices*

---

## Description

The `dgCMatrix` class is a class of sparse numeric matrices in the compressed, sparse, column-oriented format. In this implementation the non-zero elements in the columns are sorted into increasing row order. `dgCMatrix` is the “*standard*” class for sparse numeric matrices in the **Matrix** package.

## Objects from the Class

Objects can be created by calls of the form `new("dgCMatrix", ...)`, more typically via `as(*, "CsparseMatrix")` or similar. Often however, more easily via `Matrix(*, sparse = TRUE)`, or most efficiently via `sparseMatrix()`.

## Slots

`x`: Object of class "numeric" - the non-zero elements of the matrix.

... all other slots are inherited from the superclass "`CsparseMatrix`".

## Methods

Matrix products (e.g., [crossprod-methods](#)), and (among other)

**coerce** signature(`from` = "matrix", `to` = "dgCMatrix")

**coerce** signature(`from` = "dgCMatrix", `to` = "matrix")

**coerce** signature(`from` = "dgCMatrix", `to` = "dgTMatrix")

**diag** signature(`x` = "dgCMatrix"): returns the diagonal of `x`

**dim** signature(`x` = "dgCMatrix"): returns the dimensions of `x`

**image** signature(`x` = "dgCMatrix"): plots an image of `x` using the [levelplot](#) function

**solve** signature(`a` = "dgCMatrix", `b` = "..."): see [solve-methods](#), notably the extra argument `sparse`.

**lu** signature(`x` = "dgCMatrix"): computes the LU decomposition of a square `dgCMatrix` object

## See Also

Classes [dsCMatrix](#), [dtCMatrix](#), [lu](#)

## Examples

```
(m <- Matrix(c(0,0,2:0), 3,5))
str(m)
m[,1]
```

---

dgeMatrix-class      *Class "dgeMatrix" of Dense Numeric (S4 Class) Matrices*

---

## Description

A general numeric dense matrix in the S4 Matrix representation. `dgeMatrix` is the “standard” class for dense numeric matrices in the **Matrix** package.

## Objects from the Class

Objects can be created by calls of the form `new("dgeMatrix", ...)` or, more commonly, by coercion from the `Matrix` class (see [Matrix](#)) or by `Matrix(...)`.

## Slots

**x:** Object of class "numeric" - the numeric values contained in the matrix, in column-major order.

**Dim:** Object of class "integer" - the dimensions of the matrix - must be an integer vector with exactly two non-negative values.

**Dimnames:** a list of length two - inherited from class [Matrix](#).

**factors:** Object of class "list" - a list of factorizations of the matrix.

## Methods

There are group methods (see, e.g., [Arith](#))

**Arith** signature(e1 = "dgeMatrix", e2 = "dgeMatrix"): ...

**Arith** signature(e1 = "dgeMatrix", e2 = "numeric"): ...

**Arith** signature(e1 = "numeric", e2 = "dgeMatrix"): ...

**Math** signature(x = "dgeMatrix"): ...

**Math2** signature(x = "dgeMatrix", digits = "numeric"): ...

matrix products `%*%`, `crossprod()` and `tcrossprod()`, several [solve](#) methods, and other matrix methods available:

**Schur** signature(x = "dgeMatrix", vectors = "logical"): ...

**Schur** signature(x = "dgeMatrix", vectors = "missing"): ...

**chol** signature(x = "dgeMatrix"): see [chol](#).

**coerce** signature(from = "dgeMatrix", to = "lgeMatrix"): ...

**coerce** signature(from = "dgeMatrix", to = "matrix"): ...

**coerce** signature(from = "matrix", to = "dgeMatrix"): ...

**colMeans** signature(x = "dgeMatrix"): columnwise means (averages)

**colSums** signature(x = "dgeMatrix"): columnwise sums

**diag** signature(x = "dgeMatrix"): ...

**dim** signature(x = "dgeMatrix"): ...

**dimnames** signature(x = "dgeMatrix"): ...

**eigen** signature(x = "dgeMatrix", only.values = "logical"): ...

**eigen** signature(x = "dgeMatrix", only.values = "missing"): ...  
**norm** signature(x = "dgeMatrix", type = "character"): ...  
**norm** signature(x = "dgeMatrix", type = "missing"): ...  
**rcond** signature(x = "dgeMatrix", norm = "character") or norm = "missing":  
the reciprocal condition number, [rcond\(\)](#).  
**rowMeans** signature(x = "dgeMatrix"): rowwise means (averages)  
**rowSums** signature(x = "dgeMatrix"): rowwise sums  
**t** signature(x = "dgeMatrix"): matrix transpose

---

|                 |                                                         |
|-----------------|---------------------------------------------------------|
| dgRMatrix-class | <i>Sparse Compressed, Row-oriented Numeric Matrices</i> |
|-----------------|---------------------------------------------------------|

---

### Description

The `dgRMatrix` class is a class of sparse numeric matrices in the compressed, sparse, row-oriented format. In this implementation the non-zero elements in the rows are sorted into increasing column order.

**Note:** The column-oriented sparse classes, e.g., [dgCMatrix](#), are preferred and better supported in the **Matrix** package.

### Objects from the Class

Objects can be created by calls of the form `new("dgRMatrix", ...)`.

### Slots

**j**: Object of class "integer" of length `nnzero` (number of non-zero elements). These are the column numbers for each non-zero element in the matrix.  
**p**: Object of class "integer" of pointers, one for each row, to the initial (zero-based) index of elements in the row.  
**x**: Object of class "numeric" - the non-zero elements of the matrix.  
**Dim**: Object of class "integer" - the dimensions of the matrix.

### Methods

**coerce** signature(from = "matrix", to = "dgRMatrix")  
**coerce** signature(from = "dgRMatrix", to = "matrix")  
**coerce** signature(from = "dgRMatrix", to = "dgTMatrix")  
**diag** signature(x = "dgRMatrix"): returns the diagonal of x  
**dim** signature(x = "dgRMatrix"): returns the dimensions of x  
**image** signature(x = "dgRMatrix"): plots an image of x using the [levelplot](#) function

### See Also

the [RsparseMatrix](#) class, the virtual class of all sparse compressed row-oriented matrices, with its methods. The [dgCMatrix](#) class (column compressed sparse) is really preferred.

---

 dgTMatrix-class      *Sparse matrices in triplet form*

---

## Description

The "dgTMatrix" class is the class of sparse matrices stored as (possibly redundant) triplets. The internal representation is not at all unique, contrary to the one for class [dgCMatrix](#).

## Objects from the Class

Objects can be created by calls of the form `new("dgTMatrix", ...)`, but more typically via `as(*, "dgTMatrix")`, `spMatrix()`, or `sparseMatrix(*, repr = "T")`.

## Slots

- i:** [integer](#) row indices of non-zero entries *in 0-base*, i.e., must be in `0:(nrow(.)-1)`.
- j:** [integer](#) column indices of non-zero entries. Must be the same length as slot **i** and *0-based* as well, i.e., in `0:(ncol(.)-1)`.
- x:** [numeric](#) vector - the (non-zero) entry at position `(i, j)`. Must be the same length as slot **i**. If an index pair occurs more than once, the corresponding values of slot **x** are added to form the element of the matrix.
- Dim:** Object of class "integer" of length 2 - the dimensions of the matrix.

## Methods

- +** `signature(e1 = "dgTMatrix", e2 = "dgTMatrix")`
- coerce** `signature(from = "dgTMatrix", to = "dgCMatrix")`
- coerce** `signature(from = "dgTMatrix", to = "dgeMatrix")`
- coerce** `signature(from = "dgTMatrix", to = "matrix")`, and typically coercion methods for more specific signatures, we are not mentioning here.  
Note that these are not guaranteed to continue to exist, but rather you should use calls like `as(x, "CsparseMatrix")`, `as(x, "generalMatrix")`, `as(x, "dMatrix")`, i.e. coercion to higher level virtual classes.
- coerce** `signature(from = "matrix", to = "dgTMatrix")`, (direct coercion from tradition matrix).
- image** `signature(x = "dgTMatrix")`: plots an image of **x** using the [levelplot](#) function
- t** `signature(x = "dgTMatrix")`: returns the transpose of **x**

## Note

Triplet matrices are a convenient form in which to construct sparse matrices after which they can be coerced to [dgCMatrix](#) objects.

Note that both `new(.)` and [spMatrix](#) constructors for "dgTMatrix" (and other "[TsparseMatrix](#)" classes) implicitly add  $x_k$ 's that belong to identical  $(i_k, j_k)$  pairs.

However this means that a matrix typically can be stored in more than one possible "[TsparseMatrix](#)" representations. Use [uniqTsparse\(\)](#) in order to ensure uniqueness of the internal representation of such a matrix.

**See Also**

Class `dgCMatrix` or the superclasses `dsparseMatrix` and `TsparseMatrix`; `uniqTsparse`.

**Examples**

```
m <- Matrix(0+1:28, nrow = 4)
m[-3,c(2,4:5,7)] <- m[ 3, 1:4] <- m[1:3, 6] <- 0
(mT <- as(m, "dgTMatrix"))
str(mT)
mT[1,]
mT[4, drop = FALSE]
stopifnot(identical(mT[lower.tri(mT)],
                    m [lower.tri(m) ]))
mT[lower.tri(mT,diag=TRUE)] <- 0
mT

## Triplet representation with repeated (i,j) entries
## *adds* the corresponding x's:
T2 <- new("dgTMatrix",
          i = as.integer(c(1,1,0,3,3)),
          j = as.integer(c(2,2,4,0,0)), x=10*1:5, Dim=4:5)
str(T2) # contains (i,j,x) slots exactly as above, but
T2 ## has only three non-zero entries, as for repeated (i,j)'s,
    ## the corresponding x's are "implicitly" added
stopifnot(nnzero(T2) == 3)
```

---

Diagonal

---

*Create Diagonal Matrix Object*

---

**Description**

Create a diagonal matrix object, i.e., an object inheriting from `diagonalMatrix` (or a “standard” `CsparseMatrix` diagonal matrix in cases that is preferred).

**Usage**

```
Diagonal(n, x = NULL)

.symDiagonal(n, x = rep.int(1,n), uplo = "U", kind)
.trDiagonal(n, x = 1, uplo = "U", unitri=TRUE, kind)
.sparseDiagonal(n, x = 1, uplo = "U",
                 shape = if(missing(cols)) "t" else "g",
                 unitri, kind, cols = if(n) 0:(n - 1L) else integer(0))
```

**Arguments**

**n** integer specifying the dimension of the (square) matrix. If missing, `length(x)` is used.

**x** numeric or logical; if missing, a *unit* diagonal  $n \times n$  matrix is created.

|        |                                                                                                                                                                                                                                                                                               |
|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| uplo   | for <code>.symDiagonal</code> ( <code>.trDiagonal</code> ), the resulting sparse <code>symmetricMatrix</code> (or <code>triangularMatrix</code> ) will have slot <code>uplo</code> set from this argument, either "U" or "L". Only rarely will it make sense to change this from the default. |
| shape  | string of 1 character, one of <code>c("t", "s", "g")</code> , to choose a triangular, symmetric or general result matrix.                                                                                                                                                                     |
| unitri | optional logical indicating if a triangular result should be “unit-triangular”, i.e., with <code>diag = "U"</code> slot, if possible. The default, <code>missing</code> , is the same as <code>TRUE</code> .                                                                                  |
| kind   | string of 1 character, one of <code>c("d", "l", "n")</code> , to choose the storage mode of the result, from classes <code>dsparseMatrix</code> , <code>lsparseMatrix</code> , or <code>nsparseMatrix</code> , respectively.                                                                  |
| cols   | integer vector with values from <code>0:(n-1)</code> , denoting the <i>columns</i> to subselect conceptually, i.e., get the equivalent of <code>Diagonal(n, *)[, cols + 1]</code> .                                                                                                           |

### Value

`Diagonal()` returns an object of class `ddiMatrix` or `ldiMatrix` (with “superclass” `diagonalMatrix`).

`.symDiagonal()` returns an object of class `dsCMatrix` or `lsCMatrix`, i.e., a *sparse symmetric* matrix. Analogously, `.triDiagonal` gives a sparse `triangularMatrix`. This can be more efficient than `Diagonal(n)` when the result is combined with further symmetric (sparse) matrices, e.g., in `kronecker`, however *not* for matrix multiplications where `Diagonal()` is clearly preferred.

`.sparseDiagonal()`, the workhorse of `.symDiagonal` and `.trDiagonal` returns a `CsparseMatrix` (the resulting class depending on `shape` and `kind`) representation of `Diagonal(n)`, or, when `cols` are specified, of `Diagonal(n)[, cols+1]`.

### Author(s)

Martin Maechler

### See Also

the generic function `diag` for *extraction* of the diagonal from a matrix works for all “Matrices”.

`bandSparse` constructs a *banded* sparse matrix from its non-zero sub-/super - diagonals. `band(A)` returns a band matrix containing some sub-/super - diagonals of `A`.

`Matrix` for general matrix construction; further, class `diagonalMatrix`.

### Examples

```
Diagonal(3)
Diagonal(x = 10^(3:1))
Diagonal(x = (1:4) >= 2) #-> "ldiMatrix"

## Use Diagonal() + kronecker() for "repeated-block" matrices:
M1 <- Matrix(0+0:5, 2, 3)
(M <- kronecker(Diagonal(3), M1))

(S <- crossprod(Matrix(rbinom(60, size=1, prob=0.1), 10, 6)))
(SI <- S + 10*.symDiagonal(6)) # sparse symmetric still
stopifnot(is(SI, "dsCMatrix"))
(I4 <- .sparseDiagonal(4, shape="t")) # now (2012-10) unittriangular
```

```
stopifnot(I4@diag == "U", all(I4 == diag(4)))
```

---

diagonalMatrix-class

*Class "diagonalMatrix" of Diagonal Matrices*

---

## Description

Class "diagonalMatrix" is the virtual class of all diagonal matrices.

## Objects from the Class

A virtual Class: No objects may be created from it.

## Slots

**diag:** code"character" string, either "U" or "N", where "U" means ‘unit-diagonal’.

**Dim:** matrix dimension, and

**Dimnames:** the [dimnames](#), a [list](#), see the [Matrix](#) class description. Typically [list](#)(NULL, NULL) for diagonal matrices.

## Extends

Class "[sparseMatrix](#)", directly.

## Methods

These are just a subset of the signature for which defined methods. Currently, there are (too) many explicit methods defined in order to ensure efficient methods for diagonal matrices.

**coerce** signature(from = "matrix", to = "diagonalMatrix"): ...

**coerce** signature(from = "Matrix", to = "diagonalMatrix"): ...

**coerce** signature(from = "diagonalMatrix", to = "generalMatrix"): ...

**coerce** signature(from = "diagonalMatrix", to = "triangularMatrix"): ...

**coerce** signature(from = "diagonalMatrix", to = "nMatrix"): ...

**coerce** signature(from = "diagonalMatrix", to = "matrix"): ...

**coerce** signature(from = "diagonalMatrix", to = "sparseVector"): ...

**t** signature(x = "diagonalMatrix"): ...

and many more methods

**solve** signature(a = "diagonalMatrix", b, ...): is trivially implemented, of course; see also [solve-methods](#).

**which** signature(x = "nMatrix"), semantically equivalent to **base** function [which](#)(x, arr.ind).

**"Math"** signature(x = "diagonalMatrix"): all these group methods return a "diagonalMatrix", apart from [cumsum](#)() etc which return a *vector* also for **base** [matrix](#).

\* signature(e1 = "ddiMatrix", e2 = "denseMatrix"): arithmetic and other operators from the `Ops` group have a few dozen explicit method definitions, in order to keep the results *diagonal* in many cases, including the following:

/ signature(e1 = "ddiMatrix", e2 = "denseMatrix"): the result is from class `ddiMatrix` which is typically very desirable. Note that when e2 contains off-diagonal zeros or `NA`s, we implicitly use  $0/x = 0$ , hence differing from traditional R arithmetic (where  $0/0 \mapsto \text{NaN}$ ), in order to preserve sparsity.

**summary** (object = "diagonalMatrix"): Returns an object of S3 class "diagSummary" which is the summary of the vector `object@x` plus a simple heading, and an appropriate `print` method.

### See Also

`Diagonal()` as constructor of these matrices, and `isDiagonal`. `ddiMatrix` and `ldiMatrix` are “actual” classes extending "diagonalMatrix".

### Examples

```
I5 <- Diagonal(5)
D5 <- Diagonal(x = 10*(1:5))
## trivial (but explicitly defined) methods:
stopifnot(identical(crossprod(I5), I5),
           identical(tcrossprod(I5), I5),
           identical(crossprod(I5, D5), D5),
           identical(tcrossprod(D5, I5), D5),
           identical(solve(D5), solve(D5, I5)),
           all.equal(D5, solve(solve(D5)), tolerance = 1e-12)
)
solve(D5) # efficient as is diagonal

# an unusual way to construct a band matrix:
rbind2(cbind2(I5, D5),
       cbind2(D5, I5))
```

---

diagU2N

*Transform Triangular Matrices from Unit Triangular to General Triangular and Back*

---

### Description

Transform a triangular matrix `x`, i.e., of class "`triangularMatrix`", from (internally!) unit triangular (“unitriangular”) to “general” triangular (`diagU2N(x)`) or back (`diagN2U(x)`). Note that the latter, `diagN2U(x)`, also sets the diagonal to one in cases where `diag(x)` was not all one.

`.diagU2N(x)` assumes but does *not* check that `x` is a `triangularMatrix` with `diag` slot "`U`", and should hence be used with care.

### Usage

```
diagN2U(x, cl = getClassDef(class(x)), checkDense = FALSE)

diagU2N(x, cl = getClassDef(class(x)), checkDense = FALSE)
.diagU2N(x, cl, checkDense = FALSE)
```

**Arguments**

|                         |                                                                                                                                                                                                  |
|-------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>          | a <code>triangularMatrix</code> , often sparse.                                                                                                                                                  |
| <code>cl</code>         | (optional, for speedup only:) class (definition) of <code>x</code> .                                                                                                                             |
| <code>checkDense</code> | logical indicating if dense (see <code>denseMatrix</code> ) matrices should be considered at all; i.e., when false, as per default, the result will be sparse even when <code>x</code> is dense. |

**Details**

The concept of unit triangular matrices with a `diag` slot of "U" stems from LAPACK.

**Value**

a triangular matrix of the same `class` but with a different `diag` slot. For `diagU2N` (semantically) with identical entries as `x`, whereas in `diagN2U(x)`, the off-diagonal entries are unchanged and the diagonal is set to all 1 even if it was not previously.

**Note**

Such internal storage details should rarely be of relevance to the user. Hence, these functions really are rather *internal* utilities.

**See Also**

"`triangularMatrix`", "`dtCMatrix`".

**Examples**

```
(T <- Diagonal(7) + triu(Matrix(rpois(49, 1/4), 7,7), k = 1))
(uT <- diagN2U(T)) # "unittriangular"
(t.u <- diagN2U(10*T)) # changes the diagonal!
stopifnot(all(T == uT), diag(t.u) == 1,
           identical(T, diagU2N(uT)))
T[upper.tri(T)] <- 5
T <- diagN2U(as(T, "triangularMatrix"))
stopifnot(T@diag == "U")
dT <- as(T, "denseMatrix")
dt. <- diagN2U(dT)
dtU <- diagN2U(dT, checkDense=TRUE)
stopifnot(is(dtU, "denseMatrix"), is(dt., "sparseMatrix"),
           all(dT == dt.), all(dT == dtU),
           dt.@diag == "U", dtU@diag == "U")
```

---

dMatrix-class

(Virtual) Class "dMatrix" of "double" Matrices

---

**Description**

The `dMatrix` class is a virtual class contained by all actual classes of numeric matrices in the **Matrix** package. Similarly, all the actual classes of logical matrices inherit from the `lMatrix` class.

## Slots

Common to *all* matrix object in the package:

**Dim:** Object of class "integer" - the dimensions of the matrix - must be an integer vector with exactly two non-negative values.

**Dimnames:** list of length two; each component containing NULL or a [character](#) vector length equal the corresponding Dim element.

## Methods

There are (relatively simple) group methods (see, e.g., [Arith](#))

**Arith** signature(e1 = "dMatrix", e2 = "dMatrix"): ...

**Arith** signature(e1 = "dMatrix", e2 = "numeric"): ...

**Arith** signature(e1 = "numeric", e2 = "dMatrix"): ...

**Math** signature(x = "dMatrix"): ...

**Math2** signature(x = "dMatrix", digits = "numeric"): this group contains [round\(\)](#) and [signif\(\)](#).

**Compare** signature(e1 = "numeric", e2 = "dMatrix"): ...

**Compare** signature(e1 = "dMatrix", e2 = "numeric"): ...

**Compare** signature(e1 = "dMatrix", e2 = "dMatrix"): ...

**Summary** signature(x = "dMatrix"): The "Summary" group contains the seven functions [max\(\)](#), [min\(\)](#), [range\(\)](#), [prod\(\)](#), [sum\(\)](#), [any\(\)](#), and [all\(\)](#).

The following methods are also defined for all double matrices:

**coerce** signature(from = "dMatrix", to = "matrix"): ...

**expm** signature(x = "dMatrix"): computes the "*Matrix Exponential*", see [expm](#).

**zapsmall** signature(x = "dMatrix"): ...

The following methods are defined for all logical matrices:

**which** signature(x = "lsparseMatrix") and many other subclasses of "lMatrix": as the **base** function [which](#)(x, arr.ind) returns the indices of the [TRUE](#) entries in x; if arr.ind is true, as a 2-column matrix of row and column indices. Since **Matrix** version 1.2-9, if useNames is true, as by default, with [dimnames](#), the same as `base::which`.

## See Also

The nonzero-pattern matrix class [nMatrix](#), which can be used to store non-NA [logical](#) matrices even more compactly.

The numeric matrix classes [dgeMatrix](#), [dgCMatrix](#), and [Matrix](#).

[drop0](#)(x, tol=1e-10) is sometimes preferable to (and more efficient than) [zapsmall](#)(x, digits=10).

## Examples

```
showClass("dMatrix")

set.seed(101)
round(Matrix(rnorm(28), 4, 7), 2)
M <- Matrix(rlnorm(56, sd=10), 4, 14)
(M. <- zapsmall(M))
table(as.logical(M. == 0))
```

---

|                 |                                                                            |
|-----------------|----------------------------------------------------------------------------|
| dpoMatrix-class | <i>Positive Semi-definite Dense (Packed   Non-packed) Numeric Matrices</i> |
|-----------------|----------------------------------------------------------------------------|

---

## Description

- The "dpoMatrix" class is the class of positive-semidefinite symmetric matrices in non-packed storage.
- The "dppMatrix" class is the same except in packed storage. Only the upper triangle or the lower triangle is required to be available.
- The "corMatrix" class of correlation matrices extends "dpoMatrix" with a slot `sd`, which allows to restore the original covariance matrix.

## Objects from the Class

Objects can be created by calls of the form `new("dpoMatrix", ...)` or from `crossprod` applied to an "dgeMatrix" object.

## Slots

**uplo:** Object of class "character". Must be either "U", for upper triangular, and "L", for lower triangular.

**x:** Object of class "numeric". The numeric values that constitute the matrix, stored in column-major order.

**Dim:** Object of class "integer". The dimensions of the matrix which must be a two-element vector of non-negative integers.

**Dimnames:** inherited from class "Matrix"

**factors:** Object of class "list". A named list of factorizations that have been computed for the matrix.

**sd:** (for "corMatrix") a [numeric](#) vector of length `n` containing the (original)  $\sqrt{\text{var}(\cdot)}$  entries which allow reconstruction of a covariance matrix from the correlation matrix.

## Extends

Class "dsyMatrix", directly.  
 Classes "dgeMatrix", "symmetricMatrix", and many more by class "dsyMatrix".

## Methods

**chol** signature (x = "dpoMatrix"): Returns (and stores) the Cholesky decomposition of x, see [chol](#).

**determinant** signature (x = "dpoMatrix"): Returns the [determinant](#) of x, via `chol(x)`, see above.

**rcond** signature (x = "dpoMatrix", norm = "character"): Returns (and stores) the reciprocal of the condition number of x. The norm can be "O" for the one-norm (the default) or "I" for the infinity-norm. For symmetric matrices the result does not depend on the norm.

**solve** signature (a = "dpoMatrix", b = "..."), and

**solve** signature (a = "dppMatrix", b = "...") work via the Cholesky composition, see also the Matrix [solve-methods](#).

**Arith** signature (e1 = "dpoMatrix", e2 = "numeric") (and quite a few other signatures): The result of ("elementwise" defined) arithmetic operations is typically *not* positive-definite anymore. The only exceptions, currently, are multiplications, divisions or additions with *positive* `length(.) == 1` numbers (or [logicals](#)).

## See Also

Classes [dsyMatrix](#) and [dgeMatrix](#); further, [Matrix](#), [rcond](#), [chol](#), [solve](#), [crossprod](#).

## Examples

```
h6 <- Hilbert(6)
rcond(h6)
str(h6)
h6 * 27720 # is ``integer``
solve(h6)
str(hp6 <- as(h6, "dppMatrix"))

### Note that as(*, "corMatrix") *scales* the matrix
(ch6 <- as(h6, "corMatrix"))
stopifnot(all.equal(h6 * 27720, round(27720 * h6), tolerance = 1e-14),
          all.equal(ch6@sd^(-2), 2*(1:6)-1, tolerance= 1e-12))
chch <- chol(ch6)
stopifnot(identical(chch, ch6@factors$Cholesky),
          all(abs(crossprod(chch) - ch6) < 1e-10))
```

---

drop0

*Drop "Explicit Zeroes" from a Sparse Matrix*

---

## Description

Returns a sparse matrix with no "explicit zeroes", i.e., all zero or FALSE entries are dropped from the explicitly indexed matrix entries.

## Usage

```
drop0(x, tol = 0, is.Csparse = NA)
```

**Arguments**

|                         |                                                                                                                              |
|-------------------------|------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>          | a Matrix, typically sparse, i.e., inheriting from <code>sparseMatrix</code> .                                                |
| <code>tol</code>        | non-negative number to be used as tolerance for checking if an entry $x_{i,j}$ should be considered to be zero.              |
| <code>is.Csparse</code> | logical indicating prior knowledge about the “Cspareness” of <code>x</code> . This exists for possible speedup reasons only. |

**Value**

a Matrix like `x` but with no explicit zeros, i.e., `!any(x@x == 0)`, always inheriting from `CsparseMatrix`.

**Note**

When a sparse matrix is the result of matrix multiplications, you may want to consider combining `drop0()` with `zapsmall()`, see the example.

**See Also**

`spMatrix`, class `sparseMatrix`; `nnzero`

**Examples**

```
m <- spMatrix(10,20, i= 1:8, j=2:9, x = c(0:2,3:-1))
m
drop0(m)

## A larger example:
t5 <- new("dtCMatrix", Dim = c(5L, 5L), uplo = "L",
        x = c(10, 1, 3, 10, 1, 10, 1, 10, 10),
        i = c(0L,2L,4L, 1L, 3L,2L,4L, 3L, 4L),
        p = c(0L, 3L, 5L, 7:9))
TT <- kronecker(t5, kronecker(kronecker(t5,t5), t5))
IT <- solve(TT)
I. <- TT %*% IT ; nnzero(I.) # 697 ( = 625 + 72 )
I.0 <- drop0(zapsmall(I.))
## which actually can be more efficiently achieved by
I.. <- drop0(I., tol = 1e-15)
stopifnot(all(I.0 == Diagonal(625)),
          nnzero(I..) == 625)
```

---

dsCMatrix-class

*Numeric Symmetric Sparse (column compressed) Matrices*

---

**Description**

The `dsCMatrix` class is a class of symmetric, sparse numeric matrices in the compressed, column-oriented format. In this implementation the non-zero elements in the columns are sorted into increasing row order.

The `dsTMatrix` class is the class of symmetric, sparse numeric matrices in triplet format.

## Objects from the Class

Objects can be created by calls of the form `new("dsCMatrix",...)` or `new("dsTMatrix",...)`, or automatically via e.g., `as(*,"symmetricMatrix")`, or (for `dsCMatrix`) also from `Matrix(.)`.

Creation “from scratch” most efficiently happens via `sparseMatrix(*, symmetric=TRUE)`.

## Slots

**uplo:** A character object indicating if the upper triangle ("U") or the lower triangle ("L") is stored.

**i:** Object of class "integer" of length `nnZ` (*half* number of non-zero elements). These are the row numbers for each non-zero element in the lower triangle of the matrix.

**p:** (only in class "dsCMatrix":) an `integer` vector for providing pointers, one for each column, see the detailed description in `CsparseMatrix`.

**j:** (only in class "dsTMatrix":) Object of class "integer" of length `nnZ` (as `i`). These are the column numbers for each non-zero element in the lower triangle of the matrix.

**x:** Object of class "numeric" of length `nnZ` – the non-zero elements of the matrix (to be duplicated for full matrix).

**factors:** Object of class "list" - a list of factorizations of the matrix.

**Dim:** Object of class "integer" - the dimensions of the matrix - must be an integer vector with exactly two non-negative values.

## Extends

Both classes extend classes `symmetricMatrix` `dsparseMatrix` directly; `dsCMatrix` further directly extends `CsparseMatrix`, where `dsTMatrix` does `TsparseMatrix`.

## Methods

**solve** signature(`a` = "dsCMatrix", `b` = "..."): `x <- solve(a,b)` solves  $Ax = b$  for `x`; see `solve-methods`.

**chol** signature(`x` = "dsCMatrix", `pivot` = "logical"): Returns (and stores) the Cholesky decomposition of `x`, see `chol`.

**Cholesky** signature(`A` = "dsCMatrix", ...): Computes more flexibly Cholesky decompositions, see `Cholesky`.

**determinant** signature(`x` = "dsCMatrix", `logarithm` = "missing"): Evaluate the determinant of `x` on the logarithm scale. This creates and stores the Cholesky factorization.

**determinant** signature(`x` = "dsCMatrix", `logarithm` = "logical"): Evaluate the determinant of `x` on the logarithm scale or not, according to the `logarithm` argument. This creates and stores the Cholesky factorization.

**t** signature(`x` = "dsCMatrix"): Transpose. As for all symmetric matrices, a matrix for which the upper triangle is stored produces a matrix for which the lower triangle is stored and vice versa, i.e., the `uplo` slot is swapped, and the row and column indices are interchanged.

**t** signature(`x` = "dsTMatrix"): Transpose. The `uplo` slot is swapped from "U" to "L" or vice versa, as for a "dsCMatrix", see above.

**coerce** signature(`from` = "dsCMatrix", `to` = "dgTMatrix")

**coerce** signature(`from` = "dsCMatrix", `to` = "dgeMatrix")

**coerce** signature(`from` = "dsCMatrix", `to` = "matrix")

```

coerce signature(from = "dsTMatrix",to = "dgeMatrix")
coerce signature(from = "dsTMatrix",to = "dsCMatrix")
coerce signature(from = "dsTMatrix",to = "dsyMatrix")
coerce signature(from = "dsTMatrix",to = "matrix")

```

### See Also

Classes [dgCMatrix](#), [dgTMatrix](#), [dgeMatrix](#) and those mentioned above.

### Examples

```

mm <- Matrix(toeplitz(c(10, 0, 1, 0, 3)), sparse = TRUE)
mm # automatically dsCMatrix
str(mm)

## how would we go from a manually constructed Tsparse* :
mT <- as(mm, "dgTMatrix")

## Either
(symM <- as(mT, "symmetricMatrix"))# dsT
(symC <- as(symM, "CsparseMatrix"))# dsC
## or
sC <- Matrix(mT, sparse=TRUE, forceCheck=TRUE)

sym2 <- as(symC, "TsparseMatrix")
## --> the same as 'symM', a "dsTMatrix"

```

---

dsparseMatrix-class

*Virtual Class "dsparseMatrix" of Numeric Sparse Matrices*

---

### Description

The Class "dsparseMatrix" is the virtual (super) class of all numeric sparse matrices.

### Slots

**Dim:** the matrix dimension, see class "[Matrix](#)".  
**Dimnames:** see the "Matrix" class.  
**x:** a [numeric](#) vector containing the (non-zero) matrix entries.

### Extends

Class "dMatrix" and "sparseMatrix", directly.  
 Class "Matrix", by the above classes.

### See Also

the documentation of the (non virtual) sub classes, see `showClass("dsparseMatrix")`; in particular, [dgTMatrix](#), [dgCMatrix](#), and [dgRMatrix](#).

**Examples**

```
showClass("dsparseMatrix")
```

---

|                 |                                                 |
|-----------------|-------------------------------------------------|
| dsRMatrix-class | <i>Symmetric Sparse Compressed Row Matrices</i> |
|-----------------|-------------------------------------------------|

---

**Description**

The `dsRMatrix` class is a class of symmetric, sparse matrices in the compressed, row-oriented format. In this implementation the non-zero elements in the rows are sorted into increasing column order.

**Objects from the Class**

These `"..RMatrix"` classes are currently still mostly unimplemented!

Objects can be created by calls of the form `new("dsRMatrix", ...)`.

**Slots**

**uplo:** A character object indicating if the upper triangle ("U") or the lower triangle ("L") is stored. At present only the lower triangle form is allowed.

**j:** Object of class `"integer"` of length `nnzero` (number of non-zero elements). These are the row numbers for each non-zero element in the matrix.

**p:** Object of class `"integer"` of pointers, one for each row, to the initial (zero-based) index of elements in the row.

**factors:** Object of class `"list"` - a list of factorizations of the matrix.

**x:** Object of class `"numeric"` - the non-zero elements of the matrix.

**Dim:** Object of class `"integer"` - the dimensions of the matrix - must be an integer vector with exactly two non-negative values.

**Dimnames:** List of length two, see [Matrix](#).

**Extends**

Classes [RsparseMatrix](#), [dsparseMatrix](#) and [symmetricMatrix](#), directly.

Class `"dMatrix"`, by class `"dsparseMatrix"`, class `"sparseMatrix"`, by class `"dsparseMatrix"` or `"RsparseMatrix"`; class `"compMatrix"` by class `"symmetricMatrix"` and of course, class `"Matrix"`.

**Methods**

**forceSymmetric** signature (`x = "dsRMatrix"`, `uplo = "missing"`): a trivial method just returning `x`

**forceSymmetric** signature (`x = "dsRMatrix"`, `uplo = "character"`): if `uplo == x@uplo`, this trivially returns `x`; otherwise `t(x)`.

**coerce** signature (`from = "dsCMatrix"`, `to = "dsRMatrix"`)

**See Also**

the classes [dgCMatrix](#), [dgTMatrix](#), and [dgeMatrix](#).

**Examples**

```
(m0 <- new("dsRMatrix"))
m2 <- new("dsRMatrix", Dim = c(2L,2L),
          x = c(3,1), j = c(1L,1L), p = 0:2)
m2
stopifnot(colSums(as(m2, "TsparseMatrix")) == 3:4)
str(m2)
(ds2 <- forceSymmetric(diag(2))) # dsy*
dR <- as(ds2, "RsparseMatrix")
dR # dsRMatrix
```

---

|                 |                                                               |
|-----------------|---------------------------------------------------------------|
| dsyMatrix-class | <i>Symmetric Dense (Packed   Non-packed) Numeric Matrices</i> |
|-----------------|---------------------------------------------------------------|

---

**Description**

- The "dsyMatrix" class is the class of symmetric, dense matrices in *non-packed* storage and
- "dspMatrix" is the class of symmetric dense matrices in *packed* storage. Only the upper triangle or the lower triangle is stored.

**Objects from the Class**

Objects can be created by calls of the form `new("dsyMatrix",...)` or `new("dspMatrix",...)`, respectively.

**Slots**

**uplo:** Object of class "character". Must be either "U", for upper triangular, and "L", for lower triangular.

**x:** Object of class "numeric". The numeric values that constitute the matrix, stored in column-major order.

**Dim,Dimnames:** The dimension (a length-2 "integer") and corresponding names (or NULL), see the [Matrix](#).

**factors:** Object of class "list". A named list of factorizations that have been computed for the matrix.

**Extends**

"dsyMatrix" extends class "dgeMatrix", directly, whereas

"dspMatrix" extends class "ddenseMatrix", directly.

Both extend class "symmetricMatrix", directly, and class "Matrix" and others, *indirectly*, use `showClass("dsyMatrix")`, e.g., for details.

**Methods**

**coerce** signature(from = "ddenseMatrix", to = "dgeMatrix")

**coerce** signature(from = "dspMatrix", to = "matrix")

**coerce** signature(from = "dsyMatrix", to = "matrix")

**coerce** signature(from = "dsyMatrix", to = "dspMatrix")

**coerce** signature(from = "dspMatrix", to = "dsyMatrix")

**norm** signature(x = "dspMatrix", type = "character"), or x = "dsyMatrix" or type = "missing": Computes the matrix norm of the desired type, see, [norm](#).

**rcond** signature(x = "dspMatrix", type = "character"), or x = "dsyMatrix" or type = "missing": Computes the reciprocal condition number, [rcond\(\)](#).

**solve** signature(a = "dspMatrix", b = "..."), and

**solve** signature(a = "dsyMatrix", b = "..."):  $x \leftarrow \text{solve}(a, b)$  solves  $Ax = b$  for  $x$ ; see [solve-methods](#).

**t** signature(x = "dsyMatrix"): Transpose; swaps from upper triangular to lower triangular storage, i.e., the uplo slot from "U" to "L" or vice versa, the same as for all symmetric matrices.

### See Also

The *positive (Semi-)definite* dense (packed or non-packed numeric matrix classes [dpoMatrix](#), [dppMatrix](#) and [corMatrix](#),

Classes [dgeMatrix](#) and [Matrix](#); [solve](#), [norm](#), [rcond](#), [t](#)

### Examples

```
## Only upper triangular part matters (when uplo == "U" as per default)
(sy2 <- new("dsyMatrix", Dim = as.integer(c(2,2)), x = c(14, NA, 32, 77)))
str(t(sy2)) # uplo = "L", and the lower tri. (i.e. NA is replaced).

chol(sy2) #-> "Cholesky" matrix
(sp2 <- pack(sy2)) # a "dspMatrix"

## Coercing to dpoMatrix gives invalid object:
sy3 <- new("dsyMatrix", Dim = as.integer(c(2,2)), x = c(14, -1, 2, -7))
try(as(sy3, "dpoMatrix")) # -> error: not positive definite
```

---

|                 |                                                        |
|-----------------|--------------------------------------------------------|
| dtCMatrix-class | <i>Triangular, (compressed) sparse column matrices</i> |
|-----------------|--------------------------------------------------------|

---

### Description

The "dtCMatrix" class is a class of triangular, sparse matrices in the compressed, column-oriented format. In this implementation the non-zero elements in the columns are sorted into increasing row order.

The "dtTMatrix" class is a class of triangular, sparse matrices in triplet format.

### Objects from the Class

Objects can be created by calls of the form `new("dtCMatrix", ...)` or calls of the form `new("dtTMatrix", ...)`, but more typically automatically via [Matrix\(\)](#) or coercion such as `as(x, "triangularMatrix")`, or `as(x, "dtCMatrix")`.

## Slots

- uplo:** Object of class "character". Must be either "U", for upper triangular, and "L", for lower triangular.
- diag:** Object of class "character". Must be either "U", for unit triangular (diagonal is all ones), or "N"; see [triangularMatrix](#).
- p:** (only present in "dtCMatrix":) an [integer](#) vector for providing pointers, one for each column, see the detailed description in [CsparseMatrix](#).
- i:** Object of class "integer" of length nnzero (number of non-zero elements). These are the row numbers for each non-zero element in the matrix.
- j:** Object of class "integer" of length nnzero (number of non-zero elements). These are the column numbers for each non-zero element in the matrix. (Only present in the [dtTMatrix](#) class.)
- x:** Object of class "numeric" - the non-zero elements of the matrix.
- Dim,Dimnames:** The dimension (a length-2 "integer") and corresponding names (or NULL), inherited from the [Matrix](#), see there.

## Extends

Class "dgCMatrix", directly. Class "triangularMatrix", directly. Class "dMatrix", "sparseMatrix", and more by class "dgCMatrix" etc, see the examples.

## Methods

- coerce** signature(from = "dtCMatrix",to = "dgTMatrix")
- coerce** signature(from = "dtCMatrix",to = "dgeMatrix")
- coerce** signature(from = "dtTMatrix",to = "dgeMatrix")
- coerce** signature(from = "dtTMatrix",to = "dtrMatrix")
- coerce** signature(from = "dtTMatrix",to = "matrix")
- solve** signature(a = "dtCMatrix",b = "..."): sparse triangular solve (aka "back-solve" or "forwardsolve"), see [solve-methods](#).
- t** signature(x = "dtCMatrix"): returns the transpose of x
- t** signature(x = "dtTMatrix"): returns the transpose of x

## See Also

Classes [dgCMatrix](#), [dgTMatrix](#), [dgeMatrix](#), and [dtrMatrix](#).

## Examples

```
showClass("dtCMatrix")

showClass("dtTMatrix")
t1 <- new("dtTMatrix", x= c(3,7), i= 0:1, j=3:2, Dim= as.integer(c(4,4)))
t1
## from 0-diagonal to unit-diagonal {low-level step}:
tu <- t1 ; tu@diag <- "U"
tu
(cu <- as(tu, "dtCMatrix"))
str(cu)# only two entries in @i and @x
stopifnot(cu@i == 1:0,
```

```

all(2 * symmpart(cu) == Diagonal(4) + forceSymmetric(cu))

t1[1,2:3] <- -1:-2
diag(t1) <- 10*c(1:2,3:2)
t1 # still triangular
(it1 <- solve(t1))
t1. <- solve(it1)
all(abs(t1 - t1.) < 10 * .Machine$double.eps)

## 2nd example
U5 <- new("dtCMatrix", i= c(1L, 0:3), p=c(0L,0L,0:2, 5L), Dim = c(5L, 5L),
          x = rep(1, 5), diag = "U")
U5
(iu <- solve(U5)) # contains one '0'
validObject(iu2 <- solve(U5, Diagonal(5)))# failed in earlier versions

I5 <- iu %*% U5 # should equal the identity matrix
i5 <- iu2 %*% U5
m53 <- matrix(1:15, 5,3, dimnames=list(NULL,letters[1:3]))
asDiag <- function(M) as(drop0(M), "diagonalMatrix")
stopifnot(
  all.equal(Diagonal(5), asDiag(I5), tolerance=1e-14) ,
  all.equal(Diagonal(5), asDiag(i5), tolerance=1e-14) ,
  identical(list(NULL, dimnames(m53)[[2]]), dimnames(solve(U5, m53)))
)

```

dtpMatrix-class

*Packed Triangular Dense Matrices - "dtpMatrix"*

## Description

The "dtpMatrix" class is the class of triangular, dense, numeric matrices in packed storage. The "dtrMatrix" class is the same except in nonpacked storage.

## Objects from the Class

Objects can be created by calls of the form `new("dtpMatrix", ...)` or by coercion from other classes of matrices.

## Slots

**uplo:** Object of class "character". Must be either "U", for upper triangular, and "L", for lower triangular.

**diag:** Object of class "character". Must be either "U", for unit triangular (diagonal is all ones), or "N"; see [triangularMatrix](#).

**x:** Object of class "numeric". The numeric values that constitute the matrix, stored in column-major order. For a packed square matrix of dimension  $d \times d$ , `length(x)` is of length  $d(d+1)/2$  (also when `diag == "U"`!).

**Dim,Dimnames:** The dimension (a length-2 "integer") and corresponding names (or NULL), inherited from the [Matrix](#), see there.

## Extends

Class "ddenseMatrix", directly. Class "triangularMatrix", directly. Class "dMatrix" and more by class "ddenseMatrix" etc, see the examples.

## Methods

```
%% signature(x = "dtpMatrix", y = "dgeMatrix"): Matrix multiplication;
ditto for several other signature combinations, see showMethods("%*%", class =
"dtpMatrix").

coerce signature(from = "dtpMatrix", to = "dtrMatrix")

coerce signature(from = "dtpMatrix", to = "matrix")

determinant signature(x = "dtpMatrix", logarithm = "logical"): the
determinant(x) trivially is prod(diag(x)), but computed on log scale to pre-
vent over- and underflow.

diag signature(x = "dtpMatrix"): ...

norm signature(x = "dtpMatrix", type = "character"): ...

rcond signature(x = "dtpMatrix", norm = "character"): ...

solve signature(a = "dtpMatrix", b = "..."): efficiently using internal backsolve or
forwardsolve, see solve-methods.

t signature(x = "dtpMatrix"): t(x) remains a "dtpMatrix", lower triangular if x is
upper triangular, and vice versa.
```

## See Also

Class [dtrMatrix](#)

## Examples

```
showClass("dtrMatrix")

example("dtrMatrix-class", echo=FALSE)
(p1 <- as(T2, "dtpMatrix"))
str(p1)
(pp <- as(T, "dtpMatrix"))
ip1 <- solve(p1)
stopifnot(length(p1@x) == 3, length(pp@x) == 3,
           p1 @ uplo == T2 @ uplo, pp @ uplo == T @ uplo,
           identical(t(pp), p1), identical(t(p1), pp),
           all((l.d <- p1 - T2) == 0), is(l.d, "dtpMatrix"),
           all((u.d <- pp - T) == 0), is(u.d, "dtpMatrix"),
           l.d@uplo == T2@uplo, u.d@uplo == T@uplo,
           identical(t(ip1), solve(pp)), is(ip1, "dtpMatrix"),
           all.equal(as(solve(p1,p1), "diagonalMatrix"), Diagonal(2)))
```

---

dtRMatrix-class      *Triangular Sparse Compressed Row Matrices*

---

## Description

The `dtRMatrix` class is a class of triangular, sparse matrices in the compressed, row-oriented format. In this implementation the non-zero elements in the rows are sorted into increasing columnnd order.

## Objects from the Class

This class is currently still mostly unimplemented!

Objects can be created by calls of the form `new("dtRMatrix", ...)`.

## Slots

**uplo:** Object of class "character". Must be either "U", for upper triangular, and "L", for lower triangular. At present only the lower triangle form is allowed.

**diag:** Object of class "character". Must be either "U", for unit triangular (diagonal is all ones), or "N"; see [triangularMatrix](#).

**j:** Object of class "integer" of length `nnzero(.)` (number of non-zero elements). These are the row numbers for each non-zero element in the matrix.

**p:** Object of class "integer" of pointers, one for each row, to the initial (zero-based) index of elements in the row. (Only present in the `dsRMatrix` class.)

**x:** Object of class "numeric" - the non-zero elements of the matrix.

**Dim:** The dimension (a length-2 "integer")

**Dimnames:** corresponding names (or NULL), inherited from the [Matrix](#), see there.

## Extends

Class "dgRMatrix", directly. Class "dsparseMatrix", by class "dgRMatrix". Class "dMatrix", by class "dgRMatrix". Class "sparseMatrix", by class "dgRMatrix". Class "Matrix", by class "dgRMatrix".

## Methods

No methods currently with class "dsRMatrix" in the signature.

## See Also

Classes [dgCMatrix](#), [dgTMatrix](#), [dgeMatrix](#)

## Examples

```
(m0 <- new("dtRMatrix"))
(m2 <- new("dtRMatrix", Dim = c(2L,2L),
              x = c(5, 1:2), p = c(0L,2:3), j= c(0:1,1L)))
str(m2)
(m3 <- as(Diagonal(2), "RsparseMatrix"))# --> dtRMatrix
```

|-----------------|--------------------------------------------|
| dtrMatrix-class | <i>Triangular, dense, numeric matrices</i> |
|-----------------|--------------------------------------------|

---

## Description

The "dtrMatrix" class is the class of triangular, dense, numeric matrices in nonpacked storage. The "dtpMatrix" class is the same except in packed storage.

## Objects from the Class

Objects can be created by calls of the form `new("dtrMatrix", ...)`.

## Slots

**uplo:** Object of class "character". Must be either "U", for upper triangular, and "L", for lower triangular.

**diag:** Object of class "character". Must be either "U", for unit triangular (diagonal is all ones), or "N"; see [triangularMatrix](#).

**x:** Object of class "numeric". The numeric values that constitute the matrix, stored in column-major order.

**Dim:** Object of class "integer". The dimensions of the matrix which must be a two-element vector of non-negative integers.

## Extends

Class "ddenseMatrix", directly. Class "triangularMatrix", directly. Class "Matrix" and others, by class "ddenseMatrix".

## Methods

Among others (such as matrix products, e.g. [?crossprod-methods](#)),

**coerce** signature (from = "dgeMatrix", to = "dtrMatrix")

**coerce** signature (from = "dtrMatrix", to = "matrix")

**coerce** signature (from = "dtrMatrix", to = "ltrMatrix")

**coerce** signature (from = "dtrMatrix", to = "matrix")

**coerce** signature (from = "matrix", to = "dtrMatrix")

**norm** signature (x = "dtrMatrix", type = "character")

**rcond** signature (x = "dtrMatrix", norm = "character")

**solve** signature (a = "dtrMatrix", b = "...") efficiently use a "forwardsolve" or backsolve for a lower or upper triangular matrix, respectively, see also [solve-methods](#).

**+, -, \*, ..., ==, >=, ...** all the [Ops](#) group methods are available. When applied to two triangular matrices, these return a triangular matrix when easily possible.

**Examples**

```
(m <- rbind(2:3, 0:-1))
(M <- as(m, "dgeMatrix"))

(T <- as(M, "dtrMatrix")) ## upper triangular is default
(T2 <- as(t(M), "dtrMatrix"))
stopifnot(T@uplo == "U", T2@uplo == "L", identical(T2, t(T)))
```

expand

*Expand a (Matrix) Decomposition into Factors***Description**

Expands decompositions stored in compact form into factors.

**Usage**

```
expand(x, ...)
```

**Arguments**

`x` a matrix decomposition.  
`...` further arguments passed to or from other methods.

**Details**

This is a generic function with special methods for different types of decompositions, see [showMethods](#) (expand) to list them all.

**Value**

The expanded decomposition, typically a list of matrix factors.

**Note**

Factors for decompositions such as `lu` and `qr` can be stored in a compact form. The function `expand` allows all factors to be fully expanded.

**See Also**

The LU [lu](#), and the [Cholesky](#) decompositions which have `expand` methods; [facmul](#).

**Examples**

```
(x <- Matrix(round(rnorm(9), 2), 3, 3))
(ex <- expand(lux <- lu(x)))
```

---

expm*Matrix Exponential*

---

## Description

Compute the exponential of a matrix.

## Usage

`expm(x)`

## Arguments

`x` a matrix, typically inheriting from the `dMatrix` class.

## Details

The exponential of a matrix is defined as the infinite Taylor series  $\text{expm}(A) = I + A + A^2/2! + A^3/3! + \dots$  (although this is definitely not the way to compute it). The method for the `dgeMatrix` class uses Ward's diagonal Pade' approximation with three step preconditioning.

## Value

The matrix exponential of `x`.

## Note

The **expm** package contains newer (partly faster and more accurate) algorithms for `expm()` and includes `logm` and `sqrtm`.

## Author(s)

This is a translation of the implementation of the corresponding Octave function contributed to the Octave project by A. Scottedward Hodel <A.S.Hodel@Eng.Auburn.EDU>. A bug in there has been fixed by Martin Maechler.

`Schur`; additionally, `expm`, `logm`, etc in package **expm**.

## Examples

```
(m1 <- Matrix(c(1,0,1,1), nc = 2))
(e1 <- expm(m1)) ; e <- exp(1)
stopifnot(all.equal(e1@x, c(e,0,e,e), tolerance = 1e-15))
(m2 <- Matrix(c(-49, -64, 24, 31), nc = 2))
(e2 <- expm(m2))
(m3 <- Matrix(cbind(0, rbind(6*diag(3), 0)))) # sparse!
(e3 <- expm(m3)) # upper triangular
```

externalFormats

*Read and write external matrix formats*

## Description

Read matrices stored in the Harwell-Boeing or MatrixMarket formats or write `sparseMatrix` objects to one of these formats.

## Usage

```
readHB(file)
readMM(file)
writeMM(obj, file, ...)
```

## Arguments

|                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>obj</code>  | a real sparse matrix                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <code>file</code> | for <code>writeMM</code> - the name of the file to be written. For <code>readHB</code> and <code>readMM</code> the name of the file to read, as a character scalar. The names of files storing matrices in the Harwell-Boeing format usually end in <code>".rua"</code> or <code>".rsa"</code> . Those storing matrices in the MatrixMarket format usually end in <code>".mtx"</code> . Alternatively, <code>readHB</code> and <code>readMM</code> accept connection objects. |
| <code>...</code>  | optional additional arguments. Currently none are used in any methods.                                                                                                                                                                                                                                                                                                                                                                                                        |

## Value

The `readHB` and `readMM` functions return an object that inherits from the `"Matrix"` class. Methods for the `writeMM` generic functions usually return `NULL` and, as a side effect, the matrix `obj` is written to `file` in the MatrixMarket format (`writeMM`).

## Note

The Harwell-Boeing format is older and less flexible than the MatrixMarket format. The function `writeHB` was deprecated and has now been removed. Please use `writeMM` instead.

A very simple way to export small sparse matrices `S`, is to use `summary(S)` which returns a `data.frame` with columns `i`, `j`, and possibly `x`, see `summary` in `sparseMatrix-class`, and an example below.

## References

<https://sparse.tamu.edu/>

## Examples

```
str(pores <- readMM(system.file("external/pores_1.mtx",
                                package = "Matrix")))
str(utm <- readHB(system.file("external/utm300.rua",
                                package = "Matrix")))
str(lundA <- readMM(system.file("external/lund_a.mtx",
                                package = "Matrix")))
str(lundA <- readHB(system.file("external/lund_a.rsa",
                                package = "Matrix")))

## Not run:
## NOTE: The following examples take quite some time
## ---- even on a fast internet connection:
if(FALSE) # the URL has been corrected, but we need an un-tar step!
str(sm <-
  readHB(gzcon(url("https://www.cise.ufl.edu/research/sparse/RB/Boeing/msc00726.tar.gz"))))

str(jgl009 <-
  readMM(gzcon(url("ftp://math.nist.gov/pub/MatrixMarket2/Harwell-Boeing/counterx/jgl009.mtx"))))

## End(Not run)
data(KNex)
## Store as MatrixMarket (".mtx") file, here inside temporary dir./folder:
(MMfile <- file.path(tempdir(), "mmMM.mtx"))
writeMM(KNex$mm, file=MMfile)
file.info(MMfile)[,c("size", "ctime")] # (some confirmation of the file's)

## very simple export - in triplet format - to text file:
data(CAex)
s.CA <- summary(CAex)
s.CA # shows (i, j, x) [columns of a data frame]
message("writing to ", outf <- tempfile())
write.table(s.CA, file = outf, row.names=FALSE)
## and read it back -- showing off sparseMatrix():
str(dd <- read.table(outf, header=TRUE))
## has columns (i, j, x) -> we can use via do.call() as arguments to sparseMatrix():
mm <- do.call(sparseMatrix, dd)
stopifnot(all.equal(mm, CAex, tolerance=1e-15))
```

---

facmul

*Multiplication by Decomposition Factors*

---

## Description

Performs multiplication by factors for certain decompositions (and allows explicit formation of those factors).

## Usage

```
facmul(x, factor, y, transpose, left, ...)
```

## Arguments

**x** a matrix decomposition. No missing values or IEEE special values are allowed.

|           |                                                                                                                                |
|-----------|--------------------------------------------------------------------------------------------------------------------------------|
| factor    | an indicator for selecting a particular factor for multiplication.                                                             |
| y         | a matrix or vector to be multiplied by the factor or its transpose. No missing values or IEEE special values are allowed.      |
| transpose | a logical value. When FALSE (the default) the factor is applied. When TRUE the transpose of the factor is applied.             |
| left      | a logical value. When TRUE (the default) the factor is applied from the left. When FALSE the factor is applied from the right. |
| ...       | the method for "qr.Matrix" has additional arguments.                                                                           |

### Value

the product of the selected factor (or its transpose) and y

### NOTE

Factors for decompositions such as `lu` and `qr` can be stored in a compact form. The function `facmul` allows multiplication without explicit formation of the factors, saving both storage and operations.

### References

Golub, G., and Van Loan, C. F. (1989). *Matrix Computations*, 2nd edition, Johns Hopkins, Baltimore.

### Examples

```
library(Matrix)
x <- Matrix(rnorm(9), 3, 3)
## Not run:
qrx <- qr(x)                # QR factorization of x
y <- rnorm(3)
facmul( qr(x), factor = "Q", y) # form Q y

## End(Not run)
```

---

forceSymmetric

*Force a Matrix to 'symmetricMatrix' Without Symmetry Checks*

---

### Description

Force a square matrix x to a [symmetricMatrix](#), **without** a symmetry check as it would be applied for `as(x, "symmetricMatrix")`.

### Usage

```
forceSymmetric(x, uplo)
```

**Arguments**

|                   |                                                                                                                                                                                                                                                                                                                                      |
|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>    | any square matrix (of numbers), either “traditional” ( <a href="#">matrix</a> ) or inheriting from <a href="#">Matrix</a> .                                                                                                                                                                                                          |
| <code>uplo</code> | optional string, "U" or "L" indicating which “triangle” half of <code>x</code> should determine the result. The default is "U" unless <code>x</code> already has a <code>uplo</code> slot (i.e., when it is <a href="#">symmetricMatrix</a> , or <a href="#">triangularMatrix</a> ), where the default will be <code>x@uplo</code> . |

**Value**

a square matrix inheriting from class [symmetricMatrix](#).

**See Also**

[symmpart](#) for the symmetric part of a matrix, or the coercions `as(x, <symmetricMatrix class>)`.

**Examples**

```
## Hilbert matrix
i <- 1:6
h6 <- 1/outer(i - 1L, i, "+")
sd <- sqrt(diag(h6))
hh <- t(h6/sd)/sd # theoretically symmetric
isSymmetric(hh, tol=0) # FALSE; hence
try( as(hh, "symmetricMatrix") ) # fails, but this works fine:
H6 <- forceSymmetric(hh)

## result can be pretty surprising:
(M <- Matrix(1:36, 6))
forceSymmetric(M) # symmetric, hence very different in lower triangle
(tm <- tril(M))
forceSymmetric(tm)
```

**Description**

Utilities for formatting sparse numeric matrices in a flexible way. These functions are used by the [format](#) and [print](#) methods for sparse matrices and can be applied as well to standard R matrices. Note that *all* arguments but the first are optional.

`formatSparseM()` is the main “workhorse” of [formatSpMatrix](#), the `format` method for sparse matrices.

`.formatSparseSimple()` is a simple helper function, also dealing with (short/empty) column names construction.

**Usage**

```
formatSparseM(x, zero.print = ".", align = c("fancy", "right"),
              m = as(x, "matrix"), asLogical=NULL, uniDiag=NULL,
              digits=NULL, cx, iN0, dn = dimnames(m))

.formatSparseSimple(m, asLogical=FALSE, digits=NULL,
                   col.names, note.dropping.colnames = TRUE,
                   dn=dimnames(m))
```

**Arguments**

|                                                |                                                                                                                                                                                                             |
|------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>                                 | an R object inheriting from class <code>sparseMatrix</code> .                                                                                                                                               |
| <code>zero.print</code>                        | character which should be used for <i>structural</i> zeroes. The default "." may occasionally be replaced by " " (blank); using "0" would look almost like <code>print()</code> ing of non-sparse matrices. |
| <code>align</code>                             | a string specifying how the <code>zero.print</code> codes should be aligned, see <code>formatSpMatrix</code> .                                                                                              |
| <code>m</code>                                 | (optional) a (standard R) <code>matrix</code> version of <code>x</code> .                                                                                                                                   |
| <code>asLogical</code>                         | should the matrix be formatted as a logical matrix (or rather as a numeric one); mostly for <code>formatSparseM()</code> .                                                                                  |
| <code>uniDiag</code>                           | logical indicating if the diagonal entries of a sparse unit triangular or unit-diagonal matrix should be formatted as "I" instead of "1" (to emphasize that the 1's are "structural").                      |
| <code>digits</code>                            | significant digits to use for printing, see <code>print.default</code> .                                                                                                                                    |
| <code>cx</code>                                | (optional) character matrix; a formatted version of <code>x</code> , still with strings such as "0.00" for the zeros.                                                                                       |
| <code>iN0</code>                               | (optional) integer vector, specifying the location of the <i>non</i> -zeroes of <code>x</code> .                                                                                                            |
| <code>col.names, note.dropping.colnames</code> | see <code>formatSpMatrix</code> .                                                                                                                                                                           |
| <code>dn</code>                                | <code>dimnames</code> to be used; a list (of length two) with row and column names (or <code>NULL</code> ).                                                                                                 |

**Value**

a character matrix like `cx`, where the zeros have been replaced with (padded versions of) `zero.print`. As this is a *dense* matrix, do not use these functions for really large (really) sparse matrices!

**Author(s)**

Martin Maechler

**See Also**

`formatSpMatrix` which calls `formatSparseM()` and is the `format` method for sparse matrices.  
`printSpMatrix` which is used by the (typically implicitly called) `show` and `print` methods for sparse matrices.

**Examples**

```

m <- suppressWarnings(matrix(c(0, 3.2, 0, 0, 11, 0, 0, 0, 0, -7, 0), 4, 9))
fm <- formatSparseM(m)
noquote(fm)
## nice, but this is nicer {with "units" vertically aligned}:
print(fm, quote=FALSE, right=TRUE)
## and "the same" as :
Matrix(m)

## align = "right" is cheaper --> the "." are not aligned:
noquote(f2 <- formatSparseM(m, align="r"))
stopifnot(f2 == fm | m == 0, dim(f2) == dim(m),
          (f2 == ".") == (m == 0))

```

---

generalMatrix-class

*Class "generalMatrix" of General Matrices*

---

**Description**

Virtual class of “general” matrices; i.e., matrices that do not have a known property such as symmetric, triangular, or diagonal.

**Objects from the Class**

A virtual Class: No objects may be created from it.

**Slots**

factors ,

Dim ,

Dimnames: all slots inherited from [compMatrix](#); see its description.

**Extends**

Class "compMatrix", directly. Class "Matrix", by class "compMatrix".

**See Also**

Classes [compMatrix](#), and the non-general virtual classes: [symmetricMatrix](#), [triangularMatrix](#), [diagonalMatrix](#).

---

graph-sparseMatrix *Conversions "graph" <-> (sparse) Matrix*

---

## Description

The **Matrix** package has supported conversion from and to "graph" objects from (Bioconductor) package **graph** since summer 2005, via the usual `as(., "<class>")` coercion,

```
as(from, Class)
```

Since 2013, this functionality is further exposed as the `graph2T()` and `T2graph()` functions (with further arguments than just `from`), which convert graphs to and from the triplet form of sparse matrices (of class "`TsparseMatrix`").

## Usage

```
graph2T(from, use.weights = )
T2graph(from, need.uniq = is_not_uniqT(from), edgemode = NULL)
```

## Arguments

|                          |                                                                                                                                                                                                                                                                                                                                                             |
|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>from</code>        | for <code>graph2T()</code> , an R object of class "graph";<br>for <code>T2graph()</code> , a sparse matrix inheriting from " <code>TsparseMatrix</code> ".                                                                                                                                                                                                  |
| <code>use.weights</code> | logical indicating if weights should be used, i.e., equivalently the result will be numeric, i.e. of class <code>dgTMatrix</code> ; otherwise the result will be <code>ngTMatrix</code> or <code>nsTMatrix</code> , the latter if the graph is undirected. The default looks if there are weights in the graph, and if any differ from 1, weights are used. |
| <code>need.uniq</code>   | a logical indicating if <code>from</code> may need to be internally "uniquified"; do not set this and hence rather use the default, unless you know what you are doing!                                                                                                                                                                                     |
| <code>edgemode</code>    | one of <code>NULL</code> , "directed", or "undirected". The default <code>NULL</code> looks if the matrix is symmetric and assumes "undirected" in that case.                                                                                                                                                                                               |

## Value

For `graph2T()`, a sparse matrix inheriting from "`TsparseMatrix`".

For `T2graph()` an R object of class "graph".

## See Also

Note that the CRAN package **igraph** also provides conversions from and to sparse matrices (of package **Matrix**) via its `graph.adjacency()` and `get.adjacency()`.

## Examples

```
if(isTRUE(try(require(graph)))) { ## super careful .. for "checking reasons"
  n4 <- LETTERS[1:4]; dns <- list(n4,n4)
  show(a1 <- sparseMatrix(i= c(1:4), j=c(2:4,1), x = 2, dimnames=dns))
  show(g1 <- as(a1, "graph")) # directed
  unlist(edgeWeights(g1)) # all '2'

  show(a2 <- sparseMatrix(i= c(1:4,4), j=c(2:4,1:2), x = TRUE, dimnames=dns))
```

```

show(g2 <- as(a2, "graph")) # directed
# now if you want it undirected:
show(g3 <- T2graph(as(a2, "TsparseMatrix"), edgemode="undirected"))
show(m3 <- as(g3, "Matrix"))
show( graph2T(g3) ) # a "pattern Matrix" (nsTMatrix)

a. <- sparseMatrix(i= 4:1, j=1:4, dimnames=list(n4,n4), giveC=FALSE) # no 'x'
show(a.) # "ngTMatrix"
show(g. <- as(a., "graph"))

}

```

Hilbert

*Generate a Hilbert matrix***Description**

Generate the  $n$  by  $n$  symmetric Hilbert matrix. Because these matrices are ill-conditioned for moderate to large  $n$ , they are often used for testing numerical linear algebra code.

**Usage**

```
Hilbert(n)
```

**Arguments**

$n$  a non-negative integer.

**Value**

the  $n$  by  $n$  symmetric Hilbert matrix as a "dpoMatrix" object.

**See Also**

the class [dpoMatrix](#)

**Examples**

```
Hilbert(6)
```

image-methods

*Methods for image() in Package 'Matrix'***Description**

Methods for function [image](#) in package **Matrix**. An image of a matrix simply color codes all matrix entries and draws the  $n \times m$  matrix using an  $n \times m$  grid of (colored) rectangles.

The **Matrix** package image methods are based on [levelplot\(\)](#) from package **lattice**; hence these methods return an “object” of class "trellis", producing a graphic when (auto-) [print\(\)](#) ed.

**Usage**

```
## S4 method for signature 'dgTMatrix'
image(x,
      xlim = c(1, di[2]),
      ylim = c(di[1], 1), aspect = "iso",
      sub = sprintf("Dimensions: %d x %d", di[1], di[2]),
      xlab = "Column", ylab = "Row", cuts = 15,
      useRaster = FALSE,
      useAbs = NULL, colorkey = !useAbs,
      col.regions = NULL,
      lwd = NULL, border.col = NULL, ...)
```

**Arguments**

|                              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>               | a Matrix object, i.e., fulfilling <code>is(x, "Matrix")</code> .                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>xlim, ylim</code>      | x- and y-axis limits; may be used to “zoom into” matrix. Note that <i>x, y</i> “feel reversed”: <code>ylim</code> is for the rows (= 1st index) and <code>xlim</code> for the columns (= 2nd index). For convenience, when the limits are integer valued, they are both extended by 0.5; also, <code>ylim</code> is always used decreasingly.                                                                                                                            |
| <code>aspect</code>          | aspect ratio specified as number ( <i>y/x</i> ) or string; see <code>levelplot</code> .                                                                                                                                                                                                                                                                                                                                                                                  |
| <code>sub, xlab, ylab</code> | axis annotation with sensible defaults; see <code>plot.default</code> .                                                                                                                                                                                                                                                                                                                                                                                                  |
| <code>cuts</code>            | number of levels the range of matrix values would be divided into.                                                                                                                                                                                                                                                                                                                                                                                                       |
| <code>useRaster</code>       | logical indicating if raster graphics should be used (instead of the tradition rectangle vector drawing). If true, <code>panel.levelplot.raster</code> (from <b>lattice</b> package) is used, and the colorkey is also done via rasters, see also <code>levelplot</code> and possibly <code>grid.raster</code> .<br><br>Note that using raster graphics may often be faster, but can be slower, depending on the matrix dimensions and the graphics device (dimensions). |
| <code>useAbs</code>          | logical indicating if <code>abs(x)</code> should be shown; if TRUE, the former (implicit) default, the default <code>col.regions</code> will be <code>grey</code> colors (and no colorkey drawn). The default is FALSE unless the matrix has no negative entries.                                                                                                                                                                                                        |
| <code>colorkey</code>        | logical indicating if a color key aka ‘legend’ should be produced. Default is to draw one, unless <code>useAbs</code> is true. You can also specify a <code>list</code> , see <code>levelplot</code> , such as <code>list(raster=TRUE)</code> in the case of rastering.                                                                                                                                                                                                  |
| <code>col.regions</code>     | vector of gradually varying colors; see <code>levelplot</code> .                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>lwd</code>             | (only used when <code>useRaster</code> is false:) non-negative number or NULL (default), specifying the line-width of the rectangles of each non-zero matrix entry (drawn by <code>grid.rect</code> ). The default depends on the matrix dimension and the device size.                                                                                                                                                                                                  |
| <code>border.col</code>      | color for the border of each rectangle. NA means no border is drawn. When NULL as by default, <code>border.col &lt;- if (lwd &lt; .01) NA else NULL</code> is used. Consider using an opaque color instead of NULL which corresponds to <code>grid::get.gpar("col")</code> .                                                                                                                                                                                             |
| <code>...</code>             | further arguments passed to methods and <code>levelplot</code> , notably at for specifying (possibly non equidistant) cut values for dividing the matrix values (superseeding <code>cuts</code> above).                                                                                                                                                                                                                                                                  |

**Value**

as all **lattice** graphics functions, `image(<Matrix>)` returns a "trellis" object, effectively the result of `levelplot()`.

**Methods**

All methods currently end up calling the method for the `dgTMatrix` class. Use `showMethods(image)` to list them all.

**See Also**

`levelplot`, and `print.trellis` from package **lattice**.

**Examples**

```
showMethods(image)
## If you want to see all the methods' implementations:
showMethods(image, incl=TRUE, inherit=FALSE)

data(CAex)
image(CAex, main = "image(CAex)")
image(CAex, useAbs=TRUE, main = "image(CAex, useAbs=TRUE)")

cCA <- Cholesky(crossprod(CAex), Imult = .01)
## See ?print.trellis --- place two image() plots side by side:
print(image(cCA, main="Cholesky(crossprod(CAex), Imult = .01)",
  split=c(x=1,y=1,nx=2, ny=1), more=TRUE)
print(image(cCA, useAbs=TRUE),
  split=c(x=2,y=1,nx=2,ny=1))

data(USCounties)
image(USCounties)# huge
image(sign(USCounties))## just the pattern
# how the result looks, may depend heavily on
# the device, screen resolution, antialiasing etc
# e.g. x11(type="Xlib") may show very differently than cairo-based

## Drawing borders around each rectangle;
# again, viewing depends very much on the device:
image(USCounties[1:400,1:200], lwd=.1)
## Using (xlim,ylim) has advantage : matrix dimension and (col/row) indices:
image(USCounties, c(1,200), c(1,400), lwd=.1)
image(USCounties, c(1,300), c(1,200), lwd=.5 )
image(USCounties, c(1,300), c(1,200), lwd=.01)
## These 3 are all equivalent :
(I1 <- image(USCounties, c(1,100), c(1,100), useAbs=FALSE))
I2 <- image(USCounties, c(1,100), c(1,100), useAbs=FALSE, border.col=NA)
I3 <- image(USCounties, c(1,100), c(1,100), useAbs=FALSE, lwd=2, border.col=NA)
stopifnot(all.equal(I1, I2, check.environment=FALSE),
  all.equal(I2, I3, check.environment=FALSE))
## using an opaque border color
image(USCounties, c(1,100), c(1,100), useAbs=FALSE, lwd=3, border.col = adjustcolor("skyb

if(doExtras <- interactive() || nzchar(Sys.getenv("R_MATRIX_CHECK_EXTRA"))) ||
  identical("true", unname(Sys.getenv("R_PKG_CHECKING_doExtras")))) {
## Using raster graphics: For PDF this would give a 77 MB file,
```

```
## however, for such a large matrix, this is typically considerably
## *slower* (than vector graphics rectangles) in most cases :
if(doPNG <- !dev.interactive())
  png("image-USCounties-raster.png", width=3200, height=3200)
image(USCounties, useRaster = TRUE) # should not suffer from anti-aliasing
if(doPNG)
  dev.off()
  ## and now look at the *.png image in a viewer you can easily zoom in and out
}#only if(doExtras)
```

---

index-class

---

*Virtual Class "index" - Simple Class for Matrix Indices*

---

### Description

The class "index" is a virtual class used for indices (in signatures) for matrix indexing and sub-assignment of **Matrix** matrices.

In fact, it is currently implemented as a simple class union ([setClassUnion](#)) of "numeric", "logical" and "character".

### Objects from the Class

Since it is a virtual Class, no objects may be created from it.

### See Also

[\[-methods\]](#), and  
[Subassign-methods](#), also for examples.

### Examples

```
showClass("index")
```

---

indMatrix-class

---

*Index Matrices*

---

### Description

The "indMatrix" class is the class of index matrices, stored as 1-based integer index vectors. An index matrix is a matrix with exactly one non-zero entry per row. Index matrices are useful for mapping observations to unique covariate values, for example.

Matrix (vector) multiplication with index matrices is equivalent to replicating and permuting rows, or "sampling rows with replacement", and is implemented that way in the **Matrix** package, see the 'Details' below.

## Details

Matrix (vector) multiplication with index matrices from the left is equivalent to replicating and permuting rows of the matrix on the right hand side. (Similarly, matrix multiplication with the transpose of an index matrix from the right corresponds to selecting *columns*.) The crossproduct of an index matrix  $M$  with itself is a diagonal matrix with the number of entries in each column of  $M$  on the diagonal, i.e.,  $M'M = \text{Diagonal}(x = \text{table}(M@perm))$ .

Permutation matrices (of class `pMatrix`) are special cases of index matrices: They are square, of dimension, say,  $n \times n$ , and their index vectors contain exactly all of  $1:n$ .

While “row-indexing” (of more than one row *or* using `drop=FALSE`) stays within the “indMatrix” class, all other subsetting/indexing operations (“column-indexing”, including, `diag`) on “indMatrix” objects treats them as nonzero-pattern matrices (“ngTMatrix” specifically), such that non-matrix subsetting results in `logical` vectors. Sub-assignment (`M[i, j] <- v`) is not sensible and hence an error for these matrices.

## Objects from the Class

Objects can be created by calls of the form `new("indMatrix", ...)` or by coercion from an integer index vector, see below.

## Slots

**perm:** An integer, 1-based index vector, i.e. an integer vector of length `Dim[1]` whose elements are taken from `1:Dim[2]`.

**Dim:** `integer` vector of length two. In some applications, the matrix will be skinny, i.e., with at least as many rows as columns.

**Dimnames:** a `list` of length two where each component is either `NULL` or a `character` vector of length equal to the corresponding `Dim` element.

## Extends

Class “`sparseMatrix`” and “`generalMatrix`”, directly.

## Methods

`%*%` signature(`x = "matrix"`, `y = "indMatrix"`) and other signatures (use `showMethods("%*%", class="indMatrix")`): ...

**coerce** signature(`from = "integer"`, `to = "indMatrix"`): This enables typical “indMatrix” construction, given an index vector from elements in `1:Dim[2]`, see the first example.

**coerce** signature(`from = "numeric"`, `to = "indMatrix"`): a user convenience, to allow `as(perm, "indMatrix")` for numeric `perm` with integer values.

**coerce** signature(`from = "list"`, `to = "indMatrix"`): The list must have two (integer-valued) entries: the first giving the index vector with elements in `1:Dim[2]`, the second giving `Dim[2]`. This allows “indMatrix” construction for cases in which the values represented by the rightmost column(s) are not associated with any observations, i.e., in which the index does not contain values `Dim[2], Dim[2]-1, Dim[2]-2, ...`

**coerce** signature(`from = "indMatrix"`, `to = "matrix"`): coercion to a traditional FALSE/TRUE `matrix` of mode `logical`.

**coerce** signature(`from = "indMatrix"`, `to = "ngTMatrix"`): coercion to sparse logical matrix of class `ngTMatrix`.

**t** signature(x = "indMatrix"): return the transpose of the index matrix (which is no longer an indMatrix, but of class [ngTMatrix](#).

**colSums, colMeans, rowSums, rowMeans** signature(x = "indMatrix"): return the column or row sums or means.

**rbind2** signature(x = "indMatrix", y = "indMatrix"): a fast method for rowwise catenation of two index matrices (with the same number of columns).

**kronecker** signature(X = "indMatrix", Y = "indMatrix"): return the kronecker product of two index matrices, which corresponds to the index matrix of the interaction of the two.

### Author(s)

Fabian Scheipl, Uni Muenchen, building on existing ["pMatrix"](#), after a nice hike's conversation with Martin Maechler; diverse tweaks by the latter. The [crossprod\(x, y\)](#) and [kronecker\(x, y\)](#) methods when both arguments are ["indMatrix"](#) have been made considerably faster thanks to a suggestion by Boris Vaillant.

### See Also

The permutation matrices [pMatrix](#) are special index matrices. The “pattern” matrices, [nMatrix](#) and its subclasses.

### Examples

```
p1 <- as(c(2,3,1), "pMatrix")
(sm1 <- as(rep(c(2,3,1), e=3), "indMatrix"))
stopifnot(all(sm1 == p1[rep(1:3, each=3),]))

## row-indexing of a <pMatrix> turns it into an <indMatrix>:
class(p1[rep(1:3, each=3),])

set.seed(12) # so we know '10' is in sample
## random index matrix for 30 observations and 10 unique values:
(s10 <- as(sample(10, 30, replace=TRUE), "indMatrix"))

## Sample rows of a numeric matrix :
(mm <- matrix(1:10, nrow=10, ncol=3))
s10 %*% mm

set.seed(27)
IM1 <- as(sample(1:20, 100, replace=TRUE), "indMatrix")
IM2 <- as(sample(1:18, 100, replace=TRUE), "indMatrix")
(c12 <- crossprod(IM1, IM2))
## same as cross-tabulation of the two index vectors:
stopifnot(all(c12 - unclass(table(IM1@perm, IM2@perm)) == 0))

# 3 observations, 4 implied values, first does not occur in sample:
as(2:4, "indMatrix")
# 3 observations, 5 values, first and last do not occur in sample:
as(list(2:4, 5), "indMatrix")

as(sm1, "ngTMatrix")
s10[1:7, 1:4] # gives an "ngTMatrix" (most economic!)
s10[1:4, ] # preserves "indMatrix"-class
```

```
I1 <- as(c(5:1,6:4,7:3), "indMatrix")
I2 <- as(7:1, "pMatrix")
(I12 <- suppressWarnings(rBind(I1, I2)))
stopifnot(is(I12, "indMatrix"),
          if(getRversion() >= "3.2.0") identical(I12, rbind(I1, I2)) else TRUE,
          colSums(I12) == c(2L,2:4,4:2))
```

invPerm

*Inverse Permutation Vector*

## Description

From a permutation vector *p*, compute its *inverse* permutation vector.

## Usage

```
invPerm(p, zero.p = FALSE, zero.res = FALSE)
```

## Arguments

|                 |                                                                                                                                          |
|-----------------|------------------------------------------------------------------------------------------------------------------------------------------|
| <i>p</i>        | an integer vector of length, say, <i>n</i> .                                                                                             |
| <i>zero.p</i>   | logical indicating if <i>p</i> contains values 0 : ( <i>n</i> -1) or rather (by default, <i>zero.p</i> = FALSE) 1 : <i>n</i> .           |
| <i>zero.res</i> | logical indicating if the result should contain values 0 : ( <i>n</i> -1) or rather (by default, <i>zero.res</i> = FALSE) 1 : <i>n</i> . |

## Value

an integer vector of the same length (*n*) as *p*. By default, (*zero.p* = FALSE, *zero.res* = FALSE), `invPerm(p)` is the same as `order(p)` or `sort.list(p)` and for that case, the function is equivalent to `invPerm. <-function(p) { p[p] <-seq_along(p) ; p }`.

## Author(s)

Martin Maechler

## See Also

the class of permutation matrices, `pMatrix`.

## Examples

```
p <- sample(10) # a random permutation vector
ip <- invPerm(p)
p[ip] # == 1:10
## they are indeed inverse of each other:
stopifnot(
  identical(p[ip], 1:10),
  identical(ip[p], 1:10),
  identical(invPerm(ip), p)
)
```

is.na-methods

*is.na(), is.infinite() Methods for 'Matrix' Objects***Description**

Methods for function `is.na()`, `is.finite()`, and `is.infinite()` for all Matrices (objects extending the `Matrix` class):

`x = "denseMatrix"` returns a `nMatrix` object of same dimension as `x`, with TRUE's whenever `x` is `NA`, finite, or infinite, respectively.

`x = "sparseMatrix"` ditto.

**Usage**

```
## S4 method for signature 'sparseMatrix'
is.na(x)
## S4 method for signature 'dsparseMatrix'
is.finite(x)
## S4 method for signature 'ddenseMatrix'
is.infinite(x)
## ...
## and for other classes

## S4 method for signature 'xMatrix'
anyNA(x)
## S4 method for signature 'nsparseMatrix'
anyNA(x)
## S4 method for signature 'sparseVector'
anyNA(x)
## S4 method for signature 'nsparseVector'
anyNA(x)
```

**Arguments**

`x` sparse or dense matrix or sparse vector (here; any R object in general).

**See Also**

`NA`, `is.na`; `is.finite`, `is.infinite`; `nMatrix`, `denseMatrix`, `sparseMatrix`.

The `sparseVector` class.

**Examples**

```
M <- Matrix(1:6, nrow=4, ncol=3,
            dimnames = list(c("a", "b", "c", "d"), c("A", "B", "C")))
stopifnot(all(!is.na(M)))
M[2:3,2] <- NA
is.na(M)
if(exists("anyNA", mode="function"))
  anyNA(M)

A <- spMatrix(10,20, i = c(1,3:8),
```

```
j = c(2,9,6:10),
x = 7 * (1:7))
stopifnot(all(!is.na(A)))

A[2,3] <- A[1,2] <- A[5, 5:9] <- NA
inA <- is.na(A)
stopifnot(sum(inA) == 1+1+5)
```

---

`is.null.DN`*Are the Dimnames dn NULL-like ?*

---

## Description

Are the `dimnames` `dn` `NULL`-like?

`is.null.DN(dn)` is less strict than `is.null(dn)`, because it is also true (`TRUE`) when the `dimnames dn` are “like” `NULL`, or `list(NULL, NULL)`, as they can easily be for the traditional R matrices (`matrix`) which have no formal `class` definition, and hence much freedom in how their `dimnames` look like.

## Usage

```
is.null.DN(dn)
```

## Arguments

`dn`                    `dimnames()` of a `matrix`-like R object.

## Value

logical `TRUE` or `FALSE`.

## Note

This function is really to be used on “traditional” matrices rather than those inheriting from `Matrix`, as the latter will always have `dimnames list(NULL, NULL)` exactly, in such a case.

## Author(s)

Martin Maechler

## See Also

`is.null`, `dimnames`, `matrix`.

**Examples**

```

m <- matrix(round(100 * rnorm(6)), 2,3); m1 <- m2 <- m3 <- m4 <- m
dimnames(m1) <- list(NULL, NULL)
dimnames(m2) <- list(NULL, character())
dimnames(m3) <- rev(dimnames(m2))
dimnames(m4) <- rep(list(character()),2)

m4 ## prints absolutely identically to m

stopifnot(m == m1, m1 == m2, m2 == m3, m3 == m4,
  identical(capture.output(m) -> cm,
    capture.output(m1)),
  identical(cm, capture.output(m2)),
  identical(cm, capture.output(m3)),
  identical(cm, capture.output(m4)))

```

---

isSymmetric-methods

*Methods for Function isSymmetric in Package 'Matrix'*

---

**Description**

isSymmetric(M) returns a **logical** indicating if M is a symmetric matrix. This (now) is a **base** function with a default method for the traditional matrices of **class** "matrix". Methods here are defined for virtual Matrix classes such that it works for all objects inheriting from class **Matrix**.

**See Also**

[forceSymmetric](#), [symmpart](#), and the formal class (and subclasses) "[symmetricMatrix](#)".

**Examples**

```

isSymmetric(Diagonal(4)) # TRUE of course
M <- Matrix(c(1,2,2,1), 2,2)
isSymmetric(M) # TRUE (*and* of formal class "dsyMatrix")
isSymmetric(as(M, "dgeMatrix")) # still symmetric, even if not "formally"
isSymmetric(triu(M)) # FALSE

## Look at implementations:
showMethods("isSymmetric", includeDefs=TRUE) # "ANY": base's S3 generic; 6 more

```

---

isTriangular

*isTriangular() and isDiagonal() Methods*

---

**Description**

isTriangular(M) returns a **logical** indicating if M is a triangular matrix. Analogously, isDiagonal(M) is true iff M is a diagonal matrix.

Contrary to [isSymmetric\(\)](#), these two functions are generically from package **Matrix**, and hence also define methods for traditional (**class** "matrix") matrices.

By our definition, triangular, diagonal and symmetric matrices are all *square*, i.e. have the same number of rows and columns.

**Usage**

```
isDiagonal(object)

isTriangular(object, upper = NA, ...)
```

**Arguments**

|                     |                                                                                                                                     |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code> | any R object, typically a matrix (traditional or Matrix package).                                                                   |
| <code>upper</code>  | logical, one of NA (default), FALSE, or TRUE where the last two cases require a lower or upper triangular object to result in TRUE. |
| <code>...</code>    | potentially further arguments for other methods.                                                                                    |

**Value**

a (“scalar”) logical, TRUE or FALSE, never NA. For `isTriangular()`, if the result is TRUE, it may contain an attribute (see [attributes](#) "kind", either "L" or "U" indicating if it is a lower or upper triangular matrix.

**See Also**

`isSymmetric`; formal class (and subclasses) `"triangularMatrix"` and `"diagonalMatrix"`.

**Examples**

```
isTriangular(Diagonal(4))
## is TRUE: a diagonal matrix is also (both upper and lower) triangular
(M <- Matrix(c(1,2,0,1), 2,2))
isTriangular(M) # TRUE (*and* of formal class "dtrMatrix")
isTriangular(as(M, "dgeMatrix")) # still triangular, even if not "formally"
isTriangular(crossprod(M)) # FALSE

isDiagonal(matrix(c(2,0,0,1), 2,2)) # TRUE
```

---

KhatriRao

*Khatri-Rao Matrix Product*

---

**Description**

Computes Khatri-Rao products for any kind of matrices.

The Khatri-Rao product is a column-wise Kronecker product. Originally introduced by Khatri and Rao (1968), it has many different applications, see Liu and Trenkler (2008) for a survey. Notably, it is used in higher-dimensional tensor decompositions, see Bader and Kolda (2008).

**Usage**

```
KhatriRao(X, Y = X, FUN = "*", make.dimnames = FALSE)
```

## Arguments

|                            |                                                                                                                                                                       |
|----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>X, Y</code>          | matrices of with the same number of columns.                                                                                                                          |
| <code>FUN</code>           | the (name of the) <a href="#">function</a> to be used for the column-wise Kronecker products, see <a href="#">kronecker</a> , defaulting to the usual multiplication. |
| <code>make.dimnames</code> | logical indicating if the result should inherit <a href="#">dimnames</a> from <code>X</code> and <code>Y</code> in a simple way.                                      |

## Value

a "[CsparseMatrix](#)", say `R`, the Khatri-Rao product of `X` ( $n \times k$ ) and `Y` ( $m \times k$ ), is of dimension  $(n \cdot m) \times k$ , where the  $j$ -th column, `R[,j]` is the kronecker product [kronecker](#)(`X[,j]`, `Y[,j]`).

## Note

The current implementation is efficient for large sparse matrices.

## Author(s)

Original by Michael Cysouw, Univ. Marburg; minor tweaks, bug fixes etc, by Martin Maechler.

           all(KhatRao(d0, m0) == 0), all(KhatRao(m0, m0) == 0),
           identical(dimnames(KhatRao(m, d0, make.dimnames=TRUE)), dimnames(Kmd)))

```

KNex

*Koenker-Ng Example Sparse Model Matrix and Response Vector*

## Description

A model matrix `mm` and corresponding response vector `y` used in an example by Koenker and Ng. The matrix `mm` is a sparse matrix with 1850 rows and 712 columns but only 8758 non-zero entries. It is a "dgCMatrix" object. The vector `y` is just `numeric` of length 1850.

## Usage

```
data(KNex)
```

## References

Roger Koenker and Pin Ng (2003). SparseM: A sparse matrix package for R; *J. of Statistical Software*, **8** (6), doi: [10.18637/jss.v008.i06](https://doi.org/10.18637/jss.v008.i06)

## Examples

```

data(KNex)
class(KNex$mm)
dim(KNex$mm)
image(KNex$mm)
str(KNex)

system.time( # a fraction of a second
  sparse.sol <- with(KNex, solve(crossprod(mm), crossprod(mm, y))))

head(round(sparse.sol, 3))

## Compare with QR-based solution ("more accurate, but slightly slower"):
system.time(
  sp.sol2 <- with(KNex, qr.coef(qr(mm), y) ))

all.equal(sparse.sol, sp.sol2, tolerance = 1e-13) # TRUE

```

---

kronecker-methods    *Methods for Function 'kronecker()' in Package 'Matrix'*

---

## Description

Computes Kronecker products for objects inheriting from "[Matrix](#)".

In order to preserve sparseness, we treat  $0 * NA$  as 0, not as [NA](#) as usually in R (and as used for the base function [kronecker](#)).

## Methods

```
kronecker signature(X = "Matrix", Y = "ANY") .....
kronecker signature(X = "ANY", Y = "Matrix") .....
kronecker signature(X = "diagonalMatrix", Y = "ANY") .....
kronecker signature(X = "sparseMatrix", Y = "ANY") .....
kronecker signature(X = "TsparseMatrix", Y = "TsparseMatrix") .....
kronecker signature(X = "dgTMatrix", Y = "dgTMatrix") .....
kronecker signature(X = "dtTMatrix", Y = "dtTMatrix") .....
kronecker signature(X = "indMatrix", Y = "indMatrix") .....
```

## Examples

```
(t1 <- spMatrix(5,4, x= c(3,2,-7,11), i= 1:4, j=4:1)) # 5 x 4
(t2 <- kronecker(Diagonal(3, 2:4), t1))                # 15 x 12

## should also work with special-cased logical matrices
l3 <- upper.tri(matrix(,3,3))
M <- Matrix(l3)
(N <- as(M, "nsparseMatrix")) # "ntCMatrix" (upper triangular)
N2 <- as(N, "generalMatrix")  # (lost "t"riangularity)
MM <- kronecker(M,M)
NN <- kronecker(N,N) # "dtTMatrix" i.e. did keep
NN2 <- kronecker(N2,N2)
stopifnot(identical(NN,MM),
           is(NN2, "sparseMatrix"), all(NN2 == NN),
           is(NN, "triangularMatrix"))
```

---

ldenseMatrix-class    *Virtual Class "ldenseMatrix" of Dense Logical Matrices*

---

## Description

[ldenseMatrix](#) is the virtual class of all dense logical (S4) matrices. It extends both [denseMatrix](#) and [lMatrix](#) directly.

## Slots

**x:** logical vector containing the entries of the matrix.

**Dim, Dimnames:** see [Matrix](#).

**Extends**

Class "lMatrix", directly. Class "denseMatrix", directly. Class "Matrix", by class "lMatrix". Class "Matrix", by class "denseMatrix".

**Methods**

**coerce** signature(from = "matrix", to = "ldenseMatrix"): ...  
**coerce** signature(from = "ldenseMatrix", to = "matrix"): ...  
**as.vector** signature(x = "ldenseMatrix", mode = "missing"): ...  
**which** signature(x = "ndenseMatrix"), semantically equivalent to **base** function `which(x, arr.ind)`; for details, see the [lMatrix](#) class documentation.

**See Also**

Class [lgeMatrix](#) and the other subclasses.

**Examples**

```
showClass("ldenseMatrix")

as(diag(3) > 0, "ldenseMatrix")
```

---

lDiMatrix-class

---

Class "lDiMatrix" of Diagonal Logical Matrices

---

**Description**

The class "lDiMatrix" of logical diagonal matrices.

**Objects from the Class**

Objects can be created by calls of the form `new("lDiMatrix", ...)` but typically rather via [Diagonal](#).

**Slots**

**x**: "logical" vector.  
**diag**: "character" string, either "U" or "N", see [ddiMatrix](#).  
**Dim, Dimnames**: matrix dimension and **dimnames**, see the [Matrix](#) class description.

**Extends**

Class "[diagonalMatrix](#)" and class "[lMatrix](#)", directly.  
Class "[sparseMatrix](#)", by class "diagonalMatrix".

**See Also**

Classes [ddiMatrix](#) and [diagonalMatrix](#); function [Diagonal](#).

**Examples**

```
(lM <- Diagonal(x = c(TRUE,FALSE,FALSE)))
str(lM) #> gory details (slots)

crossprod(lM) # numeric
(nM <- as(lM, "nMatrix")) # -> sparse (not formally ``diagonal'')
crossprod(nM) # logical sparse
```

---

|                 |                                                            |
|-----------------|------------------------------------------------------------|
| lgeMatrix-class | <i>Class "lgeMatrix" of General Dense Logical Matrices</i> |
|-----------------|------------------------------------------------------------|

---

**Description**

This is the class of general dense [logical](#) matrices.

**Slots**

**x:** Object of class "logical". The logical values that constitute the matrix, stored in column-major order.

**Dim,Dimnames:** The dimension (a length-2 "integer") and corresponding names (or NULL), see the [Matrix](#) class.

**factors:** Object of class "list". A named list of factorizations that have been computed for the matrix.

**Extends**

Class "ldenseMatrix", directly. Class "lMatrix", by class "ldenseMatrix". Class "denseMatrix", by class "ldenseMatrix". Class "Matrix", by class "ldenseMatrix". Class "Matrix", by class "ldenseMatrix".

**Methods**

Currently, mainly [t\(\)](#) and coercion methods (for [as\(.\)](#)); use, e.g., [showMethods](#)(class="lgeMatrix") for details.

**See Also**

Non-general logical dense matrix classes such as [ltrMatrix](#), or [lsyMatrix](#); *sparse* logical classes such as [lgCMatrix](#).

**Examples**

```
showClass("lgeMatrix")
str(new("lgeMatrix"))
set.seed(1)
(lM <- Matrix(matrix(rnorm(28), 4,7) > 0)) # a simple random lgeMatrix
set.seed(11)
(lC <- Matrix(matrix(rnorm(28), 4,7) > 0)) # a simple random lgCMatrix
as(lM, "lgCMatrix")
```

---

lsparseMatrix-classes

*Sparse logical matrices*

---

## Description

The `lsparseMatrix` class is a virtual class of sparse matrices with TRUE/FALSE or NA entries. Only the positions of the elements that are TRUE are stored.

These can be stored in the “triplet” form (class `TsparseMatrix`, subclasses `lgTMatrix`, `lsTMatrix`, and `ltTMatrix`) or in compressed column-oriented form (class `CsparseMatrix`, subclasses `lgCMatrix`, `lsCMatrix`, and `ltCMatrix`) or—rarely—in compressed row-oriented form (class `RsparseMatrix`, subclasses `lgRMatrix`, `lsRMatrix`, and `ltRMatrix`). The second letter in the name of these non-virtual classes indicates general, symmetric, or triangular.

## Details

Note that triplet stored (`TsparseMatrix`) matrices such as `lgTMatrix` may contain duplicated pairs of indices  $(i, j)$  as for the corresponding numeric class `dgTMatrix` where for such pairs, the corresponding `x` slot entries are added. For logical matrices, the `x` entries corresponding to duplicated index pairs  $(i, j)$  are “added” as well if the addition is defined as logical *or*, i.e., “TRUE + TRUE  $\rightarrow$  TRUE” and “TRUE + FALSE  $\rightarrow$  TRUE”. Note the use of `uniqTsparse()` for getting an internally unique representation without duplicated  $(i, j)$  entries.

## Objects from the Class

Objects can be created by calls of the form `new("lgCMatrix", ...)` and so on. More frequently objects are created by coercion of a numeric sparse matrix to the logical form, e.g. in an expression `x != 0`.

The logical form is also used in the symbolic analysis phase of an algorithm involving sparse matrices. Such algorithms often involve two phases: a symbolic phase wherein the positions of the non-zeros in the result are determined and a numeric phase wherein the actual results are calculated. During the symbolic phase only the positions of the non-zero elements in any operands are of interest, hence any numeric sparse matrices can be treated as logical sparse matrices.

## Slots

- x:** Object of class "logical", i.e., either TRUE, NA, or FALSE.
- uplo:** Object of class "character". Must be either "U", for upper triangular, and "L", for lower triangular. Present in the triangular and symmetric classes but not in the general class.
- diag:** Object of class "character". Must be either "U", for unit triangular (diagonal is all ones), or "N" for non-unit. The implicit diagonal elements are not explicitly stored when `diag` is "U". Present in the triangular classes only.
- p:** Object of class "integer" of pointers, one for each column (row), to the initial (zero-based) index of elements in the column. Present in compressed column-oriented and compressed row-oriented forms only.
- i:** Object of class "integer" of length `nnzero` (number of non-zero elements). These are the row numbers for each TRUE element in the matrix. All other elements are FALSE. Present in triplet and compressed column-oriented forms only.

**j**: Object of class "integer" of length nnzero (number of non-zero elements). These are the column numbers for each TRUE element in the matrix. All other elements are FALSE. Present in triplet and compressed row-oriented forms only.

**Dim**: Object of class "integer" - the dimensions of the matrix.

## Methods

**coerce** signature (from = "dgCMatrix", to = "lgCMatrix")

**t** signature (x = "lgCMatrix"): returns the transpose of x

**which** signature (x = "lsparseMatrix"), semantically equivalent to **base** function `which(x, arr.ind)`; for details, see the `lMatrix` class documentation.

## See Also

the class `dgCMatrix` and `dgTMatrix`

## Examples

```
(m <- Matrix(c(0,0,2:0), 3,5, dimnames=list(LETTERS[1:3],NULL)))
(lm <- (m > 1)) # lgC
!lm           # no longer sparse
stopifnot(is(lm,"lsparseMatrix"),
           identical(!lm, m <= 1))

data(KNex)
str(mmG.1 <- (KNex $ mm) > 0.1) # "lgC..."
table(mmG.1@x) # however with many ``non-structural zeros''
## from logical to nz_pattern -- okay when there are no NA's :
nmG.1 <- as(mmG.1, "nMatrix") # <<< has "TRUE" also where mmG.1 had FALSE
## from logical to "double"
dmG.1 <- as(mmG.1, "dMatrix") # has '0' and back:
lmG.1 <- as(dmG.1, "lMatrix") # has no extra FALSE, i.e. drop0() included
stopifnot(identical(nmG.1, as((KNex $ mm) != 0, "nMatrix")),
           validObject(lmG.1), all(lmG.1@x),
           # same "logical" but lmG.1 has no 'FALSE' in x slot:
           all(lmG.1 == mmG.1))

class(xnx <- crossprod(nmG.1)) # "nsC.."
class(xlx <- crossprod(mmG.1)) # "dsC.." : numeric
is0 <- (xlx == 0)
mean(as.vector(is0)) # 99.3% zeros: quite sparse, but
table(xlx@x == 0) # more than half of the entries are (non-structural!) 0
stopifnot(isSymmetric(xlx), isSymmetric(xnx),
           ## compare xnx and xlx : have the *same* non-structural 0s :
           sapply(slotNames(xnx),
                   function(n) identical(slot(xnx, n), slot(xlx, n)))))
```

## Description

The "lsyMatrix" class is the class of symmetric, dense logical matrices in non-packed storage and "lspMatrix" is the class of these in packed storage. In the packed form, only the upper triangle or the lower triangle is stored.

## Objects from the Class

Objects can be created by calls of the form `new("lsyMatrix", ...)`.

## Slots

**uplo:** Object of class "character". Must be either "U", for upper triangular, and "L", for lower triangular.

**x:** Object of class "logical". The logical values that constitute the matrix, stored in column-major order.

**Dim,Dimnames:** The dimension (a length-2 "integer") and corresponding names (or NULL), see the [Matrix](#) class.

**factors:** Object of class "list". A named list of factorizations that have been computed for the matrix.

## Extends

Both extend classes "[ldenseMatrix](#)" and "[symmetricMatrix](#)", directly; further, class "[Matrix](#)" and others, indirectly. Use `showClass("lsyMatrix")`, e.g., for details.

## Methods

Currently, mainly `t()` and coercion methods (for `as(.)`; use, e.g., `showMethods(class="dsyMatrix")` for details.

## See Also

[lgeMatrix](#), [Matrix](#), [t](#)

## Examples

```
(M2 <- Matrix(c(TRUE, NA,FALSE,FALSE), 2,2)) # logical dense (ltr)
str(M2)
# can
(sM <- M2 | t(M2)) # "lge"
as(sM, "lsyMatrix")
str(sM <- as(sM, "lspMatrix")) # packed symmetric
```

---

ltrMatrix-class      *Triangular Dense Logical Matrices*

---

## Description

The "ltrMatrix" class is the class of triangular, dense, logical matrices in nonpacked storage. The "ltpMatrix" class is the same except in packed storage.

## Slots

**x:** Object of class "logical". The logical values that constitute the matrix, stored in column-major order.

**uplo:** Object of class "character". Must be either "U", for upper triangular, and "L", for lower triangular.

**diag:** Object of class "character". Must be either "U", for unit triangular (diagonal is all ones), or "N"; see [triangularMatrix](#).

**Dim,Dimnames:** The dimension (a length-2 "integer") and corresponding names (or NULL), see the [Matrix](#) class.

**factors:** Object of class "list". A named list of factorizations that have been computed for the matrix.

## Extends

Both extend classes "[ldenseMatrix](#)" and "[triangularMatrix](#)", directly; further, class "[Matrix](#)", "[lMatrix](#)" and others, indirectly. Use [showClass](#)("ltrMatrix"), e.g., for details.

## Methods

Currently, mainly [t\(\)](#) and coercion methods (for [as\(.\)](#); use, e.g., [showMethods](#)(class="ltpMatrix") for details.

## See Also

Classes [lgeMatrix](#), [Matrix](#); function [t](#)

## Examples

```
showClass("ltrMatrix")

str(new("ltpMatrix"))
(lutr <- as(upper.tri(matrix(,4,4)), "ltrMatrix"))
str(lutp <- as(lutr, "ltpMatrix"))# packed matrix: only 10 = (4+1)*4/2 entries
!lutp ## the logical negation (is *not* logical triangular !)
## but this one is:
stopifnot(all.equal(lutp, as(!lutp, "ltpMatrix")))
```

lu

*(Generalized) Triangular Decomposition of a Matrix***Description**

Computes (generalized) triangular decompositions of square (sparse or dense) and non-square dense matrices.

**Usage**

```
lu(x, ...)
## S4 method for signature 'matrix'
lu(x, warnSing = TRUE, ...)
## S4 method for signature 'dgeMatrix'
lu(x, warnSing = TRUE, ...)
## S4 method for signature 'dgCMatrix'
lu(x, errSing = TRUE, order = TRUE, tol = 1,
   keep.dimnames = TRUE, ...)
```

**Arguments**

|                            |                                                                                                                                                                                                                                                                                                                                                                                |
|----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>             | a dense or sparse matrix, in the latter case of square dimension. No missing values or IEEE special values are allowed.                                                                                                                                                                                                                                                        |
| <code>warnSing</code>      | (when <code>x</code> is a " <a href="#">denseMatrix</a> ") logical specifying if a <a href="#">warning</a> should be signalled when <code>x</code> is singular.                                                                                                                                                                                                                |
| <code>errSing</code>       | (when <code>x</code> is a " <a href="#">sparseMatrix</a> ") logical specifying if an error (see <a href="#">stop</a> ) should be signalled when <code>x</code> is singular. When <code>x</code> is singular, <code>lu(x, errSing=FALSE)</code> returns <a href="#">NA</a> instead of an LU decomposition. No warning is signalled and the user should be careful in that case. |
| <code>order</code>         | logical or integer, used to choose which fill-reducing permutation technique will be used internally. Do not change unless you know what you are doing.                                                                                                                                                                                                                        |
| <code>tol</code>           | positive number indicating the pivoting tolerance used in <code>cs_lu</code> . Do only change with much care.                                                                                                                                                                                                                                                                  |
| <code>keep.dimnames</code> | logical indicating that <a href="#">dimnames</a> should be propagated to the result, i.e., “kept”. This was hardcoded to <code>FALSE</code> in upto <b>Matrix</b> version 1.2-0. Setting to <code>FALSE</code> may gain some performance.                                                                                                                                      |
| <code>...</code>           | further arguments passed to or from other methods.                                                                                                                                                                                                                                                                                                                             |

**Details**

`lu()` is a generic function with special methods for different types of matrices. Use [showMethods](#)("`lu`") to list all the methods for the `lu` generic.

The method for class [dgeMatrix](#) (and all dense matrices) is based on LAPACK's "`dgetrf`" subroutine. It returns a decomposition also for singular and non-square matrices.

The method for class [dgCMatrix](#) (and all sparse matrices) is based on functions from the CSparse library. It signals an error (or returns `NA`, when `errSing = FALSE`, see above) when the decomposition algorithm fails, as when `x` is (too close to) singular.

**Value**

An object of class "LU", i.e., "[denseLU](#)" (see its separate help page), or "[sparseLU](#)", see [sparseLU](#); this is a representation of a triangular decomposition of  $x$ .

**Note**

Because the underlying algorithm differ entirely, in the *dense* case (class [denseLU](#)), the decomposition is

$$A = PLU,$$

where as in the *sparse* case (class [sparseLU](#)), it is

$$A = P'LUQ.$$

**Examples**

```
##--- Dense -----
x <- Matrix(rnorm(9), 3, 3)
lu(x)
dim(x2 <- round(10 * x[, -3])) # non-square
expand(lu2 <- lu(x2))

##--- Sparse (see more in ?"sparseLU-class")----- % ./sparseLU-class.Rd

pm <- as(readMM(system.file("external/pores_1.mtx",
                           package = "Matrix")),
         "CsparseMatrix")
str(pmLU <- lu(pm)) # p is a 0-based permutation of the rows
                   # q is a 0-based permutation of the columns
## permute rows and columns of original matrix
ppm <- pm[pmLU@p + 1L, pmLU@q + 1L]
pLU <- drop0(pmLU@L %*% pmLU@U) # L %*% U -- dropping extra zeros
## equal up to "rounding"
ppm[1:14, 1:5]
pLU[1:14, 1:5]
```

LU-class

*LU (dense) Matrix Decompositions***Description**

The "LU" class is the *virtual* class of LU decompositions of real matrices. "denseLU" the class of LU decompositions of dense real matrices.

**Details**

The decomposition is of the form

$$A = PLU$$

where typically all matrices are of size  $n \times n$ , and the matrix  $P$  is a permutation matrix,  $L$  is lower triangular and  $U$  is upper triangular (both of class [dtrMatrix](#)).

Note that the *dense* decomposition is also implemented for a  $m \times n$  matrix  $A$ , when  $m \neq n$ .

If  $m < n$  ("wide case"),  $U$  is  $m \times n$ , and hence not triangular.

If  $m > n$  ("long case"),  $L$  is  $m \times n$ , and hence not triangular.

**Objects from the Class**

Objects can be created by calls of the form `new("denseLU", ...)`. More commonly the objects are created explicitly from calls of the form `lu(mm)` where `mm` is an object that inherits from the "dgeMatrix" class or as a side-effect of other functions applied to "dgeMatrix" objects.

**Extends**

"LU" directly extends the virtual class "MatrixFactorization".

"denseLU" directly extends "LU".

**Slots**

**x:** object of class "numeric". The "L" (unit lower triangular) and "U" (upper triangular) factors of the original matrix. These are stored in a packed format described in the Lapack manual, and can retrieved by the `expand()` method, see below.

**perm:** Object of class "integer" - a vector of length `min(Dim)` that describes the permutation applied to the rows of the original matrix. The contents of this vector are described in the Lapack manual.

**Dim:** the dimension of the original matrix; inherited from class [MatrixFactorization](#).

**Methods**

**expand** signature(`x = "denseLU"`): Produce the "L" and "U" (and "P") factors as a named list of matrices, see also the example below.

**solve** signature(`a = "denseLU"`, `b = "missing"`): Compute the inverse of  $A$ ,  $A^{-1}$ , `solve(A)` using the LU decomposition, see also [solve-methods](#).

**See Also**

class [sparseLU](#) for LU decompositions of *sparse* matrices; further, class [dgeMatrix](#) and functions [lu](#), [expand](#).

## Examples

```
set.seed(1)
mm <- Matrix(round(rnorm(9),2), nrow = 3)
mm
str(lum <- lu(mm))
elu <- expand(lum)
elu # three components: "L", "U", and "P", the permutation
elu$L %*% elu$U
(m2 <- with(elu, P %*% L %*% U)) # the same as 'mm'
stopifnot(all.equal(as(mm, "matrix"),
                    as(m2, "matrix")))
```

---

mat2triplet

---

*Map Matrix to its Triplet Representation*

---

## Description

From an R object coercible to `"TsparseMatrix"`, typically a (sparse) matrix, produce its triplet representation which may collapse to a “Duplet” in the case of binary aka pattern, such as `"nMatrix"` objects.

## Usage

```
mat2triplet(x, uniqT = FALSE)
```

## Arguments

|                    |                                                                                                                                                 |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>     | any R object for which <code>as(x, "TsparseMatrix")</code> works; typically a <code>matrix</code> of one of the <b>Matrix</b> package matrices. |
| <code>uniqT</code> | <code>logical</code> indicating if the triplet representation should be ‘unique’ in the sense of <code>uniqTsparse()</code> .                   |

## Value

A `list`, typically with three components,

|                |                                                                                                                                                               |
|----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>i</code> | vector of row indices for all non-zero entries of <code>x</code>                                                                                              |
| <code>j</code> | vector of columns indices for all non-zero entries of <code>x</code>                                                                                          |
| <code>x</code> | vector of all non-zero entries of <code>x</code> ; exists <b>only</b> when <code>as(x, "TsparseMatrix")</code> is <b>not</b> a <code>"nsparseMatrix"</code> . |

Note that the `order` of the entries is determined by the coercion to `"TsparseMatrix"` and hence typically with increasing `j` (and increasing `i` within ties of `j`).

## Note

The `mat2triplet()` utility was created to be a more efficient and more predictable substitute for `summary(<sparseMatrix>)`. UseRs have wrongly expected the latter to return a data frame with columns `i` and `j` which however is wrong for a `"diagonalMatrix"`.

See Also

The `summary()` method for "sparseMatrix", [summary, sparseMatrix-method](#).  
`mat2triplet()` is conceptually the *inverse* function of [spMatrix](#) and (one case of) [sparseMatrix](#).

Examples

```
if(FALSE) ## The function is defined (don't redefine here!), simply as
mat2triplet <- function(x, uniqT = FALSE) {
  T <- as(x, "TsparseMatrix")
  if(uniqT && anyDuplicatedT(T)) T <- .uniqTsparse(T)
  if(is(T, "nsparseMatrix"))
    list(i = T@i + 1L, j = T@j + 1L)
  else list(i = T@i + 1L, j = T@j + 1L, x = T@x)
}

i <- c(1,3:8); j <- c(2,9,6:10); x <- 7 * (1:7)
(Ax <- sparseMatrix(i, j, x = x)) ## 8 x 10 "dgCMatrix"
str(trA <- mat2triplet(Ax))
stopifnot(i == sort(trA$i), sort(j) == trA$j, x == sort(trA$x))

D <- Diagonal(x=4:2)
summary(D)
str(mat2triplet(D))
```

---

|        |                                   |
|--------|-----------------------------------|
| Matrix | <i>Construct a Classed Matrix</i> |
|--------|-----------------------------------|

---

Description

Construct a Matrix of a class that inherits from `Matrix`.

Usage

```
Matrix(data=NA, nrow=1, ncol=1, byrow=FALSE, dimnames=NULL,
        sparse = NULL, doDiag = TRUE, forceCheck = FALSE)
```

Arguments

|                       |                                                                                                                                                          |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>data</code>     | an optional numeric data vector or matrix.                                                                                                               |
| <code>nrow</code>     | when data is not a matrix, the desired number of rows                                                                                                    |
| <code>ncol</code>     | when data is not a matrix, the desired number of columns                                                                                                 |
| <code>byrow</code>    | logical. If <code>FALSE</code> (the default) the matrix is filled by columns, otherwise the matrix is filled by rows.                                    |
| <code>dimnames</code> | a <a href="#">dimnames</a> attribute for the matrix: a list of two character components. They are set if not <code>NULL</code> (as per default).         |
| <code>sparse</code>   | logical or <code>NULL</code> , specifying if the result should be sparse or not. By default, it is made sparse when more than half of the entries are 0. |

|                         |                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>doDiag</code>     | logical indicating if a <code>diagonalMatrix</code> object should be returned when the resulting matrix is diagonal ( <i>mathematically</i> ). As class <code>diagonalMatrix</code> extends <code>sparseMatrix</code> , this is a natural default for all values of <code>sparse</code> . Otherwise, if <code>doDiag</code> is false, a dense or sparse (depending on <code>sparse</code> ) <i>symmetric</i> matrix will be returned. |
| <code>forceCheck</code> | logical indicating if the checks for structure should even happen when data is already a "Matrix" object.                                                                                                                                                                                                                                                                                                                             |

### Details

If either of `nrow` or `ncol` is not given, an attempt is made to infer it from the length of `data` and the other parameter. Further, `Matrix()` makes efforts to keep `logical` matrices logical, i.e., inheriting from class `lMatrix`, and to determine specially structured matrices such as symmetric, triangular or diagonal ones. Note that a *symmetric* matrix also needs symmetric `dimnames`, e.g., by specifying `dimnames = list(NULL, NULL)`, see the examples.

Most of the time, the function works via a traditional (*full*) `matrix`. However, `Matrix(0, nrow, ncol)` directly constructs an “empty” `sparseMatrix`, as does `Matrix(FALSE, *)`.

Although it is sometime possible to mix unclassed matrices (created with `matrix`) with ones of class "Matrix", it is much safer to always use carefully constructed ones of class "Matrix".

### Value

Returns matrix of a class that inherits from "Matrix". Only if `data` is not a `matrix` and does not already inherit from class `Matrix` are the arguments `nrow`, `ncol` and `byrow` made use of.

### See Also

The classes `Matrix`, `symmetricMatrix`, `triangularMatrix`, and `diagonalMatrix`; further, `matrix`.

Special matrices can be constructed, e.g., via `sparseMatrix` (`sparse`), `bdiag` (block-diagonal), `bandSparse` (banded sparse), or `Diagonal`.

### Examples

```
Matrix(0, 3, 2)           # 3 by 2 matrix of zeros -> sparse
Matrix(0, 3, 2, sparse=FALSE) # -> 'dense'

## 4 cases - 3 different results :
Matrix(0, 2, 2)           # diagonal !
Matrix(0, 2, 2, sparse=FALSE) # (ditto)
Matrix(0, 2, 2, doDiag=FALSE) # -> sparse symm. "dsCMatrix"
Matrix(0, 2, 2, sparse=FALSE, doDiag=FALSE) # -> dense symm. "dsyMatrix"

Matrix(1:6, 3, 2)         # a 3 by 2 matrix (+ integer warning)
Matrix(1:6 + 1, nrow=3)

## logical ones:
Matrix(diag(4) > 0) # -> "ldiMatrix" with diag = "U"
Matrix(diag(4) > 0, sparse=TRUE) # (ditto)
Matrix(diag(4) >= 0) # -> "lsyMatrix" (of all 'TRUE')
## triangular
l3 <- upper.tri(matrix(,3,3))
(M <- Matrix(l3)) # -> "ltCMatrix"
```

```

Matrix(! 13)          # -> "ltrMatrix"
as(13, "CsparseMatrix")# "lgCMatrix"

Matrix(1:9, nrow=3,
       dimnames = list(c("a", "b", "c"), c("A", "B", "C")))
(I3 <- Matrix(diag(3)))# identity, i.e., unit "diagonalMatrix"
str(I3) # note 'diag = "U"' and the empty 'x' slot

(A <- cbind(a=c(2,1), b=1:2))# symmetric *apart* from dimnames
Matrix(A)                  # hence 'dgeMatrix'
(As <- Matrix(A, dimnames = list(NULL,NULL)))# -> symmetric
forceSymmetric(A) # also symmetric, w/ symm. dimnames
stopifnot(is(As, "symmetricMatrix"),
           is(Matrix(0, 3,3), "sparseMatrix"),
           is(Matrix(FALSE, 1,1), "sparseMatrix"))

```

Matrix-class

Virtual Class "Matrix" Class of Matrices

## Description

The `Matrix` class is a class contained by all actual classes in the **Matrix** package. It is a “virtual” class.

## Slots

Common to *all* matrix objects in the package:

**Dim:** Object of class "integer" - the dimensions of the matrix - must be an integer vector with exactly two non-negative values.

**Dimnames:** list of length two; each component containing NULL or a [character](#) vector length equal the corresponding `Dim` element.

## Methods

**determinant** signature(x = "Matrix", logarithm = "missing"): and

**determinant** signature(x = "Matrix", logarithm = "logical"): compute the (log) determinant of x. The method chosen depends on the actual `Matrix` class of x. Note that [det](#) also works for all our matrices, calling the appropriate `determinant()` method. The `Matrix::det` is an exact copy of `base::det`, but in the correct namespace, and hence calling the S4-aware version of `determinant()`.

**diff** signature(x = "Matrix"): As [diff\(\)](#) for traditional matrices, i.e., applying `diff()` to each column.

**dim** signature(x = "Matrix"): extract matrix dimensions [dim](#).

**dim<-** signature(x = "Matrix", value = "ANY"): where value is integer of length 2. Allows to *reshape* `Matrix` objects, but only when `prod(value) == prod(dim(x))`.

**dimnames** signature(x = "Matrix"): extract [dimnames](#).

**dimnames<-** signature(x = "Matrix", value = "list"): set the `dimnames` to a [list](#) of length 2, see [dimnames<-](#).

**length** signature(x = "Matrix"): simply defined as `prod(dim(x))` (and hence of mode "double").

**show** signature(object = "Matrix"): [show](#) method for [printing](#). For printing *sparse* matrices, see [printSpMatrix](#).

**image** signature(object = "Matrix"): draws an [image](#) of the matrix entries, using [levelplot\(\)](#) from package [lattice](#).

**head** signature(object = "Matrix"): return only the “*head*”, i.e., the first few rows.

**tail** signature(object = "Matrix"): return only the “*tail*”, i.e., the last few rows of the respective matrix.

**as.matrix, as.array** signature(x = "Matrix"): the same as `as(x, "matrix")`; see also the note below.

**as.vector** signature(x = "Matrix", mode = "missing"): `as.vector(m)` should be identical to `as.vector(as(m, "matrix"))`, implemented more efficiently for some subclasses.

`as(x, "vector")`, `as(x, "numeric")` etc, similarly.

**coerce** signature(from = "ANY", to = "Matrix"): This relies on a correct [as.matrix\(\)](#) method for from.

There are many more methods that (conceptually should) work for all "Matrix" objects, e.g., [colSums](#), [rowMeans](#). Even **base** functions may work automatically (if they first call [as.matrix\(\)](#) on their principal argument), e.g., [apply](#), [eigen](#), [svd](#) or [kappa](#) all do work via coercion to a “traditional” (dense) [matrix](#).

## Note

Loading the `Matrix` namespace “overloads” [as.matrix](#) and [as.array](#) in the **base** namespace by the equivalent of `function(x) as(x, "matrix")`. Consequently, `as.matrix(m)` or `as.array(m)` will properly work when `m` inherits from the "Matrix" class — *also* for functions in package **base** and other packages. E.g., [apply](#) or [outer](#) can therefore be applied to "Matrix" matrices.

## See Also

the classes [dgeMatrix](#), [dgCMatrix](#), and function [Matrix](#) for construction (and examples).  
Methods, e.g., for [kronecker](#).

## Examples

```
slotNames("Matrix")

cl <- getClass("Matrix")
names(cl@subclasses) # more than 40 ..

showClass("Matrix")#> output with slots and all subclasses

(M <- Matrix(c(0,1,0,0), 6, 4))
dim(M)
diag(M)
cm <- M[1:4,] + 10*Diagonal(4)
diff(M)
```

```
## can reshape it even :
dim(M) <- c(2, 12)
M
stopifnot(identical(M, Matrix(c(0,1,0,0), 2,12)),
           all.equal(det(cm),
                      determinant(as(cm,"matrix"), log=FALSE)$modulus,
                      check.attributes=FALSE))
```

|                 |                                               |
|-----------------|-----------------------------------------------|
| matrix-products | <i>Matrix (Cross) Products (of Transpose)</i> |
|-----------------|-----------------------------------------------|

---

## Description

The basic matrix product, `%%` is implemented for all our [Matrix](#) and also for [sparseVector](#) classes, fully analogously to R's base `matrix` and vector objects.

The functions `crossprod` and `tcrossprod` are matrix products or “cross products”, ideally implemented efficiently without computing `t(.)`'s unnecessarily. They also return [symmetricMatrix](#) classed matrices when easily detectable, e.g., in `crossprod(m)`, the one argument case.

`tcrossprod()` takes the cross-product of the transpose of a matrix. `tcrossprod(x)` is formally equivalent to, but faster than, the call `x %*% t(x)`, and so is `tcrossprod(x, y)` instead of `x %*% t(y)`.

*Boolean* matrix products are computed via either `%&%` or `boolArith = TRUE`.

## Usage

```
## S4 method for signature 'CsparseMatrix,diagonalMatrix'
x %*% y

## S4 method for signature 'dgeMatrix,missing'
crossprod(x, y = NULL, boolArith = NA, ...)
## S4 method for signature 'CsparseMatrix,diagonalMatrix'
crossprod(x, y = NULL, boolArith = NA, ...)
## .... and for many more signatures

## S4 method for signature 'CsparseMatrix,ddenseMatrix'
tcrossprod(x, y = NULL, boolArith = NA, ...)
## S4 method for signature 'TsparseMatrix,missing'
tcrossprod(x, y = NULL, boolArith = NA, ...)
## .... and for many more signatures
```

## Arguments

|                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>         | a matrix-like object                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <code>y</code>         | a matrix-like object, or for <code>[t]crossprod()</code> <code>NULL</code> (by default); the latter case is formally equivalent to <code>y = x</code> .                                                                                                                                                                                                                                                                                                                                               |
| <code>boolArith</code> | <a href="#">logical</a> , i.e., <code>NA</code> , <code>TRUE</code> , or <code>FALSE</code> . If true the result is (coerced to) a pattern matrix, i.e., <code>"nMatrix"</code> , unless there are <code>NA</code> entries and the result will be a <code>"lMatrix"</code> . If false the result is (coerced to) numeric. When <code>NA</code> , currently the default, the result is a pattern matrix when <code>x</code> and <code>y</code> are <code>"nsparseMatrix"</code> and numeric otherwise. |
| <code>...</code>       | potentially more arguments passed to and from methods.                                                                                                                                                                                                                                                                                                                                                                                                                                                |

## Details

For some classes in the `Matrix` package, such as `dgCMatrix`, it is much faster to calculate the cross-product of the transpose directly instead of calculating the transpose first and then its cross-product.

`boolArith = TRUE` for regular (“non cross”) matrix products, `%%` cannot be specified. Instead, we provide the `%&%` operator for *boolean* matrix products.

## Value

A `Matrix` object, in the one argument case of an appropriate *symmetric* matrix class, i.e., inheriting from `symmetricMatrix`.

## Methods

`%%` signature (`x = "dgeMatrix"`, `y = "dgeMatrix"`): `Matrix` multiplication; ditto for several other signature combinations, see `showMethods("%*", class = "dgeMatrix")`.

`%%` signature (`x = "dtrMatrix"`, `y = "matrix"`) and other signatures (use `showMethods("%*", class = "dtrMatrix")`): matrix multiplication. Multiplication of (matching) triangular matrices now should remain triangular (in the sense of class `triangularMatrix`).

**crossprod** signature (`x = "dgeMatrix"`, `y = "dgeMatrix"`): ditto for several other signatures, use `showMethods("crossprod", class = "dgeMatrix")`, matrix crossproduct, an efficient version of `t(x) %*% y`.

**crossprod** signature (`x = "CsparseMatrix"`, `y = "missing"`) returns `t(x) %*% x` as an `dsCMatrix` object.

**crossprod** signature (`x = "TsparseMatrix"`, `y = "missing"`) returns `t(x) %*% x` as an `dsCMatrix` object.

**crossprod, tcrossprod** signature (`x = "dtrMatrix"`, `y = "matrix"`) and other signatures, see `"%*%"` above.

## Note

`boolArith = TRUE`, `FALSE` or `NA` has been newly introduced for **Matrix** 1.2.0 (March 2015). Its implementation may be incomplete and partly missing. Please report such omissions if detected!

Currently, `boolArith = TRUE` is implemented via `CsparseMatrix` coercions which may be quite inefficient for dense matrices. Contributions for efficiency improvements are welcome.

## See Also

`tcrossprod` in R's base, `crossprod` and `%%`.

## Examples

```
## A random sparse "incidence" matrix :
m <- matrix(0, 400, 500)
set.seed(12)
m[runif(314, 0, length(m))] <- 1
mm <- as(m, "dgCMatrix")
object.size(m) / object.size(mm) # smaller by a factor of > 200
```

```
## tcrossprod() is very fast:
system.time(tCmm <- tcrossprod(mm)) # 0      (PIII, 933 MHz)
system.time(cm <- crossprod(t(m))) # 0.16
system.time(cm. <- tcrossprod(m))  # 0.02

stopifnot(cm == as(tCmm, "matrix"))

## show sparse sub matrix
tCmm[1:16, 1:30]
```

MatrixClass

*The Matrix (Super-) Class of a Class*

## Description

Return the (maybe super-)class of class `cl` from package **Matrix**, returning `character(0)` if there is none.

## Usage

```
MatrixClass(cl, cld = getClassDef(cl), ...Matrix = TRUE,
            dropVirtual = TRUE, ...)
```

## Arguments

|                          |                                                                                                                                               |
|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------|
| <code>cl</code>          | string, class name                                                                                                                            |
| <code>cld</code>         | its class definition                                                                                                                          |
| <code>...Matrix</code>   | <code>logical</code> indicating if the result must be of pattern "[dlniz]..Matrix" where the first letter "[dlniz]" denotes the content kind. |
| <code>dropVirtual</code> | <code>logical</code> indicating if virtual classes are included or not.                                                                       |
| <code>...</code>         | further arguments are passed to <code>.selectSuperClasses()</code> .                                                                          |

## Value

a `character` string

## Author(s)

Martin Maechler, 24 Mar 2009

```

---

MatrixFactorization-class

*Class "MatrixFactorization" of Matrix Factorizations*

---

## Description

The class "MatrixFactorization" is the virtual (super) class of (potentially) all matrix factorizations of matrices from package **Matrix**.

The class "CholeskyFactorization" is the virtual class of all Cholesky decompositions from **Matrix** (and trivial sub class of "MatrixFactorization").

## Objects from the Class

A virtual Class: No objects may be created from it.

## Slots

**Dim:** Object of class "integer" - the dimensions of the original matrix - must be an integer vector with exactly two non-negative values.

## Methods

**dim** (x) simply returns x@Dim, see above.

**expand** signature (x = "MatrixFactorization"): this has not been implemented yet for all matrix factorizations. It should return a list whose components are matrices which when multiplied return the original [Matrix](#) object.

**show** signature (object = "MatrixFactorization"): simple printing, see [show](#).

**solve** signature (a = "MatrixFactorization", b = .): solve  $Ax = b$  for  $x$ ; see [solve-methods](#).

## See Also

classes inheriting from "MatrixFactorization", such as [LU](#), [Cholesky](#), [CHMfactor](#), and [sparseQR](#).

## Examples

```
showClass("MatrixFactorization")
getClass("CholeskyFactorization")
```

---

ndenseMatrix-class *Virtual Class "ndenseMatrix" of Dense Logical Matrices*

---

## Description

`ndenseMatrix` is the virtual class of all dense logical (S4) matrices. It extends both `denseMatrix` and `lMatrix` directly.

## Slots

**x:** logical vector containing the entries of the matrix.

**Dim, Dimnames:** see `Matrix`.

## Extends

Class "`nMatrix`", directly. Class "`denseMatrix`", directly. Class "`Matrix`", by class "`nMatrix`". Class "`Matrix`", by class "`denseMatrix`".

## Methods

**%%** signature(x = "`nsparseMatrix`", y = "`ndenseMatrix`"): ...

**%%** signature(x = "`ndenseMatrix`", y = "`nsparseMatrix`"): ...

**coerce** signature(from = "`matrix`", to = "`ndenseMatrix`"): ...

**coerce** signature(from = "`ndenseMatrix`", to = "`matrix`"): ...

**crossprod** signature(x = "`nsparseMatrix`", y = "`ndenseMatrix`"): ...

**crossprod** signature(x = "`ndenseMatrix`", y = "`nsparseMatrix`"): ...

**as.vector** signature(x = "`ndenseMatrix`", mode = "`missing`"): ...

**diag** signature(x = "`ndenseMatrix`"): extracts the diagonal as for all matrices, see the generic `diag()`.

**which** signature(x = "`ndenseMatrix`"), semantically equivalent to **base** function `which(x, arr.ind)`; for details, see the `lMatrix` class documentation.

```

```
as(diag(3) > 0, "ndenseMatrix")# -> "nge"
```

nearPD

Nearest Positive Definite Matrix

## Description

Compute the nearest positive definite matrix to an approximate one, typically a correlation or variance-covariance matrix.

## Usage

```
nearPD(x, corr = FALSE, keepDiag = FALSE, base.matrix = FALSE,
       do2eigen = TRUE, doSym = FALSE,
       doDykstra = TRUE, only.values = FALSE,
       ensureSymmetry = !isSymmetric(x),
       eig.tol = 1e-06, conv.tol = 1e-07, posd.tol = 1e-08,
       maxit = 100, conv.norm.type = "I", trace = FALSE)
```

## Arguments

|                             |                                                                                                                                                                                                                                                                                                  |
|-----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>              | numeric $n \times n$ approximately positive definite matrix, typically an approximation to a correlation or covariance matrix. If <code>x</code> is not symmetric (and <code>ensureSymmetry</code> is not false), <code>symmpart(x)</code> is used.                                              |
| <code>corr</code>           | logical indicating if the matrix should be a <i>correlation</i> matrix.                                                                                                                                                                                                                          |
| <code>keepDiag</code>       | logical, generalizing <code>corr</code> : if TRUE, the resulting matrix should have the same diagonal ( <code>diag(x)</code> ) as the input matrix.                                                                                                                                              |
| <code>base.matrix</code>    | logical indicating if the resulting <code>mat</code> component should be a <b>base matrix</b> or (by default) a <b>Matrix</b> of class <code>dpoMatrix</code> .                                                                                                                                  |
| <code>do2eigen</code>       | logical indicating if a <code>posdefify()</code> eigen step should be applied to the result of the Higham algorithm.                                                                                                                                                                             |
| <code>doSym</code>          | logical indicating if <code>X &lt;- (X + t(X))/2</code> should be done, after <code>X &lt;- tcrossprod(Qd, Q)</code> ; some doubt if this is necessary.                                                                                                                                          |
| <code>doDykstra</code>      | logical indicating if Dykstra's correction should be used; true by default. If false, the algorithm is basically the direct fixpoint iteration $Y_k = P_U(P_S(Y_{k-1}))$ .                                                                                                                       |
| <code>only.values</code>    | logical; if TRUE, the result is just the vector of eigenvalues of the approximating matrix.                                                                                                                                                                                                      |
| <code>ensureSymmetry</code> | logical; by default, <code>symmpart(x)</code> is used whenever <code>isSymmetric(x)</code> is not true. The user can explicitly set this to TRUE or FALSE, saving the symmetry test. <i>Beware</i> however that setting it FALSE for an asymmetric input <code>x</code> , is typically nonsense! |
| <code>eig.tol</code>        | defines relative positiveness of eigenvalues compared to largest one, $\lambda_1$ . Eigenvalues $\lambda_k$ are treated as if zero when $\lambda_k/\lambda_1 \leq \text{eig.tol}$ .                                                                                                              |
| <code>conv.tol</code>       | convergence tolerance for Higham algorithm.                                                                                                                                                                                                                                                      |
| <code>posd.tol</code>       | tolerance for enforcing positive definiteness (in the final <code>posdefify</code> step when <code>do2eigen</code> is TRUE).                                                                                                                                                                     |
| <code>maxit</code>          | maximum number of iterations allowed.                                                                                                                                                                                                                                                            |

|                             |                                                                                                                                                                                                                 |
|-----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>conv.norm.type</code> | convergence norm type ( <code>norm(*, type)</code> ) used for Higham algorithm. The default is "I" (infinity), for reasons of speed (and back compatibility); using "F" is more in line with Higham's proposal. |
| <code>trace</code>          | logical or integer specifying if convergence monitoring should be traced.                                                                                                                                       |

## Details

This implements the algorithm of Higham (2002), and then (if `do2eigen` is true) forces positive definiteness using code from `posdefify`. The algorithm of Knol and ten Berge (1989) (not implemented here) is more general in that it allows constraints to (1) fix some rows (and columns) of the matrix and (2) force the smallest eigenvalue to have a certain value.

Note that setting `corr = TRUE` just sets `diag(.) <- 1` within the algorithm.

Higham (2002) uses Dykstra's correction, but the version by Jens Oehlschlaegel did not use it (accidentally), and still gave reasonable results; this simplification, now only used if `doDykstra = FALSE`, was active in `nearPD()` up to Matrix version 0.999375-40.

## Value

If `only.values = TRUE`, a numeric vector of eigenvalues of the approximating matrix; Otherwise, as by default, an S3 object of class "nearPD", basically a list with components

|                          |                                                                                                                     |
|--------------------------|---------------------------------------------------------------------------------------------------------------------|
| <code>mat</code>         | a matrix of class <code>dpoMatrix</code> , the computed positive-definite matrix.                                   |
| <code>eigenvalues</code> | numeric vector of eigenvalues of <code>mat</code> .                                                                 |
| <code>corr</code>        | logical, just the argument <code>corr</code> .                                                                      |
| <code>normF</code>       | the Frobenius norm ( <code>norm(x-X, "F")</code> ) of the difference between the original and the resulting matrix. |
| <code>iterations</code>  | number of iterations needed.                                                                                        |
| <code>converged</code>   | logical indicating if iterations converged.                                                                         |

## Author(s)

Jens Oehlschlaegel donated a first version. Subsequent changes by the Matrix package authors.

## See Also

A first version of this (with non-optional `corr=TRUE`) has been available as `nearcor()`; and more simple versions with a similar purpose `posdefify()`, both from package `sfsmisc`.

**Examples**

```
## Higham(2002), p.334f - simple example
A <- matrix(1, 3,3); A[1,3] <- A[3,1] <- 0
n.A <- nearPD(A, corr=TRUE, do2eigen=FALSE)
n.A[c("mat", "normF")]
n.A.m <- nearPD(A, corr=TRUE, do2eigen=FALSE, base.matrix=TRUE)$mat
stopifnot(exprs = { #-----
  all.equal(n.A$mat[1,2], 0.760689917)
  all.equal(n.A$normF, 0.52779033, tolerance=1e-9)
  all.equal(n.A.m, unname(as.matrix(n.A$mat)), tolerance = 1e-15) # seen rel.d.= 1.46e-16
})
set.seed(27)
m <- matrix(round(rnorm(25),2), 5, 5)
m <- m + t(m)
diag(m) <- pmax(0, diag(m)) + 1
(m <- round(cov2cor(m), 2))

str(near.m <- nearPD(m, trace = TRUE))
round(near.m$mat, 2)
norm(m - near.m$mat) # 1.102 / 1.08

if(require("sfsmisc")) {
  m2 <- posdefify(m) # a simpler approach
  norm(m - m2) # 1.185, i.e., slightly "less near"
}

round(nearPD(m, only.values=TRUE), 9)

## A longer example, extended from Jens' original,
## showing the effects of some of the options:

pr <- Matrix(c(1,      0.477, 0.644, 0.478, 0.651, 0.826,
               0.477, 1,      0.516, 0.233, 0.682, 0.75,
               0.644, 0.516, 1,      0.599, 0.581, 0.742,
               0.478, 0.233, 0.599, 1,      0.741, 0.8,
               0.651, 0.682, 0.581, 0.741, 1,      0.798,
               0.826, 0.75, 0.742, 0.8, 0.798, 1),
             nrow = 6, ncol = 6)

nc. <- nearPD(pr, conv.tol = 1e-7) # default
nc.$iterations # 2
nc.l <- nearPD(pr, conv.tol = 1e-7, corr = TRUE)
nc.l$iterations # 11 / 12 (!)
ncr <- nearPD(pr, conv.tol = 1e-15)
str(ncr) # still 2 iterations
ncr.l <- nearPD(pr, conv.tol = 1e-15, corr = TRUE)
ncr.l $ iterations # 27 / 30 !

ncF <- nearPD(pr, conv.tol = 1e-15, conv.norm = "F")
stopifnot(all.equal(ncr, ncF)) # norm type does not matter at all in this example

## But indeed, the 'corr = TRUE' constraint did ensure a better solution;
## cov2cor() does not just fix it up equivalently :
norm(pr - cov2cor(ncr$mat)) # = 0.09994
norm(pr - ncr.l$mat) # = 0.08746 / 0.08805
```

```

### 3) a real data example from a 'systemfit' model (3 eq.):
(load(system.file("external", "symW.rda", package="Matrix"))) # "symW"
dim(symW) # 24 x 24
class(symW) # "dsCMatrix": sparse symmetric
if(dev.interactive()) image(symW)
EV <- eigen(symW, only=TRUE)$values
summary(EV) ## looking more closely {EV sorted decreasingly}:
tail(EV) # all 6 are negative
EV2 <- eigen(sWpos <- nearPD(symW)$mat, only=TRUE)$values
stopifnot(EV2 > 0)
if(require("sfsmisc")) {
  plot(pmax(1e-3, EV), EV2, type="o", log="xy", xaxt="n", yaxt="n")
  eaxis(1); eaxis(2)
} else plot(pmax(1e-3, EV), EV2, type="o", log="xy")
abline(0, 1, col="red3", lty=2)

```

---

ngeMatrix-class      *Class "ngeMatrix" of General Dense Nonzero-pattern Matrices*

---

## Description

This is the class of general dense nonzero-pattern matrices, see [nMatrix](#).

## Slots

**x:** Object of class "logical". The logical values that constitute the matrix, stored in column-major order.

**Dim, Dimnames:** The dimension (a length-2 "integer") and corresponding names (or NULL), see the [Matrix](#) class.

**factors:** Object of class "list". A named list of factorizations that have been computed for the matrix.

## Extends

Class "ndenseMatrix", directly. Class "lMatrix", by class "ndenseMatrix". Class "denseMatrix", by class "ndenseMatrix". Class "Matrix", by class "ndenseMatrix". Class "Matrix", by class "ndenseMatrix".

## Methods

Currently, mainly `t()` and coercion methods (for `as(.)`); use, e.g., `showMethods(class="ngeMatrix")` for details.

## See Also

Non-general logical dense matrix classes such as [ntrMatrix](#), or [nsyMatrix](#); *sparse* logical classes such as [ngCMatrix](#).

## Examples

```

showClass("ngeMatrix")
## "lgeMatrix" is really more relevant

```

---

nMatrix-class

Class "nMatrix" of Non-zero Pattern Matrices

---

## Description

The `nMatrix` class is the virtual “mother” class of all *non-zero pattern* (or simply *pattern*) matrices in the **Matrix** package.

## Slots

Common to *all* matrix object in the package:

**Dim:** Object of class “integer” - the dimensions of the matrix - must be an integer vector with exactly two non-negative values.

**Dimnames:** list of length two; each component containing NULL or a `character` vector length equal the corresponding `Dim` element.

## Methods

There is a bunch of coercion methods (for `as(.)`), e.g.,

**coerce** signature(`from` = “matrix”, `to` = “nMatrix”): Note that these coercions (must) coerce NAs to non-zero, hence conceptually TRUE. This is particularly important when `sparseMatrix` objects are coerced to “nMatrix” and hence to `nsparseMatrix`.

**coerce** signature(`from` = “dMatrix”, `to` = “nMatrix”), and

**coerce** signature(`from` = “lMatrix”, `to` = “nMatrix”): For dense matrices with NAs, these coercions are valid since **Matrix** version 1.2.0 (still with a `warning` or a `message` if “Matrix.warn”, or “Matrix.verbose” `options` are set.)

**coerce** signature(`from` = “nMatrix”, `to` = “matrix”): ...

**coerce** signature(`from` = “nMatrix”, `to` = “dMatrix”): ...

**coerce** signature(`from` = “nMatrix”, `to` = “lMatrix”): ...

— — —

Additional methods contain group methods, such as

**Ops** signature(`e1` = “nMatrix”, `e2` = “....”), ...

**Arith** signature(`e1` = “nMatrix”, `e2` = “....”), ...

**Compare** signature(`e1` = “nMatrix”, `e2` = “....”), ...

**Logic** signature(`e1` = “nMatrix”, `e2` = “....”), ...

**Summary** signature(`x` = “nMatrix”, “....”), ...

## See Also

The classes `lMatrix`, `nsparseMatrix`, and the mother class, `Matrix`.

## Examples

```
getClass("nMatrix")

L3 <- Matrix(upper.tri(diag(3)))
L3 # an "ltCMatrix"
as(L3, "nMatrix") # -> ntC*

## similar, not using Matrix()
as(upper.tri(diag(3)), "nMatrix") # currently "ngTMatrix"
```

nnzero

*The Number of Non-Zero Values of a Matrix*

## Description

Returns the number of non-zero values of a numeric-like R object, and in particular an object `x` inheriting from class `Matrix`.

## Usage

```
nnzero(x, na.counted = NA)
```

## Arguments

`x` an R object, typically inheriting from class `Matrix` or `numeric`.

`na.counted` a `logical` describing how `NA`s should be counted. There are three possible settings for `na.counted`:

- TRUE** `NA`s are counted as non-zero (since “they are not zero”).
- NA** (default) the result will be `NA` if there are `NA`’s in `x` (since “`NA`’s are not known, i.e., *may be* zero”).
- FALSE** `NA`s are *omitted* from `x` before the non-zero entries are counted.

For sparse matrices, you may often want to use `na.counted = TRUE`.

## Value

the number of non zero entries in `x` (typically `integer`).

Note that for a *symmetric* sparse matrix `S` (i.e., inheriting from class `symmetricMatrix`), `nnzero(S)` is typically *twice* the `length(S@x)`.

## Methods

`signature(x = "ANY")` the default method for non-`Matrix` class objects, simply counts the number 0s in `x`, counting `NA`’s depending on the `na.counted` argument, see above.

`signature(x = "denseMatrix")` conceptually the same as for traditional `matrix` objects, care has to be taken for `"symmetricMatrix"` objects.

`signature(x = "diagonalMatrix")`, **and** `signature(x = "indMatrix")` fast simple methods for these special `"sparseMatrix"` classes.

`signature(x = "sparseMatrix")` typically, the most interesting method, also carefully taking `"symmetricMatrix"` objects into account.

See Also

The `Matrix` class also has a `length` method; typically, `length(M)` is much larger than `nnzero(M)` for a sparse matrix `M`, and the latter is a better indication of the *size* of `M`.  
`drop0`, `zapsmall`.

Examples

```
m <- Matrix(0+1:28, nrow = 4)
m[-3,c(2,4:5,7)] <- m[ 3, 1:4] <- m[1:3, 6] <- 0
(mT <- as(m, "dgTMatrix"))
nnzero(mT)
(S <- crossprod(mT))
nnzero(S)
str(S) # slots are smaller than nnzero()
stopifnot(nnzero(S) == sum(as.matrix(S) != 0)) # failed earlier

data(KNex)
M <- KNex$mm
class(M)
dim(M)
length(M); stopifnot(length(M) == prod(dim(M)))
nnzero(M) # more relevant than length
## the above are also visible from
str(M)
```

---

|      |                     |
|------|---------------------|
| norm | <i>Matrix Norms</i> |
|------|---------------------|

---

Description

Computes a matrix norm of `x`, using Lapack for dense matrices. The norm can be the one ("O", or "1") norm, the infinity ("I") norm, the Frobenius ("F") norm, the maximum modulus ("M") among elements of a matrix, or the spectral norm or 2-norm ("2"), as determined by the value of `type`.

Usage

```
norm(x, type, ...)
```

Arguments

- |                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>    | a real or complex matrix.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>type</code> | A character indicating the type of norm desired.<br>"O", "o" or "1" specifies the one norm, (maximum absolute column sum);<br>"I" or "i" specifies the infinity norm (maximum absolute row sum);<br>"F" or "f" specifies the Frobenius norm (the Euclidean norm of <code>x</code> treated as if it were a vector);<br>"M" or "m" specifies the maximum modulus of all the elements in <code>x</code> ; and<br>"2" specifies the “spectral norm” or 2-norm, which is the largest singular value ( <a href="#">svd</a> ) of <code>x</code> .<br>The default is "O". Only the first character of <code>type[1]</code> is used. |
| <code>...</code>  | further arguments passed to or from other methods.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

## Details

For dense matrices, the methods eventually call the Lapack functions `dlange`, `dlansy`, `dlantr`, `zlange`, `zlansy`, and `zlantr`.

## Value

A numeric value of class `"norm"`, representing the quantity chosen according to `type`.

## Examples

```
x <- Hilbert(9)
norm(x) # = "O" = "1"
stopifnot(identical(norm(x), norm(x, "1")))
norm(x, "I") # the same, because 'x' is symmetric

allnorms <- function(d) vapply(c("1", "I", "F", "M", "2"),
                               norm, x = d, double(1))

allnorms(x)
allnorms(Hilbert(10))

i <- c(1,3:8); j <- c(2,9,6:10); x <- 7 * (1:7)
A <- sparseMatrix(i, j, x = x) ## 8 x 10 "dgCMatrix"
(sA <- sparseMatrix(i, j, x = x, symmetric = TRUE)) ## 10 x 10 "dsCMatrix"
(tA <- sparseMatrix(i, j, x = x, triangular = TRUE)) ## 10 x 10 "dtCMatrix"
(allnorms(A) -> nA)
allnorms(sA)
allnorms(tA)
stopifnot(all.equal(nA, allnorms(as(A, "matrix"))),
  all.equal(nA, allnorms(tA))) # because tA == rbind(A, 0, 0)
A. <- A; A.[1,3] <- NA
stopifnot(is.na(allnorms(A.))) # gave error
```

---

nsparseMatrix-classes

*Sparse "pattern" Matrices*

---

## Description

The `nsparseMatrix` class is a virtual class of sparse “*pattern*” matrices, i.e., binary matrices conceptually with TRUE/FALSE entries. Only the positions of the elements that are TRUE are stored.

These can be stored in the “triplet” form ([TsparseMatrix](#), subclasses `ngTMatrix`, `nsTMatrix`, and `ntTMatrix` which really contain pairs, not triplets) or in compressed column-oriented form (class [CsparseMatrix](#), subclasses `ngCMatrix`, `nsCMatrix`, and `ntCMatrix`) or—rarely—in compressed row-oriented form (class [RsparseMatrix](#), subclasses `ngRMatrix`, `nsRMatrix`, and `ntRMatrix`). The second letter in the name of these non-virtual classes indicates general, symmetric, or triangular.

### Objects from the Class

Objects can be created by calls of the form `new("ngCMatrix", ...)` and so on. More frequently objects are created by coercion of a numeric sparse matrix to the pattern form for use in the symbolic analysis phase of an algorithm involving sparse matrices. Such algorithms often involve two phases: a symbolic phase wherein the positions of the non-zeros in the result are determined and a numeric phase wherein the actual results are calculated. During the symbolic phase only the positions of the non-zero elements in any operands are of interest, hence numeric sparse matrices can be treated as sparse pattern matrices.

### Slots

- uplo:** Object of class "character". Must be either "U", for upper triangular, and "L", for lower triangular. Present in the triangular and symmetric classes but not in the general class.
- diag:** Object of class "character". Must be either "U", for unit triangular (diagonal is all ones), or "N" for non-unit. The implicit diagonal elements are not explicitly stored when `diag` is "U". Present in the triangular classes only.
- p:** Object of class "integer" of pointers, one for each column (row), to the initial (zero-based) index of elements in the column. Present in compressed column-oriented and compressed row-oriented forms only.
- i:** Object of class "integer" of length `nnzero` (number of non-zero elements). These are the row numbers for each TRUE element in the matrix. All other elements are FALSE. Present in triplet and compressed column-oriented forms only.
- j:** Object of class "integer" of length `nnzero` (number of non-zero elements). These are the column numbers for each TRUE element in the matrix. All other elements are FALSE. Present in triplet and compressed column-oriented forms only.
- Dim:** Object of class "integer" - the dimensions of the matrix.

### Methods

**coerce** signature (`from = "dgCMatrix"`, `to = "ngCMatrix"`), and many similar ones; typically you should coerce to "nsparseMatrix" (or "nMatrix"). Note that coercion to a sparse pattern matrix records all the potential non-zero entries, i.e., explicit (“non-structural”) zeroes are coerced to TRUE, not FALSE, see the example.

**t** signature (`x = "ngCMatrix"`): returns the transpose of `x`

**which** signature (`x = "lsparseMatrix"`), semantically equivalent to **base** function `which(x, arr.ind)`; for details, see the [lMatrix](#) class documentation.

the class [dgCMatrix](#)

## Examples

```
(m <- Matrix(c(0,0,2:0), 3,5, dimnames=list(LETTERS[1:3],NULL)))
## ``extract the nonzero-pattern of (m) into an nMatrix'':
nm <- as(m, "nsparseMatrix") ## -> will be a "ngCMatrix"
str(nm) # no 'x' slot
nnm <- !nm # no longer sparse
(nnm <- as(nnm, "sparseMatrix"))# "lgCMatrix"
## consistency check:
stopifnot(xor(as( nm, "matrix"),
               as(nnm, "matrix"))

## low-level way of adding "non-structural zeros" :
nnm@x[2:4] <- c(FALSE,NA,NA)
nnm
as(nnm, "nMatrix") # NAs *and* non-structural 0 |---> 'TRUE'

data(KNex)
nmm <- as(KNex $ mm, "ngCMatrix")
str(xlx <- crossprod(nmm))# "nsCMatrix"
stopifnot(isSymmetric(xlx))
image(xlx, main=paste("crossprod(nmm) : Sparse", class(xlx)))
```

nsyMatrix-class

*Symmetric Dense Nonzero-Pattern Matrices*

---

## Description

The "nsyMatrix" class is the class of symmetric, dense nonzero-pattern matrices in non-packed storage and "nspMatrix" is the class of these in packed storage. Only the upper triangle or the lower triangle is stored.

## Objects from the Class

Objects can be created by calls of the form `new("nsyMatrix", ...)`.

## Slots

**uplo:** Object of class "character". Must be either "U", for upper triangular, and "L", for lower triangular.

**x:** Object of class "logical". The logical values that constitute the matrix, stored in column-major order.

**Dim,Dimnames:** The dimension (a length-2 "integer") and corresponding names (or NULL), see the [Matrix](#) class.

**factors:** Object of class "list". A named list of factorizations that have been computed for the matrix.

## Extends

"nsyMatrix" extends class "ngeMatrix", directly, whereas

"nspMatrix" extends class "ndenseMatrix", directly.

Both extend class "symmetricMatrix", directly, and class "Matrix" and others, *indirectly*, use `showClass("nsyMatrix")`, e.g., for details.

## Methods

Currently, mainly `t()` and coercion methods (for `as(.)`; use, e.g., `showMethods(class="dsyMatrix")` for details.

## See Also

`ngeMatrix`, `Matrix`, `t`

## Examples

```
(s0 <- new("nsyMatrix"))

(M2 <- Matrix(c(TRUE, NA,FALSE,FALSE), 2,2)) # logical dense (ltr)
(sM <- M2 & t(M2)) # "lge"
class(sM <- as(sM, "nMatrix")) # -> "nge"
(sM <- as(sM, "nsyMatrix")) # -> "nsy"
str ( sM <- as(sM, "nspMatrix")) # -> "nsp": packed symmetric
```

---

|                 |                                          |
|-----------------|------------------------------------------|
| ntrMatrix-class | <i>Triangular Dense Logical Matrices</i> |
|-----------------|------------------------------------------|

---

## Description

The "ntrMatrix" class is the class of triangular, dense, logical matrices in nonpacked storage. The "ntpMatrix" class is the same except in packed storage.

## Slots

**x:** Object of class "logical". The logical values that constitute the matrix, stored in column-major order.

**uplo:** Object of class "character". Must be either "U", for upper triangular, and "L", for lower triangular.

**diag:** Object of class "character". Must be either "U", for unit triangular (diagonal is all ones), or "N"; see `triangularMatrix`.

**Dim,Dimnames:** The dimension (a length-2 "integer") and corresponding names (or NULL), see the `Matrix` class.

**factors:** Object of class "list". A named list of factorizations that have been computed for the matrix.

## Extends

"ntrMatrix" extends class "ngeMatrix", directly, whereas  
 "ntpMatrix" extends class "ndenseMatrix", directly.

Both extend Class "triangularMatrix", directly, and class "denseMatrix", "lMatrix" and others, *indirectly*, use `showClass("nsyMatrix")`, e.g., for details.

## Methods

Currently, mainly `t()` and coercion methods (for `as(.)`; use, e.g., `showMethods(class="nsyMatrix")` for details.

**See Also**

Classes [ngeMatrix](#), [Matrix](#); function [t](#)

**Examples**

```
showClass("ntrMatrix")

str(new("ntpMatrix"))
(nutr <- as(upper.tri(matrix(,4,4)), "ntrMatrix"))
str(nutp <- as(nutr, "ntpMatrix"))# packed matrix: only 10 = (4+1)*4/2 entries
!nutp ## the logical negation (is *not* logical triangular !)
## but this one is:
stopifnot(all.equal(nutp, as(!!nutp, "ntpMatrix")))
```

---

number-class

---

*Class "number" of Possibly Complex Numbers*

---

**Description**

The class "number" is a virtual class, currently used for vectors of eigen values which can be "numeric" or "complex".

It is a simple class union ([setClassUnion](#)) of "numeric" and "complex".

**Objects from the Class**

Since it is a virtual Class, no objects may be created from it.

**Examples**

```
showClass("number")
stopifnot( is(1i, "number"), is(pi, "number"), is(1:3, "number") )
```

---

pMatrix-class

---

*Permutation matrices*

---

**Description**

The "pMatrix" class is the class of permutation matrices, stored as 1-based integer permutation vectors.

Matrix (vector) multiplication with permutation matrices is equivalent to row or column permutation, and is implemented that way in the **Matrix** package, see the 'Details' below.

## Details

Matrix multiplication with permutation matrices is equivalent to row or column permutation. Here are the four different cases for an arbitrary matrix  $M$  and a permutation matrix  $P$  (where we assume matching dimensions):

$$\begin{aligned}
 MP &= M \%*\% P &&= M[, i(p)] \\
 PM &= P \%*\% M &&= M[p, ] \\
 P'M &= \text{crossprod}(P, M) (\approx t(P) \%*\% M) &&= M[i(p), ] \\
 MP' &= \text{tcrossprod}(M, P) (\approx M \%*\% t(P)) &&= M[, p]
 \end{aligned}$$

where  $p$  is the “permutation vector” corresponding to the permutation matrix  $P$  (see first note), and  $i(p)$  is short for `invPerm(p)`.

Also one could argue that these are really only two cases if you take into account that inversion (`solve`) and transposition (`t`) are the same for permutation matrices  $P$ .

## Objects from the Class

Objects can be created by calls of the form `new("pMatrix", ...)` or by coercion from an integer permutation vector, see below.

## Slots

**perm:** An integer, 1-based permutation vector, i.e. an integer vector of length `Dim[1]` whose elements form a permutation of `1:Dim[1]`.

**Dim:** Object of class "integer". The dimensions of the matrix which must be a two-element vector of equal, non-negative integers.

**Dimnames:** list of length two; each component containing NULL or a `character` vector length equal the corresponding `Dim` element.

## Extends

Class "`indMatrix`", directly.

## Methods

`%*%` signature(`x` = "matrix", `y` = "pMatrix") and other signatures (use `showMethods("%*%", class="pMatrix")`): ...

**coerce** signature(`from` = "integer", `to` = "pMatrix"): This enables typical "pMatrix" construction, given a permutation vector of `1:n`, see the first example.

**coerce** signature(`from` = "numeric", `to` = "pMatrix"): a user convenience, to allow `as(perm, "pMatrix")` for numeric `perm` with integer values.

**coerce** signature(`from` = "pMatrix", `to` = "matrix"): coercion to a traditional FALSE/TRUE `matrix` of `mode` logical. (in earlier version of **Matrix**, it resulted in a 0/1-integer matrix; logical makes slightly more sense, corresponding better to the “natural” `sparseMatrix` counterpart, "`ngTMatrix`".)

**coerce** signature(`from` = "pMatrix", `to` = "ngTMatrix"): coercion to sparse logical matrix of class `ngTMatrix`.

**determinant** signature(`x` = "pMatrix", `logarithm` = "logical"): Since permutation matrices are orthogonal, the determinant must be +1 or -1. In fact, it is exactly the *sign of the permutation*.

**solve** signature (a = "pMatrix", b = "missing"): return the inverse permutation matrix; note that solve(P) is identical to t(P) for permutation matrices. See [solve-methods](#) for other methods.

**t** signature (x = "pMatrix"): return the transpose of the permutation matrix (which is also the inverse of the permutation matrix).

### Note

For every permutation matrix  $P$ , there is a corresponding permutation vector  $p$  (of indices, 1:n), and these are related by

```
P <- as(p, "pMatrix")
p <- P@perm
```

see also the ‘Examples’.

“Row-indexing” a permutation matrix typically returns an "indMatrix". See ["indMatrix"](#) for all other subsetting/indexing and subassignment ( $A[. .] <- v$ ) operations.

### See Also

[invPerm](#)(p) computes the inverse permutation of an integer (index) vector p.

### Examples

```
(pml <- as(as.integer(c(2,3,1)), "pMatrix"))
t(pml) # is the same as
solve(pml)
pml %*% t(pml) # check that the transpose is the inverse
stopifnot(all(diag(3) == as(pml %*% t(pml), "matrix")),
           is.logical(as(pml, "matrix")))

set.seed(11)
## random permutation matrix :
(p10 <- as(sample(10), "pMatrix"))

## Permute rows / columns of a numeric matrix :
(mm <- round(array(rnorm(3 * 3), c(3, 3)), 2))
mm %*% pml
pml %*% mm
try(as(as.integer(c(3,3,1)), "pMatrix")) # Error: not a permutation

as(pml, "ngTMatrix")
p10[1:7, 1:4] # gives an "ngTMatrix" (most economic!)

## row-indexing of a <pMatrix> keeps it as an <indMatrix>:
p10[1:3, ]
```

---

|               |                                                  |
|---------------|--------------------------------------------------|
| printSpMatrix | <i>Format and Print Sparse Matrices Flexibly</i> |
|---------------|--------------------------------------------------|

---

## Description

Format and print sparse matrices flexibly. These are the “workhorses” used by the `format`, `show` and `print` methods for sparse matrices. If `x` is large, `printSpMatrix2(x)` calls `printSpMatrix()` twice, namely, for the first and the last few rows, suppressing those in between, and also suppresses columns when `x` is too wide.

`printSpMatrix()` basically prints the result of `formatSpMatrix()`.

## Usage

```
formatSpMatrix(x, digits = NULL, maxp = 1e9,
               cld = getClassDef(class(x)), zero.print = ".",
               col.names, note.dropping.colnames = TRUE, uniDiag = TRUE,
               align = c("fancy", "right"))

printSpMatrix(x, digits = NULL, maxp = max(100L, getOption("max.print")),
              cld = getClassDef(class(x)),
              zero.print = ".", col.names, note.dropping.colnames = TRUE,
              uniDiag = TRUE, col.trailer = "",
              align = c("fancy", "right"))

printSpMatrix2(x, digits = NULL, maxp = max(100L, getOption("max.print")),
               zero.print = ".", col.names, note.dropping.colnames = TRUE,
               uniDiag = TRUE, suppRows = NULL, suppCols = NULL,
               col.trailer = if(suppCols) "....." else "",
               align = c("fancy", "right"),
               width = getOption("width"), fitWidth = TRUE)
```

## Arguments

|                         |                                                                                                                                                                                                                                                                                                                                  |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>          | an R object inheriting from class <code>sparseMatrix</code> .                                                                                                                                                                                                                                                                    |
| <code>digits</code>     | significant digits to use for printing, see <code>print.default</code> , the default, <code>NULL</code> , corresponds to using <code>getOption("digits")</code> .                                                                                                                                                                |
| <code>maxp</code>       | integer, default from <code>options(max.print)</code> , influences how many entries of large matrices are printed at all. Typically should not be smaller than around 1000; values smaller than 100 are silently “rounded up” to 100.                                                                                            |
| <code>cld</code>        | the class definition of <code>x</code> ; must be equivalent to <code>getClassDef(class(x))</code> and exists mainly for possible speedup.                                                                                                                                                                                        |
| <code>zero.print</code> | character which should be printed for <i>structural</i> zeroes. The default <code>"."</code> may occasionally be replaced by <code>" "</code> (blank); using <code>"0"</code> would look almost like <code>print()</code> ing of non-sparse matrices.                                                                            |
| <code>col.names</code>  | logical or string specifying if and how column names of <code>x</code> should be printed, possibly abbreviated. The default is taken from <code>options("sparse.colnames")</code> if that is set, otherwise <code>FALSE</code> unless there are less than ten columns. When <code>TRUE</code> the full column names are printed. |

|                                     |                                                                                                                                                                                                                                                                                                                                                                                                   |
|-------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                     | When <code>col.names</code> is a string beginning with "abb" or "sub" and ending with an integer <code>n</code> (i.e., of the form "abb...<n>"), the column names are <code>abbreviate()</code> d or <code>substring()</code> ed to (target) length <code>n</code> , see the examples.                                                                                                            |
| <code>note.dropping.colnames</code> | logical specifying, when <code>col.names</code> is FALSE if the dropping of the column names should be noted, TRUE by default.                                                                                                                                                                                                                                                                    |
| <code>uniDiag</code>                | logical indicating if the diagonal entries of a sparse unit triangular or unit-diagonal matrix should be formatted as "I" instead of "1" (to emphasize that the 1's are "structural").                                                                                                                                                                                                            |
| <code>col.trailer</code>            | a string to be appended to the right of each column; this is typically made use of by <code>show(&lt;sparseMatrix&gt;)</code> only, when suppressing columns.                                                                                                                                                                                                                                     |
| <code>suppRows, suppCols</code>     | logicals or NULL, for <code>printSpMatrix2()</code> specifying if rows or columns should be suppressed in printing. If NULL, sensible defaults are determined from <code>dim(x)</code> and <code>options(c("width", "max.print"))</code> . Setting both to FALSE may be a very bad idea.                                                                                                          |
| <code>align</code>                  | a string specifying how the <code>zero.print</code> codes should be aligned, i.e., padded as strings. The default, "fancy", takes some effort to align the typical <code>zero.print = "."</code> with the position of 0, i.e., the first decimal (one left of decimal point) of the numbers printed, whereas <code>align = "right"</code> just makes use of <code>print(*, right = TRUE)</code> . |
| <code>width</code>                  | number, a positive integer, indicating the approximately desired (line) width of the output, see also <code>fitWidth</code> .                                                                                                                                                                                                                                                                     |
| <code>fitWidth</code>               | logical indicating if some effort should be made to match the desired <code>width</code> or temporarily enlarge that if deemed necessary.                                                                                                                                                                                                                                                         |

## Details

**formatSpMatrix:** If `x` is large, only the first rows making up the approximately first `maxp` entries is used, otherwise all of `x`. `.formatSparseSimple()` is applied to (a dense version of) the matrix. Then, `formatSparseM` is used, unless in trivial cases or for sparse matrices without `x` slot.

## Value

`formatSpMatrix()`  
returns a character matrix with possibly empty column names, depending on `col.names` etc, see above.

`printSpMatrix*()`  
return `x` *invisibly*, see `invisible`.

## Author(s)

Martin Maechler

## See Also

the virtual class `sparseMatrix` and the classes extending it; maybe `sparseMatrix` or `spMatrix` as simple constructors of such matrices.

The underlying utilities `formatSparseM` and `.formatSparseSimple()` (on the same page).

## Examples

```
f1 <- gl(5, 3, labels = LETTERS[1:5])
X <- as(f1, "sparseMatrix")
X ## <==> show(X) <==> print(X)
t(X) ## shows column names, since only 5 columns

X2 <- as(gl(12, 3, labels = paste(LETTERS[1:12], "c", sep=".")),
        "sparseMatrix")
X2
## less nice, but possible:
print(X2, col.names = TRUE) # use [,1] [,2] .. => does not fit

## Possibilities with column names printing:
t(X2) # suppressing column names
print(t(X2), col.names=TRUE)
print(t(X2), zero.print = "", col.names="abbr. 1")
print(t(X2), zero.print = "-", col.names="substring 2")
```

qr-methods

---

*QR Decomposition – S4 Methods and Generic*

---

## Description

The **Matrix** package provides methods for the QR decomposition of special classes of matrices. There is a generic function which uses `qr` as default, but methods defined in this package can take extra arguments. In particular there is an option for determining a fill-reducing permutation of the columns of a sparse, rectangular matrix.

## Usage

```
qr(x, ...)
qrR(qr, complete=FALSE, backPermute=TRUE, row.names = TRUE)
```

## Arguments

|                          |                                                                                                                                                                                         |
|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>           | a numeric or complex matrix whose QR decomposition is to be computed. Logical matrices are coerced to numeric.                                                                          |
| <code>qr</code>          | a QR decomposition of the type computed by <code>qr</code> .                                                                                                                            |
| <code>complete</code>    | logical indicating whether the <b>R</b> matrix is to be completed by binding zero-value rows beneath the square upper triangle.                                                         |
| <code>backPermute</code> | logical indicating if the rows of the <b>R</b> matrix should be back permuted such that <code>qrR()</code> 's result can be used directly to reconstruct the original matrix <b>X</b> . |
| <code>row.names</code>   | logical indicating if <code>rownames</code> should be propagated to the result.                                                                                                         |
| <code>...</code>         | further arguments passed to or from other methods                                                                                                                                       |

## Methods

**x = "dgCMatrix"** QR decomposition of a general sparse double-precision matrix with `nrow(x) >= ncol(x)`. Returns an object of class `"sparseQR"`.

**x = "sparseMatrix"** works via `"dgCMatrix"`.

## See Also

`qr`; then, the class documentations, mainly `sparseQR`, and also `dgCMatrix`.

## Examples

```
##----- example of pivoting -- from base'  qraux.Rd -----
X <- cbind(int = 1,
           b1=rep(1:0, each=3), b2=rep(0:1, each=3),
           c1=rep(c(1,0,0), 2), c2=rep(c(0,1,0), 2), c3=rep(c(0,0,1),2))
rownames(X) <- paste0("r", seq_len(nrow(X)))
dnX <- dimnames(X)
bX <- X # [b]ase version of X
X <- as(bX, "sparseMatrix")
X # is singular, columns "b2" and "c3" are "extra"
stopifnot(identical(dimnames(X), dnX)) # some versions changed X's dimnames!
c(rankMatrix(X)) # = 4 (not 6)
m <- function(.) as(., "matrix")

##----- regular case -----

)

##----- rank-deficient ("singular") case -----

(qX <- qr(X)) # both @p and @q are non-trivial permutations
qx <- qr(m(X)) ; str(qx) # $pivot is non-trivial, too

drop0(R. <- qr.R(qX), tol=tolE) # columns *permuted*: c3 b1 ..
Q. <- qr.Q(qX)
qI <- sort.list(qX@q) # the inverse 'q' permutation
(X. <- drop0(Q. %*% R., qI, tol=tolE)) ## just = X, incl. correct colnames
stopifnot(all(X - X.) < 8*.Machine$double.eps,
```

```

## qrR(.) returns R already "back permuted" (as with qI):
identical(R[, qI], qrR(qX)) )
##
## In this sense, classical qr.coef() is fine:
cfqx <- qr.coef(qx, y) # quite different from
nna <- !is.na(cfqx)
stopifnot(all.equal(unname(qr.fitted(qx,y)),
                    as.numeric(X[,nna] %*% cfqx[nna])))
## FIXME: do these make *any* sense? --- should give warnings !
qr.coef(qX, y)
qr.coef(qX, Y)
rm(m)

```

rankMatrix

*Rank of a Matrix*

## Description

Compute ‘the’ matrix rank, a well-defined functional in theory(\*), somewhat ambiguous in practice. We provide several methods, the default corresponding to Matlab’s definition.

(\*) The rank of a  $n \times m$  matrix  $A$ ,  $rk(A)$ , is the maximal number of linearly independent columns (or rows); hence  $rk(A) \leq \min(n, m)$ .

## Usage

```

rankMatrix(x, tol = NULL,
           method = c("tolNorm2", "qr.R", "qrLINPACK", "qr",
                     "useGrad", "maybeGrad"),
           sval = svd(x, 0, 0)$d, warn.t = TRUE, warn.qr = TRUE)

qr2rankMatrix(qr, tol = NULL, isBqr = is.qr(qr), do.warn = TRUE)

```

## Arguments

|        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x      | numeric matrix, of dimension $n \times m$ , say.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| tol    | nonnegative number specifying a (relative, “scalefree”) tolerance for testing of “practically zero” with specific meaning depending on method; by default, $\max(\dim(x)) * .Machine\$double.eps$ is according to Matlab’s default (for its only method which is our <code>method="tolNorm2"</code> ).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| method | <p>a character string specifying the computational method for the rank, can be abbreviated:</p> <p><b>"tolNorm2"</b>: the number of singular values <math>\geq \text{tol} * \max(\text{sval})</math>;</p> <p><b>"qrLINPACK"</b>: for a dense matrix, this is the rank of <code>qr(x, tol, LAPACK=FALSE)</code> (which is <code>qr(...)\$rank</code>); This ("qr*", dense) version used to be <i>the</i> recommended way to compute a matrix rank for a while in the past. For sparse x, this is equivalent to <code>"qr.R"</code>.</p> <p><b>"qr.R"</b>: this is the rank of triangular matrix <math>R</math>, where <code>qr()</code> uses LAPACK or a "sparseQR" method (see <a href="#">qr-methods</a>) to compute the decomposition <math>QR</math>. The rank of <math>R</math> is then defined as the number of “non-zero” diagonal entries <math>d_i</math> of <math>R</math>, and “non-zero”s fulfill <math> d_i  \geq \text{tol} \cdot \max( d_i )</math>.</p> |

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                      | <p>"qr": is for back compatibility; for dense <code>x</code>, it corresponds to "qrLAPACK", whereas for sparse <code>x</code>, it uses "qr.R".</p> <p>For all the "qr*" methods, singular values <code>sval</code> are not used, which may be crucially important for a large sparse matrix <code>x</code>, as in that case, when <code>sval</code> is not specified, the default, computing <code>svd()</code> currently coerces <code>x</code> to a dense matrix.</p> <p>"useGrad": considering the "gradient" of the (decreasing) singular values, the index of the <i>smallest</i> gap.</p> <p>"maybeGrad": choosing method "useGrad" only when that seems <i>reasonable</i>; otherwise using "tolNorm2".</p> |
| <code>sval</code>    | numeric vector of non-increasing singular values of <code>x</code> ; typically unspecified and computed from <code>x</code> when needed, i.e., unless <code>method = "qr"</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>warn.t</code>  | logical indicating if <code>rankMatrix()</code> should warn when it needs <code>t(x)</code> instead of <code>x</code> . Currently, for <code>method = "qr"</code> only, gives a warning by default because the caller often could have passed <code>t(x)</code> directly, more efficiently.                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <code>warn.qr</code> | in the <i>QR</i> cases (i.e., if <code>method</code> starts with "qr"), <code>rankMatrix()</code> calls <code>qr2rankMatrix(..., do.warn = warn.qr)</code> , see below.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>qr</code>      | an R object resulting from <code>qr(x, ...)</code> , i.e., typically inheriting from class "qr" or "sparseQR".                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>isBqr</code>   | logical indicating if <code>qr</code> is resulting from <code>base qr()</code> . (Otherwise, it is typically from <b>Matrix</b> package <code>sparse qr</code> .)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <code>do.warn</code> | logical; if true, warn about non-finite (or in the <code>sparseQR</code> case negative) diagonal entries in the <i>R</i> matrix of the <i>QR</i> decomposition. Do not change lightly!                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

## Details

`qr2rankMatrix()` is typically called from `rankMatrix()` for the "qr"\* methods, but can be used directly - much more efficiently in case the *qr*-decomposition is available anyway.

## Value

If `x` is a matrix of all 0 (or of zero dimension), the rank is zero; otherwise, typically a positive integer in `1:min(dim(x))` with attributes detailing the method used.

There are rare cases where the sparse *QR* decomposition "fails" in so far as the diagonal entries of *R*, the  $d_i$  (see above), end with non-finite, typically NaN entries. Then, a warning is signalled (unless `warn.qr / do.warn` is not true) and NA (specifically, `NA_integer_`) is returned.

## Note

For large sparse matrices `x`, unless you can specify `sval` yourself, currently `method = "qr"` may be the only feasible one, as the others need `sval` and call `svd()` which currently coerces `x` to a `denseMatrix` which may be very slow or impossible, depending on the matrix dimensions.

Note that in the case of sparse `x`, `method = "qr"`, all non-strictly zero diagonal entries  $d_i$  where counted, up to including **Matrix** version 1.1-0, i.e., that method implicitly used `tol = 0`, see also the `set.seed(42)` example below.

**Examples**

```
rankMatrix(cbind(1, 0, 1:3)) # 2

(meths <- eval(formals(rankMatrix)$method))

## a "border" case:
H12 <- Hilbert(12)
rankMatrix(H12, tol = 1e-20) # 12; but 11 with default method & tol.
sapply(meths, function(.m.) rankMatrix(H12, method = .m.))
##      tolNorm2      qr.R qrLINPACK      qr useGrad maybeGrad
##           11           11           12      12           11           11
## The meaning of 'tol' for method="qrLINPACK" and *dense* x is not entirely "scale free"
rMQL <- function(ex, M) rankMatrix(M, method="qrLINPACK", tol = 10^-ex)
rMQR <- function(ex, M) rankMatrix(M, method="qr.R",      tol = 10^-ex)
sapply(5:15, rMQL, M = H12) # result is platform dependent
##      7  7  8 10 10 11 11 11 12 12 12 {x86_64}
sapply(5:15, rMQL, M = 1000 * H12) # not identical unfortunately
##      7  7  8 10 11 11 12 12 12 12 12
sapply(5:15, rMQR, M = H12)
##      5  6  7  8  8  9  9 10 10 11 11
sapply(5:15, rMQR, M = 1000 * H12) # the *same*

## "sparse" case:
M15 <- kronecker(diag(x=c(100,1,10)), Hilbert(5))
sapply(meths, function(.m.) rankMatrix(M15, method = .m.))
#--> all 15, but 'useGrad' has 14.
sapply(meths, function(.m.) rankMatrix(M15, method = .m., tol = 1e-7)) # all 14

## "large" sparse
n <- 250000; p <- 33; nnz <- 10000
L <- sparseMatrix(i = sample.int(n, nnz, replace=TRUE),
                  j = sample.int(p, nnz, replace=TRUE), x = rnorm(nnz))
(st1 <- system.time(r1 <- rankMatrix(L))) # warning+ ~1.5 sec (2013)
(st2 <- system.time(r2 <- rankMatrix(L, method = "qr"))) # considerably faster!
r1[[1]] == print(r2[[1]]) ## --> ( 33 TRUE )

## another sparse-"qr" one, which ``failed'' till 2013-11-23:
set.seed(42)
f1 <- factor(sample(50, 1000, replace=TRUE))
f2 <- factor(sample(50, 1000, replace=TRUE))
f3 <- factor(sample(50, 1000, replace=TRUE))
rbind. <- if(getRversion() < "3.2.0") rBind else rbind
D <- t(do.call(rbind., lapply(list(f1,f2,f3), as, 'sparseMatrix'))))
dim(D); nnzero(D) ## 1000 x 150 // 3000 non-zeros (= 2%)
stopifnot(rankMatrix(D, method='qr') == 148,
           rankMatrix(crossprod(D),method='qr') == 148)

## zero matrix has rank 0 :
stopifnot(sapply(meths, function(.m.)
                 rankMatrix(matrix(0, 2, 2), method = .m.)) == 0)
```

rcond

*Estimate the Reciprocal Condition Number***Description**

Estimate the reciprocal of the condition number of a matrix.

This is a generic function with several methods, as seen by [showMethods\(rcond\)](#).

**Usage**

```
rcond(x, norm, ...)
```

```
## S4 method for signature 'sparseMatrix,character'
rcond(x, norm, useInv=FALSE, ...)
```

**Arguments**

|        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x      | an R object that inherits from the <code>Matrix</code> class.                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| norm   | character string indicating the type of norm to be used in the estimate. The default is "O" for the 1-norm ("O" is equivalent to "1"). For sparse matrices, when <code>useInv=TRUE</code> , <code>norm</code> can be any of the kinds allowed for <a href="#">norm</a> ; otherwise, the other possible value is "I" for the infinity norm, see also <a href="#">norm</a> .                                                                                                                                                                |
| useInv | logical (or "Matrix" containing <a href="#">solve(x)</a> ). If not false, compute the reciprocal condition number as $1/(\ x\  \cdot \ x^{-1}\ )$ , where $x^{-1}$ is the inverse of $x$ , <a href="#">solve(x)</a> .<br>This may be an efficient alternative (only) in situations where <a href="#">solve(x)</a> is fast (or known), e.g., for (very) sparse or triangular matrices.<br>Note that the <i>result</i> may differ depending on <code>useInv</code> , as per default, when it is false, an <i>approximation</i> is computed. |
| ...    | further arguments passed to or from other methods.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

**Value**

An estimate of the reciprocal condition number of `x`.

**BACKGROUND**

The condition number of a regular (square) matrix is the product of the [norm](#) of the matrix and the norm of its inverse (or pseudo-inverse).

More generally, the condition number is defined (also for non-square matrices  $A$ ) as

$$\kappa(A) = \frac{\max_{\|v\|=1} \|Av\|}{\min_{\|v\|=1} \|Av\|}.$$

Whenever `x` is *not* a square matrix, in our method definitions, this is typically computed via `rcond(qr.R(qr(X)), ...)` where  $X$  is `x` or `t(x)`.

The condition number takes on values between 1 and infinity, inclusive, and can be viewed as a factor by which errors in solving linear systems with this matrix as coefficient matrix could be magnified.

`rcond()` computes the *reciprocal* condition number  $1/\kappa$  with values in  $[0, 1]$  and can be viewed as a scaled measure of how close a matrix is to being rank deficient (aka “singular”).

Condition numbers are usually estimated, since exact computation is costly in terms of floating-point operations. An (over) estimate of reciprocal condition number is given, since by doing so overflow is avoided. Matrices are well-conditioned if the reciprocal condition number is near 1 and ill-conditioned if it is near zero.

## References

Golub, G., and Van Loan, C. F. (1989). *Matrix Computations*, 2nd edition, Johns Hopkins, Baltimore.

## See Also

`norm`, `kappa()` from package **base** computes an *approximate* condition number of a “traditional” matrix, even non-square ones, with respect to the  $p = 2$  (Euclidean) `norm.solve`.

`condest`, a newer *approximate* estimate of the (1-norm) condition number, particularly efficient for large sparse matrices.

## Examples

```
x <- Matrix(rnorm(9), 3, 3)
rcond(x)
## typically "the same" (with more computational effort):
1 / (norm(x) * norm(solve(x)))
rcond(Hilbert(9)) # should be about 9.1e-13

## For non-square matrices:
rcond(x1 <- cbind(1,1:10))# 0.05278
rcond(x2 <- cbind(x1, 2:11))# practically 0, since x2 does not have full rank

## sparse
(S1 <- Matrix(rbind(0:1,0, diag(3:-2))))
rcond(S1)
m1 <- as(S1, "denseMatrix")
all.equal(rcond(S1), rcond(m1))

## wide and sparse
rcond(Matrix(cbind(0, diag(2:-1))))

## Large sparse example -----
m <- Matrix(c(3,0:2), 2,2)
M <- bdiag(kronecker(Diagonal(2), m), kronecker(m,m))
36*(iM <- solve(M)) # still sparse
MM <- kronecker(Diagonal(10), kronecker(Diagonal(5),kronecker(m,M)))
dim(M3 <- kronecker(bdiag(M,M),MM)) # 12'800 ^ 2
if(interactive()) ## takes about 2 seconds if you have >= 8 GB RAM
  system.time(r <- rcond(M3))
## whereas this is *fast* even though it computes solve(M3)
system.time(r. <- rcond(M3, useInv=TRUE))
if(interactive()) ## the values are not the same
  c(r, r.) # 0.05555 0.013888
## for all 4 norms available for sparseMatrix :
cbind(rr <- sapply(c("1","I","F","M"),
  function(N) rcond(M3, norm=N, useInv=TRUE)))
```

---

|         |                                                |
|---------|------------------------------------------------|
| rep2abI | <i>Replicate Vectors into 'abIndex' Result</i> |
|---------|------------------------------------------------|

---

**Description**

rep2abI(x,times) conceptually computes `rep.int(x,times)` but with an `abIndex` class result.

**Usage**

```
rep2abI(x, times)
```

**Arguments**

|       |                                                    |
|-------|----------------------------------------------------|
| x     | numeric vector                                     |
| times | integer (valued) scalar: the number of repetitions |

**Value**

a vector of `class abIndex`

**See Also**

`rep.int()`, the base function; `abIseq`, `abIndex`.

**Examples**

```
(ab <- rep2abI(2:7, 4))
stopifnot(identical(as(ab, "numeric"),
  rep(2:7, 4)))
```

---

|                 |                                                                          |
|-----------------|--------------------------------------------------------------------------|
| replValue-class | <i>Virtual Class "replValue" - Simple Class for subassignment Values</i> |
|-----------------|--------------------------------------------------------------------------|

---

**Description**

The class "replValue" is a virtual class used for values in signatures for sub-assignment of **Matrix** matrices.

In fact, it is a simple class union (`setClassUnion`) of "numeric" and "logical" (and maybe "complex" in the future).

**Objects from the Class**

Since it is a virtual Class, no objects may be created from it.

**See Also**

`Subassign-methods`, also for examples.

**Examples**

```
showClass("replValue")
```

---

|               |                                                |
|---------------|------------------------------------------------|
| rleDiff-class | Class "rleDiff" of rle(diff(.)) Stored Vectors |
|---------------|------------------------------------------------|

---

## Description

Class "rleDiff" is for compactly storing long vectors which mainly consist of *linear* stretches. For such a vector `x`, `diff(x)` consists of *constant* stretches and is hence well compressable via `rle()`.

## Objects from the Class

Objects can be created by calls of the form `new("rleDiff", ...)`.

Currently experimental, see below.

## Slots

**first:** A single number (of class "numLike", a class union of "numeric" and "logical").

**rle:** Object of class "rle", basically a `list` with components "lengths" and "values", see `rle()`. As this is used to encode potentially huge index vectors, lengths may be of type `double` here.

## Methods

There is a simple `show` method only.

## Note

This is currently an *experimental* auxiliary class for the class `abIndex`, see there.

## See Also

`rle`, `abIndex`.

## Examples

```
showClass("rleDiff")

ab <- c(abIseq(2, 100), abIseq(20, -2))
ab@rleD # is "rleDiff"
```

---

rsparsematrix      *Random Sparse Matrix*

---

## Description

Generate a random sparse matrix efficiently. The default has rounded gaussian non-zero entries, and `rand.x = NULL` generates random pattern matrices, i.e. inheriting from `nsparseMatrix`.

## Usage

```
rsparsematrix(nrow, ncol, density, nnz = round(density * maxE),
              symmetric = FALSE,
              rand.x = function(n) signif(rnorm(n), 2), ...)
```

## Arguments

|                         |                                                                                                                                                                                                                                                                                                                               |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>nrow, ncol</code> | number of rows and columns, i.e., the matrix dimension ( <code>dim</code> ).                                                                                                                                                                                                                                                  |
| <code>density</code>    | optional number in $[0, 1]$ , the density is the proportion of non-zero entries among all matrix entries. If specified it determines the default for <code>nnz</code> , otherwise <code>nnz</code> needs to be specified.                                                                                                     |
| <code>nnz</code>        | number of non-zero entries, for a sparse matrix typically considerably smaller than <code>nrow*ncol</code> . Must be specified if <code>density</code> is not.                                                                                                                                                                |
| <code>symmetric</code>  | logical indicating if result should be a matrix of class <code>symmetricMatrix</code> . Note that in the symmetric case, <code>nnz</code> denotes the number of non zero entries of the upper (or lower) part of the matrix, including the diagonal.                                                                          |
| <code>rand.x</code>     | <code>NULL</code> or the random number generator for the <code>x</code> slot, a <code>function</code> such that <code>rand.x(n)</code> generates a numeric vector of length <code>n</code> . Typical examples are <code>rand.x = rnorm</code> , or <code>rand.x = runif</code> ; the default is nice for didactical purposes. |
| <code>...</code>        | optionally further arguments passed to <code>sparseMatrix()</code> , notably <code>repr</code> .                                                                                                                                                                                                                              |

## Details

The algorithm first samples “encoded”  $(i, j)$ s without replacement, via one dimensional indices, if not symmetric `sample.int(nrow*ncol, nnz)`, then—if `rand.x` is not `NULL`—gets `x <- rand.x(nnz)` and calls `sparseMatrix(i=i, j=j, x=x, ...)`. When `rand.x=NULL`, `sparseMatrix(i=i, j=j, ...)` will return a pattern matrix (i.e., inheriting from `nsparseMatrix`).

## Value

a `sparseMatrix`, say `M` of dimension  $(nrow, ncol)$ , i.e., with `dim(M) == c(nrow, ncol)`, if `symmetric` is not true, with `nzM <- nnzero(M)` fulfilling `nzM <= nnz` and typically, `nzM == nnz`.

## Author(s)

Martin Maechler

**Examples**

```

set.seed(17) # to be reproducible
M <- rsparsematrix(8, 12, nnz = 30) # small example, not very sparse
M
M1 <- rsparsematrix(1000, 20, nnz = 123, rand.x = runif)
summary(M1)

## a random *symmetric* Matrix
(S9 <- rsparsematrix(9, 9, nnz = 10, symmetric=TRUE)) # dsCMatrix
nnzero(S9) # ~ 20: as 'nnz' only counts one "triangle"

## a random patter*n* aka boolean Matrix (no 'x' slot):
(n7 <- rsparsematrix(5, 12, nnz = 10, rand.x = NULL))

## a [T]riplet representation sparseMatrix:
T2 <- rsparsematrix(40, 12, nnz = 99, repr = "T")
head(T2)

```

---

RsparseMatrix-class

*Class "RsparseMatrix" of Sparse Matrices in Column-compressed Form*

---

**Description**

The "RsparseMatrix" class is the virtual class of all sparse matrices coded in sorted compressed row-oriented form. Since it is a virtual class, no objects may be created from it. See `showClass("RsparseMatrix")` for its subclasses.

**Slots**

**j**: Object of class "integer" of length `nnzero` (number of non-zero elements). These are the row numbers for each non-zero element in the matrix.

**p**: Object of class "integer" of pointers, one for each row, to the initial (zero-based) index of elements in the row.

**Dim, Dimnames**: inherited from the superclass, see [sparseMatrix](#).

**Extends**

Class "sparseMatrix", directly. Class "Matrix", by class "sparseMatrix".

**Methods**

Only **few** methods are defined currently on purpose, since we rather use the [CsparseMatrix](#) in **Matrix**. Recently, more methods were added but *beware* that these typically do *not* return "RsparseMatrix" results, but rather *Csparse\** or *Tsparse\** ones.

```

t signature(x = "RsparseMatrix"): ...
coerce signature(from = "RsparseMatrix", to = "CsparseMatrix"): ...
coerce signature(from = "RsparseMatrix", to = "TsparseMatrix"): ...

```

**See Also**

its superclass, [sparseMatrix](#), and, e.g., class [dgRMatrix](#) for the links to other classes.

**Examples**

```
showClass("RsparseMatrix")
```

---

 Schur

---

*Schur Decomposition of a Matrix*

---

**Description**

Computes the Schur decomposition and eigenvalues of a square matrix; see the BACKGROUND information below.

**Usage**

```
Schur(x, vectors, ...)
```

**Arguments**

|                      |                                                                                                                                                                   |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>       | numeric square Matrix (inheriting from class "Matrix") or traditional <a href="#">matrix</a> . Missing values (NAs) are not allowed.                              |
| <code>vectors</code> | logical. When TRUE (the default), the Schur vectors are computed, and the result is a proper <a href="#">MatrixFactorization</a> of class <a href="#">Schur</a> . |
| <code>...</code>     | further arguments passed to or from other methods.                                                                                                                |

**Details**

Based on the Lapack subroutine dgees.

**Value**

If `vectors` are TRUE, as per default: If `x` is a [Matrix](#) an object of class [Schur](#), otherwise, for a traditional [matrix](#) `x`, a [list](#) with components `T`, `Q`, and `EValues`.

If `vectors` are FALSE, a list with components

|                      |                                                                                               |
|----------------------|-----------------------------------------------------------------------------------------------|
| <code>T</code>       | the upper quasi-triangular (square) matrix of the Schur decomposition.                        |
| <code>EValues</code> | the vector of <a href="#">numeric</a> or <a href="#">complex</a> eigen values of $T$ or $A$ . |

**BACKGROUND**

If  $A$  is a square matrix, then  $A = Q T t(Q)$ , where  $Q$  is orthogonal, and  $T$  is upper block-triangular (nearly triangular with either 1 by 1 or 2 by 2 blocks on the diagonal) where the 2 by 2 blocks correspond to (non-real) complex eigenvalues. The eigenvalues of  $A$  are the same as those of  $T$ , which are easy to compute. The Schur form is used most often for computing non-symmetric eigenvalue decompositions, and for computing functions of matrices such as matrix exponentials.

**References**

Anderson, E., et al. (1994). *LAPACK User's Guide*, 2nd edition, SIAM, Philadelphia.

## Examples

```
Schur(Hilbert(9))           # Schur factorization (real eigenvalues)

(A <- Matrix(round(rnorm(5*5, sd = 100)), nrow = 5))
(Sch.A <- Schur(A))

eTA <- eigen(Sch.A@T)
str(SchA <- Schur(A, vectors=FALSE)) # no 'T' ==> simple list
stopifnot(all.equal(eTA$values, eigen(A)$values, tolerance = 1e-13),
           all.equal(eTA$values,
                     local({z <- Sch.A@EValues
                           z[order(Mod(z), decreasing=TRUE)]}), tolerance = 1e-13),
           identical(SchA$T, Sch.A@T),
           identical(SchA$EValues, Sch.A@EValues))

## For the faint of heart, we provide Schur() also for traditional matrices:

a.m <- function(M) unname(as(M, "matrix"))
a <- a.m(A)
Sch.a <- Schur(a)
stopifnot(identical(Sch.a, list(Q = a.m(Sch.A @ Q),
T = a.m(Sch.A @ T),
EValues = Sch.A@EValues)),
           all.equal(a, with(Sch.a, Q %*% T %*% t(Q))))
)
```

---

Schur-class

---

Class "Schur" of Schur Matrix Factorizations

---

## Description

Class "Schur" is the class of Schur matrix factorizations. These are a generalization of eigen value (or "spectral") decompositions for general (possibly asymmetric) square matrices, see the [Schur\(\)](#) function.

## Objects from the Class

Objects of class "Schur" are typically created by [Schur\(\)](#).

## Slots

"Schur" has slots

**T:** Upper Block-triangular [Matrix](#) object.

**Q:** Square *orthogonal* "Matrix".

**EValues:** numeric or complex vector of eigenvalues of T.

**Dim:** the matrix dimension: equal to `c(n,n)` of class "integer".

## Extends

Class "[MatrixFactorization](#)", directly.

**See Also**

`Schur()` for object creation; [MatrixFactorization](#).

**Examples**

```
showClass("Schur")
Schur(M <- Matrix(c(1:7, 10:2), 4,4))
## Trivial, of course:
str(Schur(Diagonal(5)))

## for more examples, see Schur()
```

---

solve-methods

*Methods in Package Matrix for Function solve()*

---

**Description**

Methods for function `solve` to solve a linear system of equations, or equivalently, solve for  $X$  in

$$AX = B$$

where  $A$  is a square matrix, and  $X$ ,  $B$  are matrices or vectors (which are treated as 1-column matrices), and the R syntax is

```
X <- solve(A,B)
```

In `solve(a,b)` in the **Matrix** package,  $a$  may also be a [MatrixFactorization](#) instead of directly a matrix.

**Usage**

```
## S4 method for signature 'CHMfactor,ddenseMatrix'
solve(a, b,
      system = c("A", "LDLt", "LD", "DLt", "L", "Lt", "D", "P", "Pt"), ...)

## S4 method for signature 'dgCMatrix,matrix'
solve(a, b, sparse = FALSE, tol = .Machine$double.eps, ...)

      solve(a, b, ...) ## *the* two-argument version, almost always preferred to
# solve(a)           ## the *rarely* needed one-argument version
```

**Arguments**

|                     |                                                                                                                                                                                                                                |
|---------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>a</code>      | a square numeric matrix, $A$ , typically of one of the classes in <b>Matrix</b> . Logical matrices are coerced to corresponding numeric ones.                                                                                  |
| <code>b</code>      | numeric vector or matrix (dense or sparse) as RHS of the linear system $Ax = b$ .                                                                                                                                              |
| <code>system</code> | only if <code>a</code> is a <a href="#">CHMfactor</a> : character string indicating the kind of linear system to be solved, see below. Note that the default, "A", does <i>not</i> solve the triangular system (but "L" does). |

|        |                                                                                                                                                                |
|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| sparse | only when a is a <code>sparseMatrix</code> , i.e., typically a <code>dgCMatrix</code> : logical specifying if the result should be a (formally) sparse matrix. |
| tol    | only used when a is sparse, in the <code>isSymmetric(a, tol=*)</code> test, where that applies.                                                                |
| ...    | potentially further arguments to the methods.                                                                                                                  |

## Methods

`signature(a = "ANY", b = "ANY")` is simply the **base** package's S3 generic `solve`.

`signature(a = "CHMfactor", b = "....")`, `system=*` The `solve` methods for a "`CHMfactor`" object take an optional third argument `system` whose value can be one of the character strings "A", "LDLt", "LD", "DLt", "L", "Lt", "D", "P" or "Pt". This argument describes the system to be solved. The default, "A", is to solve  $Ax = b$  for  $x$  where  $A$  is sparse, positive-definite matrix that was factored to produce  $a$ . Analogously, `system = "L"` returns the solution  $x$ , of  $Lx = b$ ; similarly, for all system codes **but** "P" and "Pt" where, e.g., `x <- solve(a, b, system="P")` is equivalent to `x <- P %*% b`.

If  $b$  is a `sparseMatrix`, `system` is used as above the corresponding sparse CHOLMOD algorithm is called.

`signature(a = "ddenseMatrix", b = "....")` (for all  $b$ ) work via `as(a, "dgeMatrix")`, using the its methods, see below.

`signature(a = "denseLU", b = "missing")` basically computes uses triangular forward- and back-solve.

`signature(a = "dgCMatrix", b = "matrix")` , and

`signature(a = "dgCMatrix", b = "ddenseMatrix")` with extra argument list (`sparse=FALSE, tol=.Machine$double.eps`) : Uses the sparse `lu(a)` decomposition (which is cached in  $a$ 's `factor` slot). By default, `sparse=FALSE`, returns a `denseMatrix`, since  $U^{-1}L^{-1}B$  may not be sparse at all, even when  $L$  and  $U$  are.

If `sparse=TRUE`, returns a `sparseMatrix` (which may not be very sparse at all, even if  $a$  was sparse).

`signature(a = "dgCMatrix", b = "dsparseMatrix")` , and

`signature(a = "dgCMatrix", b = "missing")` with extra argument list (`sparse=FALSE, tol=.Machine$double.eps`) : Checks if  $a$  is symmetric, and in that case, coerces it to "`symmetricMatrix`", and then computes a *sparse* solution via sparse Cholesky factorization, independently of the `sparse` argument. If  $a$  is not symmetric, the sparse `lu` decomposition is used and the result will be sparse or dense, depending on the `sparse` argument, exactly as for the above ( $b = "ddenseMatrix"$ ) case.

`signature(a = "dgeMatrix", b = "....")` solve the system via internal LU, calling LAPACK routines `dgetri` or `dgetrs`.

`signature(a = "diagonalMatrix", b = "matrix")` and other  $b$ s: Of course this is trivially implemented, as  $D^{-1}$  is diagonal with entries  $1/D[i, i]$ .

`signature(a = "dpoMatrix", b = "....Matrix")` , and

`signature(a = "dppMatrix", b = "....Matrix")` The Cholesky decomposition of  $a$  is calculated (if needed) while solving the system.

`signature(a = "dsCMatrix", b = "....")` All these methods first try Cholmod's Cholesky factorization; if that works, i.e., typically if  $a$  is positive semi-definite, it is made use of. Otherwise, the sparse LU decomposition is used as for the "general" matrices of class "`dgCMatrix`".

```
signature(a = "dspMatrix", b = "....") , and
signature(a = "dsyMatrix", b = "....") all end up calling LAPACK routines
  dsptri, dsptrs, dsytrs and dsytri.
signature(a = "dtCMatrix", b = "CsparseMatrix") ,
signature(a = "dtCMatrix", b = "dgeMatrix") , etc sparse triangular solve, in tra-
ditional S/R also known as backsolve, or forwardsolve. solve(a,b) is a
sparseMatrix if b is, and hence a denseMatrix otherwise.
signature(a = "dtrMatrix", b = "ddenseMatrix") , and
signature(a = "dtpMatrix", b = "matrix") , and similar b, including "missing",
  and "diagonalMatrix":
  all use LAPACK based versions of efficient triangular backsolve, or forwardsolve.
signature(a = "Matrix", b = "diagonalMatrix") works via
  as(b, "CsparseMatrix").
signature(a = "sparseQR", b = "ANY") simply uses qr.coef(a,b).
signature(a = "pMatrix", b = ".....") these methods typically use
  crossprod(a,b), as the inverse of a permutation matrix is the same as its transpose.
signature(a = "TsparseMatrix", b = "ANY") all work via
  as(a, "CsparseMatrix").
```

### Examples

```
## A close to symmetric example with "quite sparse" inverse:
n1 <- 7; n2 <- 3
dd <- data.frame(a = gl(n1,n2), b = gl(n2,1,n1*n2))# balanced 2-way
X <- sparse.model.matrix(~ -1+ a + b, dd)# no intercept --> even sparser
XXt <- tcrossprod(X)
diag(XXt) <- rep(c(0,0,1,0), length.out = nrow(XXt))

n <- nrow(ZZ <- kronecker(XXt, Diagonal(x=c(4,1))))
image(a <- 2*Diagonal(n) + ZZ %*% Diagonal(x=c(10, rep(1, n-1))))
isSymmetric(a) # FALSE
image(drop0(skewpart(a)))
image(ia0 <- solve(a)) # checker board, dense [but really, a is singular!]
try(solve(a, sparse=TRUE))##-> error [ TODO: assertError ]
ia. <- solve(a, sparse=TRUE, tol = 1e-19)##-> *no* error
if(R.version$sarch == "x86_64")
  ## Fails on 32-bit [Fedora 19, R 3.0.2] from Matrix 1.1-0 on [FIXME ??] only
  stopifnot(all.equal(as.matrix(ia.), as.matrix(ia0)))
a <- a + Diagonal(n)
iad <- solve(a)
ias <- solve(a, sparse=TRUE)
stopifnot(all.equal(as(ias,"denseMatrix"), iad, tolerance=1e-14))
I. <- iad %*% a ; image(I.)
I0 <- drop0(zapsmall(I.)); image(I0)
.I <- a %*% iad
.I0 <- drop0(zapsmall(.I))
stopifnot( all.equal(as(I0, "diagonalMatrix"), Diagonal(n)),
```

```
all.equal(as(.I0,"diagonalMatrix"), Diagonal(n)) )
```

---

```
sparse.model.matrix
```

*Construct Sparse Design / Model Matrices*

---

## Description

Construct a sparse model or “design” matrix, from a formula and data frame (`sparse.model.matrix`) or a single factor (`fac2sparse`).

The `fac2[Ss]parse()` functions are utilities, also used internally in the principal user level function `sparse.model.matrix()`.

## Usage

```
sparse.model.matrix(object, data = environment(object),
  contrasts.arg = NULL, xlev = NULL, transpose = FALSE,
  drop.unused.levels = FALSE, row.names = TRUE,
  sep = "", verbose = FALSE, ...)

fac2sparse(from, to = c("d", "i", "l", "n", "z"),
  drop.unused.levels = TRUE, repr = c("C", "T", "R"), giveCsparse)
fac2Sparse(from, to = c("d", "i", "l", "n", "z"),
  drop.unused.levels = TRUE, repr = c("C", "T", "R"), giveCsparse,
  factorPatt12, contrasts.arg = NULL)
```

## Arguments

|                                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|---------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code>             | an object of an appropriate class. For the default method, a model formula or terms object.                                                                                                                                                                                                                                                                                                                                                      |
| <code>data</code>               | a data frame created with <code>model.frame</code> . If another sort of object, <code>model.frame</code> is called first.                                                                                                                                                                                                                                                                                                                        |
| <code>contrasts.arg</code>      | <p><b>for</b> <code>sparse.model.matrix()</code>: A list, whose entries are contrasts suitable for input to the <code>contrasts</code> replacement function and whose names are the names of columns of data containing <code>factors</code>.</p> <p><b>for</b> <code>fac2Sparse()</code>: character string or <code>NULL</code> or (coercable to) <code>"sparseMatrix"</code>, specifying the contrasts to be applied to the factor levels.</p> |
| <code>xlev</code>               | to be used as argument of <code>model.frame</code> if data has no "terms" attribute.                                                                                                                                                                                                                                                                                                                                                             |
| <code>transpose</code>          | logical indicating if the <i>transpose</i> should be returned; if the transposed is used anyway, setting <code>transpose = TRUE</code> is more efficient.                                                                                                                                                                                                                                                                                        |
| <code>drop.unused.levels</code> | should factors have unused levels dropped? The default for <code>sparse.model.matrix</code> has been changed to <code>FALSE</code> , 2010-07, for compatibility with R's standard (dense) <code>model.matrix()</code> .                                                                                                                                                                                                                          |
| <code>row.names</code>          | logical indicating if row names should be used.                                                                                                                                                                                                                                                                                                                                                                                                  |

|              |                                                                                                                                                                                                                                       |
|--------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| sep          | character string passed to <code>paste()</code> when constructing column names from the variable name and its levels.                                                                                                                 |
| verbose      | logical or integer indicating if (and how much) progress output should be printed.                                                                                                                                                    |
| ...          | further arguments passed to or from other methods.                                                                                                                                                                                    |
| from         | (for <code>fac2sparse()</code> ) a <code>factor</code> .                                                                                                                                                                              |
| to           | a character indicating the “kind” of sparse matrix to be returned. The default, “d” is for <code>double</code> .                                                                                                                      |
| giveCsparse  | <b>deprecated</b> , replaced with <code>repr</code> ; logical indicating if the result must be a <code>CsparseMatrix</code> .                                                                                                         |
| repr         | character string, one of “C”, “T”, or “R”, specifying the sparse representation to be used for the result, i.e., one from the super classes <code>CsparseMatrix</code> , <code>TsparseMatrix</code> , or <code>RsparseMatrix</code> . |
| factorPatt12 | logical vector, say <code>fp</code> , of length two; when <code>fp[1]</code> is true, return “contrasted” $t(X)$ ; when <code>fp[2]</code> is true, the original (“dummy”) $t(X)$ , i.e., the result of <code>fac2sparse()</code> .   |

### Value

a sparse matrix, extending `CsparseMatrix` (for `fac2sparse()` if `repr = "C"` as per default; a `TsparseMatrix` or `RsparseMatrix`, otherwise).

For `fac2Sparse()`, a `list` of length two, both components with the corresponding transposed model matrix, where the corresponding `factorPatt12` is true.

Note that `model.Matrix(*, sparse=TRUE)` from package **MatrixModels** may be often be preferable to `sparse.model.matrix()` nowadays, as `model.Matrix()` returns `modelMatrix` objects with additional slots `assign` and `contrasts` which relate back to the variables used.

`fac2sparse()`, the basic workhorse of `sparse.model.matrix()`, returns the *transpose* (`t`) of the model matrix.

### Author(s)

Doug Bates and Martin Maechler, with initial suggestions from Tim Hesterberg.

### See Also

`model.matrix` in standard R’s package **stats**.

`model.Matrix` which calls `sparse.model.matrix` or `model.matrix` depending on its `sparse` argument may be preferred to `sparse.model.matrix`.

`as(f, "sparseMatrix")` (see `coerce(from = "factor", ...)` in the class doc `sparseMatrix`) produces the *transposed* sparse model matrix for a single factor `f` (and *no* contrasts).

### Examples

```
dd <- data.frame(a = gl(3,4), b = gl(4,1,12)) # balanced 2-way
options("contrasts") # the default: "contr.treatment"
sparse.model.matrix(~ a + b, dd)
sparse.model.matrix(~ -1+ a + b, dd) # no intercept --> even sparser
sparse.model.matrix(~ a + b, dd, contrasts = list(a="contr.sum"))
sparse.model.matrix(~ a + b, dd, contrasts = list(b="contr.SAS"))
```

```
## Sparse method is equivalent to the traditional one :
stopifnot(all(sparse.model.matrix(~ a + b, dd) ==
  Matrix(model.matrix(~ a + b, dd), sparse=TRUE)),
  all(sparse.model.matrix(~ 0+ a + b, dd) ==
  Matrix(model.matrix(~ 0+ a + b, dd), sparse=TRUE)))

(ff <- gl(3,4,, c("X","Y", "Z")))
fac2sparse(ff) # 3 x 12 sparse Matrix of class "dgCMatrix"
##
## X 1 1 1 1 . . . . .
## Y . . . . 1 1 1 1 . . . .
## Z . . . . . . . 1 1 1 1

## can also be computed via sparse.model.matrix():
f30 <- gl(3,0 )
f12 <- gl(3,0, 12)
stopifnot(
  all.equal(t( fac2sparse(ff) ),
    sparse.model.matrix(~ 0+ff),
    tolerance = 0, check.attributes=FALSE),
  is(M <- fac2sparse(f30, drop= TRUE), "CsparseMatrix"), dim(M) == c(0, 0),
  is(M <- fac2sparse(f30, drop=FALSE), "CsparseMatrix"), dim(M) == c(3, 0),
  is(M <- fac2sparse(f12, drop= TRUE), "CsparseMatrix"), dim(M) == c(0,12),
  is(M <- fac2sparse(f12, drop=FALSE), "CsparseMatrix"), dim(M) == c(3,12)
)
```

sparseLU-class

*Sparse LU decomposition of a square sparse matrix*

---

## Description

Objects of this class contain the components of the LU decomposition of a sparse square matrix.

## Objects from the Class

Objects can be created by calls of the form `new("sparseLU", ...)` but are more commonly created by function `lu()` applied to a sparse matrix, such as a matrix of class `dgCMatrix`.

## Slots

**L:** Object of class "`dtCMatrix`", the lower triangular factor from the left.  
**U:** Object of class "`dtCMatrix`", the upper triangular factor from the right.  
**p:** Object of class "`integer`", permutation applied from the left.  
**q:** Object of class "`integer`", permutation applied from the right.  
**Dim:** the dimension of the original matrix; inherited from class `MatrixFactorization`.

## Extends

Class "`LU`", directly. Class "`MatrixFactorization`", by class "`LU`".

**Methods**

**expand** signature(x = "sparseLU") Returns a list with components P, L, U, and Q, where *P* and *Q* represent fill-reducing permutations, and *L*, and *U* the lower and upper triangular matrices of the decomposition. The original matrix corresponds to the product  $P'LUQ$ .

**Note**

The decomposition is of the form

$$A = P'LUQ,$$

or equivalently  $PAQ' = LU$ , where all matrices are sparse and of size  $n \times n$ . The matrices *P* and *Q*, and their transposes *P'* and *Q'* are permutation matrices, *L* is lower triangular and *U* is upper triangular.

**See Also**

[lu](#), [solve](#), [dgCMatrix](#)

**Examples**

```
## Extending the one in  examples(lu), calling the matrix A,
## and confirming the factorization identities :
A <- as(readMM(system.file("external/pores_1.mtx",
                           package = "Matrix")),
        "CsparseMatrix")
## with dimnames(.) - to see that they propagate to L, U :
dimnames(A) <- dnA <- list(paste0("r", seq_len(nrow(A))),
                           paste0("C", seq_len(ncol(A))))
str(luA <- lu(A)) # p is a 0-based permutation of the rows
                  # q is a 0-based permutation of the columns
xA <- expand(luA)
## which is simply doing
stopifnot(identical(xA$L, luA@L),
          identical(xA$U, luA@U),
          identical(xA$P, as(luA@p + 1L, "pMatrix")),
          identical(xA$Q, as(luA@q + 1L, "pMatrix")))

P.LUQ <- with(xA, t(P) %*% L %*% U %*% Q)
stopifnot(all.equal(A, P.LUQ, tolerance = 1e-12),
          identical(dimnames(P.LUQ), dnA))
## permute rows and columns of original matrix
pA <- A[luA@p + 1L, luA@q + 1L]
stopifnot(identical(pA, with(xA, P %*% A %*% t(Q))))

pLU <- drop0(luA@L %*% luA@U) # L %*% U -- dropping extra zeros
stopifnot(all.equal(pA, pLU, tolerance = 1e-12))
```

## Description

Methods for coercion from and to sparse matrices from package **SparseM** are provided here, for ease of porting functionality to the **Matrix** package, and comparing functionality of the two packages. All these work via the usual `as(., "<class>")` coercion,

```
as(from, Class)
```

## Methods

```
from = "matrix.csr", to = "dgRMatrix" ...
from = "matrix.csc", to = "dgCMatrix" ...
from = "matrix.coo", to = "dgTMatrix" ...
from = "dgRMatrix", to = "matrix.csr" ...
from = "dgCMatrix", to = "matrix.csc" ...
from = "dgTMatrix", to = "matrix.coo" ...
from = "sparseMatrix", to = "matrix.csr" ...
from = "matrix.csr", to = "dgCMatrix" ...
from = "matrix.coo", to = "dgCMatrix" ...
from = "matrix.csr", to = "Matrix" ...
from = "matrix.csc", to = "Matrix" ...
from = "matrix.coo", to = "Matrix" ...
```

## See Also

---

sparseMatrix

*General Sparse Matrix Construction from Nonzero Entries*

---

## Description

User friendly construction of a compressed, column-oriented, sparse matrix, inheriting from `class CsparseMatrix` (or `TsparseMatrix` if `giveCsparse` is false), from locations (and values) of its non-zero entries.

This is the recommended user interface rather than direct `new("***Matrix", ...)` calls.

## Usage

```
sparseMatrix(i = ep, j = ep, p, x, dims, dimnames,
             symmetric = FALSE, triangular = FALSE, index1 = TRUE,
             repr = "C", giveCsparse = (repr == "C"),
             check = TRUE, use.last.ij = FALSE)
```

**Arguments**

|                          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>i, j</code>        | integer vectors of the same length specifying the locations (row and column indices) of the non-zero (or non-TRUE) entries of the matrix. Note that for <i>repeated</i> pairs $(i_k, j_k)$ , when <code>x</code> is not missing, the corresponding $x_k$ are <i>added</i> , in consistency with the definition of the "TsparseMatrix" class, unless <code>use.last.ij</code> is true, in which case only the <i>last</i> of the corresponding $(i_k, j_k, x_k)$ triplet is used. |
| <code>p</code>           | numeric (integer valued) vector of pointers, one for each column (or row), to the initial (zero-based) index of elements in the column (or row). Exactly one of <code>i</code> , <code>j</code> or <code>p</code> must be missing.                                                                                                                                                                                                                                               |
| <code>x</code>           | optional values of the matrix entries. If specified, must be of the same length as <code>i</code> / <code>j</code> , or of length one where it will be recycled to full length. If missing, the resulting matrix will be a 0/1 pattern matrix, i.e., extending class <code>nsparseMatrix</code> .                                                                                                                                                                                |
| <code>dims</code>        | optional, non-negative, integer, dimensions vector of length 2. Defaults to <code>c(max(i), max(j))</code> .                                                                                                                                                                                                                                                                                                                                                                     |
| <code>dimnames</code>    | optional list of <code>dimnames</code> ; if not specified, none, i.e., <code>NULL</code> ones, are used.                                                                                                                                                                                                                                                                                                                                                                         |
| <code>symmetric</code>   | logical indicating if the resulting matrix should be symmetric. In that case, only the lower or upper triangle needs to be specified via $(i/j/p)$ .                                                                                                                                                                                                                                                                                                                             |
| <code>triangular</code>  | logical indicating if the resulting matrix should be triangular. In that case, the lower or upper triangle needs to be specified via $(i/j/p)$ .                                                                                                                                                                                                                                                                                                                                 |
| <code>index1</code>      | logical scalar. If TRUE, the default, the index vectors <code>i</code> and/or <code>j</code> are 1-based, as is the convention in R. That is, counting of rows and columns starts at 1. If FALSE the index vectors are 0-based so counting of rows and columns starts at 0; this corresponds to the internal representation.                                                                                                                                                     |
| <code>repr</code>        | character string, one of "C", "T", or "R", specifying the sparse representation to be used for the result, i.e., one from the super classes <code>CsparseMatrix</code> , <code>TsparseMatrix</code> , or <code>RsparseMatrix</code> .                                                                                                                                                                                                                                            |
| <code>giveCsparse</code> | <b>(deprecated, replaced with repr):</b> logical indicating if the result should be a <code>CsparseMatrix</code> or a <code>TsparseMatrix</code> , where the default was TRUE, and now is determined from <code>repr</code> ; very often Csparse matrices are more efficient subsequently, but not always.                                                                                                                                                                       |
| <code>check</code>       | logical indicating if a validity check is performed; do not set to FALSE unless you know what you're doing!                                                                                                                                                                                                                                                                                                                                                                      |
| <code>use.last.ij</code> | logical indicating if in the case of repeated, i.e., duplicated pairs $(i_k, j_k)$ only the last one should be used. The default, FALSE, corresponds to the "TsparseMatrix" definition.                                                                                                                                                                                                                                                                                          |

**Details**

Exactly one of the arguments `i`, `j` and `p` must be missing.

In typical usage, `p` is missing, `i` and `j` are vectors of positive integers and `x` is a numeric vector. These three vectors, which must have the same length, form the triplet representation of the sparse matrix.

If `i` or `j` is missing then `p` must be a non-decreasing integer vector whose first element is zero. It provides the compressed, or "pointer" representation of the row or column indices, whichever is missing. The expanded form of `p`, `rep(seq_along(dp), dp)` where `dp <- diff(p)`, is used as the (1-based) row or column indices.

You cannot set both `singular` and `triangular` to `true`; rather use `Diagonal()` (or its alternatives, see there).

The values of `i`, `j`, `p` and `index1` are used to create 1-based index vectors `i` and `j` from which a `TsparseMatrix` is constructed, with numerical values given by `x`, if non-missing. Note that in that case, when some pairs  $(i_k, j_k)$  are repeated (aka “duplicated”), the corresponding  $x_k$  are *added*, in consistency with the definition of the “`TsparseMatrix`” class, unless use `.last.ij` is set to `true`.

By default, when `repr = "C"`, the `CsparseMatrix` derived from this triplet form is returned, where `repr = "R"` now allows to directly get an `RsparseMatrix` and `repr = "T"` leaves the result as `TsparseMatrix`.

The reason for returning a `CsparseMatrix` object instead of the triplet format by default is that the compressed column form is easier to work with when performing matrix operations. In particular, if there are no zeros in `x` then a `CsparseMatrix` is a unique representation of the sparse matrix.

### Value

A sparse matrix, by default (from `repr = "C"`) in compressed, column-oriented form, as an R object inheriting from both `CsparseMatrix` and `generalMatrix`.

### Note

You *do* need to use `index1 = FALSE` (or add + 1 to `i` and `j`) if you want use the 0-based `i` (and `j`) slots from existing sparse matrices.

### See Also

`Matrix(*, sparse=TRUE)` for the constructor of such matrices from a *dense* matrix. That is easier in small sample, but much less efficient (or impossible) for large matrices, where something like `sparseMatrix()` is needed. Further `bdiag` and `Diagonal` for (block-)diagonal and `bandSparse` for banded sparse matrix constructors.

Random sparse matrices via `rsparsematrix()`.

The standard R `xtabs(*, sparse=TRUE)`, for sparse tables and `sparse.model.matrix()` for building sparse model matrices.

Consider `CsparseMatrix` and similar class definition help files.

### Examples

```
## simple example
i <- c(1,3:8); j <- c(2,9,6:10); x <- 7 * (1:7)
(A <- sparseMatrix(i, j, x = x)) ## 8 x 10 "dgCMatrix"
summary(A)
str(A) # note that *internally* 0-based row indices are used

(sA <- sparseMatrix(i, j, x = x, symmetric = TRUE)) ## 10 x 10 "dsCMatrix"
(tA <- sparseMatrix(i, j, x = x, triangular= TRUE)) ## 10 x 10 "dtCMatrix"
stopifnot( all(sA == tA + t(tA)) ,
           identical(sA, as(tA + t(tA), "symmetricMatrix")))

## dims can be larger than the maximum row or column indices
(AA <- sparseMatrix(c(1,3:8), c(2,9,6:10), x = 7 * (1:7), dims = c(10,20)))
summary(AA)
```

```

## i, j and x can be in an arbitrary order, as long as they are consistent
set.seed(1); (perm <- sample(1:7))
(A1 <- sparseMatrix(i[perm], j[perm], x = x[perm]))
stopifnot(identical(A, A1))

## The slots are 0-index based, so
try( sparseMatrix(i=A@i, p=A@p, x= seq_along(A@x)) )
## fails and you should say so: 1-indexing is FALSE:
  sparseMatrix(i=A@i, p=A@p, x= seq_along(A@x), index1 = FALSE)

## the (i,j) pairs can be repeated, in which case the x's are summed
(args <- data.frame(i = c(i, 1), j = c(j, 2), x = c(x, 2)))
(Aa <- do.call(sparseMatrix, args))
## explicitly ask for elimination of such duplicates, so
## that the last one is used:
(A. <- do.call(sparseMatrix, c(args, list(use.last.ij = TRUE))))
stopifnot(Aa[1,2] == 9, # 2+7 == 9
          A.[1,2] == 2) # 2 was *after* 7

## for a pattern matrix, of course there is no "summing":
(nA <- do.call(sparseMatrix, args[c("i","j")]))

dn <- list(LETTERS[1:3], letters[1:5])
## pointer vectors can be used, and the (i,x) slots are sorted if necessary:

---

sparseMatrix-class *Virtual Class "sparseMatrix" — Mother of Sparse Matrices*

---

## Description

Virtual Mother Class of All Sparse Matrices

## Slots

**Dim:** Object of class "integer" - the dimensions of the matrix - must be an integer vector with exactly two non-negative values.

**Dimnames:** a list of length two - inherited from class Matrix, see [Matrix](#).

## Extends

Class "Matrix", directly.

## Methods

**show** (object = "sparseMatrix"): The [show](#) method for sparse matrices prints “*structural*” zeroes as "." using [printSpMatrix\(\)](#) which allows further customization.

**print** signature(x = "sparseMatrix"), ...

The [print](#) method for sparse matrices by default is the same as [show\(\)](#) but can be called with extra optional arguments, see [printSpMatrix\(\)](#).

**format** signature(x = "sparseMatrix"), ...

The [format](#) method for sparse matrices, see [formatSpMatrix\(\)](#) for details such as the extra optional arguments.

**summary** (object = "sparseMatrix", uniqT=FALSE): Returns an object of S3 class "sparseSummary" which is basically a [data.frame](#) with columns (i, j, x) (or just (i, j) for [nsparseMatrix](#) class objects) with the stored (typically non-zero) entries. The [print](#) method resembles Matlab's way of printing sparse matrices, and also the MatrixMarket format, see [writeMM](#).

**cbind2** (x = \*, y = \*): several methods for binding matrices together, column-wise, see the basic [cbind](#) and [rbind](#) functions.

Note that the result will typically be sparse, even when one argument is dense and larger than the sparse one.

**rbind2** (x = \*, y = \*): binding matrices together row-wise, see [cbind2](#) above.

**determinant** (x = "sparseMatrix", logarithm=TRUE): [determinant\(\)](#) methods for sparse matrices typically work via [Cholesky](#) or [lu](#) decompositions.

**diag** (x = "sparseMatrix"): extracts the diagonal of a sparse matrix.

**dim<-** signature(x = "sparseMatrix", value = "ANY"): allows to *reshape* a sparse matrix to a sparse matrix with the same entries but different dimensions. value must be of length two and fulfill `prod(value) == prod(dim(x))`.

**coerce** signature (from = "factor", to = "sparseMatrix"): Coercion of a factor to "sparseMatrix" produces the matrix of indicator **rows** stored as an object of class "dgCMatrix". To obtain columns representing the interaction of the factor and a numeric covariate, replace the "x" slot of the result by the numeric covariate then take the transpose. Missing values (NA) from the factor are translated to columns of all 0s.

See also [colSums](#), [norm](#), ... for methods with separate help pages.

### Note

In method selection for multiplication operations (i.e. `%%` and the two-argument form of [crossprod](#)) the `sparseMatrix` class takes precedence in the sense that if one operand is a sparse matrix and the other is any type of dense matrix then the dense matrix is coerced to a `dgeMatrix` and the appropriate sparse matrix method is used.

### See Also

[sparseMatrix](#), and its references, such as [xtabs](#)(\*, sparse=TRUE), or [sparse.model.matrix](#)(), for constructing sparse matrices.

[T2graph](#) for conversion of "graph" objects (package **graph**) to and from sparse matrices.

### Examples

```
showClass("sparseMatrix") ## and look at the help() of its subclasses
M <- Matrix(0, 10000, 100)
M[1,1] <- M[2,3] <- 3.14
M ## show(.) method suppresses printing of the majority of rows

data(CAex); dim(CAex) # 72 x 72 matrix
determinant(CAex) # works via sparse lu(.)

## factor -> t( <sparse design matrix> ) :
(fact <- gl(5, 3, 30, labels = LETTERS[1:5]))
(Xt <- as(fact, "sparseMatrix")) # indicator rows

## missing values --> all-0 columns:
f.mis <- fact
i.mis <- c(3:5, 17)
is.na(f.mis) <- i.mis
Xt != (X. <- as(f.mis, "sparseMatrix")) # differ only in columns 3:5,17
stopifnot(all(X.[,i.mis] == 0), all(Xt[,-i.mis] == X.[,-i.mis]))
```

### Description

Objects class "sparseQR" represent a QR decomposition of a sparse  $m \times n$  ("long":  $m \geq n$ ) rectangular matrix  $A$ , typically resulting from [qr](#) (), see 'Details' notably about row and column permutations for pivoting.

## Details

For a sparse  $m \times n$  ("long":  $m \geq n$ ) rectangular matrix  $A$ , the sparse QR decomposition is either of the form  $PA = QR$  with a (row) permutation matrix  $P$ , (encoded in the `p` slot of the result) if the `q` slot is of length 0,

or of the form  $PAP^* = QR$  with an extra (column) permutation matrix  $P^*$  (encoded in the `q` slot). Note that the row permutation  $PA$  in R is simply  $A[p+1, ]$  where `p` is the `p`-slot, a 0-based permutation of  $1:m$  applied to the rows of the original matrix.

If the `q` slot has length `n` it is a 0-based permutation of  $1:n$  applied to the columns of the original matrix to reduce the amount of "fill-in" in the matrix  $R$ , and  $AP^*$  in R is simply  $A[, q+1]$ .

$R$  is an  $m \times n$  matrix that is zero below the main diagonal, i.e., upper triangular ( $m \times m$ ) with  $m - n$  extra zero rows.

The matrix  $Q$  is a "virtual matrix". It is the product of  $n$  Householder transformations. The information to generate these Householder transformations is stored in the `V` and `beta` slots.

Note however that `qr.Q()` returns the row permuted matrix  $Q^* := P^{-1}Q = P'Q$  as permutation matrices are orthogonal; and  $Q^*$  is orthogonal itself because  $Q$  and  $P$  are. This is useful because then, as in the dense matrix and **base** R matrix `qr` case, we have the mathematical identity

$$PA = Q^* R,$$

in R as

```
A[p+1, ] == qr.Q(*) %*% R .
```

The "sparseQR" methods for the `qr.*` functions return objects of class "dgcMatrix" (see [dgcMatrix](#)). Results from `qr.coef`, `qr.resid` and `qr.fitted` (when `k == ncol(R)`) are well-defined and should match those from the corresponding dense matrix calculations. However, because the matrix  $Q$  is not uniquely defined, the results of `qr.qy` and `qr.qty` do not necessarily match those from the corresponding dense matrix calculations.

Also, the results of `qr.qy` and `qr.qty` apply to the permuted column order when the `q` slot has length `n`.

## Objects from the Class

Objects can be created by calls of the form `new("sparseQR", ...)` but are more commonly created by function `qr` applied to a sparse matrix such as a matrix of class [dgCMatrix](#).

## Slots

**V:** Object of class "dgCMatrix". The columns of `V` are the vectors that generate the Householder transformations of which the matrix  $Q$  is composed.

**beta:** Object of class "numeric", the normalizing factors for the Householder transformations.

**p:** Object of class "integer": Permutation (of  $0:(n-1)$ ) applied to the rows of the original matrix.

**R:** Object of class "dgCMatrix": An upper triangular matrix of the same dimension as  $X$ .

**q:** Object of class "integer": Permutation applied from the right, i.e., to the *columns* of the original matrix. Can be of length 0 which implies no permutation.

## Methods

**qr.R** signature(`qr = "sparseQR"`): compute the upper triangular  $R$  matrix of the QR decomposition. Note that this currently warns because of possible permutation mismatch with the classical `qr.R()` result, *and* you can suppress these warnings by setting `options()` either `"Matrix.quiet.qr.R"` or (the more general) either `"Matrix.quiet"` to `TRUE`.

**qr.Q** signature(`qr = "sparseQR"`): compute the orthogonal  $Q$  matrix of the QR decomposition.

**qr.coef** signature(`qr = "sparseQR"`, `y = "ddenseMatrix"`): ...

**qr.coef** signature(`qr = "sparseQR"`, `y = "matrix"`): ...

**qr.coef** signature(`qr = "sparseQR"`, `y = "numeric"`): ...

**qr.fitted** signature(`qr = "sparseQR"`, `y = "ddenseMatrix"`): ...

**qr.fitted** signature(`qr = "sparseQR"`, `y = "matrix"`): ...

**qr.fitted** signature(`qr = "sparseQR"`, `y = "numeric"`): ...

**qr.qty** signature(`qr = "sparseQR"`, `y = "ddenseMatrix"`): ...

**qr.qty** signature(`qr = "sparseQR"`, `y = "matrix"`): ...

**qr.qty** signature(`qr = "sparseQR"`, `y = "numeric"`): ...

**qr.qy** signature(`qr = "sparseQR"`, `y = "ddenseMatrix"`): ...

**qr.qy** signature(`qr = "sparseQR"`, `y = "matrix"`): ...

**qr.qy** signature(`qr = "sparseQR"`, `y = "numeric"`): ...

**qr.resid** signature(`qr = "sparseQR"`, `y = "ddenseMatrix"`): ...

**qr.resid** signature(`qr = "sparseQR"`, `y = "matrix"`): ...

**qr.resid** signature(`qr = "sparseQR"`, `y = "numeric"`): ...

**solve** signature(`a = "sparseQR"`, `b = "ANY"`): For `solve(a,b)`, simply uses `qr.coef(a,b)`.

## See Also

 Permutation matrices in the **Matrix** package: `pMatrix`; `dgCMatrix`, `dgeMatrix`.

## Examples

```
data(KNex)
mm <- KNex $ mm
y <- KNex $ y
y. <- as(as.matrix(y), "dgCMatrix")
str(qrm <- qr(mm))
qc <- qr.coef (qrm, y); qc. <- qr.coef (qrm, y.) # 2nd failed in Matrix <= 1.1-0
qf <- qr.fitted(qrm, y); qf. <- qr.fitted(qrm, y.)
qs <- qr.resid (qrm, y); qs. <- qr.resid (qrm, y.)
stopifnot(all.equal(qc, as.numeric(qc.), tolerance=1e-12),
          all.equal(qf, as.numeric(qf.), tolerance=1e-12),
          all.equal(qs, as.numeric(qs.), tolerance=1e-12),
          all.equal(qf+qs, y, tolerance=1e-12))
```

## sparseVector

*Sparse Vector Construction from Nonzero Entries***Description**

User friendly construction of sparse vectors, i.e., objects inheriting from `class sparseVector`, from indices and values of its non-zero entries.

**Usage**

```
sparseVector(x, i, length)
```

**Arguments**

|                     |                                                                                                                                           |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>      | vector of the non zero entries; may be missing in which case a "nsparseVector" will be returned.                                          |
| <code>i</code>      | integer vector (of the same length as <code>x</code> ) specifying the indices of the non-zero (or non-TRUE) entries of the sparse vector. |
| <code>length</code> | length of the sparse vector.                                                                                                              |

**Details**

zero entries in `x` are dropped automatically, analogously as `drop0()` acts on sparse matrices.

**Value**

a sparse vector, i.e., inheriting from `class sparseVector`.

**Author(s)**

Martin Maechler

**See Also**

`sparseMatrix()` constructor for sparse matrices; the class `sparseVector`.

**Examples**

```
str(sv <- sparseVector(x = 1:10, i = sample(999, 10), length=1000))

sx <- c(0,0,3, 3.2, 0,0,0,-3:1,0,0,2,0,0,5,0,0)
ss <- as(sx, "sparseVector")
stopifnot(identical(ss,
  sparseVector(x = c(2, -1, -2, 3, 1, -3, 5, 3.2),
    i = c(15L, 10:9, 3L,12L,8L,18L, 4L), length = 20L)))

(ns <- sparseVector(i= c(7, 3, 2), length = 10))
stopifnot(identical(ns,
  new("nsparseVector", length = 10, i = c(2, 3, 7))))
```

---

sparseVector-class *Sparse Vector Classes*

---

**Description**

**Sparse Vector Classes:** The virtual mother class "sparseVector" has the five actual daughter classes "dsparseVector", "isparseVector", "lsparseVector", "nsparseVector", and "zsparseVector", where we've mainly implemented methods for the d\*, l\* and n\* ones.

**Slots**

- length:** class "numeric" - the [length](#) of the sparse vector. Note that "numeric" can be considerably larger than the maximal "integer", `.Machine$integer.max`, on purpose.
- i:** class "numeric" - the (1-based) indices of the non-zero entries. Must *not* be NA and strictly sorted increasingly.  
Note that "integer" is "part of" "numeric", and can (and often will) be used for non-huge sparseVectors.
- x:** (for all but "nsparseVector"): the non-zero entries. This is of class "numeric" for class "dsparseVector", "logical" for class "lsparseVector", etc.  
Note that "nsparseVector"s have no x slot. Further, mainly for ease of method definitions, we've defined the class union (see [setClassUnion](#)) of all sparse vector classes which *have* an x slot, as class "xsparseVector".

**Methods**

- length** signature (x = "sparseVector"): simply extracts the length slot.
- show** signature (object = "sparseVector"): The [show](#) method for sparse vectors prints "structural" zeroes as "." using the non-exported `prSpVector` function which allows further customization such as replacing "." by " " (blank).  
Note that [options](#)(max.print) will influence how many entries of large sparse vectors are printed at all.
- as.vector** signature (x = "sparseVector", mode = "character") coerces sparse vectors to "regular", i.e., atomic vectors. This is the same as `as(x, "vector")`.
- as** `..`: see [coerce](#) below
- coerce** signature (from = "sparseVector", to = "sparseMatrix"), and  
**coerce** signature (from = "sparseMatrix", to = "sparseVector"), etc: coercions to and from sparse matrices ([sparseMatrix](#)) are provided and work analogously as in standard R, i.e., a vector is coerced to a 1-column matrix.
- dim<-** signature (x = "sparseVector", value = "integer") coerces a sparse vector to a sparse Matrix, i.e., an object inheriting from [sparseMatrix](#), of the appropriate dimension.
- head** signature (x = "sparseVector"): as with R's (package [util](#)) [head](#), `head(x, n)` (for  $n \geq 1$ ) is equivalent to `x[1:n]`, but here can be much more efficient, see the example.
- tail** signature (x = "sparseVector"): analogous to [head](#), see above.

**toeplitz** signature( $x = \text{"sparseVector"}$ ): as `toeplitz(x)`, produce the  $n \times n$  Toeplitz matrix from  $x$ , where  $n = \text{length}(x)$ .

**rep** signature( $x = \text{"sparseVector"}$ ) repeat  $x$ , with the same argument list ( $x, \text{times}, \text{length.out}, \text{each}, \dots$ ) as the default method for `rep()`.

**which** signature( $x = \text{"nsparseVector"}$ ) and

**which** signature( $x = \text{"lsparseVector"}$ ) return the indices of the non-zero entries (which is trivial for sparse vectors).

**Ops** signature( $e1 = \text{"sparseVector"}, e2 = "*"$ ): define arithmetic, compare and logic operations, (see [Ops](#)).

**Summary** signature( $x = \text{"sparseVector"}$ ): define all the [Summary](#) methods.

[ signature( $x = \text{"atomicVector"}, i = \dots$ ): not only can you subset (aka “index into”) sparseVectors  $x[i]$  using sparseVectors  $i$ , but we also support efficient subsetting of traditional vectors  $x$  by logical sparse vectors (i.e.,  $i$  of class “nsparseVector” or “lsparseVector”).

**is.na, is.finite, is.infinite** ( $x = \text{"sparseVector"}$ ), and

**is.na, is.finite, is.infinite** ( $x = \text{"nsparseVector"}$ ): return [logical](#) or “nsparseVector” of the same length as  $x$ , indicating if/where  $x$  is [NA](#) (or [NaN](#)), finite or infinite, entirely analogously to the corresponding base R functions.

`c.sparseVector()` is an S3 method for all “sparseVector”s, but automatic dispatch only happens for the first argument, so it is useful also as regular R function, see the examples.

## See Also

[sparseVector\(\)](#) for friendly construction of sparse vectors (apart from `as(*, "sparseVector")`).

## Examples

```
getClass("sparseVector")
getClass("dsparseVector")
getClass("xsparseVector") # those with an 'x' slot

sx <- c(0,0,3, 3.2, 0,0,0,-3:1,0,0,2,0,0,5,0,0)
(ss <- as(sx, "sparseVector"))

ix <- as.integer(round(sx))
(is <- as(ix, "sparseVector")) ## an "isparseVector" (!)
(ns <- sparseVector(i= c(7, 3, 2), length = 10)) # "nsparseVector"
## rep() works too:
(ri <- rep(is, length.out= 25))

## Using `dim<-` as in base R :
r <- ss
dim(r) <- c(4,5) # becomes a sparse Matrix:
r
## or coercion (as as.matrix() in base R):
as(ss, "Matrix")
stopifnot(all(ss == print(as(ss, "CsparseMatrix"))))

## currently has "non-structural" FALSE -- printing as ":"
(lis <- is & FALSE)
(nn <- is[is == 0]) # all "structural" FALSE
```

```

## NA-case
sN <- sx; sN[4] <- NA
(svN <- as(sN, "sparseVector"))

v <- as(c(0,0,3, 3.2, rep(0,9),-3,0,-1, rep(0,20),5,0),
        "sparseVector")
v <- rep(rep(v, 50), 5000)
set.seed(1); v[sample(v@i, 1e6)] <- 0
str(v)

system.time(for(i in 1:4) hv <- head(v, 1e6))
##   user   system elapsed
## 0.033   0.000   0.032
system.time(for(i in 1:4) h2 <- v[1:1e6])
##   user   system elapsed
## 1.317   0.000   1.319

stopifnot(identical(hv, h2),
           identical(is | FALSE, is != 0),
           validObject(svN), validObject(lis), as.logical(is.na(svN[4])),
           identical(is^2 > 0, is & TRUE),

           sum(lis) == 0, !prod(lis), range(lis) == c(0,0))

## create and use the t(.) method:
t(x20 <- sparseVector(c(9,3:1), i=c(1:2,4,7), length=20))
(T20 <- toeplitz(x20))
stopifnot(is(T20, "symmetricMatrix"), is(T20, "sparseMatrix"),
           identical(unname(as.matrix(T20)),
                     toeplitz(as.vector(x20))))

## c() method for "sparseVector" - also available as regular function
(c1 <- c(x20, 0,0,0, -10*x20))
(c2 <- c(ns, is, FALSE))
(c3 <- c(ns, !ns, TRUE, NA, FALSE))
(c4 <- c(ns, rev(ns)))
## here, c() would produce a list {not dispatching to c.sparseVector()}
(c5 <- c.sparseVector(0,0, x20))

## checking (consistency)
.v <- as.vector
.s <- function(v) as(v, "sparseVector")
stopifnot(
  all.equal(c1, .s(c(.v(x20), 0,0,0, -10*.v(x20))), tol=0),
  all.equal(c2, .s(c(.v(ns), .v(is), FALSE)), tol=0),
  all.equal(c3, .s(c(.v(ns), !.v(ns), TRUE, NA, FALSE)), tol=0),
  all.equal(c4, .s(c(.v(ns), rev(.v(ns)))), tol=0),
  all.equal(c5, .s(c(0,0, .v(x20))), tol=0)
)

```

## Description

User friendly construction of a sparse matrix (inheriting from class `TsparseMatrix`) from the triplet representation.

This is much less flexible than `sparseMatrix()` and hence somewhat *deprecated*.

## Usage

```
spMatrix(nrow, ncol, i = integer(), j = integer(), x = numeric())
```

## Arguments

|                         |                                                                                                                        |
|-------------------------|------------------------------------------------------------------------------------------------------------------------|
| <code>nrow, ncol</code> | integers specifying the desired number of rows and columns.                                                            |
| <code>i, j</code>       | integer vectors of the same length specifying the locations of the non-zero (or non-TRUE) entries of the matrix.       |
| <code>x</code>          | atomic vector of the same length as <code>i</code> and <code>j</code> , specifying the values of the non-zero entries. |

## Value

A sparse matrix in triplet form, as an R object inheriting from both `TsparseMatrix` and `generalMatrix`.

The matrix  $M$  will have  $M[i[k], j[k]] == x[k]$ , for  $k = 1, 2, \dots, n$ , where  $n = \text{length}(i)$  and  $M[i', j'] == 0$  for all other pairs  $(i', j')$ .

## See Also

`Matrix(*, sparse=TRUE)` for the more usual constructor of such matrices. Then, `sparseMatrix` is more general and flexible than `spMatrix()` and by default returns a `CsparseMatrix` which is often slightly more desirable. Further, `bdiag` and `Diagonal` for (block-)diagonal matrix constructors.

Consider `TsparseMatrix` and similar class definition help files.

## Examples

```
## simple example
A <- spMatrix(10,20, i = c(1,3:8),
              j = c(2,9,6:10),
              x = 7 * (1:7))

A # a "dgTMatrix"
summary(A)
str(A) # note that *internally* 0-based indices (i,j) are used

L <- spMatrix(9, 30, i = rep(1:9, 3), 1:27,
              (1:27) %% 4 != 1)
L # an "lgTMatrix"

## A simplified predecessor of Matrix' rsparsematrix() function :

rSpMatrix <- function(nrow, ncol, nnz,
                      rand.x = function(n) round(rnorm(nnz), 2))
{
  ## Purpose: random sparse matrix
```

```
## -----
## Arguments: (nrow,ncol): dimension
##           nnz   : number of non-zero entries
##           rand.x: random number generator for 'x' slot
## -----
## Author: Martin Maechler, Date: 14.-16. May 2007
stopifnot((nnz <- as.integer(nnz)) >= 0,
          nrow >= 0, ncol >= 0, nnz <= nrow * ncol)
spMatrix(nrow, ncol,
         i = sample(nrow, nnz, replace = TRUE),
         j = sample(ncol, nnz, replace = TRUE),
         x = rand.x(nnz))
}

M1 <- rSpMatrix(100000, 20, nnz = 200)
summary(M1)

symmetricMatrix-class

*Virtual Class of Symmetric Matrices in Package Matrix*

---

## Description

The virtual class of symmetric matrices, "symmetricMatrix", from the package **Matrix** contains numeric and logical, dense and sparse matrices, e.g., see the examples with the "actual" sub-classes.

The main use is in methods (and C functions) that can deal with all symmetric matrices, and in `as(*, "symmetricMatrix")`.

## Slots

**uplo**: Object of class "character". Must be either "U", for upper triangular, and "L", for lower triangular.

**Dim, Dimnames**: The dimension (a length-2 "integer") and corresponding names (or NULL), inherited from the [Matrix](#), see there. See below, about storing only one of the two Dimnames components.

**factors**: a list of matrix factorizations, also from the `Matrix` class.

## Extends

Class "Matrix", directly.

## Methods

**coerce** signature (from = "ddiMatrix", to = "symmetricMatrix"): and many other coercion methods, some of which are particularly optimized.

**dimnames** signature (object = "symmetricMatrix"): returns *symmetric* [dimnames](#), even when the Dimnames slot only has row or column names. This allows to save storage for large (typically sparse) symmetric matrices.

**isSymmetric** signature (object = "symmetricMatrix"): returns TRUE trivially.

There's a C function `symmetricMatrix_validate()` called by the internal validity checking functions, and also from [getValidity](#) (`getClass("symmetricMatrix")`).

**Validity and `dimnames`**

The validity checks do not require a symmetric `Dimnames` slot, so it can be `list(NULL, <character>)`, e.g., for efficiency. However, `dimnames()` and other functions and methods should behave as if the `dimnames` were symmetric, i.e., with both list components identical.

**See Also**

`isSymmetric` which has efficient methods ([isSymmetric-methods](#)) for the **Matrix** classes. Classes `triangularMatrix`, and, e.g., `dsyMatrix` for numeric *dense* matrices, or `lsCMatrix` for a logical *sparse* matrix class.

**Examples**

```
## An example about the symmetric Dimnames:
sy <- sparseMatrix(i= c(2,4,3:5), j= c(4,7:5,5), x = 1:5, dims = c(7,7),
                  symmetric=TRUE, dimnames = list(NULL, letters[1:7]))
sy # shows symmetrical dimnames
sy@Dimnames # internally only one part is stored
dimnames(sy) # both parts - as sy *is* symmetrical

showClass("symmetricMatrix")

## The names of direct subclasses:
scl <- getClass("symmetricMatrix")@subclasses
directly <- sapply(lapply(scl, slot, "by"), length) == 0
names(scl)[directly]

## Methods -- applicable to all subclasses above:
showMethods(classes = "symmetricMatrix")
```

---

symmpart

---

*Symmetric Part and Skew(symmetric) Part of a Matrix*

---

**Description**

`symmpart(x)` computes the symmetric part  $(x + t(x))/2$  and `skewpart(x)` the skew symmetric part  $(x - t(x))/2$  of a square matrix `x`, more efficiently for specific **Matrix** classes.

Note that `x == symmpart(x) + skewpart(x)` for all square matrices – apart from extraneous [NA](#) values in the RHS.

**Usage**

```
symmpart(x)
skewpart(x)
```

**Arguments**

`x` a *square* matrix; either “traditional” of class `"matrix"`, or typically, inheriting from the [Matrix](#) class.

## Details

These are generic functions with several methods for different matrix classes, use e.g., `showMethods(sympart)` to see them.

If the row and column names differ, the result will use the column names unless they are (partly) NULL where the row names are non-NULL (see also the examples).

## Value

`sympart()` returns a symmetric matrix, inheriting from `symmetricMatrix` iff `x` inherited from `Matrix`.

`skewpart()` returns a skew-symmetric matrix, typically of the same class as `x` (or the closest “general” one, see `generalMatrix`).

## See Also

`isSymmetric`.

## Examples

```
m <- Matrix(1:4, 2, 2)
sympart(m)
skewpart(m)

stopifnot(all(m == sympart(m) + skewpart(m)))

dn <- dimnames(m) <- list(row = c("r1", "r2"), col = c("var.1", "var.2"))
stopifnot(all(m == sympart(m) + skewpart(m)))
colnames(m) <- NULL
stopifnot(all(m == sympart(m) + skewpart(m)))
dimnames(m) <- unname(dn)
stopifnot(all(m == sympart(m) + skewpart(m)))

## investigate the current methods:
showMethods(skewpart, include = TRUE)
```

---

triangularMatrix-class

*Virtual Class of Triangular Matrices in Package Matrix*

---

## Description

The virtual class of triangular matrices, "triangularMatrix", the package **Matrix** contains *square* (`nrow == ncol`) numeric and logical, dense and sparse matrices, e.g., see the examples. A main use of the virtual class is in methods (and C functions) that can deal with all triangular matrices.

**Slots**

**uplo:** String (of class "character"). Must be either "U", for upper triangular, and "L", for lower triangular.

**diag:** String (of class "character"). Must be either "U", for unit triangular (diagonal is all ones), or "N" for non-unit. The diagonal elements are not accessed internally when `diag` is "U". For `denseMatrix` classes, they need to be allocated though, i.e., the length of the `x` slot does not depend on `diag`.

**Dim, Dimnames:** The dimension (a length-2 "integer") and corresponding names (or NULL), inherited from the `Matrix`, see there.

**Extends**

Class "Matrix", directly.

**Methods**

There's a C function `triangularMatrix_validity()` called by the internal validity checking functions.

Currently, `Schur`, `isSymmetric` and `as()` (i.e. `coerce`) have methods with `triangularMatrix` in their signature.

**See Also**

`isTriangular()` for testing any matrix for triangularity; classes `symmetricMatrix`, and, e.g., `dtrMatrix` for numeric *dense* matrices, or `ltcMatrix` for a logical *sparse* matrix subclass of "triangularMatrix".

**Examples**

```
showClass("triangularMatrix")

## The names of direct subclasses:
scl <- getClass("triangularMatrix")@subclasses
directly <- sapply(lapply(scl, slot, "by"), length) == 0
names(scl)[directly]

(m <- matrix(c(5,1,0,3), 2))
as(m, "triangularMatrix")
```

---

TsparseMatrix-class

*Class "TsparseMatrix" of Sparse Matrices in Triplet Form*

---

**Description**

The "TsparseMatrix" class is the virtual class of all sparse matrices coded in triplet form. Since it is a virtual class, no objects may be created from it. See `showClass("TsparseMatrix")` for its subclasses.

**Slots**

Dim, Dimnames: from the "Matrix" class,

i: Object of class "integer" - the row indices of non-zero entries *in 0-base*, i.e., must be in  $0:(\text{nrow}(.)-1)$ .

j: Object of class "integer" - the column indices of non-zero entries. Must be the same length as slot i and *0-based* as well, i.e., in  $0:(\text{ncol}(.)-1)$ . For numeric Tsparse matrices, (i, j) pairs can occur more than once, see [dgTMatrix](#).

**Extends**

Class "sparseMatrix", directly. Class "Matrix", by class "sparseMatrix".

**Methods**

Extraction ("[" ) methods, see [\[-methods](#).

**Note**

Most operations with sparse matrices are performed using the compressed, column-oriented or [CsparseMatrix](#) representation. The triplet representation is convenient for creating a sparse matrix or for reading and writing such matrices. Once it is created, however, the matrix is generally coerced to a [CsparseMatrix](#) for further operations.

Note that all `new()`, [spMatrix](#) and [sparseMatrix](#)(\*, repr="T") constructors for "TsparseMatrix" classes implicitly add (i.e., "sum up")  $x_k$ 's that belong to identical  $(i_k, j_k)$  pairs, see, the example below, or also [dgTMatrix](#).

For convenience, methods for some operations such as `%%` and `crossprod` are defined for [TsparseMatrix](#) objects. These methods simply coerce the [TsparseMatrix](#) object to a [CsparseMatrix](#) object then perform the operation.

**See Also**

its superclass, [sparseMatrix](#), and the [dgTMatrix](#) class, for the links to other classes.

**Examples**

```
showClass("TsparseMatrix")
## or just the subclasses' names
names(getClass("TsparseMatrix")@subclasses)

T3 <- spMatrix(3,4, i=c(1,3:1), j=c(2,4:2), x=1:4)
T3 # only 3 non-zero entries, 5 = 1+4 !
```

---

 uniqTsparse

 Unique (Sorted) TsparseMatrix Representations
 

---

## Description

Detect or “unify” (or “standardize”) non-unique `TsparseMatrix` matrices, producing unique  $(i, j, x)$  triplets which are *sorted*, first in  $j$ , then in  $i$  (in the sense of `order(j, i)`).

Note that `new()`, `spMatrix` or `sparseMatrix` constructors for “dgTMatrix” (and other “`TsparseMatrix`” classes) implicitly add  $x_k$ ’s that belong to identical  $(i_k, j_k)$  pairs.

`anyDuplicatedT()` reports the index of the first duplicated pair, or 0 if there is none.

`uniqTsparse(x)` replaces duplicated index pairs  $(i, j)$  and their corresponding  $x$  slot entries by the triple  $(i, j, sx)$  where  $sx = \sum(x[<\text{all pairs matching } (i, j)>])$ , and for logical  $x$ , addition is replaced by logical *or*.

## Usage

```
uniqTsparse(x, class.x = c(class(x)))
anyDuplicatedT(x, di = dim(x))
```

## Arguments

|                      |                                                                                                  |
|----------------------|--------------------------------------------------------------------------------------------------|
| <code>x</code>       | a sparse matrix stored in triplet form, i.e., inheriting from class <code>TsparseMatrix</code> . |
| <code>class.x</code> | optional character string specifying <code>class(x)</code> .                                     |
| <code>di</code>      | the matrix dimension of <code>x</code> , <code>dim(x)</code> .                                   |

## Value

`uniqTsparse(x)` returns a `TsparseMatrix` “like `x`”, of the same class and with the same elements, just internally possibly changed to “unique”  $(i, j, x)$  triplets in *sorted* order.

`anyDuplicatedT(x)` returns an *integer* as `anyDuplicated`, the *index* of the first duplicated entry (from the  $(i, j)$  pairs) if there is one, and 0 otherwise.

## See Also

`TsparseMatrix`, for uniqueness, notably `dgTMatrix`.

## Examples

```
example("dgTMatrix-class", echo=FALSE)
## -> 'T2' with (i,j,x) slots of length 5 each
T2u <- uniqTsparse(T2)
stopifnot(## They "are" the same (and print the same):
  all.equal(T2, T2u, tol=0),
  ## but not internally:
  anyDuplicatedT(T2) == 2,
  anyDuplicatedT(T2u) == 0,
  length(T2 @x) == 5,
  length(T2u @x) == 3)

## is 'x' a "uniq Tsparse" Matrix ? [requires x to be TsparseMatrix!]
```

```

non_uniqT <- function(x, di = dim(x))
  is.unsorted(x@j) || anyDuplicatedT(x, di)
non_uniqT(T2 ) # TRUE
non_uniqT(T2u) # FALSE

T3 <- T2u
T3[1, c(1,3)] <- 10; T3[2, c(1,5)] <- 20
T3u <- uniqTsparse(T3)
str(T3u) # sorted in 'j', and within j, sorted in i
stopifnot(!non_uniqT(T3u))

## Logical l.TMatrix and n.TMatrix :
(L2 <- T2 > 0)
validObject(L2u <- uniqTsparse(L2))
(N2 <- as(L2, "nMatrix"))
validObject(N2u <- uniqTsparse(N2))
stopifnot(N2u@i == L2u@i, L2u@i == T2u@i, N2@i == L2@i, L2@i == T2@i,
          N2u@j == L2u@j, L2u@j == T2u@j, N2@j == L2@j, L2@j == T2@j)
# now with a nasty NA [partly failed in Matrix 1.1-5]:
L2.N <- L2; L2.N@x[2] <- NA; L2.N
validObject(L2.N)
(m2N <- as.matrix(L2.N)) # looks "ok"
iL <- as.integer(m2N)
stopifnot(identical(10L, which(is.na(match(iL, 0:1)))))
symnum(m2N)

```

unpack

*Representation of Packed and Unpacked (Dense) Matrices*

## Description

“Packed” matrix storage here applies to dense matrices ([denseMatrix](#)) only, and there is available only for symmetric ([symmetricMatrix](#)) or triangular ([triangularMatrix](#)) matrices, where only one triangle of the matrix needs to be stored.

`unpack()` unpacks “packed” matrices, where  
`pack()` produces “packed” matrices.

## Usage

```

pack(x, ...)
## S4 method for signature 'matrix'
pack(x, symmetric = NA, upperTri = NA, ...)

unpack(x, ...)

```

## Arguments

|                        |                                                                                                                                                                                                                                                                                                        |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>         | <b>for</b> <code>unpack()</code> : a matrix stored in packed form, e.g., of class <code>"d?pMatrix"</code> where <code>"?"</code> is <code>"t"</code> for triangular or <code>"s"</code> for symmetric.<br><b>for</b> <code>pack()</code> : a (symmetric or triangular) matrix stored in full storage. |
| <code>symmetric</code> | logical (including NA) for optionally specifying if <code>x</code> is symmetric (or rather triangular).                                                                                                                                                                                                |

`upperTri` (for the triangular case only) logical (incl. NA) indicating if `x` is upper (or lower) triangular.

`...` further arguments passed to or from other methods.

### Details

These are generic functions with special methods for different types of packed (or non-packed) symmetric or triangular dense matrices. Use `showMethods("unpack")` to list the methods for `unpack()`, and similarly for `pack()`.

### Value

**for** `unpack()`: A `Matrix` object containing the full-storage representation of `x`.

**for** `pack()`: A packed `Matrix` (i.e. of class `"..pMatrix"`) representation of `x`.

### Examples

```
showMethods("unpack")
(cp4 <- chol(Hilbert(4))) # is triangular
tp4 <- as(cp4,"dtpMatrix")# [t]riangular [p]acked
str(tp4)
(unpack(tp4))
stopifnot(identical(tp4, pack(unpack(tp4))))

(s <- crossprod(matrix(sample(15), 5,3))) # traditional symmetric matrix
(sp <- pack(s))
mt <- as.matrix(tt <- tril(s))
(pt <- pack(mt))
stopifnot(identical(pt, pack(tt)),
  dim(s) == dim(sp), all(s == sp),
  dim(mt) == dim(pt), all(mt == pt), all(mt == tt))
showMethods("pack")
```

### Description

`iMatrix` is the virtual class of all integer (S4) matrices. It extends the `Matrix` class directly.

`zMatrix` is the virtual class of all `complex` (S4) matrices. It extends the `Matrix` class directly.

### Examples

```
showClass("iMatrix")
showClass("zMatrix")
```

updown

*Up- and Down-Dating a Cholesky Decomposition***Description**

Compute the up- or down-dated Cholesky decomposition

**Usage**

```
updown(update, C, L)
```

**Arguments**

|        |                                                                                                  |
|--------|--------------------------------------------------------------------------------------------------|
| update | logical (TRUE or FALSE) or "+" or "-" indicating if an up- or a down-date is to be computed.     |
| C      | any R object, coercable to a sparse matrix (i.e., of subclass of <a href="#">sparseMatrix</a> ). |
| L      | a Cholesky factor, specifically, of class " <a href="#">CHMfactor</a> ".                         |

**Value**

an updated Cholesky factor, of the same dimension as L. Typically of class "[dCHMsimpl](#)" (a subclass of "[CHMfactor](#)").

**Methods**

```
signature(update = "character", C = "mMatrix", L = "CHMfactor") ..
signature(update = "logical", C = "mMatrix", L = "CHMfactor") ..
```

**Author(s)**

[Cholesky](#),

**Examples**

```
dn <- list(LETTERS[1:3], letters[1:5])
## pointer vectors can be used, and the (i,x) slots are sorted if necessary:
m <- sparseMatrix(i = c(3,1, 3:2, 2:1), p = c(0:2, 4,4,6), x = 1:6, dimnames = dn)
cA <- Cholesky(A <- crossprod(m) + Diagonal(5))
166 * as(cA,"Matrix") ^ 2
uc1 <- updown("+", Diagonal(5), cA)
## Hmm: this loses positive definiteness:
uc2 <- updown("-", 2*Diagonal(5), cA)
image(show(as(cA, "Matrix")))
```

```
image(show(c2 <- as(uc2, "Matrix")))# severely negative entries
##--> Warning
```

---

USCounties

*USCounties Contiguity Matrix*

---

## Description

This matrix represents the contiguities of 3111 US counties using the Queen criterion of at least a single shared boundary point. The representation is as a row standardised spatial weights matrix transformed to a symmetric matrix (see Ord (1975), p. 125).

## Usage

```
data(USCounties)
```

## Format

A  $3111^2$  symmetric sparse matrix of class `dsCMatrix` with 9101 non-zero entries.

## Details

The data were read into R using `read.gal`, and row-standardised and transformed to symmetry using `nb2listw` and `similar.listw`. This spatial weights object was converted to class `dsCMatrix` using `as_dsTMatrix_listw` and coercion.

## Source

The data were retrieved from <http://sal.uiuc.edu/weights/zips/usc.zip>, files “usc.txt” and “usc\\_q.GAL”, with permission for use and distribution from Luc Anselin (in early 2008).

## References

Ord, J. K. (1975) Estimation methods for models of spatial interaction; *Journal of the American Statistical Association* **70**, 120–126.

## Examples

```
data(USCounties)
(n <- ncol(USCounties))
IM <- .symDiagonal(n)
nn <- 50
set.seed(1)
rho <- runif(nn, 0, 1)
system.time(MJ <- sapply(rho, function(x)
  determinant(IM - x * USCounties, logarithm = TRUE)$modulus))

## can be done faster, by update()ing the Cholesky factor:
nWC <- -USCounties
C1 <- Cholesky(nWC, Imult = 2)
system.time(MJ1 <- n * log(rho) +
  sapply(rho, function(x)
```

```

                2 * c(determinant(update(C1, nWC, 1/x))$modulus)))
all.equal(MJ, MJ1)

C2 <- Cholesky(nWC, super = TRUE, Imult = 2)
system.time(MJ2 <- n * log(rho) +
            sapply(rho, function(x)
                2 * c(determinant(update(C2, nWC, 1/x))$modulus)))
all.equal(MJ, MJ2)
system.time(MJ3 <- n * log(rho) + Matrix::ldetL2up(C1, nWC, 1/rho))
stopifnot(all.equal(MJ, MJ3))
system.time(MJ4 <- n * log(rho) + Matrix::ldetL2up(C2, nWC, 1/rho))
stopifnot(all.equal(MJ, MJ4))

```

wrlld\_1deg

*World 1-degree grid contiguity matrix*

### Description

This matrix represents the distance-based contiguities of 15260 one-degree grid cells of land areas. The representation is as a row standardised spatial weights matrix transformed to a symmetric matrix (see Ord (1975), p. 125).

### Usage

```
data(wrlld_1deg)
```

### Format

A  $15260^2$  symmetric sparse matrix of class `dsCMatrix` with 55973 non-zero entries.

### Details

The data were created into R using the coordinates of a ‘SpatialPixels’ object containing approximately one-degree grid cells for land areas only (world excluding Antarctica), using package **spdep**’s `dnearneigh` with a cutoff distance of `sqrt(2)`, and row-standardised and transformed to symmetry using `nb2listw` and `similar.listw`. This spatial weights object was converted to a `dsTMatrix` using `as_dsTMatrix_listw` and then coerced (column-compressed).

### Source

The shoreline data was read into R using `Rgshhs` from the GSHHS coarse shoreline database distributed with the **maptools** package, omitting Antarctica. A matching approximately one-degree grid was generated using `Sobj_SpatialGrid`, and the grids on land were found using the appropriate `over` method for the ‘SpatialPolygons’ and ‘SpatialGrid’ objects, yielding a ‘SpatialPixels’ one containing only the grid cells with centres on land.

)
system.time(MJ3 <- n * log(rho) + Matrix::ldetL2up(C1, nWC, 1/rho))
system.time(MJ4 <- n * log(rho) + Matrix::ldetL2up(C2, nWC, 1/rho))
stopifnot(all.equal(MJ, MJ2),
  all.equal(MJ, MJ3),
  all.equal(MJ, MJ4))
```

---

[-methods

---

*Methods for "[": Extraction or Subsetting in Package 'Matrix'*

---

## Description

Methods for "[", i.e., extraction or subsetting mostly of matrices, in package **Matrix**.

## Methods

There are more than these:

```
x = "Matrix", i = "missing", j = "missing", drop= "ANY" ...
x = "Matrix", i = "numeric", j = "missing", drop= "missing" ...
x = "Matrix", i = "missing", j = "numeric", drop= "missing" ...
x = "dsparseMatrix", i = "missing", j = "numeric", drop= "logical" ...
x = "dsparseMatrix", i = "numeric", j = "missing", drop= "logical" ...
x = "dsparseMatrix", i = "numeric", j = "numeric", drop= "logical" ...
```

## See Also

[\[<--methods](#) for subassignment to "Matrix" objects. [Extract](#) about the standard extraction.

## Examples

```
str(m <- Matrix(round(rnorm(7*4),2), nrow = 7))
stopifnot(identical(m, m[]))
m[2, 3]    # simple number
m[2, 3:4]  # simple numeric of length 2
m[2, 3:4, drop=FALSE] # sub matrix of class 'dgeMatrix'
## rows or columns only:
m[1,]      # first row, as simple numeric vector
m[,1:2]    # sub matrix of first two columns

showMethods("[", inherited = FALSE)
```

[&lt;-methods

Methods for "[&lt;-" - Assigning to Subsets for 'Matrix'

## Description

Methods for "[<-", i.e., extraction or subsetting mostly of matrices, in package **Matrix**.

**Note:** Contrary to standard `matrix` assignment in base R, in `x[...]` <- val it is typically an **error** (see [stop](#)) when the [type](#) or [class](#) of val would require the class of x to be changed, e.g., when x is logical, say "lsparseMatrix", and val is numeric. In other cases, e.g., when x is a "nsparseMatrix" and val is not TRUE or FALSE, a warning is signalled, and val is “interpreted” as [logical](#), and (logical) [NA](#) is interpreted as TRUE.

## Methods

There are *many many* more than these:

`x = "Matrix", i = "missing", j = "missing", value = "ANY"` is currently a simple fallback method implementation which ensures “readable” error messages.

`x = "Matrix", i = "ANY", j = "ANY", value = "ANY"` currently gives an error

`x = "denseMatrix", i = "index", j = "missing", value = "numeric" ...`

`x = "denseMatrix", i = "index", j = "index", value = "numeric" ...`

`x = "denseMatrix", i = "missing", j = "index", value = "numeric" ...`

## See Also

[\[-methods](#) for subsetting "Matrix" objects; the [index](#) class; [Extract](#) about the standard subset assignment (and extraction).

## Examples

```
set.seed(101)
(a <- m <- Matrix(round(rnorm(7*4),2), nrow = 7))

a[] <- 2.2 # <- replaces every entry
a
## as do these:
a[,] <- 3 ; a[TRUE,] <- 4

m[2, 3] <- 3.14 # simple number
```

```

m[3, 3:4] <- 3:4 # simple numeric of length 2

## sub matrix assignment:
m[-(4:7), 3:4] <- cbind(1,2:4) #-> upper right corner of 'm'
m[3:5, 2:3] <- 0
m[6:7, 1:2] <- Diagonal(2)
m

## rows or columns only:
m[1,] <- 10
m[,2] <- 1:7
m[-(1:6), ] <- 3:0 # not the first 6 rows, i.e. only the 7th
as(m, "sparseMatrix")

```

---

%&%-methods*Boolean Arithmetic Matrix Products: %&% and Methods*

---

## Description

For boolean or “pattern” matrices, i.e., R objects of class `nMatrix`, it is natural to allow matrix products using boolean instead of numerical arithmetic.

In package **Matrix**, we use the binary operator `%&%` (aka “infix”) function) for this and provide methods for all our matrices and the traditional R matrices (see `matrix`).

## Value

a pattern matrix, i.e., inheriting from `"nMatrix"`, or an `"ldiMatrix"` in case of a diagonal matrix.

## Methods

We provide methods for both the “traditional” (R base) matrices and numeric vectors and conceptually all matrices and `sparseVectors` in package **Matrix**.

```

signature(x = "ANY", y = "ANY")
signature(x = "ANY", y = "Matrix")
signature(x = "Matrix", y = "ANY")
signature(x = "mMatrix", y = "mMatrix")
signature(x = "nMatrix", y = "nMatrix")
signature(x = "nMatrix", y = "nsparseMatrix")
signature(x = "nsparseMatrix", y = "nMatrix")
signature(x = "nsparseMatrix", y = "nsparseMatrix")
signature(x = "sparseVector", y = "mMatrix")
signature(x = "mMatrix", y = "sparseVector")
signature(x = "sparseVector", y = "sparseVector")

```

## Note

The current implementation ends up coercing both `x` and `y` to (virtual) class `nsparseMatrix` which may be quite inefficient. A future implementation may well return a matrix with **different** class, but the “same” content, i.e., the same matrix entries  $m_{ij}$ .

**Examples**

```

set.seed(7)
L <- Matrix(rnorm(20) > 1,      4,5)
(N <- as(L, "nMatrix"))
D <- Matrix(round(rnorm(30)), 5,6) # -> values in -1:1 (for this seed)
L %&% D
stopifnot(identical(L %&% D, N %&% D),
           all(L %&% D == as((L %*% abs(D)) > 0, "sparseMatrix")))

## cross products , possibly with boolArith = TRUE :
crossprod(N)      # -> sparse patter'n' (TRUE/FALSE : boolean arithmetic)
crossprod(N +0)   # -> numeric Matrix (with same "pattern")
stopifnot(all(crossprod(N) == t(N) %&% N),
           identical(crossprod(N), crossprod(N +0, boolArith=TRUE)),
           identical(crossprod(L), crossprod(N , boolArith=FALSE)))
crossprod(D, boolArith = TRUE) # pattern: "nsCMatrix"
crossprod(L, boolArith = TRUE) # ditto
crossprod(L, boolArith = FALSE) # numeric: "dsCMatrix"

```

## Chapter 18

# The boot package

---

`abc.ci`

*Nonparametric ABC Confidence Intervals*

---

### Description

Calculate equi-tailed two-sided nonparametric approximate bootstrap confidence intervals for a parameter, given a set of data and an estimator of the parameter, using numerical differentiation.

### Usage

```
abc.ci(data, statistic, index=1, strata=rep(1, n), conf=0.95,
       eps=0.001/n, ...)
```

### Arguments

|                        |                                                                                                                                                                                                                                                                                                                                                                                     |
|------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>data</code>      | A data set expressed as a vector, matrix or data frame.                                                                                                                                                                                                                                                                                                                             |
| <code>statistic</code> | A function which returns the statistic of interest. The function must take at least 2 arguments; the first argument should be the data and the second a vector of weights. The weights passed to <code>statistic</code> will be normalized to sum to 1 within each stratum. Any other arguments should be passed to <code>abc.ci</code> as part of the <code>...{}</code> argument. |
| <code>index</code>     | If <code>statistic</code> returns a vector of length greater than 1, then this indicates the position of the variable of interest within that vector.                                                                                                                                                                                                                               |
| <code>strata</code>    | A factor or numerical vector indicating to which sample each observation belongs in multiple sample problems. The default is the one-sample case.                                                                                                                                                                                                                                   |
| <code>conf</code>      | A scalar or vector containing the confidence level(s) of the required interval(s).                                                                                                                                                                                                                                                                                                  |
| <code>eps</code>       | The value of epsilon to be used for the numerical differentiation.                                                                                                                                                                                                                                                                                                                  |
| <code>...</code>       | Any other arguments for <code>statistic</code> . These will be passed unchanged to <code>statistic</code> each time it is called within <code>abc.ci</code> .                                                                                                                                                                                                                       |

## Details

This function is based on the function `abcnon` written by R. Tibshirani. A listing of the original function is available in DiCiccio and Efron (1996). The function uses numerical differentiation for the first and second derivatives of the statistic and then uses these values to approximate the bootstrap BCa intervals. The total number of evaluations of the statistic is  $2 \cdot n + 2 + 2 \cdot \text{length}(\text{conf})$  where  $n$  is the number of data points (plus calculation of the original value of the statistic). The function works for the multiple sample case without the need to rewrite the statistic in an artificial form since the stratified normalization is done internally by the function.

## Value

A `length(conf)` by 3 matrix where each row contains the confidence level followed by the lower and upper end-points of the ABC interval at that level.

|------|-------------------------------|
| acme | <i>Monthly Excess Returns</i> |
|------|-------------------------------|

---

### Description

The `acme` data frame has 60 rows and 3 columns.

The excess return for the Acme Cleveland Corporation are recorded along with those for all stocks listed on the New York and American Stock Exchanges were recorded over a five year period. These excess returns are relative to the return on a risk-less investment such a U.S. Treasury bills.

### Usage

```
acme
```

### Format

This data frame contains the following columns:

`month` A character string representing the month of the observation.

`market` The excess return of the market as a whole.

`acme` The excess return for the Acme Cleveland Corporation.

### Source

The data were obtained from

Simonoff, J.S. and Tsai, C.-L. (1994) Use of modified profile likelihood for improved tests of constancy of variance in regression. *Applied Statistics*, **43**, 353–370.

|------|-----------------------------------------------------|
| aids | <i>Delay in AIDS Reporting in England and Wales</i> |
|------|-----------------------------------------------------|

---

### Description

The `aids` data frame has 570 rows and 6 columns.

Although all cases of AIDS in England and Wales must be reported to the Communicable Disease Surveillance Centre, there is often a considerable delay between the time of diagnosis and the time that it is reported. In estimating the prevalence of AIDS, account must be taken of the unknown number of cases which have been diagnosed but not reported. The data set here records the reported cases of AIDS diagnosed from July 1983 and until the end of 1992. The data are cross-classified by the date of diagnosis and the time delay in the reporting of the cases.

### Usage

```
aids
```

**Format**

This data frame contains the following columns:

`year` The year of the diagnosis.

`quarter` The quarter of the year in which diagnosis was made.

`delay` The time delay (in months) between diagnosis and reporting. 0 means that the case was reported within one month. Longer delays are grouped in 3 month intervals and the value of `delay` is the midpoint of the interval (therefore a value of 2 indicates that reporting was delayed for between 1 and 3 months).

`dud` An indicator of censoring. These are categories for which full information is not yet available and the number recorded is a lower bound only.

`time` The time interval of the diagnosis. That is the number of quarters from July 1983 until the end of the quarter in which these cases were diagnosed.

`y` The number of AIDS cases reported.

**Source**

The data were obtained from

De Angelis, D. and Gilks, W.R. (1994) Estimating acquired immune deficiency syndrome accounting for reporting delay. *Journal of the Royal Statistical Society, A*, **157**, 31–40.

aircondit

*Failures of Air-conditioning Equipment*

---

**Description**

Proschan (1963) reported on the times between failures of the air-conditioning equipment in 10 Boeing 720 aircraft. The `aircondit` data frame contains the intervals for the ninth aircraft while `aircondit7` contains those for the seventh aircraft.

Both data frames have just one column. Note that the data have been sorted into increasing order.

**Usage**

`aircondit`

**Format**

The data frames contain the following column:

`hours` The time interval in hours between successive failures of the air-conditioning equipment

**Source**

The data were taken from

Cox, D.R. and Snell, E.J. (1981) *Applied Statistics: Principles and Examples*. Chapman and Hall.

---

amis

*Car Speeding and Warning Signs*

---

## Description

The `amis` data frame has 8437 rows and 4 columns.

In a study into the effect that warning signs have on speeding patterns, Cambridgeshire County Council considered 14 pairs of locations. The locations were paired to account for factors such as traffic volume and type of road. One site in each pair had a sign erected warning of the dangers of speeding and asking drivers to slow down. No action was taken at the second site. Three sets of measurements were taken at each site. Each set of measurements was nominally of the speeds of 100 cars but not all sites have exactly 100 measurements. These speed measurements were taken before the erection of the sign, shortly after the erection of the sign, and again after the sign had been in place for some time.

## Usage

`amis`

## Format

This data frame contains the following columns:

`speed` Speeds of cars (in miles per hour).

`period` A numeric column indicating the time that the reading was taken. A value of 1 indicates a reading taken before the sign was erected, a 2 indicates a reading taken shortly after erection of the sign and a 3 indicates a reading taken after the sign had been in place for some time.

`warning` A numeric column indicating whether the location of the reading was chosen to have a warning sign erected. A value of 1 indicates presence of a sign and a value of 2 indicates that no sign was erected.

`pair` A numeric column giving the pair number at which the reading was taken. Pairs were numbered from 1 to 14.

## Source

The data were kindly made available by Mr. Graham Amis, Cambridgeshire County Council, U.K.

## References

aml

*Remission Times for Acute Myelogenous Leukaemia***Description**

The `aml` data frame has 23 rows and 3 columns.

A clinical trial to evaluate the efficacy of maintenance chemotherapy for acute myelogenous leukaemia was conducted by Embury et al. (1977) at Stanford University. After reaching a stage of remission through treatment by chemotherapy, patients were randomized into two groups. The first group received maintenance chemotherapy and the second group did not. The aim of the study was to see if maintenance chemotherapy increased the length of the remission. The data here formed a preliminary analysis which was conducted in October 1974.

**Usage**

```
aml
```

**Format**

This data frame contains the following columns:

`time` The length of the complete remission (in weeks).

`cens` An indicator of right censoring. 1 indicates that the patient had a relapse and so `time` is the length of the remission. 0 indicates that the patient had left the study or was still in remission in October 1974, that is the length of remission is right-censored.

`group` The group into which the patient was randomized. Group 1 received maintenance chemotherapy, group 2 did not.

**Note**

Package **survival** also has a dataset `aml`. It is the same data with different names and with `group` replaced by a factor `x`.

**Source**

The data were obtained from

Miller, R.G. (1981) *Survival Analysis*. John Wiley.

---

`beaver`*Beaver Body Temperature Data*

---

## Description

The `beaver` data frame has 100 rows and 4 columns. It is a multivariate time series of class `"ts"` and also inherits from class `"data.frame"`.

This data set is part of a long study into body temperature regulation in beavers. Four adult female beavers were live-trapped and had a temperature-sensitive radio transmitter surgically implanted. Readings were taken every 10 minutes. The location of the beaver was also recorded and her activity level was dichotomized by whether she was in the retreat or outside of it since high-intensity activities only occur outside of the retreat.

The data in this data frame are those readings for one of the beavers on a day in autumn.

## Usage

```
beaver
```

## Format

This data frame contains the following columns:

`day` The day number. The data includes only data from day 307 and early 308.

`time` The time of day formatted as hour-minute.

`temp` The body temperature in degrees Celsius.

`activ` The dichotomized activity indicator. 1 indicates that the beaver is outside of the retreat and therefore engaged in high-intensity activity.

## Source

The data were obtained from

Reynolds, P.S. (1994) Time-series analyses of beaver body temperatures. In *Case Studies in Biometry*. N. Lange, L. Ryan, L. Billard, D. Brillinger, L. Conquest and J. Greenhouse (editors), 211–228. John Wiley.

|      |                             |
|------|-----------------------------|
| boot | <i>Bootstrap Resampling</i> |
|------|-----------------------------|

---

### Description

Generate R bootstrap replicates of a statistic applied to data. Both parametric and nonparametric resampling are possible. For the nonparametric bootstrap, possible resampling methods are the ordinary bootstrap, the balanced bootstrap, antithetic resampling, and permutation. For nonparametric multi-sample problems stratified resampling is used: this is specified by including a vector of strata in the call to `boot`. Importance resampling weights may be specified.

### Usage

```
boot(data, statistic, R, sim = "ordinary", stype = c("i", "f", "w"),
      strata = rep(1,n), L = NULL, m = 0, weights = NULL,
      ran.gen = function(d, p) d, mle = NULL, simple = FALSE, ...,
      parallel = c("no", "multicore", "snow"),
      ncpus = getOption("boot.ncpus", 1L), cl = NULL)
```

**Arguments**

|                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>data</code>      | The data as a vector, matrix or data frame. If it is a matrix or data frame then each row is considered as one multivariate observation.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <code>statistic</code> | A function which when applied to data returns a vector containing the statistic(s) of interest. When <code>sim = "parametric"</code> , the first argument to <code>statistic</code> must be the data. For each replicate a simulated dataset returned by <code>ran.gen</code> will be passed. In all other cases <code>statistic</code> must take at least two arguments. The first argument passed will always be the original data. The second will be a vector of indices, frequencies or weights which define the bootstrap sample. Further, if predictions are required, then a third argument is required which would be a vector of the random indices used to generate the bootstrap predictions. Any further arguments can be passed to <code>statistic</code> through the <code>...</code> argument. |
| <code>R</code>         | The number of bootstrap replicates. Usually this will be a single positive integer. For importance resampling, some resamples may use one set of weights and others use a different set of weights. In this case <code>R</code> would be a vector of integers where each component gives the number of resamples from each of the rows of weights.                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>sim</code>       | A character string indicating the type of simulation required. Possible values are "ordinary" (the default), "parametric", "balanced", "permutation", or "antithetic". Importance resampling is specified by including importance weights; the type of importance resampling must still be specified but may only be "ordinary" or "balanced" in this case.                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>stype</code>     | A character string indicating what the second argument of <code>statistic</code> represents. Possible values of <code>stype</code> are "i" (indices - the default), "f" (frequencies), or "w" (weights). Not used for <code>sim = "parametric"</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <code>strata</code>    | An integer vector or factor specifying the strata for multi-sample problems. This may be specified for any simulation, but is ignored when <code>sim = "parametric"</code> . When <code>strata</code> is supplied for a nonparametric bootstrap, the simulations are done within the specified strata.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>L</code>         | Vector of influence values evaluated at the observations. This is used only when <code>sim</code> is "antithetic". If not supplied, they are calculated through a call to <code>empinf</code> . This will use the infinitesimal jackknife provided that <code>stype</code> is "w", otherwise the usual jackknife is used.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>m</code>         | The number of predictions which are to be made at each bootstrap replicate. This is most useful for (generalized) linear models. This can only be used when <code>sim</code> is "ordinary". <code>m</code> will usually be a single integer but, if there are strata, it may be a vector with length equal to the number of strata, specifying how many of the errors for prediction should come from each strata. The actual predictions should be returned as the final part of the output of <code>statistic</code> , which should also take an argument giving the vector of indices of the errors to be used for the predictions.                                                                                                                                                                         |
| <code>weights</code>   | Vector or matrix of importance weights. If a vector then it should have as many elements as there are observations in <code>data</code> . When simulation from more than one set of weights is required, <code>weights</code> should be a matrix where each row of the matrix is one set of importance weights. If <code>weights</code> is a matrix then <code>R</code> must be a vector of length <code>nrow(weights)</code> . This parameter is ignored if <code>sim</code> is not "ordinary" or "balanced".                                                                                                                                                                                                                                                                                                 |
| <code>ran.gen</code>   | This function is used only when <code>sim = "parametric"</code> when it describes how random values are to be generated. It should be a function of two arguments.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

|                       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                       | <p>The first argument should be the observed data and the second argument consists of any other information needed (e.g. parameter estimates). The second argument may be a list, allowing any number of items to be passed to <code>ran.gen</code>. The returned value should be a simulated data set of the same form as the observed data which will be passed to <code>statistic</code> to get a bootstrap replicate. It is important that the returned value be of the same shape and type as the original dataset. If <code>ran.gen</code> is not specified, the default is a function which returns the original data in which case all simulation should be included as part of <code>statistic</code>. Use of <code>sim = "parametric"</code> with a suitable <code>ran.gen</code> allows the user to implement any types of nonparametric resampling which are not supported directly.</p> |
| <code>mle</code>      | <p>The second argument to be passed to <code>ran.gen</code>. Typically these will be maximum likelihood estimates of the parameters. For efficiency <code>mle</code> is often a list containing all of the objects needed by <code>ran.gen</code> which can be calculated using the original data set only.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>simple</code>   | <p>logical, only allowed to be <code>TRUE</code> for <code>sim = "ordinary"</code>, <code>stype = "i"</code>, <code>n = 0</code> (otherwise ignored with a warning). By default a <code>n</code> by <code>R</code> index array is created: this can be large and if <code>simple = TRUE</code> this is avoided by sampling separately for each replication, which is slower but uses less memory.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>...</code>      | <p>Other named arguments for <code>statistic</code> which are passed unchanged each time it is called. Any such arguments to <code>statistic</code> should follow the arguments which <code>statistic</code> is required to have for the simulation. Beware of partial matching to arguments of <code>boot</code> listed above, and that arguments named <code>X</code> and <code>FUN</code> cause conflicts in some versions of <b>boot</b> (but not this one).</p>                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <code>parallel</code> | <p>The type of parallel operation to be used (if any). If missing, the default is taken from the option <code>"boot.parallel"</code> (and if that is not set, <code>"no"</code>).</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>ncpus</code>    | <p>integer: number of processes to be used in parallel operation: typically one would chose this to the number of available CPUs.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>cl</code>       | <p>An optional <b>parallel</b> or <b>snow</b> cluster for use if <code>parallel = "snow"</code>. If not supplied, a cluster on the local machine is created for the duration of the <code>boot</code> call.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

## Details

The statistic to be bootstrapped can be as simple or complicated as desired as long as its arguments correspond to the dataset and (for a nonparametric bootstrap) a vector of indices, frequencies or weights. `statistic` is treated as a black box by the `boot` function and is not checked to ensure that these conditions are met.

The first order balanced bootstrap is described in Davison, Hinkley and Schechtman (1986). The antithetic bootstrap is described by Hall (1989) and is experimental, particularly when used with `strata`. The other non-parametric simulation types are the ordinary bootstrap (possibly with unequal probabilities), and permutation which returns random permutations of cases. All of these methods work independently within `strata` if that argument is supplied.

For the parametric bootstrap it is necessary for the user to specify how the resampling is to be conducted. The best way of accomplishing this is to specify the function `ran.gen` which will return a simulated data set from the observed data set and a set of parameter estimates specified in `mle`.

## Value

The returned value is an object of class `"boot"`, containing the following components:

|                        |                                                                                                                                                                                                                                                                                                                                            |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>t0</code>        | The observed value of <code>statistic</code> applied to data.                                                                                                                                                                                                                                                                              |
| <code>t</code>         | A matrix with <code>sum(R)</code> rows each of which is a bootstrap replicate of the result of calling <code>statistic</code> .                                                                                                                                                                                                            |
| <code>R</code>         | The value of <code>R</code> as passed to <code>boot</code> .                                                                                                                                                                                                                                                                               |
| <code>data</code>      | The data as passed to <code>boot</code> .                                                                                                                                                                                                                                                                                                  |
| <code>seed</code>      | The value of <code>.Random.seed</code> when <code>boot</code> started work.                                                                                                                                                                                                                                                                |
| <code>statistic</code> | The function <code>statistic</code> as passed to <code>boot</code> .                                                                                                                                                                                                                                                                       |
| <code>sim</code>       | Simulation type used.                                                                                                                                                                                                                                                                                                                      |
| <code>stype</code>     | Statistic type as passed to <code>boot</code> .                                                                                                                                                                                                                                                                                            |
| <code>call</code>      | The original call to <code>boot</code> .                                                                                                                                                                                                                                                                                                   |
| <code>strata</code>    | The strata used. This is the vector passed to <code>boot</code> , if it was supplied or a vector of ones if there were no strata. It is not returned if <code>sim</code> is "parametric".                                                                                                                                                  |
| <code>weights</code>   | The importance sampling weights as passed to <code>boot</code> or the empirical distribution function weights if no importance sampling weights were specified. It is omitted if <code>sim</code> is not one of "ordinary" or "balanced".                                                                                                  |
| <code>pred.i</code>    | If predictions are required ( <code>m &gt; 0</code> ) this is the matrix of indices at which predictions were calculated as they were passed to <code>statistic</code> . Omitted if <code>m</code> is 0 or <code>sim</code> is not "ordinary".                                                                                             |
| <code>L</code>         | The influence values used when <code>sim</code> is "antithetic". If no such values were specified and <code>stype</code> is not "w" then <code>L</code> is returned as consecutive integers corresponding to the assumption that data is ordered by influence values. This component is omitted when <code>sim</code> is not "antithetic". |
| <code>ran.gen</code>   | The random generator function used if <code>sim</code> is "parametric". This component is omitted for any other value of <code>sim</code> .                                                                                                                                                                                                |
| <code>mle</code>       | The parameter estimates passed to <code>boot</code> when <code>sim</code> is "parametric". It is omitted for all other values of <code>sim</code> .                                                                                                                                                                                        |

There are `c`, `plot` and `print` methods for this class.

### Parallel operation

When `parallel = "multicore"` is used (not available on Windows), each worker process inherits the environment of the current session, including the workspace and the loaded namespaces and attached packages (but not the random number seed: see below).

More work is needed when `parallel = "snow"` is used: the worker processes are newly created R processes, and `statistic` needs to arrange to set up the environment it needs: often a good way to do that is to make use of lexical scoping since when `statistic` is sent to the worker processes its enclosing environment is also sent. (E.g. see the example for `jack.after.boot` where ancillary functions are nested inside the `statistic` function.) `parallel = "snow"` is primarily intended to be used on multi-core Windows machine where `parallel = "multicore"` is not available.

For most of the `boot` methods the resampling is done in the master process, but not if `simple = TRUE` nor `sim = "parametric"`. In those cases (or where `statistic` itself uses random numbers), more care is needed if the results need to be reproducible. Resampling is done in the worker processes by `censboot` (`sim = "wierd"`) and by most of the schemes in `tsboot` (the exceptions being `sim == "fixed"` and `sim == "geom"` with the default `ran.gen`).

Where random-number generation is done in the worker processes, the default behaviour is that each worker chooses a separate seed, non-reproducibly. However, with `parallel =`

"multicore" or `parallel = "snow"` using the default cluster, a second approach is used if `RNGkind("L'Ecuyer-CMRG")` has been selected. In that approach each worker gets a different subsequence of the RNG stream based on the seed at the time the worker is spawned and so the results will be reproducible if `ncpus` is unchanged, and for `parallel = "multicore"` if `parallel::mc.reset.stream()` is called: see the examples for `mclapply`.

Note that loading the **parallel** namespace may change the random seed, so for maximum reproducibility this should be done before calling this function.

## Examples

```
# Usual bootstrap of the ratio of means using the city data
ratio <- function(d, w) sum(d$x * w)/sum(d$u * w)
boot(city, ratio, R = 999, stype = "w")

# Stratified resampling for the difference of means. In this
# example we will look at the difference of means between the final
# two series in the gravity data.
diff.means <- function(d, f)
{
  n <- nrow(d)
  gp1 <- 1:table(as.numeric(d$series))[1]
  m1 <- sum(d[gp1,1] * f[gp1])/sum(f[gp1])
  m2 <- sum(d[-gp1,1] * f[-gp1])/sum(f[-gp1])
  ss1 <- sum(d[gp1,1]^2 * f[gp1]) - (m1 * m1 * sum(f[gp1]))
  ss2 <- sum(d[-gp1,1]^2 * f[-gp1]) - (m2 * m2 * sum(f[-gp1]))
}
```

```

      c(m1 - m2, (ss1 + ss2)/(sum(f) - 2))
    }
    grav1 <- gravity[as.numeric(gravity[,2]) >= 7,]
    boot(grav1, diff.means, R = 999, stype = "f", strata = grav1[,2])

# In this example we show the use of boot in a prediction from
# regression based on the nuclear data. This example is taken
# from Example 6.8 of Davison and Hinkley (1997). Notice also
# that two extra arguments to 'statistic' are passed through boot.
nuke <- nuclear[, c(1, 2, 5, 7, 8, 10, 11)]
nuke.lm <- glm(log(cost) ~ date+log(cap)+ne+ct+log(cum.n)+pt, data = nuke)
nuke.diag <- glm.diag(nuke.lm)
nuke.res <- nuke.diag$res * nuke.diag$sd
nuke.res <- nuke.res - mean(nuke.res)

# We set up a new data frame with the data, the standardized
# residuals and the fitted values for use in the bootstrap.
nuke.data <- data.frame(nuke, resid = nuke.res, fit = fitted(nuke.lm))

# Now we want a prediction of plant number 32 but at date 73.00
new.data <- data.frame(cost = 1, date = 73.00, cap = 886, ne = 0,
                      ct = 0, cum.n = 11, pt = 1)
new.fit <- predict(nuke.lm, new.data)

nuke.fun <- function(dat, inds, i.pred, fit.pred, x.pred)
{
  lm.b <- glm(fit+resid[inds] ~ date+log(cap)+ne+ct+log(cum.n)+pt,
             data = dat)
  pred.b <- predict(lm.b, x.pred)
  c(coef(lm.b), pred.b - (fit.pred + dat$resid[i.pred]))
}

nuke.boot <- boot(nuke.data, nuke.fun, R = 999, m = 1,
                 fit.pred = new.fit, x.pred = new.data)
# The bootstrap prediction squared error would then be found by
mean(nuke.boot$t[, 8]^2)
# Basic bootstrap prediction limits would be
new.fit - sort(nuke.boot$t[, 8])[c(975, 25)]

# Finally a parametric bootstrap. For this example we shall look
# at the air-conditioning data. In this example our aim is to test
# the hypothesis that the true value of the index is 1 (i.e. that
# the data come from an exponential distribution) against the
# alternative that the data come from a gamma distribution with
# index not equal to 1.
air.fun <- function(data) {
  ybar <- mean(data$hours)
  para <- c(log(ybar), mean(log(data$hours)))
  ll <- function(k) {
    if (k <= 0) 1e200 else lgamma(k)-k*(log(k)-1-para[1]+para[2])
  }
  khat <- nlm(ll, ybar^2/var(data$hours))$estimate
  c(ybar, khat)
}

air.rg <- function(data, mle) {

```

```

# Function to generate random exponential variates.
# mle will contain the mean of the original data
out <- data
out$hours <- rexp(nrow(out), 1/mle)
out
}

air.boot <- boot(aircondit, air.fun, R = 999, sim = "parametric",
               ran.gen = air.rg, mle = mean(aircondit$hours))

# The bootstrap p-value can then be approximated by
sum(abs(air.boot$t[,2]-1) > abs(air.boot$t0[2]-1))/(1+air.boot$R)

```

|------------|------------------------------------|
| boot.array | <i>Bootstrap Resampling Arrays</i> |
|------------|------------------------------------|

---

## Description

This function takes a bootstrap object calculated by one of the functions `boot`, `censboot`, or `tilt.boot` and returns the frequency (or index) array for the bootstrap resamples.

## Usage

```
boot.array(boot.out, indices)
```

## Arguments

|                       |                                                                                                                                                                                                                                                                     |
|-----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>boot.out</code> | An object of class "boot" returned by one of the generation functions for such an object.                                                                                                                                                                           |
| <code>indices</code>  | A logical argument which specifies whether to return the frequency array or the raw index array. The default is <code>indices=FALSE</code> unless <code>boot.out</code> was created by <code>tsboot</code> in which case the default is <code>indices=TRUE</code> . |

## Details

The process by which the original index array was generated is repeated with the same value of `.Random.seed`. If the frequency array is required then `freq.array` is called to convert the index array to a frequency array.

A resampling array can only be returned when such a concept makes sense. In particular it cannot be found for any parametric or model-based resampling schemes. Hence for objects generated by `censboot` the only resampling scheme for which such an array can be found is ordinary case resampling. Similarly if `boot.out$sim` is "parametric" in the case of `boot` or "model" in the case of `tsboot` the array cannot be found. Note also that for post-blackened bootstraps from `tsboot` the indices found will relate to those prior to any post-blackening and so will not be useful.

Frequency arrays are used in many post-bootstrap calculations such as the jackknife-after-bootstrap and finding importance sampling weights. They are also used to find empirical influence values through the regression method.

**Value**

A matrix with `boot.out$R` rows and `n` columns where `n` is the number of observations in `boot.out$data`. If `indices` is `FALSE` then this will give the frequency of each of the original observations in each bootstrap resample. If `indices` is `TRUE` it will give the indices of the bootstrap resamples in the order in which they would have been passed to the statistic.

**Side Effects**

This function temporarily resets `.Random.seed` to the value in `boot.out$seed` and then returns it to its original value at the end of the function.

**See Also**

`boot`, `censboot`, `freq.array`, `tilt.boot`, `tsboot`

**Examples**

```
# A frequency array for a nonparametric bootstrap
city.boot <- boot(city, corr, R = 40, stype = "w")
boot.array(city.boot)

perm.cor <- function(d,i) cor(d$x,d$u[i])
city.perm <- boot(city, perm.cor, R = 40, sim = "permutation")
boot.array(city.perm, indices = TRUE)
```

---

boot.ci

*Nonparametric Bootstrap Confidence Intervals*

---

**Description**

This function generates 5 different types of equi-tailed two-sided nonparametric confidence intervals. These are the first order normal approximation, the basic bootstrap interval, the studentized bootstrap interval, the bootstrap percentile interval, and the adjusted bootstrap percentile (BCa) interval. All or a subset of these intervals can be generated.

**Usage**

```
boot.ci(boot.out, conf = 0.95, type = "all",
        index = 1:min(2,length(boot.out$t0)), var.t0 = NULL,
        var.t = NULL, t0 = NULL, t = NULL, L = NULL,
        h = function(t) t, hdot = function(t) rep(1,length(t)),
        hinv = function(t) t, ...)
```

**Arguments**

|                       |                                                                                                                                                                                                                                                |
|-----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>boot.out</code> | An object of class "boot" containing the output of a bootstrap calculation.                                                                                                                                                                    |
| <code>conf</code>     | A scalar or vector containing the confidence level(s) of the required interval(s).                                                                                                                                                             |
| <code>type</code>     | A vector of character strings representing the type of intervals required. The value should be any subset of the values <code>c("norm", "basic", "stud", "perc", "bca")</code> or simply "all" which will compute all five types of intervals. |

|                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|---------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>index</code>  | This should be a vector of length 1 or 2. The first element of <code>index</code> indicates the position of the variable of interest in <code>boot.out\$t0</code> and the relevant column in <code>boot.out\$t</code> . The second element indicates the position of the variance of the variable of interest. If both <code>var.t0</code> and <code>var.t</code> are supplied then the second element of <code>index</code> (if present) is ignored. The default is that the variable of interest is in position 1 and its variance is in position 2 (as long as there are 2 positions in <code>boot.out\$t0</code> ).                          |
| <code>var.t0</code> | If supplied, a value to be used as an estimate of the variance of the statistic for the normal approximation and studentized intervals. If it is not supplied and <code>length(index)</code> is 2 then <code>var.t0</code> defaults to <code>boot.out\$t0[index[2]]</code> otherwise <code>var.t0</code> is undefined. For studentized intervals <code>var.t0</code> must be defined. For the normal approximation, if <code>var.t0</code> is undefined it defaults to <code>var(t)</code> . If a transformation is supplied through the argument <code>h</code> then <code>var.t0</code> should be the variance of the untransformed statistic. |
| <code>var.t</code>  | This is a vector (of length <code>boot.out\$R</code> ) of variances of the bootstrap replicates of the variable of interest. It is used only for studentized intervals. If it is not supplied and <code>length(index)</code> is 2 then <code>var.t</code> defaults to <code>boot.out\$t[,index[2]]</code> , otherwise its value is undefined which will cause an error for studentized intervals. If a transformation is supplied through the argument <code>h</code> then <code>var.t</code> should be the variance of the untransformed bootstrap statistics.                                                                                  |
| <code>t0</code>     | The observed value of the statistic of interest. The default value is <code>boot.out\$t0[index[1]]</code> . Specification of <code>t0</code> and <code>t</code> allows the user to get intervals for a transformed statistic which may not be in the bootstrap output object. See the second example below. An alternative way of achieving this would be to supply the functions <code>h</code> , <code>hdot</code> , and <code>hinv</code> below.                                                                                                                                                                                              |
| <code>t</code>      | The bootstrap replicates of the statistic of interest. It must be a vector of length <code>boot.out\$R</code> . It is an error to supply one of <code>t0</code> or <code>t</code> but not the other. Also if studentized intervals are required and <code>t0</code> and <code>t</code> are supplied then so should be <code>var.t0</code> and <code>var.t</code> . The default value is <code>boot.out\$t[,index]</code> .                                                                                                                                                                                                                       |
| <code>L</code>      | The empirical influence values of the statistic of interest for the observed data. These are used only for BCa intervals. If a transformation is supplied through the parameter <code>h</code> then <code>L</code> should be the influence values for <code>t</code> ; the values for <code>h(t)</code> are derived from these and <code>hdot</code> within the function. If <code>L</code> is not supplied then the values are calculated using <code>empinf</code> if they are needed.                                                                                                                                                         |
| <code>h</code>      | A function defining a transformation. The intervals are calculated on the scale of <code>h(t)</code> and the inverse function <code>hinv</code> applied to the resulting intervals. It must be a function of one variable only and for a vector argument, it must return a vector of the same length, i.e. <code>h(c(t1,t2,t3))</code> should return <code>c(h(t1),h(t2),h(t3))</code> . The default is the identity function.                                                                                                                                                                                                                   |
| <code>hdot</code>   | A function of one argument returning the derivative of <code>h</code> . It is a required argument if <code>h</code> is supplied and normal, studentized or BCa intervals are required. The function is used for approximating the variances of <code>h(t0)</code> and <code>h(t)</code> using the delta method, and also for finding the empirical influence values for BCa intervals. Like <code>h</code> it should be able to take a vector argument and return a vector of the same length. The default is the constant function 1.                                                                                                           |
| <code>hinv</code>   | A function, like <code>h</code> , which returns the inverse of <code>h</code> . It is used to transform the intervals calculated on the scale of <code>h(t)</code> back to the original scale. The default is the identity function. If <code>h</code> is supplied but <code>hinv</code> is not, then the intervals returned will be on the transformed scale.                                                                                                                                                                                                                                                                                   |

... Any extra arguments that `boot.out$statistic` is expecting. These arguments are needed only if BCa intervals are required and `L` is not supplied since in that case `L` is calculated through a call to `empinf` which calls `boot.out$statistic`.

## Details

The formulae on which the calculations are based can be found in Chapter 5 of Davison and Hinkley (1997). Function `boot` must be run prior to running this function to create the object to be passed as `boot.out`.

Variance estimates are required for studentized intervals. The variance of the observed statistic is optional for normal theory intervals. If it is not supplied then the bootstrap estimate of variance is used. The normal intervals also use the bootstrap bias correction.

Interpolation on the normal quantile scale is used when a non-integer order statistic is required. If the order statistic used is the smallest or largest of the `R` values in `boot.out` a warning is generated and such intervals should not be considered reliable.

## Value

An object of type `"bootci"` which contains the intervals. It has components

|                      |                                                                                                                                                                                                                                                                                                                                    |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>R</code>       | The number of bootstrap replicates on which the intervals were based.                                                                                                                                                                                                                                                              |
| <code>t0</code>      | The observed value of the statistic on the same scale as the intervals.                                                                                                                                                                                                                                                            |
| <code>call</code>    | The call to <code>boot.ci</code> which generated the object.<br>It will also contain one or more of the following components depending on the value of <code>type</code> used in the call to <code>bootci</code> .                                                                                                                 |
| <code>normal</code>  | A matrix of intervals calculated using the normal approximation. It will have 3 columns, the first being the level and the other two being the upper and lower endpoints of the intervals.                                                                                                                                         |
| <code>basic</code>   | The intervals calculated using the basic bootstrap method.                                                                                                                                                                                                                                                                         |
| <code>student</code> | The intervals calculated using the studentized bootstrap method.                                                                                                                                                                                                                                                                   |
| <code>percent</code> | The intervals calculated using the bootstrap percentile method.                                                                                                                                                                                                                                                                    |
| <code>bca</code>     | The intervals calculated using the adjusted bootstrap percentile (BCa) method.<br>These latter four components will be matrices with 5 columns, the first column containing the level, the next two containing the indices of the order statistics used in the calculations and the final two the calculated endpoints themselves. |

```

**Description**

The `brambles` data frame has 823 rows and 3 columns.

The location of living bramble canes in a 9m square plot was recorded. We take 9m to be the unit of distance so that the plot can be thought of as a unit square. The bramble canes were also classified by their age.

**Usage**

```
brambles
```

**Format**

This data frame contains the following columns:

`x` The x coordinate of the position of the cane in the plot.

`y` The y coordinate of the position of the cane in the plot.

`age` The age classification of the canes; 0 indicates a newly emerged cane, 1 indicates a one year old cane and 2 indicates a two year old cane.

**Source**

The data were obtained from

`breslow`*Smoking Deaths Among Doctors*

---

**Description**

The `breslow` data frame has 10 rows and 5 columns.

In 1961 Doll and Hill sent out a questionnaire to all men on the British Medical Register enquiring about their smoking habits. Almost 70% of such men replied. Death certificates were obtained for medical practitioners and causes of death were assigned on the basis of these certificates. The `breslow` data set contains the person-years of observations and deaths from coronary artery disease accumulated during the first ten years of the study.

**Usage**

```
breslow
```

**Format**

This data frame contains the following columns:

- age The mid-point of the 10 year age-group for the doctors.
- smoke An indicator of whether the doctors smoked (1) or not (0).
- n The number of person-years in the category.
- y The number of deaths attributed to coronary artery disease.
- ns The number of smoker years in the category (`smoke*n`).

**Source**

The data were obtained from

Breslow, N.E. (1985) Cohort Analysis in Epidemiology. In *A Celebration of Statistics* A.C. Atkinson and S.E. Fienberg (editors), 109–143. Springer-Verlag.

calcium

*Calcium Uptake Data*

---

**Description**

The `calcium` data frame has 27 rows and 2 columns.

Howard Grimes from the Botany Department, North Carolina State University, conducted an experiment for biochemical analysis of intracellular storage and transport of calcium across plasma membrane. Cells were suspended in a solution of radioactive calcium for a certain length of time and then the amount of radioactive calcium that was absorbed by the cells was measured. The experiment was repeated independently with 9 different times of suspension each replicated 3 times.

**Usage**

`calcium`

**Format**

This data frame contains the following columns:

- time The time (in minutes) that the cells were suspended in the solution.
- cal The amount of calcium uptake (nmoles/mg).

**Source**

The data were obtained from

Rawlings, J.O. (1988) *Applied Regression Analysis*. Wadsworth and Brooks/Cole Statistics/Probability Series.

cane

*Sugar-cane Disease Data*

---

## Description

The `cane` data frame has 180 rows and 5 columns. The data frame represents a randomized block design with 45 varieties of sugar-cane and 4 blocks.

## Usage

`cane`

## Format

This data frame contains the following columns:

`n` The total number of shoots in each plot.

`r` The number of diseased shoots.

`x` The number of pieces of the stems, out of 50, planted in each plot.

`var` A factor indicating the variety of sugar-cane in each plot.

`block` A factor for the blocks.

## Details

The aim of the experiment was to classify the varieties into resistant, intermediate and susceptible to a disease called "coal of sugar-cane" (carvão da cana-de-açúcar). This is a disease that is common in sugar-cane plantations in certain areas of Brazil.

For each plot, fifty pieces of sugar-cane stem were put in a solution containing the disease agent and then some were planted in the plot. After a fixed period of time, the total number of shoots and the number of diseased shoots were recorded.

## Source

The data were kindly supplied by Dr. C.G.B. Demetrio of Escola Superior de Agricultura, Universidade de São Paulo, Brazil.

capability

*Simulated Manufacturing Process Data*

---

**Description**

The `capability` data frame has 75 rows and 1 columns.

The data are simulated successive observations from a process in equilibrium. The process is assumed to have specification limits (5.49, 5.79).

**Usage**

`capability`

**Format**

This data frame contains the following column:

`y` The simulated measurements.

**Source**

The data were obtained from

Bissell, A.F. (1990) How reliable is your capability index? *Applied Statistics*, **39**, 331–340.

catsM

*Weight Data for Domestic Cats*

---

**Description**

The `catsM` data frame has 97 rows and 3 columns.

144 adult (over 2kg in weight) cats used for experiments with the drug digitalis had their heart and body weight recorded. 47 of the cats were female and 97 were male. The `catsM` data frame consists of the data for the male cats. The full data are in dataset `cats` in package MASS.

**Usage**

`catsM`

### Format

This data frame contains the following columns:

`Sex` A factor for the sex of the cat (levels are F and M: all cases are M in this subset).

`Bwt` Body weight in kg.

`Hwt` Heart weight in g.

### Source

The data were obtained from

Fisher, R.A. (1947) The analysis of covariance method for the relation between a part and the whole. *Biometrics*, **3**, 65–68.

cav

*Position of Muscle Caveolae*

---

### Description

The `cav` data frame has 138 rows and 2 columns.

The data gives the positions of the individual caveolae in a square region with sides of length 500 units. This grid was originally on a 2.65µm square of muscle fibre. The data are those points falling in the lower left hand quarter of the region used for the dataset `caveolae.dat` in the **spatial** package by B.D. Ripley (1994).

### Usage

`cav`

### Format

This data frame contains the following columns:

`x` The x coordinate of the caveola's position in the region.

`y` The y coordinate of the caveola's position in the region.

cd4

*CD4 Counts for HIV-Positive Patients***Description**

The `cd4` data frame has 20 rows and 2 columns.

CD4 cells are carried in the blood as part of the human immune system. One of the effects of the HIV virus is that these cells die. The count of CD4 cells is used in determining the onset of full-blown AIDS in a patient. In this study of the effectiveness of a new anti-viral drug on HIV, 20 HIV-positive patients had their CD4 counts recorded and then were put on a course of treatment with this drug. After using the drug for one year, their CD4 counts were again recorded. The aim of the experiment was to show that patients taking the drug had increased CD4 counts which is not generally seen in HIV-positive patients.

**Usage**

cd4

**Format**

This data frame contains the following columns:

`baseline` The CD4 counts (in 100's) on admission to the trial.

`oneyear` The CD4 counts (in 100's) after one year of treatment with the new drug.

**Source**

The data were obtained from

DiCiccio, T.J. and Efron B. (1996) Bootstrap confidence intervals (with Discussion). *Statistical Science*, **11**, 189–228.

cd4.nested

*Nested Bootstrap of cd4 data***Description**

This is an example of a nested bootstrap for the correlation coefficient of the `cd4` data frame. It is used in a practical in Chapter 5 of Davison and Hinkley (1997).

**References**

Davison, A.C. and Hinkley, D.V. (1997) *Bootstrap Methods and Their Application*. Cambridge University Press.

**See Also**

[cd4](#)

**Description**

This function applies types of bootstrap resampling which have been suggested to deal with right-censored data. It can also do model-based resampling using a Cox regression model.

**Usage**

```
censboot(data, statistic, R, F.surv, G.surv, strata = matrix(1,n,2),
  sim = "ordinary", cox = NULL, index = c(1, 2), ...,
  parallel = c("no", "multicore", "snow"),
  ncpus = getOption("boot.ncpus", 1L), cl = NULL)
```

**Arguments**

- |           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| data      | The data frame or matrix containing the data. It must have at least two columns, one of which contains the times and the other the censoring indicators. It is allowed to have as many other columns as desired (although efficiency is reduced for large numbers of columns) except for <code>sim = "weird"</code> when it should only have two columns - the times and censoring indicators. The columns of data referenced by the components of <code>index</code> are taken to be the times and censoring indicators.                                                                                                                                                                                                                                                                                                                                                                       |
| statistic | A function which operates on the data frame and returns the required statistic. Its first argument must be the data. Any other arguments that it requires can be passed using the <code>...</code> argument. In the case of <code>sim = "weird"</code> , the data passed to <code>statistic</code> only contains the times and censoring indicator regardless of the actual number of columns in data. In all other cases the data passed to <code>statistic</code> will be of the same form as the original data. When <code>sim = "weird"</code> , the actual number of observations in the resampled data sets may not be the same as the number in data. For this reason, if <code>sim = "weird"</code> and <code>strata</code> is supplied, <code>statistic</code> should also take a numeric vector indicating the strata. This allows the statistic to depend on the strata if required. |
| R         | The number of bootstrap replicates.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| F.surv    | An object returned from a call to <code>survfit</code> giving the survivor function for the data. This is a required argument unless <code>sim = "ordinary"</code> or <code>sim = "model"</code> and <code>cox</code> is missing.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| G.surv    | Another object returned from a call to <code>survfit</code> but with the censoring indicators reversed to give the product-limit estimate of the censoring distribution. Note that for consistency the uncensored times should be reduced by a small amount in the call to <code>survfit</code> . This is a required argument whenever <code>sim = "cond"</code> or when <code>sim = "model"</code> and <code>cox</code> is supplied.                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| strata    | The strata used in the calls to <code>survfit</code> . It can be a vector or a matrix with 2 columns. If it is a vector then it is assumed to be the strata for the survival distribution, and the censoring distribution is assumed to be the same for all observations. If it is a matrix then the first column is the strata for the survival distribution and the second is the strata for the censoring distribution. When <code>sim = "weird"</code> only the strata for the survival distribution are used since the                                                                                                                                                                                                                                                                                                                                                                     |

censoring times are considered fixed. When `sim = "ordinary"`, only one set of strata is used to stratify the observations, this is taken to be the first column of `strata` when it is a matrix.

`sim` The simulation type. Possible types are "ordinary" (case resampling), "model" (equivalent to "ordinary" if `cox` is missing, otherwise it is model-based resampling), "weird" (the weird bootstrap - this cannot be used if `cox` is supplied), and "cond" (the conditional bootstrap, in which censoring times are resampled from the conditional censoring distribution).

`cox` An object returned from `coxph`. If it is supplied, then `F.surv` should have been generated by a call of the form `survfit(cox)`.

`index` A vector of length two giving the positions of the columns in `data` which correspond to the times and censoring indicators respectively.

`...` Other named arguments which are passed unchanged to `statistic` each time it is called. Any such arguments to `statistic` must follow the arguments which `statistic` is required to have for the simulation. Beware of partial matching to arguments of `censboot` listed above, and that arguments named `X` and `FUN` cause conflicts in some versions of **boot** (but not this one).

`parallel, ncpus, cl`  
See the help for `boot`.

## Details

The various types of resampling are described in Davison and Hinkley (1997) in sections 3.5 and 7.3. The simplest is case resampling which simply resamples with replacement from the observations.

The conditional bootstrap simulates failure times from the estimate of the survival distribution. Then, for each observation its simulated censoring time is equal to the observed censoring time if the observation was censored and generated from the estimated censoring distribution conditional on being greater than the observed failure time if the observation was uncensored. If the largest value is censored then it is given a nominal failure time of `Inf` and conversely if it is uncensored it is given a nominal censoring time of `Inf`. This is necessary to allow the largest observation to be in the resamples.

If a Cox regression model is fitted to the data and supplied, then the failure times are generated from the survival distribution using that model. In this case the censoring times can either be simulated from the estimated censoring distribution (`sim = "model"`) or from the conditional censoring distribution as in the previous paragraph (`sim = "cond"`).

The weird bootstrap holds the censored observations as fixed and also the observed failure times. It then generates the number of events at each failure time using a binomial distribution with mean 1 and denominator the number of failures that could have occurred at that time in the original data set. In our implementation we insist that there is a least one simulated event in each stratum for every bootstrap dataset.

When there are strata involved and `sim` is either "model" or "cond" the situation becomes more difficult. Since the strata for the survival and censoring distributions are not the same it is possible that for some observations both the simulated failure time and the simulated censoring time are infinite. To see this consider an observation in stratum 1F for the survival distribution and stratum 1G for the censoring distribution. Now if the largest value in stratum 1F is censored it is given a nominal failure time of `Inf`, also if the largest value in stratum 1G is uncensored it is given a nominal censoring time of `Inf` and so both the simulated failure and censoring times could be infinite. When this happens the simulated value is considered to be a failure at the time of the largest observed failure time in the stratum for the survival distribution.

When `parallel = "snow"` and `cl` is not supplied, `library(survival)` is run in each of the worker processes.

## Value

An object of class `"boot"` containing the following components:

|                        |                                                                                                                                                                                                                                                                                                                                         |
|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>t0</code>        | The value of <code>statistic</code> when applied to the original data.                                                                                                                                                                                                                                                                  |
| <code>t</code>         | A matrix of bootstrap replicates of the values of <code>statistic</code> .                                                                                                                                                                                                                                                              |
| <code>R</code>         | The number of bootstrap replicates performed.                                                                                                                                                                                                                                                                                           |
| <code>sim</code>       | The simulation type used. This will usually be the input value of <code>sim</code> unless that was <code>"model"</code> but <code>cox</code> was not supplied, in which case it will be <code>"ordinary"</code> .                                                                                                                       |
| <code>data</code>      | The data used for the bootstrap. This will generally be the input value of <code>data</code> unless <code>sim = "weird"</code> , in which case it will just be the columns containing the times and the censoring indicators.                                                                                                           |
| <code>seed</code>      | The value of <code>.Random.seed</code> when <code>censboot</code> started work.                                                                                                                                                                                                                                                         |
| <code>statistic</code> | The input value of <code>statistic</code> .                                                                                                                                                                                                                                                                                             |
| <code>strata</code>    | The strata used in the resampling. When <code>sim = "ordinary"</code> this will be a vector which stratifies the observations, when <code>sim = "weird"</code> it is the strata for the survival distribution and in all other cases it is a matrix containing the strata for the survival distribution and the censoring distribution. |
| <code>call</code>      | The original call to <code>censboot</code> .                                                                                                                                                                                                                                                                                            |

*Channing House Data*

---

## Description

The channing data frame has 462 rows and 5 columns.

Channing House is a retirement centre in Palo Alto, California. These data were collected between the opening of the house in 1964 until July 1, 1975. In that time 97 men and 365 women passed through the centre. For each of these, their age on entry and also on leaving or death was recorded. A large number of the observations were censored mainly due to the resident being alive on July 1, 1975 when the data was collected. Over the time of the study 130 women and 46 men died at Channing House. Differences between the survival of the sexes, taking age into account, was one of the primary concerns of this study.

## Usage

```
channing
```

### Format

This data frame contains the following columns:

- `sex` A factor for the sex of each resident ("Male" or "Female").
- `entry` The residents age (in months) on entry to the centre
- `exit` The age (in months) of the resident on death, leaving the centre or July 1, 1975 whichever event occurred first.
- `time` The length of time (in months) that the resident spent at Channing House.  
(`time=exit-entry`)
- `cens` The indicator of right censoring. 1 indicates that the resident died at Channing House, 0 indicates that they left the house prior to July 1, 1975 or that they were still alive and living in the centre at that date.

claridge

*Genetic Links to Left-handedness*

---

### Description

The `claridge` data frame has 37 rows and 2 columns.

The data are from an experiment which was designed to look for a relationship between a certain genetic characteristic and handedness. The 37 subjects were women who had a son with mental retardation due to inheriting a defective X-chromosome. For each such mother a genetic measurement of their DNA was made. Larger values of this measurement are known to be linked to the defective gene and it was hypothesized that larger values might also be linked to a progressive shift away from right-handedness. Each woman also filled in a questionnaire regarding which hand they used for various tasks. From these questionnaires a measure of hand preference was found for each mother. The scale of this measure goes from 1, indicating someone who always favours their right hand, to 8, indicating someone who always favours their left hand. Between these two extremes are people who favour one hand for some tasks and the other for other tasks.

### Usage

`claridge`

### Format

This data frame contains the following columns:

- `dnan` The genetic measurement on each woman's DNA.
- `hand` The measure of left-handedness on an integer scale from 1 to 8.

**Source**

The data were kindly made available by Dr. Gordon S. Claridge from the Department of Experimental Psychology, University of Oxford.

`co.transfer`
*Carbon Monoxide Transfer*

---

### Description

The `co.transfer` data frame has 7 rows and 2 columns. Seven smokers with chickenpox had their levels of carbon monoxide transfer measured on entry to hospital and then again after 1 week. The main question being whether one week of hospitalization has changed the carbon monoxide transfer factor.

### Usage

```
co.transfer
```

### Format

This data frame contains the following columns:

`entry` Carbon monoxide transfer factor on entry to hospital.

`week` Carbon monoxide transfer one week after admittance to hospital.

### Source

The data were obtained from

Hand, D.J., Daly, F., Lunn, A.D., McConway, K.J. and Ostrowski, E (1994) *A Handbook of Small Data Sets*. Chapman and Hall.

---

`coal`
*Dates of Coal Mining Disasters*

---

### Description

The `coal` data frame has 191 rows and 1 columns.

This data frame gives the dates of 191 explosions in coal mines which resulted in 10 or more fatalities. The time span of the data is from March 15, 1851 until March 22 1962.

### Usage

```
coal
```

## Format

This data frame contains the following column:

`date` The date of the disaster. The integer part of `date` gives the year. The day is represented as the fraction of the year that had elapsed on that day.

## Source

The data were obtained from

Hand, D.J., Daly, F., Lunn, A.D., McConway, K.J. and Ostrowski, E. (1994) *A Handbook of Small Data Sets*, Chapman and Hall.

|         |                                     |
|---------|-------------------------------------|
| control | <i>Control Variate Calculations</i> |
|---------|-------------------------------------|

---

## Description

This function will find control variate estimates from a bootstrap output object. It can either find the adjusted bias estimate using post-simulation balancing or it can estimate the bias, variance, third cumulant and quantiles, using the linear approximation as a control variate.

## Usage

```
control(boot.out, L = NULL, distn = NULL, index = 1, t0 = NULL,
        t = NULL, bias.adj = FALSE, alpha = NULL, ...)
```

## Arguments

|                       |                                                                                                                                                                                                                                                                                                                                                             |
|-----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>boot.out</code> | A bootstrap output object returned from <code>boot</code> . The bootstrap replicates must have been generated using the usual nonparametric bootstrap.                                                                                                                                                                                                      |
| <code>L</code>        | The empirical influence values for the statistic of interest. If <code>L</code> is not supplied then <code>empinf</code> is called to calculate them from <code>boot.out</code> .                                                                                                                                                                           |
| <code>distn</code>    | If present this must be the output from <code>smooth.spline</code> giving the distribution function of the linear approximation. This is used only if <code>bias.adj</code> is <code>FALSE</code> . Normally this would be found using a saddlepoint approximation. If it is not supplied in that case then it is calculated by <code>saddle.distn</code> . |
| <code>index</code>    | The index of the variable of interest in the output of <code>boot.out\$statistic</code> .                                                                                                                                                                                                                                                                   |
| <code>t0</code>       | The observed value of the statistic of interest on the original data set <code>boot.out\$data</code> . This argument is used only if <code>bias.adj</code> is <code>FALSE</code> . The input value is ignored if <code>t</code> is not also supplied. The default value is <code>boot.out\$t0[index]</code> .                                               |
| <code>t</code>        | The bootstrap replicate values of the statistic of interest. This argument is used only if <code>bias.adj</code> is <code>FALSE</code> . The input is ignored if <code>t0</code> is not supplied also. The default value is <code>boot.out\$t[, index]</code> .                                                                                             |

|                       |                                                                                                                                                                                                                                                                                                                                                                                      |
|-----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>bias.adj</code> | A logical variable which if <code>TRUE</code> specifies that the adjusted bias estimate using post-simulation balance is all that is required. If <code>bias.adj</code> is <code>FALSE</code> (default) then the linear approximation to the statistic is calculated and used as a control variate in estimates of the bias, variance and third cumulant as well as quantiles.       |
| <code>alpha</code>    | The alpha levels for the required quantiles if <code>bias.adj</code> is <code>FALSE</code> .                                                                                                                                                                                                                                                                                         |
| <code>...</code>      | Any additional arguments that <code>boot.out\$statistic</code> requires. These are passed unchanged every time <code>boot.out\$statistic</code> is called. <code>boot.out\$statistic</code> is called once if <code>bias.adj</code> is <code>TRUE</code> , otherwise it may be called by <code>empinf</code> for empirical influence calculations if <code>L</code> is not supplied. |

### Details

If `bias.adj` is `FALSE` then the linear approximation to the statistic is found and evaluated at each bootstrap replicate. Then using the equation  $T^* = Tl^* + (T^* - Tl^*)$ , moment estimates can be found. For quantile estimation the distribution of the linear approximation to  $\tau$  is approximated very accurately by saddlepoint methods, this is then combined with the bootstrap replicates to approximate the bootstrap distribution of  $\tau$  and hence to estimate the bootstrap quantiles of  $\tau$ .

### Value

If `bias.adj` is `TRUE` then the returned value is the adjusted bias estimate.

If `bias.adj` is `FALSE` then the returned value is a list with the following components

|                        |                                                                                                                                                                                                                                                                                                                    |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>L</code>         | The empirical influence values used. These are the input values if supplied, and otherwise they are the values calculated by <code>empinf</code> .                                                                                                                                                                 |
| <code>tL</code>        | The linear approximations to the bootstrap replicates $\tau$ of the statistic of interest.                                                                                                                                                                                                                         |
| <code>bias</code>      | The control estimate of bias using the linear approximation to $\tau$ as a control variate.                                                                                                                                                                                                                        |
| <code>var</code>       | The control estimate of variance using the linear approximation to $\tau$ as a control variate.                                                                                                                                                                                                                    |
| <code>k3</code>        | The control estimate of the third cumulant using the linear approximation to $\tau$ as a control variate.                                                                                                                                                                                                          |
| <code>quantiles</code> | A matrix with two columns; the first column are the alpha levels used for the quantiles and the second column gives the corresponding control estimates of the quantiles using the linear approximation to $\tau$ as a control variate.                                                                            |
| <code>distn</code>     | An output object from <code>smooth.spline</code> describing the saddlepoint approximation to the bootstrap distribution of the linear approximation to $\tau$ . If <code>distn</code> was supplied on input then this is the same as the input otherwise it is calculated by a call to <code>saddle.distn</code> . |

**Examples**

```
# Use of control variates for the variance of the air-conditioning data
mean.fun <- function(d, i)
{
  m <- mean(d$hours[i])
  n <- nrow(d)
  v <- (n-1)*var(d$hours[i])/n^2
  c(m, v)
}
air.boot <- boot(aircondit, mean.fun, R = 999)
control(air.boot, index = 2, bias.adj = TRUE)
air.cont <- control(air.boot, index = 2)
# Now let us try the variance on the log scale.
air.cont1 <- control(air.boot, t0 = log(air.boot$t0[2]),
                    t = log(air.boot$t[, 2]))
```

corr

*Correlation Coefficient***Description**

Calculates the weighted correlation given a data set and a set of weights.

**Usage**

```
corr(d, w = rep(1, nrow(d))/nrow(d))
```

**Arguments**

|   |                                                                                                                                                                                                    |
|---|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| d | A matrix with two columns corresponding to the two variables whose correlation we wish to calculate.                                                                                               |
| w | A vector of weights to be applied to each pair of observations. The default is equal weights for each pair. Normalization takes place within the function so <code>sum(w)</code> need not equal 1. |

**Details**

This function finds the correlation coefficient in weighted form. This is often useful in bootstrap methods since it allows for numerical differentiation to get the empirical influence values. It is also necessary to have the statistic in this form to find ABC intervals.

**Value**

The correlation coefficient between `d[, 1]` and `d[, 2]`.

**See Also**

[cor](#)

cum3

*Calculate Third Order Cumulants***Description**

Calculates an estimate of the third cumulant, or skewness, of a vector. Also, if more than one vector is specified, a product-moment of order 3 is estimated.

**Usage**

```
cum3(a, b = a, c = a, unbiased = TRUE)
```

**Arguments**

|          |                                                                                                                                |
|----------|--------------------------------------------------------------------------------------------------------------------------------|
| a        | A vector of observations.                                                                                                      |
| b        | Another vector of observations, if not supplied it is set to the value of a. If supplied then it must be the same length as a. |
| c        | Another vector of observations, if not supplied it is set to the value of a. If supplied then it must be the same length as a. |
| unbiased | A logical value indicating whether the unbiased estimator should be used.                                                      |

**Details**

The unbiased estimator uses a multiplier of  $n / ((n-1) * (n-2))$  where  $n$  is the sample size, if `unbiased` is `FALSE` then a multiplier of  $1/n$  is used. This is multiplied by `sum((a-mean(a)) * (b-mean(b)) * (c-mean(c)))` to give the required estimate.

**Value**

The required estimate.

cv.glm

*Cross-validation for Generalized Linear Models***Description**

This function calculates the estimated K-fold cross-validation prediction error for generalized linear models.

**Usage**

```
cv.glm(data, glmfit, cost, K)
```

## Arguments

|                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>data</code>   | A matrix or data frame containing the data. The rows should be cases and the columns correspond to variables, one of which is the response.                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>glmfit</code> | An object of class "glm" containing the results of a generalized linear model fitted to <code>data</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>cost</code>   | A function of two vector arguments specifying the cost function for the cross-validation. The first argument to <code>cost</code> should correspond to the observed responses and the second argument should correspond to the predicted or fitted responses from the generalized linear model. <code>cost</code> must return a non-negative scalar value. The default is the average squared error function.                                                                                                                                                   |
| <code>K</code>      | The number of groups into which the data should be split to estimate the cross-validation prediction error. The value of <code>K</code> must be such that all groups are of approximately equal size. If the supplied value of <code>K</code> does not satisfy this criterion then it will be set to the closest integer which does and a warning is generated specifying the value of <code>K</code> used. The default is to set <code>K</code> equal to the number of observations in <code>data</code> which gives the usual leave-one-out cross-validation. |

## Details

The data is divided randomly into `K` groups. For each group the generalized linear model is fit to `data` omitting that group, then the function `cost` is applied to the observed responses in the group that was omitted from the fit and the prediction made by the fitted models for those observations.

When `K` is the number of observations leave-one-out cross-validation is used and all the possible splits of the data are used. When `K` is less than the number of observations the `K` splits to be used are found by randomly partitioning the data into `K` groups of approximately equal size. In this latter case a certain amount of bias is introduced. This can be reduced by using a simple adjustment (see equation 6.48 in Davison and Hinkley, 1997). The second value returned in `delta` is the estimate adjusted by this method.

## Value

The returned value is a list with the following components.

|                    |                                                                                                                                                                                                                                                                                     |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>call</code>  | The original call to <code>cv.glm</code> .                                                                                                                                                                                                                                          |
| <code>K</code>     | The value of <code>K</code> used for the <code>K</code> -fold cross validation.                                                                                                                                                                                                     |
| <code>delta</code> | A vector of length two. The first component is the raw cross-validation estimate of prediction error. The second component is the adjusted cross-validation estimate. The adjustment is designed to compensate for the bias introduced by not using leave-one-out cross-validation. |
| <code>seed</code>  | The value of <code>.Random.seed</code> when <code>cv.glm</code> was called.                                                                                                                                                                                                         |

## Side Effects

The value of `.Random.seed` is updated.

`darwin`

*Darwin's Plant Height Differences*

---

### Description

The `darwin` data frame has 15 rows and 1 columns.

Charles Darwin conducted an experiment to examine the superiority of cross-fertilized plants over self-fertilized plants. 15 pairs of plants were used. Each pair consisted of one cross-fertilized plant and one self-fertilized plant which germinated at the same time and grew in the same pot. The plants were measured at a fixed time after planting and the difference in heights between the cross- and self-fertilized plants are recorded in eighths of an inch.

### Usage

`darwin`

**Format**

This data frame contains the following column:

**y** The difference in heights for the pairs of plants (in units of 0.125 inches).

**Source**

The data were obtained from

Fisher, R.A. (1935) *Design of Experiments*. Oliver and Boyd.

**References**

---

dogs

*Cardiac Data for Domestic Dogs*

---

**Description**

The dogs data frame has 7 rows and 2 columns.

Data on the cardiac oxygen consumption and left ventricular pressure were gathered on 7 domestic dogs.

**Usage**

dogs

**Format**

This data frame contains the following columns:

**mvo** Cardiac Oxygen Consumption

**lvp** Left Ventricular Pressure

**References**

downs.bc

---

*Incidence of Down's Syndrome in British Columbia*

---

## Description

The `downs.bc` data frame has 30 rows and 3 columns.

Down's syndrome is a genetic disorder caused by an extra chromosome 21 or a part of chromosome 21 being translocated to another chromosome. The incidence of Down's syndrome is highly dependent on the mother's age and rises sharply after age 30. In the 1960's a large scale study of the effect of maternal age on the incidence of Down's syndrome was conducted at the British Columbia Health Surveillance Registry. These are the data which was collected in that study.

Mothers were classified by age. Most groups correspond to the age in years but the first group comprises all mothers with ages in the range 15-17 and the last is those with ages 46-49. No data for mothers over 50 or below 15 were collected.

## Usage

`downs.bc`

## Format

This data frame contains the following columns:

`age` The average age of all mothers in the age category.

`m` The total number of live births to mothers in the age category.

`r` The number of cases of Down's syndrome.

## Source

The data were obtained from

Geyer, C.J. (1991) Constrained maximum likelihood exemplified by isotonic convex logistic regression. *Journal of the American Statistical Association*, **86**, 717–724.

ducks*Behavioral and Plumage Characteristics of Hybrid Ducks*

---

**Description**

The `ducks` data frame has 11 rows and 2 columns.

Each row of the data frame represents a male duck who is a second generation cross of mallard and pintail ducks. For 11 such ducks a behavioural and plumage index were calculated. These were measured on scales devised for this experiment which was to examine whether there was any link between which species the ducks resembled physically and which they resembled in behaviour. The scale for the physical appearance ranged from 0 (identical in appearance to a mallard) to 20 (identical to a pintail). The behavioural traits of the ducks were on a scale from 0 to 15 with lower numbers indicating closer to mallard-like in behaviour.

**Usage**

`ducks`

**Format**

This data frame contains the following columns:

`plumage` The index of physical appearance based on the plumage of individual ducks.  
`behaviour` The index of behavioural characteristics of the ducks.

**Source**

The data were obtained from

Larsen, R.J. and Marx, M.L. (1986) *An Introduction to Mathematical Statistics and its Applications* (Second Edition). Prentice-Hall.

**References**

---

`EEF.profile`*Empirical Likelihoods*

---

**Description**

Construct the empirical log likelihood or empirical exponential family log likelihood for a mean.

**Usage**

```
EEF.profile(y, tmin = min(y) + 0.1, tmax = max(y) - 0.1, n.t = 25,
            u = function(y, t) y - t)
EL.profile(y, tmin = min(y) + 0.1, tmax = max(y) - 0.1, n.t = 25,
           u = function(y, t) y - t)
```

**Arguments**

|                   |                                                                                                                                   |
|-------------------|-----------------------------------------------------------------------------------------------------------------------------------|
| <code>y</code>    | A vector or matrix of data                                                                                                        |
| <code>tmin</code> | The minimum value of the range over which the likelihood should be computed. This must be larger than <code>min(y)</code> .       |
| <code>tmax</code> | The maximum value of the range over which the likelihood should be computed. This must be smaller than <code>max(y)</code> .      |
| <code>n.t</code>  | The number of points between <code>tmin</code> and <code>tmax</code> at which the value of the log-likelihood should be computed. |
| <code>u</code>    | A function of the data and the parameter.                                                                                         |

**Details**

These functions calculate the log likelihood for a mean using either an empirical likelihood or an empirical exponential family likelihood. They are supplied as part of the package `boot` for demonstration purposes with the practicals in chapter 10 of Davison and Hinkley (1997). The functions are not intended for general use and are not supported as part of the `boot` package. For more general and more robust code to calculate empirical likelihoods see Professor A. B. Owen's empirical likelihood home page at the URL <https://statweb.stanford.edu/~owen/empirical/>.

**Value**

A matrix with `n.t` rows. The first column contains the values of the parameter used. The second column of the output of `EL.profile` contains the values of the empirical log likelihood. The second and third columns of the output of `EEF.profile` contain two versions of the empirical exponential family log-likelihood. The final column of the output matrix contains the values of the Lagrange multiplier used in the optimization procedure.

empinf

*Empirical Influence Values***Description**

This function calculates the empirical influence values for a statistic applied to a data set. It allows four types of calculation, namely the infinitesimal jackknife (using numerical differentiation), the usual jackknife estimates, the ‘positive’ jackknife estimates and a method which estimates the empirical influence values using regression of bootstrap replicates of the statistic. All methods can be used with one or more samples.

**Usage**

```
empinf(boot.out = NULL, data = NULL, statistic = NULL,
       type = NULL, stype = NULL, index = 1, t = NULL,
       strata = rep(1, n), eps = 0.001, ...)
```

**Arguments**

|                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>boot.out</code>  | A bootstrap object created by the function <code>boot</code> . If <code>type</code> is "reg" then this argument is required. For any of the other types it is an optional argument. If it is included when optional then the values of <code>data</code> , <code>statistic</code> , <code>stype</code> , and <code>strata</code> are taken from the components of <code>boot.out</code> and any values passed to <code>empinf</code> directly are ignored.                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <code>data</code>      | A vector, matrix or data frame containing the data for which empirical influence values are required. It is a required argument if <code>boot.out</code> is not supplied. If <code>boot.out</code> is supplied then <code>data</code> is set to <code>boot.out\$data</code> and any value supplied is ignored.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>statistic</code> | The statistic for which empirical influence values are required. It must be a function of at least two arguments, the data set and a vector of weights, frequencies or indices. The nature of the second argument is given by the value of <code>stype</code> . Any other arguments that it takes must be supplied to <code>empinf</code> and will be passed to <code>statistic</code> unchanged. This is a required argument if <code>boot.out</code> is not supplied, otherwise its value is taken from <code>boot.out</code> and any value supplied here will be ignored.                                                                                                                                                                                                                                                                                               |
| <code>type</code>      | The calculation type to be used for the empirical influence values. Possible values of <code>type</code> are "inf" (infinitesimal jackknife), "jack" (usual jackknife), "pos" (positive jackknife), and "reg" (regression estimation). The default value depends on the other arguments. If <code>t</code> is supplied then the default value of <code>type</code> is "reg" and <code>boot.out</code> should be present so that its frequency array can be found. If <code>t</code> is not supplied then if <code>stype</code> is "w", the default value of <code>type</code> is "inf"; otherwise, if <code>boot.out</code> is present the default is "reg". If none of these conditions apply then the default is "jack". Note that it is an error for <code>type</code> to be "reg" if <code>boot.out</code> is missing or to be "inf" if <code>stype</code> is not "w". |
| <code>stype</code>     | A character variable giving the nature of the second argument to <code>statistic</code> . It can take on three values: "w" (weights), "f" (frequencies), or "i" (indices). If <code>boot.out</code> is supplied the value of <code>stype</code> is set to <code>boot.out\$stype</code> and any value supplied here is ignored. Otherwise it is an optional argument which defaults to "w". If <code>type</code> is "inf" then <code>stype</code> MUST be "w".                                                                                                                                                                                                                                                                                                                                                                                                              |

|                     |                                                                                                                                                                                                                                                                                                     |
|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>index</code>  | An integer giving the position of the variable of interest in the output of <code>statistic</code> .                                                                                                                                                                                                |
| <code>t</code>      | A vector of length <code>boot.out\$R</code> which gives the bootstrap replicates of the statistic of interest. <code>t</code> is used only when <code>type</code> is <code>reg</code> and it defaults to <code>boot.out\$t[, index]</code> .                                                        |
| <code>strata</code> | An integer vector or a factor specifying the strata for multi-sample problems. If <code>boot.out</code> is supplied the value of <code>strata</code> is set to <code>boot.out\$strata</code> . Otherwise it is an optional argument which has default corresponding to the single sample situation. |
| <code>eps</code>    | This argument is used only if <code>type</code> is <code>"inf"</code> . In that case the value of epsilon to be used for numerical differentiation will be <code>eps</code> divided by the number of observations in <code>data</code> .                                                            |
| <code>...</code>    | Any other arguments that <code>statistic</code> takes. They will be passed unchanged to <code>statistic</code> every time that it is called.                                                                                                                                                        |

### Details

If `type` is `"inf"` then numerical differentiation is used to approximate the empirical influence values. This makes sense only for statistics which are written in weighted form (i.e. `stype` is `"w"`). If `type` is `"jack"` then the usual leave-one-out jackknife estimates of the empirical influence are returned. If `type` is `"pos"` then the positive (include-one-twice) jackknife values are used. If `type` is `"reg"` then a bootstrap object must be supplied. The regression method then works by regressing the bootstrap replicates of `statistic` on the frequency array from which they were derived. The bootstrap frequency array is obtained through a call to `boot.array`. Further details of the methods are given in Section 2.7 of Davison and Hinkley (1997).

Empirical influence values are often used frequently in nonparametric bootstrap applications. For this reason many other functions call `empinf` when they are required. Some examples of their use are for nonparametric delta estimates of variance, BCa intervals and finding linear approximations to statistics for use as control variates. They are also used for antithetic bootstrap resampling.

### Value

A vector of the empirical influence values of `statistic` applied to `data`. The values will be in the same order as the observations in `data`.

### Warning

All arguments to `empinf` must be passed using the `name = value` convention. If this is not followed then unpredictable errors can occur.

**Examples**

```
# The empirical influence values for the ratio of means in
# the city data.
ratio <- function(d, w) sum(d$x * w) / sum(d$u * w)
empinf(data = city, statistic = ratio)
city.boot <- boot(city, ratio, 499, stype="w")
empinf(boot.out = city.boot, type = "reg")

# A statistic that may be of interest in the difference of means
# problem is the t-statistic for testing equality of means. In
# the bootstrap we get replicates of the difference of means and
# the variance of that statistic and then want to use this output
# to get the empirical influence values of the t-statistic.
grav1 <- gravity[as.numeric(gravity[,2]) >= 7,]
grav.fun <- function(dat, w) {
  strata <- tapply(dat[, 2], as.numeric(dat[, 2]))
  d <- dat[, 1]
  ns <- tabulate(strata)
  w <- w / tapply(w, strata, sum)[strata]
  mns <- as.vector(tapply(d * w, strata, sum)) # drop names
  mn2 <- tapply(d * d * w, strata, sum)
  s2hat <- sum((mn2 - mns^2) / ns)
  c(mns[2] - mns[1], s2hat)
}

grav.boot <- boot(grav1, grav.fun, R = 499, stype = "w",
  strata = grav1[, 2])

# Since the statistic of interest is a function of the bootstrap
# statistics, we must calculate the bootstrap replicates and pass
# them to empinf using the t argument.
grav.z <- (grav.boot$t[,1] - grav.boot$t0[1]) / sqrt(grav.boot$t[,2])
empinf(boot.out = grav.boot, t = grav.z)
```

---

envelope

---

*Confidence Envelopes for Curves*

---

**Description**

This function calculates overall and pointwise confidence envelopes for a curve based on bootstrap replicates of the curve evaluated at a number of fixed points.

**Usage**

```
envelope(boot.out = NULL, mat = NULL, level = 0.95, index = 1:ncol(mat))
```

## Arguments

|                       |                                                                                                                                                                                                                                                                                                                                                                                   |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>boot.out</code> | An object of class "boot" for which <code>boot.out\$t</code> contains the replicates of the curve at a number of fixed points.                                                                                                                                                                                                                                                    |
| <code>mat</code>      | A matrix of bootstrap replicates of the values of the curve at a number of fixed points. This is a required argument if <code>boot.out</code> is not supplied and is set to <code>boot.out\$t</code> otherwise.                                                                                                                                                                   |
| <code>level</code>    | The confidence level of the envelopes required. The default is to find 95% confidence envelopes. It can be a scalar or a vector of length 2. If it is scalar then both the pointwise and the overall envelopes are found at that level. If is a vector then the first element gives the level for the pointwise envelope and the second gives the level for the overall envelope. |
| <code>index</code>    | The numbers of the columns of <code>mat</code> which contain the bootstrap replicates. This can be used to ensure that other statistics which may have been calculated in the bootstrap are not considered as values of the function.                                                                                                                                             |

## Details

The pointwise envelope is found by simply looking at the quantiles of the replicates at each point. The overall error for that envelope is then calculated using equation (4.17) of Davison and Hinkley (1997). A sequence of pointwise envelopes is then found until one of them has overall error approximately equal to the level required. If no such envelope can be found then the envelope returned will just contain the extreme values of each column of `mat`.

## Value

A list with the following components :

|                      |                                                                                                                                                                         |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>point</code>   | A matrix with two rows corresponding to the values of the upper and lower pointwise confidence envelope at the same points as the bootstrap replicates were calculated. |
| <code>overall</code> | A matrix similar to <code>point</code> but containing the envelope which controls the overall error.                                                                    |
| <code>k.pt</code>    | The quantiles used for the pointwise envelope.                                                                                                                          |
| <code>err.pt</code>  | A vector with two components, the first gives the pointwise error rate for the pointwise envelope, and the second the overall error rate for that envelope.             |
| <code>k.ov</code>    | The quantiles used for the overall envelope.                                                                                                                            |
| <code>err.ov</code>  | A vector with two components, the first gives the pointwise error rate for the overall envelope, and the second the overall error rate for that envelope.               |
| <code>err.nom</code> | A vector of length 2 giving the nominal error rates for the pointwise and the overall envelopes.                                                                        |

```

---

exp.tilt

*Exponential Tilting*

---

## Description

This function calculates exponentially tilted multinomial distributions such that the resampling distributions of the linear approximation to a statistic have the required means.

## Usage

```
exp.tilt(L, theta = NULL, t0 = 0, lambda = NULL,
        strata = rep(1, length(L)))
```

## Arguments

|                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>L</code>      | The empirical influence values for the statistic of interest based on the observed data. The length of <code>L</code> should be the same as the size of the original data set. Typically <code>L</code> will be calculated by a call to <code>empinf</code> .                                                                                                                                                                                                                                |
| <code>theta</code>  | The value at which the tilted distribution is to be centred. This is not required if <code>lambda</code> is supplied but is needed otherwise.                                                                                                                                                                                                                                                                                                                                                |
| <code>t0</code>     | The current value of the statistic. The default is that the statistic equals 0.                                                                                                                                                                                                                                                                                                                                                                                                              |
| <code>lambda</code> | The Lagrange multiplier(s). For each value of <code>lambda</code> a multinomial distribution is found with probabilities proportional to $\exp(\text{lambda} * L)$ . In general <code>lambda</code> is not known and so <code>theta</code> would be supplied, and the corresponding value of <code>lambda</code> found. If both <code>lambda</code> and <code>theta</code> are supplied then <code>lambda</code> is ignored and the multipliers for tilting to <code>theta</code> are found. |
| <code>strata</code> | A vector or factor of the same length as <code>L</code> giving the strata for the observed data and the empirical influence values <code>L</code> .                                                                                                                                                                                                                                                                                                                                          |

## Details

Exponential tilting involves finding a set of weights for a data set to ensure that the bootstrap distribution of the linear approximation to a statistic of interest has mean `theta`. The weights chosen to achieve this are given by `p[j]` proportional to  $\exp(\lambda L[j]/n)$ , where `n` is the number of data points. `lambda` is then chosen to make the mean of the bootstrap distribution, of the linear approximation to the statistic of interest, equal to the required value `theta`. Thus `lambda` is defined as the solution of a nonlinear equation. The equation is solved by minimizing the Euclidean distance between the left and right hand sides of the equation using the function `nlmin`. If this minimum is not equal to zero then the method fails.

Typically exponential tilting is used to find suitable weights for importance resampling. If a small tail probability or quantile of the distribution of the statistic of interest is required then a more efficient simulation is to centre the resampling distribution close to the point of interest and then use the functions `imp.prob` or `imp.quantile` to estimate the required quantity.

Another method of achieving a similar shifting of the distribution is through the use of `smooth.f`. The function `tilt.boot` uses `exp.tilt` or `smooth.f` to find the weights for a tilted bootstrap.

## Value

A list with the following components :

|                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>p</code>      | The tilted probabilities. There will be <code>m</code> distributions where <code>m</code> is the length of <code>theta</code> (or <code>lambda</code> if supplied). If <code>m</code> is 1 then <code>p</code> is a vector of length <code>(L)</code> probabilities. If <code>m</code> is greater than 1 then <code>p</code> is a matrix with <code>m</code> rows, each of which contain length <code>(L)</code> probabilities. In this case the vector <code>p[i, ]</code> is the distribution tilted to <code>theta[i]</code> . <code>p</code> is in the form required by the argument <code>weights</code> of the function <code>boot</code> for importance resampling. |
| <code>lambda</code> | The Lagrange multiplier used in the equation to determine the tilted probabilities. <code>lambda</code> is a vector of the same length as <code>theta</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>theta</code>  | The values of <code>theta</code> to which the distributions have been tilted. In general this will be the input value of <code>theta</code> but if <code>lambda</code> was supplied then this is the vector of the corresponding <code>theta</code> values.                                                                                                                                                                                                                                                                                                                                                                                                                |

## Examples

```
# Example 9.8 of Davison and Hinkley (1997) requires tilting the resampling
# distribution of the studentized statistic to be centred at the observed
# value of the test statistic 1.84. This can be achieved as follows.
grav1 <- gravity[as.numeric(gravity[,2]) >= 7 , ]
grav.fun <- function(dat, w, orig) {
  strata <- tapply(dat[, 2], as.numeric(dat[, 2]))
  d <- dat[, 1]
```

```

ns <- tabulate(strata)
w <- w/tapply(w, strata, sum)[strata]
mns <- as.vector(tapply(d * w, strata, sum)) # drop names
mn2 <- tapply(d * d * w, strata, sum)
s2hat <- sum((mn2 - mns^2)/ns)
c(mns[2]-mns[1], s2hat, (mns[2]-mns[1]-orig)/sqrt(s2hat))
}
grav.z0 <- grav.fun(grav1, rep(1, 26), 0)
grav.L <- empinf(data = grav1, statistic = grav.fun, stype = "w",
                 strata = grav1[,2], index = 3, orig = grav.z0[1])
grav.tilt <- exp.tilt(grav.L, grav.z0[3], strata = grav1[,2])
boot(grav1, grav.fun, R = 499, stype = "w", weights = grav.tilt$p,
     strata = grav1[,2], orig = grav.z0[1])

```

fir

*Counts of Balsam-fir Seedlings*

## Description

The `fir` data frame has 50 rows and 3 columns.

The number of balsam-fir seedlings in each quadrant of a grid of 50 five foot square quadrants were counted. The grid consisted of 5 rows of 10 quadrants in each row.

## Usage

```
fir
```

## Format

This data frame contains the following columns:

`count` The number of seedlings in the quadrant.

`row` The row number of the quadrant.

`col` The quadrant number within the row.

---

freq.array

*Bootstrap Frequency Arrays*

---

### Description

Take a matrix of indices for nonparametric bootstrap resamples and return the frequencies of the original observations in each resample.

### Usage

```
freq.array(i.array)
```

### Arguments

`i.array` This will be an matrix of integers between 1 and `n`, where `n` is the number of observations in a data set. The matrix will have `n` columns and `R` rows where `R` is the number of bootstrap resamples. Such matrices are found by `boot` when doing nonparametric bootstraps. They can also be found after a bootstrap has been run through the function `boot.array`.

### Value

A matrix of the same dimensions as the input matrix. Each row of the matrix corresponds to a single bootstrap resample. Each column of the matrix corresponds to one of the original observations and specifies its frequency in each bootstrap resample. Thus the first column tells us how often the first observation appeared in each bootstrap resample. Such frequency arrays are often useful for diagnostic purposes such as the jackknife-after-bootstrap plot. They are also necessary for the regression estimates of empirical influence values and for finding importance sampling weights.

frets

*Head Dimensions in Brothers*

---

### Description

The `frets` data frame has 25 rows and 4 columns.

The data consist of measurements of the length and breadth of the heads of pairs of adult brothers in 25 randomly sampled families. All measurements are expressed in millimetres.

### Usage

```
frets
```

**Format**

This data frame contains the following columns:

- l1 The head length of the eldest son.
- b1 The head breadth of the eldest son.
- l2 The head length of the second son.
- b2 The head breadth of the second son.

**Source**

The data were obtained from

Frets, G.P. (1921) Heredity of head form in man. *Genetica*, **3**, 193.

glm.diag

*Generalized Linear Model Diagnostics*

---

**Description**

Calculates jackknife deviance residuals, standardized deviance residuals, standardized Pearson residuals, approximate Cook statistic, leverage and estimated dispersion.

**Usage**

```
glm.diag(glmfit)
```

**Arguments**

glmfit            glmfit is a glm.object - the result of a call to glm()

**Value**

Returns a list with the following components

- |      |                                                                                                                                                                                                                                  |
|------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| res  | The vector of jackknife deviance residuals.                                                                                                                                                                                      |
| rd   | The vector of standardized deviance residuals.                                                                                                                                                                                   |
| rp   | The vector of standardized Pearson residuals.                                                                                                                                                                                    |
| cook | The vector of approximate Cook statistics.                                                                                                                                                                                       |
| h    | The vector of leverages of the observations.                                                                                                                                                                                     |
| sd   | The value used to standardize the residuals. This is the estimate of residual standard deviation in the Gaussian family and is the square root of the estimated shape parameter in the Gamma family. In all other cases it is 1. |

**Note**

See the help for `glm.diag.plots` for an example of the use of `glm.diag`.

|-----------------------------|--------------------------------------------------------|
| <code>glm.diag.plots</code> | <i>Diagnostics plots for generalized linear models</i> |
|-----------------------------|--------------------------------------------------------|

---

**Description**

Makes plot of jackknife deviance residuals against linear predictor, normal scores plots of standardized deviance residuals, plot of approximate Cook statistics against leverage/(1-leverage), and case plot of Cook statistic.

**Usage**

```
glm.diag.plots(glmfit, glmdiag = glm.diag(glmfit), subset = NULL,
               iden = FALSE, labels = NULL, ret = FALSE)
```

**Arguments**

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>glmfit</code>  | glm.object : the result of a call to <code>glm()</code>                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>glmdiag</code> | Diagnostics of <code>glmfit</code> obtained from a call to <code>glm.diag</code> . If it is not supplied then it is calculated.                                                                                                                                                                                                                                                                                                                                 |
| <code>subset</code>  | Subset of data for which <code>glm</code> fitting performed: should be the same as the <code>subset</code> option used in the call to <code>glm()</code> which generated <code>glmfit</code> . Needed only if the <code>subset=</code> option was used in the call to <code>glm</code> .                                                                                                                                                                        |
| <code>iden</code>    | A logical argument. If <code>TRUE</code> then, after the plots are drawn, the user will be prompted for an integer between 0 and 4. A positive integer will select a plot and invoke <code>identify()</code> on that plot. After exiting <code>identify()</code> , the user is again prompted, this loop continuing until the user responds to the prompt with 0. If <code>iden</code> is <code>FALSE</code> (default) the user cannot interact with the plots. |
| <code>labels</code>  | A vector of labels for use with <code>identify()</code> if <code>iden</code> is <code>TRUE</code> . If it is not supplied then the labels are derived from <code>glmfit</code> .                                                                                                                                                                                                                                                                                |
| <code>ret</code>     | A logical argument indicating if <code>glmdiag</code> should be returned. The default is <code>FALSE</code> .                                                                                                                                                                                                                                                                                                                                                   |

## Details

The diagnostics required for the plots are calculated by `glm.diag`. These are then used to produce the four plots on the current graphics device.

The plot on the top left is a plot of the jackknife deviance residuals against the fitted values.

The plot on the top right is a normal QQ plot of the standardized deviance residuals. The dotted line is the expected line if the standardized residuals are normally distributed, i.e. it is the line with intercept 0 and slope 1.

The bottom two panels are plots of the Cook statistics. On the left is a plot of the Cook statistics against the standardized leverages. In general there will be two dotted lines on this plot. The horizontal line is at  $8/(n-2p)$  where  $n$  is the number of observations and  $p$  is the number of parameters estimated. Points above this line may be points with high influence on the model. The vertical line is at  $2p/(n-2p)$  and points to the right of this line have high leverage compared to the variance of the raw residual at that point. If all points are below the horizontal line or to the left of the vertical line then the line is not shown.

The final plot again shows the Cook statistic this time plotted against case number enabling us to find which observations are influential.

Use of `iden=T` is encouraged for proper exploration of these four plots as a guide to how well the model fits the data and whether certain observations have an unduly large effect on parameter estimates.

## Value

If `ret` is TRUE then the value of `glm.diag` is returned otherwise there is no returned value.

## Side Effects

The current device is cleared and four plots are plotted by use of `split.screen(c(2,2))`. If `iden` is TRUE, interactive identification of points is enabled. All screens are closed, but not cleared, on termination of the function.

## Examples

```
# In this example we look at the leukaemia data which was looked at in
# Example 7.1 of Davison and Hinkley (1997)
data(leuk, package = "MASS")
leuk.mod <- glm(time ~ ag-1+log10(wbc), family = Gamma(log), data = leuk)
leuk.diag <- glm.diag(leuk.mod)
glm.diag.plots(leuk.mod, leuk.diag)
```

gravity

*Acceleration Due to Gravity***Description**

The `gravity` data frame has 81 rows and 2 columns.

The `grav` data set has 26 rows and 2 columns.

Between May 1934 and July 1935, the National Bureau of Standards in Washington D.C. conducted a series of experiments to estimate the acceleration due to gravity,  $g$ , at Washington. Each experiment produced a number of replicate estimates of  $g$  using the same methodology. Although the basic method remained the same for all experiments, that of the reversible pendulum, there were changes in configuration.

The `gravity` data frame contains the data from all eight experiments. The `grav` data frame contains the data from the experiments 7 and 8. The data are expressed as deviations from 980.000 in centimetres per second squared.

**Usage**

```
gravity
```

**Format**

This data frame contains the following columns:

`g` The deviation of the estimate from 980.000 centimetres per second squared.

`series` A factor describing from which experiment the estimate was derived.

**Source**

The data were obtained from

Cressie, N. (1982) Playing safe with misweighted means. *Journal of the American Statistical Association*, **77**, 754–759.

**References**

Davison, A.C. and Hinkley, D.V. (1997) *Bootstrap Methods and Their Application*. Cambridge University Press.

hirose

*Failure Time of PET Film***Description**

The `hirose` data frame has 44 rows and 3 columns.

PET film is used in electrical insulation. In this accelerated life test the failure times for 44 samples in gas insulated transformers. 4 different voltage levels were used.

**Usage**

```
hirose
```

**Format**

This data frame contains the following columns:

`volt` The voltage (in kV).

`time` The failure or censoring time in hours.

`cens` The censoring indicator; 1 means right-censored data.

**Source**

The data were obtained from

Hirose, H. (1993) Estimation of threshold stress in accelerated life-testing. *IEEE Transactions on Reliability*, **42**, 650–657.

**References**

Davison, A.C. and Hinkley, D.V. (1997) *Bootstrap Methods and Their Application*. Cambridge University Press.

---

Imp.Estimates

---

Importance Sampling Estimates

---

**Description**

Central moment, tail probability, and quantile estimates for a statistic under importance resampling.

**Usage**

```
imp.moments(boot.out = NULL, index = 1, t = boot.out$t[, index],
             w = NULL, def = TRUE, q = NULL)
imp.prob(boot.out = NULL, index = 1, t0 = boot.out$t0[index],
          t = boot.out$t[, index], w = NULL, def = TRUE, q = NULL)
imp.quantile(boot.out = NULL, alpha = NULL, index = 1,
              t = boot.out$t[, index], w = NULL, def = TRUE, q = NULL)
```

**Arguments**

|                       |                                                                                                                                                                                                                                                                                                                                                                                    |
|-----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>boot.out</code> | A object of class "boot" generated by a call to <code>boot</code> or <code>tilt.boot</code> . Use of these functions makes sense only when the bootstrap resampling used unequal weights for the observations. If the importance weights <code>w</code> are not supplied then <code>boot.out</code> is a required argument. It is also required if <code>t</code> is not supplied. |
| <code>alpha</code>    | The alpha levels for the required quantiles. The default is to calculate the 1%, 2.5%, 5%, 10%, 90%, 95%, 97.5% and 99% quantiles.                                                                                                                                                                                                                                                 |
| <code>index</code>    | The index of the variable of interest in the output of <code>boot.out\$statistic</code> . This is not used if the argument <code>t</code> is supplied.                                                                                                                                                                                                                             |

|                  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>t0</code>  | The values at which tail probability estimates are required. For each value <code>t0[i]</code> the function will estimate the bootstrap cdf evaluated at <code>t0[i]</code> . If <code>imp.prob</code> is called without the argument <code>t0</code> then the bootstrap cdf evaluated at the observed value of the statistic is found.                                                                                                                                                                                                                   |
| <code>t</code>   | The bootstrap replicates of a statistic. By default these are taken from the bootstrap output object <code>boot.out</code> but they can be supplied separately if required (e.g. when the statistic of interest is a function of the calculated values in <code>boot.out</code> ). Either <code>boot.out</code> or <code>t</code> must be supplied.                                                                                                                                                                                                       |
| <code>w</code>   | The importance resampling weights for the bootstrap replicates. If they are not supplied then <code>boot.out</code> must be supplied, in which case the importance weights are calculated by a call to <code>imp.weights</code> .                                                                                                                                                                                                                                                                                                                         |
| <code>def</code> | A logical value indicating whether a defensive mixture is to be used for weight calculation. This is used only if <code>w</code> is missing and it is passed unchanged to <code>imp.weights</code> to calculate <code>w</code> .                                                                                                                                                                                                                                                                                                                          |
| <code>q</code>   | A vector of probabilities specifying the resampling distribution from which any estimates should be found. In general this would correspond to the usual bootstrap resampling distribution which gives equal weight to each of the original observations. The estimates depend on this distribution only through the importance weights <code>w</code> so this argument is ignored if <code>w</code> is supplied. If <code>w</code> is missing then <code>q</code> is passed as an argument to <code>imp.weights</code> and used to find <code>w</code> . |

### Value

A list with the following components :

|                    |                                                                                                                                                                                                                                                                                                                                                                             |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>alpha</code> | The alpha levels used for the quantiles, if <code>imp.quantile</code> is used.                                                                                                                                                                                                                                                                                              |
| <code>t0</code>    | The values at which the tail probabilities are estimated, if <code>imp.prob</code> is used.                                                                                                                                                                                                                                                                                 |
| <code>raw</code>   | The raw importance resampling estimates. For <code>imp.moments</code> this has length 2, the first component being the estimate of the mean and the second being the variance estimate. For <code>imp.prob</code> , <code>raw</code> is of the same length as <code>t0</code> , and for <code>imp.quantile</code> it is of the same length as <code>alpha</code> .          |
| <code>rat</code>   | The ratio importance resampling estimates. In this method the weights <code>w</code> are rescaled to have average value one before they are used. The format of this vector is the same as <code>raw</code> .                                                                                                                                                               |
| <code>reg</code>   | The regression importance resampling estimates. In this method the weights which are used are derived from a regression of $t \cdot w$ on <code>w</code> . This choice of weights can be shown to minimize the variance of the weights and also the Euclidean distance of the weights from the uniform weights. The format of this vector is the same as <code>raw</code> . |

grav.p <- imp.prob(grav.tilt.boot, w = grav.w, index = 3, t0 = grav.z0[3])
unlist(grav.p)
grav.q <- imp.quantile(grav.tilt.boot, w = grav.w, index = 3,
  alpha = c(0.9, 0.95, 0.975, 0.99))
as.data.frame(grav.q)
```

---

imp.weights

*Importance Sampling Weights*

---

**Description**

This function calculates the importance sampling weight required to correct for simulation from a distribution with probabilities  $p$  when estimates are required assuming that simulation was from an alternative distribution with probabilities  $q$ .

**Usage**

```
imp.weights(boot.out, def = TRUE, q = NULL)
```

## Arguments

|                       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>boot.out</code> | A object of class "boot" generated by <code>boot</code> or <code>tilt.boot</code> . Typically the bootstrap simulations would have been done using importance resampling and we wish to do our calculations under the assumption of sampling with equal probabilities.                                                                                                                                                                                                                                                |
| <code>def</code>      | A logical variable indicating whether the defensive mixture distribution weights should be calculated. This makes sense only in the case where the replicates in <code>boot.out</code> were simulated under a number of different distributions. If this is the case then the defensive mixture weights use a mixture of the distributions used in the bootstrap. The alternative is to calculate the weights for each replicate using knowledge of the distribution from which the bootstrap resample was generated. |
| <code>q</code>        | A vector of probabilities specifying the resampling distribution from which we require inferences to be made. In general this would correspond to the usual bootstrap resampling distribution which gives equal weight to each of the original observations and this is the default. <code>q</code> must have length equal to the number of observations in the <code>boot.out\$data</code> and all elements of <code>q</code> must be positive.                                                                      |

## Details

The importance sampling weight for a bootstrap replicate with frequency vector  $\mathbf{f}$  is given by  $\text{prod}((q/p)^{\mathbf{f}})$ . This reweights the replicates so that estimates can be found as if the bootstrap resamples were generated according to the probabilities  $q$  even though, in fact, they came from the distribution  $p$ .

## Value

A vector of importance weights of the same length as `boot.out$t`. These weights can then be used to reweight `boot.out$t` so that estimates can be found as if the simulations were from a distribution with probabilities  $q$ .

## Note

See the example in the help for `imp.moments` for an example of using `imp.weights`.

---

`inv.logit`*Inverse Logit Function*

---

**Description**

Given a numeric object return the inverse logit of the values.

**Usage**

```
inv.logit(x)
```

**Arguments**

`x` A numeric object. Missing values (NAs) are allowed.

**Details**

The inverse logit is defined by  $\exp(x) / (1 + \exp(x))$ . Values in `x` of `-Inf` or `Inf` return logits of 0 or 1 respectively. Any NAs in the input will also be NAs in the output.

**Value**

An object of the same type as `x` containing the inverse logits of the input values.

**See Also**

[logit](#), [plogis](#) for which this is a wrapper.

---

`islay`*Jura Quartzite Azimuths on Islay*

---

**Description**

The `islay` data frame has 18 rows and 1 columns.

Measurements were taken of paleocurrent azimuths from the Jura Quartzite on the Scottish island of Islay.

**Usage**

```
islay
```

**Format**

This data frame contains the following column:

`theta` The angle of the azimuth in degrees East of North.

|-----------------|----------------------------------------|
| jack.after.boot | <i>Jackknife-after-Bootstrap Plots</i> |
|-----------------|----------------------------------------|

---

## Description

This function calculates the jackknife influence values from a bootstrap output object and plots the corresponding jackknife-after-bootstrap plot.

## Usage

```
jack.after.boot (boot.out, index = 1, t = NULL, L = NULL,
                useJ = TRUE, stinf = TRUE, alpha = NULL,
                main = "", ylab = NULL, ...)
```

## Arguments

|          |                                                                                                                                                                                                                                                                                                                                   |
|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| boot.out | An object of class "boot" which would normally be created by a call to <a href="#">boot</a> . It should represent a nonparametric bootstrap. For reliable results <code>boot.out\$R</code> should be reasonably large.                                                                                                            |
| index    | The index of the statistic of interest in the output of <code>boot.out\$statistic</code> .                                                                                                                                                                                                                                        |
| t        | A vector of length <code>boot.out\$R</code> giving the bootstrap replicates of the statistic of interest. This is useful if the statistic of interest is a function of the calculated bootstrap output. If it is not supplied then the default is <code>boot.out\$t[, index]</code> .                                             |
| L        | The empirical influence values for the statistic of interest. These are used only if <code>useJ</code> is <code>FALSE</code> . If they are not supplied and are needed, they are calculated by a call to <code>empinf</code> . If <code>L</code> is supplied then it is assumed that they are the infinitesimal jackknife values. |
| useJ     | A logical variable indicating if the jackknife influence values calculated from the bootstrap replicates should be used. If <code>FALSE</code> the empirical influence values are used. The default is <code>TRUE</code> .                                                                                                        |
| stinf    | A logical variable indicating whether to standardize the jackknife values before plotting them. If <code>TRUE</code> then the jackknife values used are divided by their standard error.                                                                                                                                          |
| alpha    | The quantiles at which the plots are required. The default is <code>c(0.05, 0.1, 0.16, 0.5, 0.84, 0.9, 0.95)</code> .                                                                                                                                                                                                             |
| main     | A character string giving the main title for the plot.                                                                                                                                                                                                                                                                            |

|                   |                                                                                                                                                                                                                                                                                          |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>ylab</code> | The label for the Y axis. If the default values of <code>alpha</code> are used and <code>ylab</code> is not supplied then a label indicating which percentiles are plotted is used. If <code>alpha</code> is supplied then the default label will not say which percentiles were used.   |
| <code>...</code>  | Any extra arguments required by <code>boot.out\$statistic</code> . These are required only if <code>useJ</code> is <code>FALSE</code> and <code>L</code> is not supplied, in which case they are passed to <code>empinf</code> for use in calculation of the empirical influence values. |

## Details

The centred jackknife quantiles for each observation are estimated from those bootstrap samples in which the particular observation did not appear. These are then plotted against the influence values. If `useJ` is `TRUE` then the influence values are found in the same way as the difference between the mean of the statistic in the samples excluding the observations and the mean in all samples. If `useJ` is `FALSE` then empirical influence values are calculated by calling `empinf`.

The resulting plots are useful diagnostic tools for looking at the way individual observations affect the bootstrap output.

The plot will consist of a number of horizontal dotted lines which correspond to the quantiles of the centred bootstrap distribution. For each data point the quantiles of the bootstrap distribution calculated by omitting that point are plotted against the (possibly standardized) jackknife values. The observation number is printed below the plots. To make it easier to see the effect of omitting points on quantiles, the plotted quantiles are joined by line segments. These plots provide a useful diagnostic tool in establishing the effect of individual observations on the bootstrap distribution. See the references below for some guidelines on the interpretation of the plots.

## Value

There is no returned value but a plot is generated on the current graphics display.

## Side Effects

A plot is created on the current graphics device.

## Examples

```
# To draw the jackknife-after-bootstrap plot for the head size data as in
# Example 3.24 of Davison and Hinkley (1997)
frets.fun <- function(data, i) {
  pcorr <- function(x) {
    # Function to find the correlations and partial correlations between
    # the four measurements.
    v <- cor(x)
```

```

v.d <- diag(var(x))
iv <- solve(v)
iv.d <- sqrt(diag(iv))
iv <- - diag(1/iv.d) %*% iv %*% diag(1/iv.d)
q <- NULL
n <- nrow(v)
for (i in 1:(n-1))
  q <- rbind( q, c(v[i, 1:i], iv[i, (i+1):n]) )
q <- rbind( q, v[n, ] )
diag(q) <- round(diag(q))
q
}
d <- data[i, ]
v <- pcorr(d)
c(v[1,], v[2,], v[3,], v[4,])
}
frets.boot <- boot(log(as.matrix(frets)), frets.fun, R = 999)
# we will concentrate on the partial correlation between head breadth
# for the first son and head length for the second. This is the 7th
# element in the output of frets.fun so we set index = 7
jack.after.boot(frets.boot, useJ = FALSE, stinf = FALSE, index = 7)

```

k3.linear

*Linear Skewness Estimate***Description**

Estimates the skewness of a statistic from its empirical influence values.

**Usage**

```
k3.linear(L, strata = NULL)
```

**Arguments**

|                     |                                                                                                                                  |
|---------------------|----------------------------------------------------------------------------------------------------------------------------------|
| <code>L</code>      | Vector of the empirical influence values of a statistic. These will usually be calculated by a call to <code>empinf</code> .     |
| <code>strata</code> | A numeric vector or factor specifying which observations (and hence which components of <code>L</code> ) come from which strata. |

**Value**

The skewness estimate calculated from `L`.

## Examples

```
# To estimate the skewness of the ratio of means for the city data.
ratio <- function(d, w) sum(d$x * w) / sum(d$u * w)
k3.linear(empinf(data = city, statistic = ratio))
```

linear.approx

*Linear Approximation of Bootstrap Replicates*

## Description

This function takes a bootstrap object and for each bootstrap replicate it calculates the linear approximation to the statistic of interest for that bootstrap sample.

## Usage

```
linear.approx(boot.out, L = NULL, index = 1, type = NULL,
              t0 = NULL, t = NULL, ...)
```

## Arguments

|                       |                                                                                                                                                                                                                                                                                                                                                                                          |
|-----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>boot.out</code> | An object of class "boot" representing a nonparametric bootstrap. It will usually be created by the function <code>boot</code> .                                                                                                                                                                                                                                                         |
| <code>L</code>        | A vector containing the empirical influence values for the statistic of interest. If it is not supplied then <code>L</code> is calculated through a call to <code>empinf</code> .                                                                                                                                                                                                        |
| <code>index</code>    | The index of the variable of interest within the output of <code>boot.out\$statistic</code> .                                                                                                                                                                                                                                                                                            |
| <code>type</code>     | This gives the type of empirical influence values to be calculated. It is not used if <code>L</code> is supplied. The possible types of empirical influence values are described in the help for <a href="#">empinf</a> .                                                                                                                                                                |
| <code>t0</code>       | The observed value of the statistic of interest. The input value is used only if one of <code>t</code> or <code>L</code> is also supplied. The default value is <code>boot.out\$t0[index]</code> . If <code>t0</code> is supplied but neither <code>t</code> nor <code>L</code> are supplied then <code>t0</code> is set to <code>boot.out\$t0[index]</code> and a warning is generated. |
| <code>t</code>        | A vector of bootstrap replicates of the statistic of interest. If <code>t0</code> is missing then <code>t</code> is not used, otherwise it is used to calculate the empirical influence values (if they are not supplied in <code>L</code> ).                                                                                                                                            |
| <code>...</code>      | Any extra arguments required by <code>boot.out\$statistic</code> . These are needed if <code>L</code> is not supplied as they are used by <code>empinf</code> to calculate empirical influence values.                                                                                                                                                                                   |

## Details

The linear approximation to a bootstrap replicate with frequency vector `f` is given by  $t_0 + \sum (L * f) / n$  in the one sample with an easy extension to the stratified case. The frequencies are found by calling `boot.array`.

## Value

A vector of length `boot.out$R` with the linear approximations to the statistic of interest for each of the bootstrap samples.

## References

## Examples

```
# Using the city data let us look at the linear approximation to the
# ratio statistic and its logarithm. We compare these with the
# corresponding plots for the bigcity data

ratio <- function(d, w) sum(d$x * w)/sum(d$u * w)
city.boot <- boot(city, ratio, R = 499, stype = "w")
bigcity.boot <- boot(bigcity, ratio, R = 499, stype = "w")
op <- par(pty = "s", mfrow = c(2, 2))

# The first plot is for the city data ratio statistic.
city.lin1 <- linear.approx(city.boot)
lim <- range(c(city.boot$t, city.lin1))
plot(city.boot$t, city.lin1, xlim = lim, ylim = lim,
      main = "Ratio; n=10", xlab = "t*", ylab = "tL*")
abline(0, 1)

# Now for the log of the ratio statistic for the city data.
city.lin2 <- linear.approx(city.boot, t0 = log(city.boot$t0),
                          t = log(city.boot$t))
lim <- range(c(log(city.boot$t), city.lin2))
plot(log(city.boot$t), city.lin2, xlim = lim, ylim = lim,
      main = "Log(Ratio); n=10", xlab = "t*", ylab = "tL*")
abline(0, 1)

# The ratio statistic for the bigcity data.
bigcity.lin1 <- linear.approx(bigcity.boot)
lim <- range(c(bigcity.boot$t, bigcity.lin1))
plot(bigcity.lin1, bigcity.boot$t, xlim = lim, ylim = lim,
      main = "Ratio; n=49", xlab = "t*", ylab = "tL*")
abline(0, 1)

# Finally the log of the ratio statistic for the bigcity data.
bigcity.lin2 <- linear.approx(bigcity.boot, t0 = log(bigcity.boot$t0),
                             t = log(bigcity.boot$t))
lim <- range(c(log(bigcity.boot$t), bigcity.lin2))
plot(bigcity.lin2, log(bigcity.boot$t), xlim = lim, ylim = lim,
      main = "Log(Ratio); n=49", xlab = "t*", ylab = "tL*")
abline(0, 1)

lines.saddle.distn *Add a Saddlepoint Approximation to a Plot*

---

## Description

This function adds a line corresponding to a saddlepoint density or distribution function approximation to the current plot.

## Usage

```
## S3 method for class 'saddle.distn'
lines(x, dens = TRUE, h = function(u) u, J = function(u) 1,
      npts = 50, lty = 1, ...)
```

## Arguments

|      |                                                                                                                                                                                                                                                                                                                 |
|------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x    | An object of class "saddle.distn" (see <a href="#">saddle.distn.object</a> representing a saddlepoint approximation to a distribution.                                                                                                                                                                          |
| dens | A logical variable indicating whether the saddlepoint density (TRUE; the default) or the saddlepoint distribution function (FALSE) should be plotted.                                                                                                                                                           |
| h    | Any transformation of the variable that is required. Its first argument must be the value at which the approximation is being performed and the function must be vectorized.                                                                                                                                    |
| J    | When dens=TRUE this function specifies the Jacobian for any transformation that may be necessary. The first argument of J must the value at which the approximation is being performed and the function must be vectorized. If h is supplied J must also be supplied and both must have the same argument list. |
| npts | The number of points to be used for the plot. These points will be evenly spaced over the range of points used in finding the saddlepoint approximation.                                                                                                                                                        |
| lty  | The line type to be used.                                                                                                                                                                                                                                                                                       |
| ...  | Any additional arguments to h and J.                                                                                                                                                                                                                                                                            |

## Details

The function uses `smooth.spline` to produce the saddlepoint curve. When `dens=TRUE` the spline is on the log scale and when `dens=FALSE` it is on the probit scale.

## Value

`sad.d` is returned invisibly.

## Side Effects

A line is added to the current plot.

**Examples**

```
# In this example we show how a plot such as that in Figure 9.9 of
# Davison and Hinkley (1997) may be produced. Note the large number of
# bootstrap replicates required in this example.
expdata <- rexp(12)
vfun <- function(d, i) {
  n <- length(d)
  (n-1)/n*var(d[i])
}
exp.boot <- boot(expdata,vfun, R = 9999)
exp.L <- (expdata - mean(expdata))^2 - exp.boot$t0
exp.tL <- linear.approx(exp.boot, L = exp.L)
hist(exp.tL, nclass = 50, probability = TRUE)
exp.t0 <- c(0, sqrt(var(exp.boot$t)))
exp.sp <- saddle.distn(A = exp.L/12,wdist = "m", t0 = exp.t0)

# The saddlepoint approximation in this case is to the density of
# t-t0 and so t0 must be added for the plot.
lines(exp.sp, h = function(u, t0) u+t0, J = function(u, t0) 1,
      t0 = exp.boot$t0)
```

---

logit

*Logit of Proportions*

---

**Description**

This function calculates the logit of proportions.

**Usage**

```
logit(p)
```

**Arguments**

**p** A numeric Splus object, all of whose values are in the range [0,1]. Missing values (NAs) are allowed.

**Details**

If any elements of **p** are outside the unit interval then an error message is generated. Values of **p** equal to 0 or 1 (to within machine precision) will return `-Inf` or `Inf` respectively. Any NAs in the input will also be NAs in the output.

**Value**

A numeric object of the same type as **p** containing the logits of the input values.

**See Also**

[inv.logit](#), [qlogis](#) for which this is a wrapper.

manaus

*Average Heights of the Rio Negro river at Manaus*

## Description

The manaus time series is of class "ts" and has 1080 observations on one variable.

The data values are monthly averages of the daily stages (heights) of the Rio Negro at Manaus. Manaus is 18km upstream from the confluence of the Rio Negro with the Amazon but because of the tiny slope of the water surface and the lower courses of its flatland affluents, they may be regarded as a good approximation of the water level in the Amazon at the confluence. The data here cover 90 years from January 1903 until December 1992.

The Manaus gauge is tied in with an arbitrary bench mark of 100m set in the steps of the Municipal Prefecture; gauge readings are usually referred to sea level, on the basis of a mark on the steps leading to the Parish Church (Matriz), which is assumed to lie at an altitude of 35.874 m according to observations made many years ago under the direction of Samuel Pereira, an engineer in charge of the Manaus Sanitation Committee Whereas such an altitude cannot, by any means, be considered to be a precise datum point, observations have been provisionally referred to it. The measurements are in metres.

## Source

The data were kindly made available by Professors H. O'Reilly Sternberg and D. R. Brillinger of the University of California at Berkeley.

melanoma

*Survival from Malignant Melanoma*

## Description

The melanoma data frame has 205 rows and 7 columns.

The data consist of measurements made on patients with malignant melanoma. Each patient had their tumour removed by surgery at the Department of Plastic Surgery, University Hospital of Odense, Denmark during the period 1962 to 1977. The surgery consisted of complete removal of the tumour together with about 2.5cm of the surrounding skin. Among the measurements taken were the thickness of the tumour and whether it was ulcerated or not. These are thought to be important prognostic variables in that patients with a thick and/or ulcerated tumour have an increased chance of death from melanoma. Patients were followed until the end of 1977.

**Usage**

```
melanoma
```

**Format**

This data frame contains the following columns:

`time` Survival time in days since the operation, possibly censored.

`status` The patients status at the end of the study. 1 indicates that they had died from melanoma, 2 indicates that they were still alive and 3 indicates that they had died from causes unrelated to their melanoma.

`sex` The patients sex; 1=male, 0=female.

`age` Age in years at the time of the operation.

`year` Year of operation.

`thickness` Tumour thickness in mm.

`ulcer` Indicator of ulceration; 1=present, 0=absent.

**Note**

This dataset is not related to the dataset in the **lattice** package with the same name.

**Source**

The data were obtained from

---

```
motor
```

*Data from a Simulated Motorcycle Accident*

---

**Description**

The `motor` data frame has 94 rows and 4 columns. The rows are obtained by removing replicate values of `time` from the dataset `mcycle`. Two extra columns are added to allow for strata with a different residual variance in each stratum.

**Usage**

```
motor
```

**Format**

This data frame contains the following columns:

`times` The time in milliseconds since impact.

`accel` The recorded head acceleration (in g).

`strata` A numeric column indicating to which of the three strata (numbered 1, 2 and 3) the observations belong.

`v` An estimate of the residual variance for the observation. `v` is constant within the strata but a different estimate is used for each of the three strata.

**Source**

---

neuro

*Neurophysiological Point Process Data*

---

**Description**

`neuro` is a matrix containing times of observed firing of a neuron in windows of 250ms either side of the application of a stimulus to a human subject. Each row of the matrix is a replication of the experiment and there were a total of 469 replicates.

**Note**

There are a lot of missing values in the matrix as different numbers of firings were observed in different replicates. The number of firings observed varied from 2 to 6.

**Source**

The data were collected and kindly made available by Dr. S.J. Boniface of the Neurophysiology Unit at the Radcliffe Infirmary, Oxford.

---

nitrofen*Toxicity of Nitrofen in Aquatic Systems*

---

### Description

The `nitrofen` data frame has 50 rows and 5 columns.

Nitrofen is a herbicide that was used extensively for the control of broad-leaved and grass weeds in cereals and rice. Although it is relatively non-toxic to adult mammals, nitrofen is a significant tetragen and mutagen. It is also acutely toxic and reproductively toxic to cladoceran zooplankton. Nitrofen is no longer in commercial use in the U.S., having been the first pesticide to be withdrawn due to tetragenic effects.

The data here come from an experiment to measure the reproductive toxicity of nitrofen on a species of zooplankton (*Ceriodaphnia dubia*). 50 animals were randomized into batches of 10 and each batch was put in a solution with a measured concentration of nitrofen. Then the number of live offspring in each of the three broods to each animal was recorded.

### Usage

```
nitrofen
```

### Format

This data frame contains the following columns:

`conc` The nitrofen concentration in the solution (mug/litre).

`brood1` The number of live offspring in the first brood.

`brood2` The number of live offspring in the second brood.

`brood3` The number of live offspring in the third brood.

`total` The total number of live offspring in the first three broods.

### Source

The data were obtained from

Bailer, A.J. and Oris, J.T. (1994) Assessing toxicity of pollutants in aquatic systems. In *Case Studies in Biometry*. N. Lange, L. Ryan, L. Billard, D. Brillinger, L. Conquest and J. Greenhouse (editors), 25–40. John Wiley.

### References

nodal

*Nodal Involvement in Prostate Cancer***Description**

The `nodal` data frame has 53 rows and 7 columns.

The treatment strategy for a patient diagnosed with cancer of the prostate depend highly on whether the cancer has spread to the surrounding lymph nodes. It is common to operate on the patient to get samples from the nodes which can then be analysed under a microscope but clearly it would be preferable if an accurate assessment of nodal involvement could be made without surgery.

For a sample of 53 prostate cancer patients, a number of possible predictor variables were measured before surgery. The patients then had surgery to determine nodal involvement. It was required to see if nodal involvement could be accurately predicted from the predictor variables and which ones were most important.

**Usage**

```
nodal
```

**Format**

This data frame contains the following columns:

`m` A column of ones.

`r` An indicator of nodal involvement.

`aged` The patients age dichotomized into less than 60 (0) and 60 or over 1.

`stage` A measurement of the size and position of the tumour observed by palpitation with the fingers via the rectum. A value of 1 indicates a more serious case of the cancer.

`grade` Another indicator of the seriousness of the cancer, this one is determined by a pathology reading of a biopsy taken by needle before surgery. A value of 1 indicates a more serious case of the cancer.

`xray` A third measure of the seriousness of the cancer taken from an X-ray reading. A value of 1 indicates a more serious case of the cancer.

`acid` The level of acid phosphatase in the blood serum.

**Source**

The data were obtained from

Brown, B.W. (1980) Prediction analysis for binary data. In *Biostatistics Casebook*. R.G. Miller, B. Efron, B.W. Brown and L.E. Moses (editors), 3–18. John Wiley.

norm.ci

*Normal Approximation Confidence Intervals***Description**

Using the normal approximation to a statistic, calculate equi-tailed two-sided confidence intervals.

**Usage**

```
norm.ci(boot.out = NULL, conf = 0.95, index = 1, var.t0 = NULL,
        t0 = NULL, t = NULL, L = NULL, h = function(t) t,
        hdot = function(t) 1, hinv = function(t) t)
```

**Arguments**

|                       |                                                                                                                                                                                                                                                                                                                                                                |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>boot.out</code> | A bootstrap output object returned from a call to <code>boot</code> . If <code>t0</code> is missing then <code>boot.out</code> is a required argument. It is also required if both <code>var.t0</code> and <code>t</code> are missing.                                                                                                                         |
| <code>conf</code>     | A scalar or vector containing the confidence level(s) of the required interval(s).                                                                                                                                                                                                                                                                             |
| <code>index</code>    | The index of the statistic of interest within the output of a call to <code>boot.out\$statistic</code> . It is not used if <code>boot.out</code> is missing, in which case <code>t0</code> must be supplied.                                                                                                                                                   |
| <code>var.t0</code>   | The variance of the statistic of interest. If it is not supplied then <code>var(t)</code> is used.                                                                                                                                                                                                                                                             |
| <code>t0</code>       | The observed value of the statistic of interest. If it is missing then it is taken from <code>boot.out</code> which is required in that case.                                                                                                                                                                                                                  |
| <code>t</code>        | Bootstrap replicates of the variable of interest. These are used to estimate the variance of the statistic of interest if <code>var.t0</code> is not supplied. The default value is <code>boot.out\$t[, index]</code> .                                                                                                                                        |
| <code>L</code>        | The empirical influence values for the statistic of interest. These are used to calculate <code>var.t0</code> if neither <code>var.t0</code> nor <code>boot.out</code> are supplied. If a transformation is supplied through <code>h</code> then the influence values must be for the untransformed statistic <code>t0</code> .                                |
| <code>h</code>        | A function defining a monotonic transformation, the intervals are calculated on the scale of <code>h(t)</code> and the inverse function <code>hinv</code> is applied to the resulting intervals. <code>h</code> must be a function of one variable only and must be vectorized. The default is the identity function.                                          |
| <code>hdot</code>     | A function of one argument returning the derivative of <code>h</code> . It is a required argument if <code>h</code> is supplied and is used for approximating the variance of <code>h(t0)</code> . The default is the constant function 1.                                                                                                                     |
| <code>hinv</code>     | A function, like <code>h</code> , which returns the inverse of <code>h</code> . It is used to transform the intervals calculated on the scale of <code>h(t)</code> back to the original scale. The default is the identity function. If <code>h</code> is supplied but <code>hinv</code> is not, then the intervals returned will be on the transformed scale. |

## Details

It is assumed that the statistic of interest has an approximately normal distribution with variance `var.t0` and so a confidence interval of length  $2 \cdot \text{qnorm}((1+\text{conf})/2) \cdot \sqrt{\text{var.t0}}$  is found. If `boot.out` or `t` are supplied then the interval is bias-corrected using the bootstrap bias estimate, and so the interval would be centred at  $2 \cdot t_0 - \text{mean}(t)$ . Otherwise the interval is centred at `t0`.

## Value

If `length(conf)` is 1 then a vector containing the confidence level and the endpoints of the interval is returned. Otherwise, the returned value is a matrix where each row corresponds to a different confidence level.

## Note

This function is primarily designed to be called by `boot.ci` to calculate the normal approximation after a bootstrap but it can also be used without doing any bootstrap calculations as long as `t0` and `var.t0` can be supplied. See the examples below.

## Examples

```
# In Example 5.1 of Davison and Hinkley (1997), normal approximation
# confidence intervals are found for the air-conditioning data.
air.mean <- mean(aircondit$hours)
air.n <- nrow(aircondit)
air.v <- air.mean^2/air.n
norm.ci(t0 = air.mean, var.t0 = air.v)
exp(norm.ci(t0 = log(air.mean), var.t0 = 1/air.n)[2:3])

# Now a more complicated example - the ratio estimate for the city data.
ratio <- function(d, w)
  sum(d$x * w)/sum(d$u * w)
city.v <- var.linear(empinf(data = city, statistic = ratio))
norm.ci(t0 = ratio(city, rep(0.1,10)), var.t0 = city.v)
```

## Description

The `nuclear` data frame has 32 rows and 11 columns.

The data relate to the construction of 32 light water reactor (LWR) plants constructed in the U.S.A in the late 1960's and early 1970's. The data was collected with the aim of predicting the cost of construction of further LWR plants. 6 of the power plants had partial turnkey guarantees and it is possible that, for these plants, some manufacturers' subsidies may be hidden in the quoted capital costs.

## Usage

```
nuclear
```

## Format

This data frame contains the following columns:

`cost` The capital cost of construction in millions of dollars adjusted to 1976 base.

`date` The date on which the construction permit was issued. The data are measured in years since January 1 1990 to the nearest month.

`t1` The time between application for and issue of the construction permit.

`t2` The time between issue of operating license and construction permit.

`cap` The net capacity of the power plant (MWe).

`pr` A binary variable where 1 indicates the prior existence of a LWR plant at the same site.

`ne` A binary variable where 1 indicates that the plant was constructed in the north-east region of the U.S.A.

`ct` A binary variable where 1 indicates the use of a cooling tower in the plant.

`bw` A binary variable where 1 indicates that the nuclear steam supply system was manufactured by Babcock-Wilcox.

`cum.n` The cumulative number of power plants constructed by each architect-engineer.

`pt` A binary variable where 1 indicates those plants with partial turnkey guarantees.

paulsen

*Neurotransmission in Guinea Pig Brains***Description**

The paulsen data frame has 346 rows and 1 columns.

Sections were prepared from the brain of adult guinea pigs. Spontaneous currents that flowed into individual brain cells were then recorded and the peak amplitude of each current measured. The aim of the experiment was to see if the current flow was quantal in nature (i.e. that it is not a single burst but instead is built up of many smaller bursts of current). If the current was indeed quantal then it would be expected that the distribution of the current amplitude would be multimodal with modes at regular intervals. The modes would be expected to decrease in magnitude for higher current amplitudes.

**Usage**

```
paulsen
```

**Format**

This data frame contains the following column:

y The current flowing into individual brain cells. The currents are measured in pico-amperes.

**Source**

The data were kindly made available by Dr. O. Paulsen from the Department of Pharmacology at the University of Oxford.

Paulsen, O. and Heggelund, P. (1994) The quantal size at retinogeniculate synapses determined from spontaneous and evoked EPSCs in guinea-pig thalamic slices. *Journal of Physiology*, **480**, 505–511.

**References**

plot.boot

*Plots of the Output of a Bootstrap Simulation***Description**

This takes a bootstrap object and produces plots for the bootstrap replicates of the variable of interest.

**Usage**

```
## S3 method for class 'boot'
plot(x, index = 1, t0 = NULL, t = NULL, jack = FALSE,
     qdist = "norm", nclass = NULL, df, ...)
```

**Arguments**

|                     |                                                                                                                                                                                                                                                         |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>      | An object of class "boot" returned from one of the bootstrap generation functions.                                                                                                                                                                      |
| <code>index</code>  | The index of the variable of interest within the output of <code>boot.out</code> . This is ignored if <code>t</code> and <code>t0</code> are supplied.                                                                                                  |
| <code>t0</code>     | The original value of the statistic. This defaults to <code>boot.out\$t0[index]</code> unless <code>t</code> is supplied when it defaults to <code>NULL</code> . In that case no vertical line is drawn on the histogram.                               |
| <code>t</code>      | The bootstrap replicates of the statistic. Usually this will take on its default value of <code>boot.out\$t[, index]</code> , however it may be useful sometimes to supply a different set of values which are a function of <code>boot.out\$t</code> . |
| <code>jack</code>   | A logical value indicating whether a jackknife-after-bootstrap plot is required. The default is not to produce such a plot.                                                                                                                             |
| <code>qdist</code>  | The distribution against which the Q-Q plot should be drawn. At present "norm" (normal distribution - the default) and "chisq" (chi-squared distribution) are the only possible values.                                                                 |
| <code>nclass</code> | An integer giving the number of classes to be used in the bootstrap histogram. The default is the integer between 10 and 100 closest to <code>ceiling(length(t)/25)</code> .                                                                            |
| <code>df</code>     | If <code>qdist</code> is "chisq" then this is the degrees of freedom for the chi-squared distribution to be used. It is a required argument in that case.                                                                                               |
| <code>...</code>    | When <code>jack</code> is TRUE additional parameters to <code>jack.after.boot</code> can be supplied. See the help file for <code>jack.after.boot</code> for details of the possible parameters.                                                        |

**Details**

This function will generally produce two side-by-side plots. The left plot will be a histogram of the bootstrap replicates. Usually the breaks of the histogram will be chosen so that `t0` is at a breakpoint and all intervals are of equal length. A vertical dotted line indicates the position of `t0`. This cannot be done if `t` is supplied but `t0` is not and so, in that case, the breakpoints are computed by `hist` using the `nclass` argument and no vertical line is drawn.

The second plot is a Q-Q plot of the bootstrap replicates. The order statistics of the replicates can be plotted against normal or chi-squared quantiles. In either case the expected line is also plotted. For the normal, this will have intercept `mean(t)` and slope `sqrt(var(t))` while for the chi-squared it has intercept 0 and slope 1.

If `jack` is TRUE a third plot is produced beneath these two. That plot is the jackknife-after-bootstrap plot. This plot may only be requested when nonparametric simulation has been used. See `jack.after.boot` for further details of this plot.

**Value**

`boot.out` is returned invisibly.

**Side Effects**

All screens are closed and cleared and a number of plots are produced on the current graphics device. Screens are closed but not cleared at termination of this function.

    q <- NULL
    n <- nrow(v)
    for (i in 1:(n-1))
      q <- rbind( q, c(v[i, 1:i], iv[i, (i+1):n]) )
    q <- rbind( q, v[n, ] )
    diag(q) <- round(diag(q))
    q
  }
  d <- data[i, ]
  v <- pcorr(d)
  c(v[1,], v[2,], v[3,], v[4,])
}
```

```

}
frets.boot <- boot(log(as.matrix(frets)), frets.fun, R = 999)
plot(frets.boot, index = 7, jack = TRUE, stinf = FALSE, useJ = FALSE)

```

---

poisons

*Animal Survival Times*

---

### Description

The `poisons` data frame has 48 rows and 3 columns.

The data form a 3x4 factorial experiment, the factors being three poisons and four treatments. Each combination of the two factors was used for four animals, the allocation to animals having been completely randomized.

### Usage

```
poisons
```

### Format

This data frame contains the following columns:

`time` The survival time of the animal in units of 10 hours.

`poison` A factor with levels 1, 2 and 3 giving the type of poison used.

`treat` A factor with levels A, B, C and D giving the treatment.

### Source

The data were obtained from

Box, G.E.P. and Cox, D.R. (1964) An analysis of transformations (with Discussion). *Journal of the Royal Statistical Society, B*, **26**, 211–252.

### References

---

polar

*Pole Positions of New Caledonian Laterites*

---

### Description

The `polar` data frame has 50 rows and 2 columns.

The data are the pole positions from a paleomagnetic study of New Caledonian laterites.

### Usage

```
polar
```

**Format**

This data frame contains the following columns:

- lat The latitude (in degrees) of the pole position. Note that all latitudes are negative as the axis is taken to be in the lower hemisphere.
- long The longitude (in degrees) of the pole position.

**Source**

The data were obtained from

Fisher, N.I., Lewis, T. and Embleton, B.J.J. (1987) *Statistical Analysis of Spherical Data*. Cambridge University Press.

|------------|---------------------------------------|
| print.boot | Print a Summary of a Bootstrap Object |
|------------|---------------------------------------|

---

**Description**

This is a method for the function `print()` for objects of the class "boot" created by a call to `boot`, `censboot`, `tilt.boot` or `tsboot`.

**Usage**

```
## S3 method for class 'boot'
print(x, digits = getOption("digits"),
      index = 1:ncol(boot.out$t), ...)
```

**Arguments**

- x A bootstrap output object of class "boot" generated by one of the bootstrap functions.
- digits The number of digits to be printed in the summary statistics.
- index Indices indicating for which elements of the bootstrap output summary statistics are required.
- ... further arguments passed to or from other methods.

**Details**

For each statistic calculated in the bootstrap the original value and the bootstrap estimates of its bias and standard error are printed. If `boot.out$t0` is missing (such as when it was created by a call to `tsboot` with `orig.t = FALSE`) the bootstrap mean and standard error are printed. If resampling was done using importance resampling weights, then the bootstrap estimates are reweighted as if uniform resampling had been done. The ratio importance sampling estimates are used and if there were a number of distributions then defensive mixture distributions are used. In this case an extra column with the mean of the observed bootstrap statistics is also printed.

**Value**

The bootstrap object is returned invisibly.

**See Also**

`boot`, `censboot`, `imp.moments`, `plot.boot`, `tilt.boot`, `tsboot`

---

`print.bootci`

*Print Bootstrap Confidence Intervals*

---

**Description**

This is a method for the function `print()` to print objects of the class "bootci".

**Usage**

```
## S3 method for class 'bootci'
print(x, hinv = NULL, ...)
```

**Arguments**

|                   |                                                                                 |
|-------------------|---------------------------------------------------------------------------------|
| <code>x</code>    | The output from a call to <code>boot.ci</code> .                                |
| <code>hinv</code> | A transformation to be made to the interval end-points before they are printed. |
| <code>...</code>  | further arguments passed to or from other methods.                              |

**Details**

This function prints out the results from `boot.ci` in a "nice" format. It also notes whether the scale of the intervals is the original scale of the input to `boot.ci` or a different scale and whether the calculations were done on a transformed scale. It also looks at the order statistics that were used in calculating the intervals. If the smallest or largest values were used then it prints a message

```
Warning : Intervals used Extreme Quantiles
```

Such intervals should be considered very unstable and not relied upon for inferences. Even if the extreme values are not used, it is possible that the intervals are unstable if they used quantiles close to the extreme values. The function alerts the user to intervals which use the upper or lower 10 order statistics with the message

```
Some intervals may be unstable
```

**Value**

The object `ci.out` is returned invisibly.

**See Also**

`boot.ci`

---

```

```

*Print Quantiles of Saddlepoint Approximations*

---

### Description

This is a method for the function `print()` to print objects of class `"saddle.distn"`.

### Usage

```
## S3 method for class 'saddle.distn'  
print(x, ...)
```

### Arguments

|                  |                                                                                                 |
|------------------|-------------------------------------------------------------------------------------------------|
| <code>x</code>   | An object of class <code>"saddle.distn"</code> created by a call to <code>saddle.distn</code> . |
| <code>...</code> | further arguments passed to or from other methods.                                              |

### Details

The quantiles of the saddlepoint approximation to the distribution are printed along with the original call and some other useful information.

### Value

The input is returned invisibly.

### See Also

`lines.saddle.distn`, `saddle.distn`

---

```
print.simplex
```

*Print Solution to Linear Programming Problem*

---

### Description

This is a method for the function `print()` to print objects of class `"simplex"`.

### Usage

```
## S3 method for class 'simplex'  
print(x, ...)
```

### Arguments

|                  |                                                                                                                                       |
|------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>   | An object of class <code>"simplex"</code> created by calling the function <code>simplex</code> to solve a linear programming problem. |
| <code>...</code> | further arguments passed to or from other methods.                                                                                    |

**Details**

The coefficients of the objective function are printed. If a solution to the linear programming problem was found then the solution and the optimal value of the objective function are printed. If a feasible solution was found but the maximum number of iterations was exceeded then the last feasible solution and the objective function value at that point are printed. If no feasible solution could be found then a message stating that is printed.

**Value**

`x` is returned silently.

**See Also**

[simplex](#)

| remission | <i>Cancer Remission and Cell Activity</i> |
|-----------|-------------------------------------------|

---

**Description**

The `remission` data frame has 27 rows and 3 columns.

**Usage**

```
remission
```

**Format**

This data frame contains the following columns:

- `LI` A measure of cell activity.
- `m` The number of patients in each group (all values are actually 1 here).
- `r` The number of patients (out of `m`) who went into remission.

**Source**

The data were obtained from  
Freeman, D.H. (1987) *Applied Categorical Data Analysis*. Marcel Dekker.

**References**

Davison, A.C. and Hinkley, D.V. (1997) *Bootstrap Methods and Their Application*. Cambridge University Press.

**Description**

This function calculates a saddlepoint approximation to the distribution of a linear combination of  $\mathbf{W}$  at a particular point  $u$ , where  $\mathbf{W}$  is a vector of random variables. The distribution of  $\mathbf{W}$  may be multinomial (default), Poisson or binary. Other distributions are possible also if the adjusted cumulant generating function and its second derivative are given. Conditional saddlepoint approximations to the distribution of one linear combination given the values of other linear combinations of  $\mathbf{W}$  can be calculated for  $\mathbf{W}$  having binary or Poisson distributions.

**Usage**

```
saddle(A = NULL, u = NULL, wdist = "m", type = "simp", d = NULL,
       d1 = 1, init = rep(0.1, d), mu = rep(0.5, n), LR = FALSE,
       strata = NULL, K.adj = NULL, K2 = NULL)
```

**Arguments**

|                     |                                                                                                                                                                                                                                                                                                                                                                                                                            |
|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>A</code>      | A vector or matrix of known coefficients of the linear combinations of $\mathbf{W}$ . It is a required argument unless <code>K.adj</code> and <code>K2</code> are supplied, in which case it is ignored.                                                                                                                                                                                                                   |
| <code>u</code>      | The value at which it is desired to calculate the saddlepoint approximation to the distribution of the linear combination of $\mathbf{W}$ . It is a required argument unless <code>K.adj</code> and <code>K2</code> are supplied, in which case it is ignored.                                                                                                                                                             |
| <code>wdist</code>  | The distribution of $\mathbf{W}$ . This can be one of "m" (multinomial), "p" (Poisson), "b" (binary) or "o" (other). If <code>K.adj</code> and <code>K2</code> are given <code>wdist</code> is set to "o".                                                                                                                                                                                                                 |
| <code>type</code>   | The type of saddlepoint approximation. Possible types are "simp" for simple saddlepoint and "cond" for the conditional saddlepoint. When <code>wdist</code> is "o" or "m", <code>type</code> is automatically set to "simp", which is the only type of saddlepoint currently implemented for those distributions.                                                                                                          |
| <code>d</code>      | This specifies the dimension of the whole statistic. This argument is required only when <code>wdist</code> = "o" and defaults to 1 if not supplied in that case. For other distributions it is set to <code>ncol(A)</code> .                                                                                                                                                                                              |
| <code>d1</code>     | When <code>type</code> is "cond" this is the dimension of the statistic of interest which must be less than <code>length(u)</code> . Then the saddlepoint approximation to the conditional distribution of the first <code>d1</code> linear combinations given the values of the remaining combinations is found. Conditional distribution function approximations can only be found if the value of <code>d1</code> is 1. |
| <code>init</code>   | Used if <code>wdist</code> is either "m" or "o", this gives initial values to <code>nlmin</code> which is used to solve the saddlepoint equation.                                                                                                                                                                                                                                                                          |
| <code>mu</code>     | The values of the parameters of the distribution of $\mathbf{W}$ when <code>wdist</code> is "m", "p" or "b". <code>mu</code> must be of the same length as $\mathbf{W}$ (i.e. <code>nrow(A)</code> ). The default is that all values of <code>mu</code> are equal and so the elements of $\mathbf{W}$ are identically distributed.                                                                                         |
| <code>LR</code>     | If TRUE then the Lugananni-Rice approximation to the cdf is used, otherwise the approximation used is based on Barndorff-Nielsen's $r^*$ .                                                                                                                                                                                                                                                                                 |
| <code>strata</code> | The strata for stratified data.                                                                                                                                                                                                                                                                                                                                                                                            |

|                    |                                                                                                                                                                                                                                                                                                                                                                                                           |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>K.adj</code> | The adjusted cumulant generating function used when <code>wdist</code> is "o". This is a function of a single parameter, <code>zeta</code> , which calculates $K(zeta) - u * zeta$ , where $K(zeta)$ is the cumulant generating function of $W$ .                                                                                                                                                         |
| <code>K2</code>    | This is a function of a single parameter <code>zeta</code> which returns the matrix of second derivatives of $K(zeta)$ for use when <code>wdist</code> is "o". If <code>K.adj</code> is given then this must be given also. It is called only once with the calculated solution to the saddlepoint equation being passed as the argument. This argument is ignored if <code>K.adj</code> is not supplied. |

### Details

If `wdist` is "o" or "m", the saddlepoint equations are solved using `nlmin` to minimize `K.adj` with respect to its parameter `zeta`. For the Poisson and binary cases, a generalized linear model is fitted such that the parameter estimates solve the saddlepoint equations. The response variable 'y' for the `glm` must satisfy the equation  $t(A) \%*\%y = u(t())$  being the transpose function). Such a vector can be found as a feasible solution to a linear programming problem. This is done by a call to `simplex`. The covariate matrix for the `glm` is given by `A`.

### Value

A list consisting of the following components

|                        |                                                                                                                                                                                |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>spa</code>       | The saddlepoint approximations. The first value is the density approximation and the second value is the distribution function approximation.                                  |
| <code>zeta.hat</code>  | The solution to the saddlepoint equation. For the conditional saddlepoint this is the solution to the saddlepoint equation for the numerator.                                  |
| <code>zeta2.hat</code> | If <code>type</code> is "cond" this is the solution to the saddlepoint equation for the denominator. This component is not returned for any other value of <code>type</code> . |

### Examples

```
# To evaluate the bootstrap distribution of the mean failure time of
# air-conditioning equipment at 80 hours
saddle(A = aircondit$hours/12, u = 80)

# Alternatively this can be done using a conditional poisson
saddle(A = cbind(aircondit$hours/12,1), u = c(80, 12),
```

```

wdist = "p", type = "cond")

# To use the Lugananni-Rice approximation to this
saddle(A = cbind(aircondit$hours/12,1), u = c(80, 12),
       wdist = "p", type = "cond",
       LR = TRUE)

# Example 9.16 of Davison and Hinkley (1997) calculates saddlepoint
# approximations to the distribution of the ratio statistic for the
# city data. Since the statistic is not in itself a linear combination
# of random Variables, its distribution cannot be found directly.
# Instead the statistic is expressed as the solution to a linear
# estimating equation and hence its distribution can be found. We
# get the saddlepoint approximation to the pdf and cdf evaluated at
# t = 1.25 as follows.
jacobian <- function(dat,t,zeta)
{
  p <- exp(zeta*(dat$x-t*dat$u))
  abs(sum(dat$u*p)/sum(p))
}
city.sp1 <- saddle(A = city$x-1.25*city$u, u = 0)
city.sp1$spa[1] <- jacobian(city, 1.25, city.sp1$zeta.hat) * city.sp1$spa[1]
city.sp1

saddle.distn

*Saddlepoint Distribution Approximations for Bootstrap Statistics*

## Description

Approximate an entire distribution using saddlepoint methods. This function can calculate simple and conditional saddlepoint distribution approximations for a univariate quantity of interest. For the simple saddlepoint the quantity of interest is a linear combination of  $\mathbf{W}$  where  $\mathbf{W}$  is a vector of random variables. For the conditional saddlepoint we require the distribution of one linear combination given the values of any number of other linear combinations. The distribution of  $\mathbf{W}$  must be one of multinomial, Poisson or binary. The primary use of this function is to calculate quantiles of bootstrap distributions using saddlepoint approximations. Such quantiles are required by the function `control` to approximate the distribution of the linear approximation to a statistic.

## Usage

```

saddle.distn(A, u = NULL, alpha = NULL, wdist = "m",
             type = "simp", npts = 20, t = NULL, t0 = NULL,
             init = rep(0.1, d), mu = rep(0.5, n), LR = FALSE,
             strata = NULL, ...)

```

## Arguments

**A** This is a matrix of known coefficients or a function which returns such a matrix. If a function then its first argument must be the point  $t$  at which a saddlepoint is required. The most common reason for  $A$  being a function would be if the statistic is not itself a linear combination of the  $\mathbf{W}$  but is the solution to a linear estimating equation.

|                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>u</code>      | If <code>A</code> is a function then <code>u</code> must also be a function returning a vector with length equal to the number of columns of the matrix returned by <code>A</code> . Usually all components other than the first will be constants as the other components are the values of the conditioning variables. If <code>A</code> is a matrix with more than one column (such as when <code>wdist = "cond"</code> ) then <code>u</code> should be a vector with length one less than <code>ncol(A)</code> . In this case <code>u</code> specifies the values of the conditioning variables. If <code>A</code> is a matrix with one column or a vector then <code>u</code> is not used.                                 |
| <code>alpha</code>  | The alpha levels for the quantiles of the distribution which should be returned. By default the 0.1, 0.5, 1, 2.5, 5, 10, 20, 50, 80, 90, 95, 97.5, 99, 99.5 and 99.9 percentiles are calculated.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>wdist</code>  | The distribution of <b>W</b> . Possible values are "m" (multinomial), "p" (Poisson), or "b" (binary).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>type</code>   | The type of saddlepoint to be used. Possible values are "simp" (simple saddlepoint) and "cond" (conditional). If <code>wdist</code> is "m", <code>type</code> is set to "simp".                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <code>npts</code>   | The number of points at which the saddlepoint approximation should be calculated and then used to fit the spline.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>t</code>      | A vector of points at which the saddlepoint approximations are calculated. These points should extend beyond the extreme quantiles required but still be in the possible range of the bootstrap distribution. The observed value of the statistic should not be included in <code>t</code> as the distribution function approximation breaks down at that point. The points should, however cover the entire effective range of the distribution including close to the centre. If <code>t</code> is supplied then <code>npts</code> is set to <code>length(t)</code> . When <code>t</code> is not supplied, the function attempts to find the effective range of the distribution and then selects points to cover this range. |
| <code>t0</code>     | If <code>t</code> is not supplied then a vector of length 2 should be passed as <code>t0</code> . The first component of <code>t0</code> should be the centre of the distribution and the second should be an estimate of spread (such as a standard error). These two are then used to find the effective range of the distribution. The range finding mechanism does rely on an accurate estimate of location in <code>t0[1]</code> .                                                                                                                                                                                                                                                                                         |
| <code>init</code>   | When <code>wdist</code> is "m", this vector should contain the initial values to be passed to <code>nlmin</code> when it is called to solve the saddlepoint equations.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <code>mu</code>     | The vector of parameter values for the distribution. The default is that the components of <b>W</b> are identically distributed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>LR</code>     | A logical flag. When <code>LR</code> is <code>TRUE</code> the Lugananni-Rice cdf approximations are calculated and used to fit the spline. Otherwise the cdf approximations used are based on Barndorff-Nielsen's $r^*$ .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <code>strata</code> | A vector giving the strata when the rows of <code>A</code> relate to stratified data. This is used only when <code>wdist</code> is "m".                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>...</code>    | When <code>A</code> and <code>u</code> are functions any additional arguments are passed unchanged each time one of them is called.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

## Details

The range at which the saddlepoint is used is such that the cdf approximation at the endpoints is more extreme than required by the extreme values of `alpha`. The lower endpoint is found by evaluating the saddlepoint at the points `t0[1]-2*t0[2]`, `t0[1]-4*t0[2]`, `t0[1]-8*t0[2]` etc. until a point is found with a cdf approximation less than `min(alpha)/10`, then a bisection method is used to find the endpoint which has cdf approximation in the range `(min(alpha)/1000, min(alpha)/10)`. Then a number of, equally spaced, points are chosen

between the lower endpoint and `t0[1]` until a total of `npts/2` approximations have been made. The remaining `npts/2` points are chosen to the right of `t0[1]` in a similar manner. Any points which are very close to the centre of the distribution are then omitted as the cdf approximations are not reliable at the centre. A smoothing spline is then fitted to the probit of the saddlepoint distribution function approximations at the remaining points and the required quantiles are predicted from the spline.

Sometimes the function will terminate with the message "Unable to find range". There are two main reasons why this may occur. One is that the distribution is too discrete and/or the required quantiles too extreme, this can cause the function to be unable to find a point within the allowable range which is beyond the extreme quantiles. Another possibility is that the value of `t0[2]` is too small and so too many steps are required to find the range. The first problem cannot be solved except by asking for less extreme quantiles, although for very discrete distributions the approximations may not be very good. In the second case using a larger value of `t0[2]` will usually solve the problem.

### Value

The returned value is an object of class "saddle.distn". See the help file for [saddle.distn.object](#) for a description of such an object.

### Examples

```
# The bootstrap distribution of the mean of the air-conditioning
# failure data: fails to find value on R (and probably on S too)
air.t0 <- c(mean(aircondit$hours), sqrt(var(aircondit$hours)/12))
## Not run: saddle.distn(A = aircondit$hours/12, t0 = air.t0)

# alternatively using the conditional poisson
saddle.distn(A = cbind(aircondit$hours/12, 1), u = 12, wdist = "p",
             type = "cond", t0 = air.t0)

# Distribution of the ratio of a sample of size 10 from the bigcity
# data, taken from Example 9.16 of Davison and Hinkley (1997).
ratio <- function(d, w) sum(d$x * w) / sum(d$u * w)
city.v <- var.linear(empinf(data = city, statistic = ratio))
bigcity.t0 <- c(mean(bigcity$x) / mean(bigcity$u), sqrt(city.v))
Afn <- function(t, data) cbind(data$x - t * data$u, 1)
ufn <- function(t, data) c(0, 10)
saddle.distn(A = Afn, u = ufn, wdist = "b", type = "cond",
             t0 = bigcity.t0, data = bigcity)
```

```
# From Example 9.16 of Davison and Hinkley (1997) again, we find the
# conditional distribution of the ratio given the sum of city$u.
Afn <- function(t, data) cbind(data$x-t*data$u, data$u, 1)
ufn <- function(t, data) c(0, sum(data$u), 10)
city.t0 <- c(mean(city$x)/mean(city$u), sqrt(city.v))
saddle.distn(A = Afn, u = ufn, wdist = "p", type = "cond", t0 = city.t0,
             data = city)
```

saddle.distn.object

*Saddlepoint Distribution Approximation Objects*

---

## Description

Class of objects that result from calculating saddlepoint distribution approximations by a call to `saddle.distn`.

## Generation

This class of objects is returned from calls to the function `saddle.distn`.

## Methods

The class "saddle.distn" has methods for the functions `lines` and `print`.

## Structure

Objects of class "saddle.distn" are implemented as a list with the following components.

**quantiles** A matrix with 2 columns. The first column contains the probabilities  $\alpha$  and the second column contains the estimated quantiles of the distribution at those probabilities derived from the spline.

**points** A matrix of evaluations of the saddlepoint approximation. The first column contains the values of  $t$  which were used, the second and third contain the density and cdf approximations at those points and the rest of the columns contain the solutions to the saddlepoint equations. When `type` is "simp", there is only one of those. When `type` is "cond" there are  $2*d-1$  where  $d$  is the number of columns in  $A$  or the output of  $A(t, \dots \{ \})$ . The first  $d$  of these correspond to the numerator and the remainder correspond to the denominator.

**distn** An object of class `smooth.spline`. This corresponds to the spline fitted to the saddlepoint cdf approximations in `points` in order to approximate the entire distribution. For the structure of the object see `smooth.spline`.

**call** The original call to `saddle.distn` which generated the object.

**LR** A logical variable indicating whether the Lugananni-Rice approximations were used.

salinity

*Water Salinity and River Discharge***Description**

The `salinity` data frame has 28 rows and 4 columns.

Biweekly averages of the water salinity and river discharge in Pamlico Sound, North Carolina were recorded between the years 1972 and 1977. The data in this set consists only of those measurements in March, April and May.

**Usage**

```
salinity
```

**Format**

This data frame contains the following columns:

`sal` The average salinity of the water over two weeks.

`lag` The average salinity of the water lagged two weeks. Since only spring is used, the value of `lag` is not always equal to the previous value of `sal`.

`trend` A factor indicating in which of the 6 biweekly periods between March and May, the observations were taken. The levels of the factor are from 0 to 5 with 0 being the first two weeks in March.

`dis` The amount of river discharge during the two weeks for which `sal` is the average salinity.

**Source**

The data were obtained from

Ruppert, D. and Carroll, R.J. (1980) Trimmed least squares estimation in the linear model. *Journal of the American Statistical Association*, **75**, 828–838.

simplex

*Simplex Method for Linear Programming Problems***Description**

This function will optimize the linear function  $a \% \% x$  subject to the constraints  $A1 \% \% x \leq b1$ ,  $A2 \% \% x \geq b2$ ,  $A3 \% \% x = b3$  and  $x \geq 0$ . Either maximization or minimization is possible but the default is minimization.

**Usage**

```
simplex(a, A1 = NULL, b1 = NULL, A2 = NULL, b2 = NULL, A3 = NULL,
       b3 = NULL, maxi = FALSE, n.iter = n + 2 * m, eps = 1e-10)
```

**Arguments**

|                     |                                                                                                                                                                                                                                                                                                                               |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>a</code>      | A vector of length <code>n</code> which gives the coefficients of the objective function.                                                                                                                                                                                                                                     |
| <code>A1</code>     | An <code>m1</code> by <code>n</code> matrix of coefficients for the $\leq$ type of constraints.                                                                                                                                                                                                                               |
| <code>b1</code>     | A vector of length <code>m1</code> giving the right hand side of the $\leq$ constraints. This argument is required if <code>A1</code> is given and ignored otherwise. All values in <code>b1</code> must be non-negative.                                                                                                     |
| <code>A2</code>     | An <code>m2</code> by <code>n</code> matrix of coefficients for the $\geq$ type of constraints.                                                                                                                                                                                                                               |
| <code>b2</code>     | A vector of length <code>m2</code> giving the right hand side of the $\geq$ constraints. This argument is required if <code>A2</code> is given and ignored otherwise. All values in <code>b2</code> must be non-negative. Note that the constraints $x \geq 0$ are included automatically and so should not be repeated here. |
| <code>A3</code>     | An <code>m3</code> by <code>n</code> matrix of coefficients for the equality constraints.                                                                                                                                                                                                                                     |
| <code>b3</code>     | A vector of length <code>m3</code> giving the right hand side of equality constraints. This argument is required if <code>A3</code> is given and ignored otherwise. All values in <code>b3</code> must be non-negative.                                                                                                       |
| <code>maxi</code>   | A logical flag which specifies minimization if <code>FALSE</code> (default) and maximization otherwise. If <code>maxi</code> is <code>TRUE</code> then the maximization problem is recast as a minimization problem by changing the objective function coefficients to their negatives.                                       |
| <code>n.iter</code> | The maximum number of iterations to be conducted in each phase of the simplex method. The default is <code>n+2*(m1+m2+m3)</code> .                                                                                                                                                                                            |
| <code>eps</code>    | The floating point tolerance to be used in tests of equality.                                                                                                                                                                                                                                                                 |

**Details**

The method employed by this function is the two phase tableau simplex method. If there are  $\geq$  or equality constraints an initial feasible solution is not easy to find. To find a feasible solution an artificial variable is introduced into each  $\geq$  or equality constraint and an auxiliary objective function is defined as the sum of these artificial variables. If a feasible solution to the set of constraints exists then the auxiliary objective will be minimized when all of the artificial variables are 0. These are then discarded and the original problem solved starting at the solution to the auxiliary problem. If the only constraints are of the  $\leq$  form, the origin is a feasible solution and so the first stage can be omitted.

**Value**

An object of class "simplex": see `simplex.object`.

**Note**

The method employed here is suitable only for relatively small systems. Also if possible the number of constraints should be reduced to a minimum in order to speed up the execution time which is approximately proportional to the cube of the number of constraints. In particular if there are any constraints of the form `x[i] >= b2[i]` they should be omitted by setting `x[i] = x[i] - b2[i]`, changing all the constraints and the objective function accordingly and then transforming back after the solution has been found.

## Examples

```
# This example is taken from Exercise 7.5 of Gill, Murray and Wright (1991).
enj <- c(200, 6000, 3000, -200)
fat <- c(800, 6000, 1000, 400)
vitx <- c(50, 3, 150, 100)
vity <- c(10, 10, 75, 100)
vitz <- c(150, 35, 75, 5)
simplex(a = enj, A1 = fat, b1 = 13800, A2 = rbind(vitx, vity, vitz),
       b2 = c(600, 300, 550), maxi = TRUE)
```

---

simplex.object

*Linear Programming Solution Objects*

---

## Description

Class of objects that result from solving a linear programming problem using `simplex`.

## Generation

This class of objects is returned from calls to the function `simplex`.

## Methods

The class `"saddle.distn"` has a method for the function `print`.

## Structure

Objects of class `"simplex"` are implemented as a list with the following components.

**soln** The values of  $x$  which optimize the objective function under the specified constraints provided those constraints are jointly feasible.

**solved** This indicates whether the problem was solved. A value of  $-1$  indicates that no feasible solution could be found. A value of  $0$  that the maximum number of iterations was reached without termination of the second stage. This may indicate an unbounded function or simply that more iterations are needed. A value of  $1$  indicates that an optimal solution has been found.

**value** The value of the objective function at `soln`.

**val.aux** This is `NULL` if a feasible solution is found. Otherwise it is a positive value giving the value of the auxiliary objective function when it was minimized.

**obj** The original coefficients of the objective function.

**a** The objective function coefficients re-expressed such that the basic variables have coefficient zero.

**a.aux** This is `NULL` if a feasible solution is found. Otherwise it is the re-expressed auxiliary objective function at the termination of the first phase of the simplex method.

**A** The final constraint matrix which is expressed in terms of the non-basic variables. If a feasible solution is found then this will have dimensions  $m_1+m_2+m_3$  by  $n+m_1+m_2$ , where the final  $m_1+m_2$  columns correspond to slack and surplus variables. If no feasible solution is found there will be an additional  $m_1+m_2+m_3$  columns for the artificial variables introduced to solve the first phase of the problem.

**basic** The indices of the basic (non-zero) variables in the solution. Indices between  $n+1$  and  $n+m_1$  correspond to slack variables, those between  $n+m_1+1$  and  $n+m_2$  correspond to surplus variables and those greater than  $n+m_2$  are artificial variables. Indices greater than  $n+m_2$  should occur only if `solved` is `-1` as the artificial variables are discarded in the second stage of the simplex method.

**slack** The final values of the  $m_1$  slack variables which arise when the " $\leq$ " constraints are re-expressed as the equalities  $A1 \% \% x + \text{slack} = b1$ .

**surplus** The final values of the  $m_2$  surplus variables which arise when the " $\leq$ " constraints are re-expressed as the equalities  $A2 \% \% x - \text{surplus} = b2$ .

**artificial** This is `NULL` if a feasible solution can be found. If no solution can be found then this contains the values of the  $m_1+m_2+m_3$  artificial variables which minimize their sum subject to the original constraints. A feasible solution exists only if all of the artificial variables can be made 0 simultaneously.

smooth.f

*Smooth Distributions on Data Points*

---

### Description

This function uses the method of frequency smoothing to find a distribution on a data set which has a required value, `theta`, of the statistic of interest. The method results in distributions which vary smoothly with `theta`.

### Usage

```
smooth.f(theta, boot.out, index = 1, t = boot.out$t[, index],
         width = 0.5)
```

### Arguments

|                       |                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>theta</code>    | The required value for the statistic of interest. If <code>theta</code> is a vector, a separate distribution will be found for each element of <code>theta</code> .                                                                                                                                                                                                                                                 |
| <code>boot.out</code> | A bootstrap output object returned by a call to <code>boot</code> .                                                                                                                                                                                                                                                                                                                                                 |
| <code>index</code>    | The index of the variable of interest in the output of <code>boot.out\$statistic</code> . This argument is ignored if <code>t</code> is supplied. <code>index</code> must be a scalar.                                                                                                                                                                                                                              |
| <code>t</code>        | The bootstrap values of the statistic of interest. This must be a vector of length <code>boot.out\$R</code> and the values must be in the same order as the bootstrap replicates in <code>boot.out</code> .                                                                                                                                                                                                         |
| <code>width</code>    | The standardized width for the kernel smoothing. The smoothing uses a value of <code>width*s</code> for epsilon, where <code>s</code> is the bootstrap estimate of the standard error of the statistic of interest. <code>width</code> should take a value in the range (0.2, 1) to produce a reasonable smoothed distribution. If <code>width</code> is too large then the distribution becomes closer to uniform. |

## Details

The new distributional weights are found by applying a normal kernel smoother to the observed values of  $\tau$  weighted by the observed frequencies in the bootstrap simulation. The resulting distribution may not have parameter value exactly equal to the required value `theta` but it will typically have a value which is close to `theta`. The details of how this method works can be found in Davison, Hinkley and Worton (1995) and Section 3.9.2 of Davison and Hinkley (1997).

## Value

If `length(theta)` is 1 then a vector with the same length as the data set `boot.out$data` is returned. The value in position `i` is the probability to be given to the data point in position `i` so that the distribution has parameter value approximately equal to `theta`. If `length(theta)` is bigger than 1 then the returned value is a matrix with `length(theta)` rows each of which corresponds to a distribution with the parameter value approximately equal to the corresponding value of `theta`.

## Examples

```
# Example 9.8 of Davison and Hinkley (1997) requires tilting the resampling
# distribution of the studentized statistic to be centred at the observed
# value of the test statistic 1.84. In the book exponential tilting was used
# but it is also possible to use smooth.f.
grav1 <- gravity[as.numeric(gravity[, 2]) >= 7, ]
grav.fun <- function(dat, w, orig) {
  strata <- tapply(dat[, 2], as.numeric(dat[, 2]))
  d <- dat[, 1]
  ns <- tabulate(strata)
  w <- w/tapply(w, strata, sum)[strata]
  mns <- as.vector(tapply(d * w, strata, sum)) # drop names
  mn2 <- tapply(d * d * w, strata, sum)
  s2hat <- sum((mn2 - mns^2)/ns)
  c(mns[2] - mns[1], s2hat, (mns[2]-mns[1]-orig)/sqrt(s2hat))
}
grav.z0 <- grav.fun(grav1, rep(1, 26), 0)
grav.boot <- boot(grav1, grav.fun, R = 499, stype = "w",
  strata = grav1[, 2], orig = grav.z0[1])
grav.sm <- smooth.f(grav.z0[3], grav.boot, index = 3)

# Now we can run another bootstrap using these weights
grav.boot2 <- boot(grav1, grav.fun, R = 499, stype = "w",
  strata = grav1[, 2], orig = grav.z0[1],
  weights = grav.sm)

# Estimated p-values can be found from these as follows
```

```

mean(grav.boot$t[, 3] >= grav.z0[3])
imp.prob(grav.boot2, t0 = -grav.z0[3], t = -grav.boot2$t[, 3])

# Note that for the importance sampling probability we must
# multiply everything by -1 to ensure that we find the correct
# probability. Raw resampling is not reliable for probabilities
# greater than 0.5. Thus
1 - imp.prob(grav.boot2, index = 3, t0 = grav.z0[3])$raw
# can give very strange results (negative probabilities).

```

sunspot

*Annual Mean Sunspot Numbers*

---

### Description

sunspot is a time series and contains 289 observations.

The Zurich sunspot numbers have been analyzed in almost all books on time series analysis as well as numerous papers. The data set, usually attributed to Rudolf Wolf, consists of means of daily relative numbers of sunspot sightings. The relative number for a day is given by  $k(f+10g)$  where  $g$  is the number of sunspot groups observed,  $f$  is the total number of spots within the groups and  $k$  is a scaling factor relating the observer and telescope to a baseline. The relative numbers are then averaged to give an annual figure. See Inzenman (1983) for a discussion of the relative numbers. The figures are for the years 1700-1988.

survival

*Survival of Rats after Radiation Doses*

---

### Description

The survival data frame has 14 rows and 2 columns.

The data measured the survival percentages of batches of rats who were given varying doses of radiation. At each of 6 doses there were two or three replications of the experiment.

### Usage

```
survival
```

**Format**

This data frame contains the following columns:

`dose` The dose of radiation administered (rads).

`surv` The survival rate of the batches expressed as a percentage.

**Source**

The data were obtained from

Efron, B. (1988) Computer-intensive methods in statistical regression. *SIAM Review*, **30**, 421–449.

|     |                                 |
|-----|---------------------------------|
| tau | <i>Tau Particle Decay Modes</i> |
|-----|---------------------------------|

---

**Description**

The `tau` data frame has 60 rows and 2 columns.

The tau particle is a heavy electron-like particle discovered in the 1970's by Martin Perl at the Stanford Linear Accelerator Center. Soon after its production the tau particle decays into various collections of more stable particles. About 86% of the time the decay involves just one charged particle. This rate has been measured independently 13 times.

The one-charged-particle event is made up of four major modes of decay as well as a collection of other events. The four main types of decay are denoted rho, pi, e and mu. These rates have been measured independently 6, 7, 14 and 19 times respectively. Due to physical constraints each experiment can only estimate the composite one-charged-particle decay rate or the rate of one of the major modes of decay.

Each experiment consists of a major research project involving many years work. One of the goals of the experiments was to estimate the rate of decay due to events other than the four main modes of decay. These are uncertain events and so cannot themselves be observed directly.

**Usage**

`tau`

**Format**

This data frame contains the following columns:

`rate` The decay rate expressed as a percentage.

`decay` The type of decay measured in the experiment. It is a factor with levels 1, rho, pi, e and mu.

|           |                                        |
|-----------|----------------------------------------|
| tilt.boot | <i>Non-parametric Tilted Bootstrap</i> |
|-----------|----------------------------------------|

---

Description

This function will run an initial bootstrap with equal resampling probabilities (if required) and will use the output of the initial run to find resampling probabilities which put the value of the statistic at required values. It then runs an importance resampling bootstrap using the calculated probabilities as the resampling distribution.

Usage

```
tilt.boot(data, statistic, R, sim = "ordinary", stype = "i",
          strata = rep(1, n), L = NULL, theta = NULL,
          alpha = c(0.025, 0.975), tilt = TRUE, width = 0.5,
          index = 1, ...)
```

Arguments

|           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| data      | The data as a vector, matrix or data frame. If it is a matrix or data frame then each row is considered as one (multivariate) observation.                                                                                                                                                                                                                                                                                                                                           |
| statistic | A function which when applied to data returns a vector containing the statistic(s) of interest. It must take at least two arguments. The first argument will always be data and the second should be a vector of indices, weights or frequencies describing the bootstrap sample. Any other arguments must be supplied to tilt.boot and will be passed unchanged to statistic each time it is called.                                                                                |
| R         | The number of bootstrap replicates required. This will generally be a vector, the first value stating how many uniform bootstrap simulations are to be performed at the initial stage. The remaining values of R are the number of simulations to be performed resampling from each reweighted distribution. The first value of R must always be present, a value of 0 implying that no uniform resampling is to be carried out. Thus length(R) should always equal 1+length(theta). |
| sim       | This is a character string indicating the type of bootstrap simulation required. There are only two possible values that this can take: "ordinary" and "balanced". If other simulation types are required for the initial un-weighted bootstrap then it will be necessary to run boot, calculate the weights appropriately, and run boot again using the calculated weights.                                                                                                         |

|        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| stype  | A character string indicating the type of second argument expected by <code>statistic</code> . The possible values that <code>stype</code> can take are "i" (indices), "w" (weights) and "f" (frequencies).                                                                                                                                                                                                                                                                                                                      |
| strata | An integer vector or factor representing the strata for multi-sample problems.                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| L      | The empirical influence values for the statistic of interest. They are used only for exponential tilting when <code>tilt</code> is TRUE. If <code>tilt</code> is TRUE and they are not supplied then <code>tilt.boot</code> uses <code>empinf</code> to calculate them.                                                                                                                                                                                                                                                          |
| theta  | The required parameter value(s) for the tilted distribution(s). There should be one value of <code>theta</code> for each of the non-uniform distributions. If <code>R[1]</code> is 0 <code>theta</code> is a required argument. Otherwise <code>theta</code> values can be estimated from the initial uniform bootstrap and the values in <code>alpha</code> .                                                                                                                                                                   |
| alpha  | The alpha level to which tilting is required. This parameter is ignored if <code>R[1]</code> is 0 or if <code>theta</code> is supplied, otherwise it is used to find the values of <code>theta</code> as quantiles of the initial uniform bootstrap. In this case <code>R[1]</code> should be large enough that <code>min(c(alpha, 1-alpha)) * R[1] &gt; 5</code> , if this is not the case then a warning is generated to the effect that the <code>theta</code> are extreme values and so the tilted output may be unreliable. |
| tilt   | A logical variable which if TRUE (the default) indicates that exponential tilting should be used, otherwise local frequency smoothing ( <code>smooth.f</code> ) is used. If <code>tilt</code> is FALSE then <code>R[1]</code> must be positive. In fact in this case the value of <code>R[1]</code> should be fairly large (in the region of 500 or more).                                                                                                                                                                       |
| width  | This argument is used only if <code>tilt</code> is FALSE, in which case it is passed unchanged to <code>smooth.f</code> as the standardized bandwidth for the smoothing operation. The value should generally be in the range (0.2, 1). See <code>smooth.f</code> for more details.                                                                                                                                                                                                                                              |
| index  | The index of the statistic of interest in the output from <code>statistic</code> . By default the first element of the output of <code>statistic</code> is used.                                                                                                                                                                                                                                                                                                                                                                 |
| ...    | Any additional arguments required by <code>statistic</code> . These are passed unchanged to <code>statistic</code> each time it is called.                                                                                                                                                                                                                                                                                                                                                                                       |

## Value

An object of class "boot" with the following components

|           |                                                                                                                                                                                                                                                                          |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| t0        | The observed value of the statistic on the original data.                                                                                                                                                                                                                |
| t         | The values of the bootstrap replicates of the statistic. There will be <code>sum(R)</code> of these, the first <code>R[1]</code> corresponding to the uniform bootstrap and the remainder to the tilted bootstrap(s).                                                    |
| R         | The input vector of the number of bootstrap replicates.                                                                                                                                                                                                                  |
| data      | The original data as supplied.                                                                                                                                                                                                                                           |
| statistic | The <code>statistic</code> function as supplied.                                                                                                                                                                                                                         |
| sim       | The simulation type used in the bootstrap(s), it can either be "ordinary" or "balanced".                                                                                                                                                                                 |
| stype     | The type of statistic supplied, it is the same as the input value <code>stype</code> .                                                                                                                                                                                   |
| call      | A copy of the original call to <code>tilt.boot</code> .                                                                                                                                                                                                                  |
| strata    | The strata as supplied.                                                                                                                                                                                                                                                  |
| weights   | The matrix of weights used. If <code>R[1]</code> is greater than 0 then the first row will be the uniform weights and each subsequent row the tilted weights. If <code>R[1]</code> equals 0 then the uniform weights are omitted and only the tilted weights are output. |

`theta`            The values of `theta` used for the tilted distributions. These are either the input values or the values derived from the uniform bootstrap and `alpha`.

                       tilt = TRUE, index = 3, bhat = acme.b[1])
```

**Description**

Generate R bootstrap replicates of a statistic applied to a time series. The replicate time series can be generated using fixed or random block lengths or can be model based replicates.

**Usage**

```
tsboot(tseries, statistic, R, l = NULL, sim = "model",
       endcorr = TRUE, n.sim = NROW(tseries), orig.t = TRUE,
       ran.gen, ran.args = NULL, norm = TRUE, ...,
       parallel = c("no", "multicore", "snow"),
       ncpus = getOption("boot.ncpus", 1L), cl = NULL)
```

**Arguments**

|                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>tseries</code>   | A univariate or multivariate time series.                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <code>statistic</code> | A function which when applied to <code>tseries</code> returns a vector containing the statistic(s) of interest. Each time <code>statistic</code> is called it is passed a time series of length <code>n.sim</code> which is of the same class as the original <code>tseries</code> . Any other arguments which <code>statistic</code> takes must remain constant for each bootstrap replicate and should be supplied through the <code>...</code> argument to <code>tsboot</code> .                       |
| <code>R</code>         | A positive integer giving the number of bootstrap replicates required.                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>sim</code>       | The type of simulation required to generate the replicate time series. The possible input values are "model" (model based resampling), "fixed" (block resampling with fixed block lengths of 1), "geom" (block resampling with block lengths having a geometric distribution with mean 1) or "scramble" (phase scrambling).                                                                                                                                                                               |
| <code>l</code>         | If <code>sim</code> is "fixed" then <code>l</code> is the fixed block length used in generating the replicate time series. If <code>sim</code> is "geom" then <code>l</code> is the mean of the geometric distribution used to generate the block lengths. <code>l</code> should be a positive integer less than the length of <code>tseries</code> . This argument is not required when <code>sim</code> is "model" but it is required for all other simulation types.                                   |
| <code>endcorr</code>   | A logical variable indicating whether end corrections are to be applied when <code>sim</code> is "fixed". When <code>sim</code> is "geom", <code>endcorr</code> is automatically set to TRUE; <code>endcorr</code> is not used when <code>sim</code> is "model" or "scramble".                                                                                                                                                                                                                            |
| <code>n.sim</code>     | The length of the simulated time series. Typically this will be equal to the length of the original time series but there are situations when it will be larger. One obvious situation is if prediction is required. Another situation in which <code>n.sim</code> is larger than the original length is if <code>tseries</code> is a residual time series from fitting some model to the original time series. In this case, <code>n.sim</code> would usually be the length of the original time series. |
| <code>orig.t</code>    | A logical variable which indicates whether <code>statistic</code> should be applied to <code>tseries</code> itself as well as the bootstrap replicate series. If <code>statistic</code> is expecting a longer time series than <code>tseries</code> or if applying <code>statistic</code> to <code>tseries</code> will not yield any useful information then <code>orig.t</code> should be set to FALSE.                                                                                                  |

|                                  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|----------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>ran.gen</code>             | This is a function of three arguments. The first argument is a time series. If <code>sim</code> is "model" then it will always be <code>tseries</code> that is passed. For other simulation types it is the result of selecting <code>n.sim</code> observations from <code>tseries</code> by some scheme and converting the result back into a time series of the same form as <code>tseries</code> (although of length <code>n.sim</code> ). The second argument to <code>ran.gen</code> is always the value <code>n.sim</code> , and the third argument is <code>ran.args</code> , which is used to supply any other objects needed by <code>ran.gen</code> . If <code>sim</code> is "model" then the generation of the replicate time series will be done in <code>ran.gen</code> (for example through use of <code>arima.sim</code> ). For the other simulation types <code>ran.gen</code> is used for 'post-blackening'. The default is that the function simply returns the time series passed to it. |
| <code>ran.args</code>            | This will be supplied to <code>ran.gen</code> each time it is called. If <code>ran.gen</code> needs any extra arguments then they should be supplied as components of <code>ran.args</code> . Multiple arguments may be passed by making <code>ran.args</code> a list. If <code>ran.args</code> is <code>NULL</code> then it should not be used within <code>ran.gen</code> but note that <code>ran.gen</code> must still have its third argument.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <code>norm</code>                | A logical argument indicating whether normal margins should be used for phase scrambling. If <code>norm</code> is <code>FALSE</code> then margins corresponding to the exact empirical margins are used.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>...</code>                 | Extra named arguments to <code>statistic</code> may be supplied here. Beware of partial matching to the arguments of <code>tsboot</code> listed above.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>parallel, ncpus, cl</code> | See the help for <code>boot</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

## Details

If `sim` is "fixed" then each replicate time series is found by taking blocks of length `l`, from the original time series and putting them end-to-end until a new series of length `n.sim` is created. When `sim` is "geom" a similar approach is taken except that now the block lengths are generated from a geometric distribution with mean 1. Post-blackening can be carried out on these replicate time series by including the function `ran.gen` in the call to `tsboot` and having `tseries` as a time series of residuals.

Model based resampling is very similar to the parametric bootstrap and all simulation must be in one of the user specified functions. This avoids the complicated problem of choosing the block length but relies on an accurate model choice being made.

Phase scrambling is described in Section 8.2.4 of Davison and Hinkley (1997). The types of statistic for which this method produces reasonable results is very limited and the other methods seem to do better in most situations. Other types of resampling in the frequency domain can be accomplished using the function `boot` with the argument `sim = "parametric"`.

## Value

An object of class "boot" with the following components.

|                        |                                                                                                                                                            |
|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>t0</code>        | If <code>orig.t</code> is <code>TRUE</code> then <code>t0</code> is the result of <code>statistic(tseries, ...)</code> otherwise it is <code>NULL</code> . |
| <code>t</code>         | The results of applying <code>statistic</code> to the replicate time series.                                                                               |
| <code>R</code>         | The value of <code>R</code> as supplied to <code>tsboot</code> .                                                                                           |
| <code>tseries</code>   | The original time series.                                                                                                                                  |
| <code>statistic</code> | The function <code>statistic</code> as supplied.                                                                                                           |

|                       |                                                                                                                                                                                                                              |
|-----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>sim</code>      | The simulation type used in generating the replicates.                                                                                                                                                                       |
| <code>endcorr</code>  | The value of <code>endcorr</code> used. The value is meaningful only when <code>sim</code> is "fixed"; it is ignored for model based simulation or phase scrambling and is always set to TRUE if <code>sim</code> is "geom". |
| <code>n.sim</code>    | The value of <code>n.sim</code> used.                                                                                                                                                                                        |
| <code>l</code>        | The value of <code>l</code> used for block based resampling. This will be NULL if block based resampling was not used.                                                                                                       |
| <code>ran.gen</code>  | The <code>ran.gen</code> function used for generating the series or for 'post-blackening'.                                                                                                                                   |
| <code>ran.args</code> | The extra arguments passed to <code>ran.gen</code> .                                                                                                                                                                         |
| <code>call</code>     | The original call to <code>tsboot</code> .                                                                                                                                                                                   |

## Examples

```
lynx.fun <- function(tsb) {
  ar.fit <- ar(tsb, order.max = 25)
  c(ar.fit$order, mean(tsb), tsb)
}

# the stationary bootstrap with mean block length 20
lynx.1 <- tsboot(log(lynx), lynx.fun, R = 99, l = 20, sim = "geom")

# the fixed block bootstrap with length 20
lynx.2 <- tsboot(log(lynx), lynx.fun, R = 99, l = 20, sim = "fixed")

# Now for model based resampling we need the original model
# Note that for all of the bootstraps which use the residuals as their
# data, we set orig.t to FALSE since the function applied to the residual
# time series will be meaningless.
lynx.ar <- ar(log(lynx))
lynx.model <- list(order = c(lynx.ar$order, 0, 0), ar = lynx.ar$ar)
lynx.res <- lynx.ar$resid[!is.na(lynx.ar$resid)]
lynx.res <- lynx.res - mean(lynx.res)

lynx.sim <- function(res, n.sim, ran.args) {
  # random generation of replicate series using arima.sim
  rgl <- function(n, res) sample(res, n, replace = TRUE)
  ts.orig <- ran.args$ts
  ts.mod <- ran.args$model
  mean(ts.orig) + ts(arima.sim(model = ts.mod, n = n.sim,
    rand.gen = rgl, res = as.vector(res)))
}
```

```

}

lynx.3 <- tsboot(lynx.res, lynx.fun, R = 99, sim = "model", n.sim = 114,
               orig.t = FALSE, ran.gen = lynx.sim,
               ran.args = list(ts = log(lynx), model = lynx.model))

# For "post-blackening" we need to define another function
lynx.black <- function(res, n.sim, ran.args) {
  ts.orig <- ran.args$ts
  ts.mod <- ran.args$model
  mean(ts.orig) + ts(arima.sim(model = ts.mod, n = n.sim, innov = res))
}

# Now we can run apply the two types of block resampling again but this
# time applying post-blackening.
lynx.1b <- tsboot(lynx.res, lynx.fun, R = 99, l = 20, sim = "fixed",
                 n.sim = 114, orig.t = FALSE, ran.gen = lynx.black,
                 ran.args = list(ts = log(lynx), model = lynx.model))

lynx.2b <- tsboot(lynx.res, lynx.fun, R = 99, l = 20, sim = "geom",
                 n.sim = 114, orig.t = FALSE, ran.gen = lynx.black,
                 ran.args = list(ts = log(lynx), model = lynx.model))

# To compare the observed order of the bootstrap replicates we
# proceed as follows.
table(lynx.1$t[, 1])
table(lynx.1b$t[, 1])
table(lynx.2$t[, 1])
table(lynx.2b$t[, 1])
table(lynx.3$t[, 1])
# Notice that the post-blackened and model-based bootstraps preserve
# the true order of the model (11) in many more cases than the others.

```

---

tuna

### *Tuna Sighting Data*

---

## Description

The tuna data frame has 64 rows and 1 columns.

The data come from an aerial line transect survey of Southern Bluefin Tuna in the Great Australian Bight. An aircraft with two spotters on board flies randomly allocated line transects. Each school of tuna sighted is counted and its perpendicular distance from the transect measured. The survey was conducted in summer when tuna tend to stay on the surface.

## Usage

```
tuna
```

## Format

This data frame contains the following column:

- y The perpendicular distance, in miles, from the transect for 64 independent sightings of tuna schools.

**Source**

The data were obtained from

Chen, S.X. (1996) Empirical likelihood confidence intervals for nonparametric density estimation. *Biometrika*, **83**, 329–341.

**References**

---

urine

*Urine Analysis Data*

---

**Description**

The `urine` data frame has 79 rows and 7 columns.

79 urine specimens were analyzed in an effort to determine if certain physical characteristics of the urine might be related to the formation of calcium oxalate crystals.

**Usage**

`urine`

**Format**

This data frame contains the following columns:

`r` Indicator of the presence of calcium oxalate crystals.

`gravity` The specific gravity of the urine.

`ph` The pH reading of the urine.

`osmo` The osmolarity of the urine. Osmolarity is proportional to the concentration of molecules in solution.

`cond` The conductivity of the urine. Conductivity is proportional to the concentration of charged ions in solution.

`urea` The urea concentration in millimoles per litre.

`calc` The calcium concentration in millimoles per litre.

**Source**

The data were obtained from

Andrews, D.F. and Herzberg, A.M. (1985) *Data: A Collection of Problems from Many Fields for the Student and Research Worker*. Springer-Verlag.

---

|                         |                                 |
|-------------------------|---------------------------------|
| <code>var.linear</code> | <i>Linear Variance Estimate</i> |
|-------------------------|---------------------------------|

---

**Description**

Estimates the variance of a statistic from its empirical influence values.

**Usage**

```
var.linear(L, strata = NULL)
```

**Arguments**

|                     |                                                                                                                              |
|---------------------|------------------------------------------------------------------------------------------------------------------------------|
| <code>L</code>      | Vector of the empirical influence values of a statistic. These will usually be calculated by a call to <code>empinf</code> . |
| <code>strata</code> | A numeric vector or factor specifying which observations (and hence empirical influence values) come from which strata.      |

**Value**

The variance estimate calculated from `L`.

**References**

Davison, A. C. and Hinkley, D. V. (1997) *Bootstrap Methods and Their Application*. Cambridge University Press.

|-------------------|----------------------------------------|
| <code>wool</code> | <i>Australian Relative Wool Prices</i> |
|-------------------|----------------------------------------|

---

**Description**

`wool` is a time series of class "ts" and contains 309 observations.

Each week that the market is open the Australian Wool Corporation set a floor price which determines their policy on intervention and is therefore a reflection of the overall price of wool for the week in question. Actual prices paid can vary considerably about the floor price. The series here is the log of the ratio between the price for fine grade wool and the floor price, each market week between July 1976 and Jun 1984.

### Source

The data were obtained from

Diggle, P.J. (1990) *Time Series: A Biostatistical Introduction*. Oxford University Press.

## Chapter 19

# The `class` package

---

`batchSOM`

*Self-Organizing Maps: Batch Algorithm*

---

### Description

Kohonen's Self-Organizing Maps are a crude form of multidimensional scaling.

### Usage

```
batchSOM(data, grid = somgrid(), radii, init)
```

### Arguments

|                    |                                                                                                                   |
|--------------------|-------------------------------------------------------------------------------------------------------------------|
| <code>data</code>  | a matrix or data frame of observations, scaled so that Euclidean distance is appropriate.                         |
| <code>grid</code>  | A grid for the representatives: see <a href="#">somgrid</a> .                                                     |
| <code>radii</code> | the radii of the neighbourhood to be used for each pass: one pass is run for each element of <code>radii</code> . |
| <code>init</code>  | the initial representatives. If missing, chosen (without replacement) randomly from <code>data</code> .           |

### Details

The batch SOM algorithm of Kohonen(1995, section 3.14) is used.

### Value

An object of class "`SOM`" with components

|                    |                                                        |
|--------------------|--------------------------------------------------------|
| <code>grid</code>  | the grid, an object of class " <code>somgrid</code> ". |
| <code>codes</code> | a matrix of representatives.                           |

     as.character(crabs.grp))
```

---

condense

---

*Condense training set for k-NN classifier*

---

**Description**

Condense training set for k-NN classifier

**Usage**

```
condense(train, class, store, trace = TRUE)
```

**Arguments**

|                    |                                                                    |
|--------------------|--------------------------------------------------------------------|
| <code>train</code> | matrix for training set                                            |
| <code>class</code> | vector of classifications for test set                             |
| <code>store</code> | initial store set. Default one randomly chosen element of the set. |
| <code>trace</code> | logical. Trace iterations?                                         |

**Details**

The store set is used to 1-NN classify the rest, and misclassified patterns are added to the store set. The whole set is checked until no additions occur.

**Value**

Index vector of cases to be retained (the final store set).

|-----|--------------------------------------------|
| knn | <i>k</i> -Nearest Neighbour Classification |
|-----|--------------------------------------------|

---

## Description

k-nearest neighbour classification for test set from training set. For each row of the test set, the k nearest (in Euclidean distance) training set vectors are found, and the classification is decided by majority vote, with ties broken at random. If there are ties for the kth nearest vector, all candidates are included in the vote.

## Usage

```
knn(train, test, cl, k = 1, l = 0, prob = FALSE, use.all = TRUE)
```

## Arguments

|                      |                                                                                                                                                                                            |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>train</code>   | matrix or data frame of training set cases.                                                                                                                                                |
| <code>test</code>    | matrix or data frame of test set cases. A vector will be interpreted as a row vector for a single case.                                                                                    |
| <code>cl</code>      | factor of true classifications of training set                                                                                                                                             |
| <code>k</code>       | number of neighbours considered.                                                                                                                                                           |
| <code>l</code>       | minimum vote for definite decision, otherwise <code>doubt</code> . (More precisely, less than k-1 dissenting votes are allowed, even if k is increased by ties.)                           |
| <code>prob</code>    | If this is true, the proportion of the votes for the winning class are returned as attribute <code>prob</code> .                                                                           |
| <code>use.all</code> | controls handling of ties. If true, all distances equal to the kth largest are included. If false, a random selection of distances equal to the kth is chosen to use exactly k neighbours. |

**Value**

Factor of classifications of test set. `doubt` will be returned as NA.

*k-Nearest Neighbour Cross-Validatory Classification*

---

**Description**

k-nearest neighbour cross-validatory classification from training set.

**Usage**

```
knn.cv(train, cl, k = 1, l = 0, prob = FALSE, use.all = TRUE)
```

**Arguments**

|                      |                                                                                                                                                                                                    |
|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>train</code>   | matrix or data frame of training set cases.                                                                                                                                                        |
| <code>cl</code>      | factor of true classifications of training set                                                                                                                                                     |
| <code>k</code>       | number of neighbours considered.                                                                                                                                                                   |
| <code>l</code>       | minimum vote for definite decision, otherwise <code>doubt</code> . (More precisely, less than $k-1$ dissenting votes are allowed, even if $k$ is increased by ties.)                               |
| <code>prob</code>    | If this is true, the proportion of the votes for the winning class are returned as attribute <code>prob</code> .                                                                                   |
| <code>use.all</code> | controls handling of ties. If true, all distances equal to the $k$ th largest are included. If false, a random selection of distances equal to the $k$ th is chosen to use exactly $k$ neighbours. |

**Details**

This uses leave-one-out cross validation. For each row of the training set `train`, the  $k$  nearest (in Euclidean distance) other training set vectors are found, and the classification is decided by majority vote, with ties broken at random. If there are ties for the  $k$ th nearest vector, all candidates are included in the vote.

**Value**

Factor of classifications of training set. `doubt` will be returned as NA.

**Examples**

```
train <- rbind(iris3[,1], iris3[,2], iris3[,3])
cl <- factor(c(rep("s",50), rep("c",50), rep("v",50)))
knn.cv(train, cl, k = 3, prob = TRUE)
attributes(.Last.value)
```

---

knn1

---

*1-Nearest Neighbour Classification*

---

**Description**

Nearest neighbour classification for test set from training set. For each row of the test set, the nearest (by Euclidean distance) training set vector is found, and its classification used. If there is more than one nearest, a majority vote is used with ties broken at random.

**Usage**

```
knn1(train, test, cl)
```

**Arguments**

|                    |                                                                                                         |
|--------------------|---------------------------------------------------------------------------------------------------------|
| <code>train</code> | matrix or data frame of training set cases.                                                             |
| <code>test</code>  | matrix or data frame of test set cases. A vector will be interpreted as a row vector for a single case. |
| <code>cl</code>    | factor of true classification of training set.                                                          |

**Value**

Factor of classifications of test set.

**References**

Ripley, B. D. (1996) *Pattern Recognition and Neural Networks*. Cambridge.

test  <- rbind(iris3[26:50,,1], iris3[26:50,,2], iris3[26:50,,3])
cl    <- factor(c(rep("s",25), rep("c",25), rep("v",25)))
knn1(train, test, cl)
```

lvq1

*Learning Vector Quantization I***Description**

Moves examples in a codebook to better represent the training set.

**Usage**

```
lvq1(x, cl, codebk, niter = 100 * nrow(codebk$x), alpha = 0.03)
```

**Arguments**

|                     |                                                        |
|---------------------|--------------------------------------------------------|
| <code>x</code>      | a matrix or data frame of examples                     |
| <code>cl</code>     | a vector or factor of classifications for the examples |
| <code>codebk</code> | a codebook                                             |
| <code>niter</code>  | number of iterations                                   |
| <code>alpha</code>  | constant for training                                  |

**Details**

Selects `niter` examples at random with replacement, and adjusts the nearest example in the codebook for each.

**Value**

A codebook, represented as a list with components `x` and `cl` giving the examples and classes.

lvq2

*Learning Vector Quantization 2.1***Description**

Moves examples in a codebook to better represent the training set.

**Usage**

```

lvq2(x, cl, codebk, niter = 100 * nrow(codebk$x), alpha = 0.03,
     win = 0.3)

```

**Arguments**

|                     |                                                           |
|---------------------|-----------------------------------------------------------|
| <code>x</code>      | a matrix or data frame of examples                        |
| <code>cl</code>     | a vector or factor of classifications for the examples    |
| <code>codebk</code> | a codebook                                                |
| <code>niter</code>  | number of iterations                                      |
| <code>alpha</code>  | constant for training                                     |
| <code>win</code>    | a tolerance for the closeness of the two nearest vectors. |

**Details**

Selects `niter` examples at random with replacement, and adjusts the nearest two examples in the codebook if one is correct and the other incorrect.

**Value**

A codebook, represented as a list with components `x` and `cl` giving the examples and classes.

**References**

lvq3

*Learning Vector Quantization 3*

---

**Description**

Moves examples in a codebook to better represent the training set.

**Usage**

```
lvq3(x, cl, codebk, niter = 100*nrow(codebk$x), alpha = 0.03,
     win = 0.3, epsilon = 0.1)
```

**Arguments**

|                      |                                                           |
|----------------------|-----------------------------------------------------------|
| <code>x</code>       | a matrix or data frame of examples                        |
| <code>cl</code>      | a vector or factor of classifications for the examples    |
| <code>codebk</code>  | a codebook                                                |
| <code>niter</code>   | number of iterations                                      |
| <code>alpha</code>   | constant for training                                     |
| <code>win</code>     | a tolerance for the closeness of the two nearest vectors. |
| <code>epsilon</code> | proportion of move for correct vectors                    |

**Details**

Selects `niter` examples at random with replacement, and adjusts the nearest two examples in the codebook for each.

**Value**

A codebook, represented as a list with components `x` and `cl` giving the examples and classes.

|---------|----------------------------------|
| lvqinit | <i>Initialize a LVQ Codebook</i> |
|---------|----------------------------------|

---

## Description

Construct an initial codebook for LVQ methods.

## Usage

```
lvqinit(x, cl, size, prior, k = 5)
```

## Arguments

- |                    |                                                                                                                                              |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>     | a matrix or data frame of training examples, $n$ by $p$ .                                                                                    |
| <code>cl</code>    | the classifications for the training examples. A vector or factor of length $n$ .                                                            |
| <code>size</code>  | the size of the codebook. Defaults to $\min(\text{round}(0.4 \cdot n_g \cdot (n_g - 1 + p/2)), 0), n)$ where $n_g$ is the number of classes. |
| <code>prior</code> | Probabilities to represent classes in the codebook. Default proportions in the training set.                                                 |
| <code>k</code>     | $k$ used for $k$ -NN test of correct classification. Default is 5.                                                                           |

## Details

Selects `size` examples from the training set without replacement with proportions proportional to the prior or the original proportions.

## Value

A codebook, represented as a list with components `x` and `cl` giving the examples and classes.

|---------|--------------------------------------------|

---

Description

Classify a test set by 1-NN from a specified LVQ codebook.

Usage

```
lvqtest(codebk, test)
```

Arguments

|        |                                                |
|--------|------------------------------------------------|
| codebk | codebook object returned by other LVQ software |
| test   | matrix of test examples                        |

Details

Uses 1-NN to classify each test example against the codebook.

Value

Factor of classification for each row of x

---

## Description

Moves examples in a codebook to better represent the training set.

## Usage

```
olvq1(x, cl, codebk, niter = 40 * nrow(codebk$x), alpha = 0.3)
```

## Arguments

|                     |                                                        |
|---------------------|--------------------------------------------------------|
| <code>x</code>      | a matrix or data frame of examples                     |
| <code>cl</code>     | a vector or factor of classifications for the examples |
| <code>codebk</code> | a codebook                                             |
| <code>niter</code>  | number of iterations                                   |
| <code>alpha</code>  | constant for training                                  |

## Details

Selects `niter` examples at random with replacement, and adjusts the nearest example in the codebook for each.

## Value

A codebook, represented as a list with components `x` and `cl` giving the examples and classes.

reduce.nn

*Reduce Training Set for a k-NN Classifier*

---

**Description**

Reduce training set for a k-NN classifier. Used after `condense`.

**Usage**

```
reduce.nn(train, ind, class)
```

**Arguments**

|                    |                                                                            |
|--------------------|----------------------------------------------------------------------------|
| <code>train</code> | matrix for training set                                                    |
| <code>ind</code>   | Initial list of members of the training set (from <code>condense</code> ). |
| <code>class</code> | vector of classifications for test set                                     |

**Details**

All the members of the training set are tried in random order. Any which when dropped do not cause any members of the training set to be wrongly classified are dropped.

**Value**

Index vector of cases to be retained.

**Examples**

```

train <- rbind(iris3[1:25,,1], iris3[1:25,,2], iris3[1:25,,3])
test  <- rbind(iris3[26:50,,1], iris3[26:50,,2], iris3[26:50,,3])
cl    <- factor(c(rep("s",25), rep("c",25), rep("v",25)))
keep  <- condense(train, cl)
knn(train[keep,], test, cl[keep])
keep2 <- reduce.nn(train, keep, cl)
knn(train[keep2,], test, cl[keep2])

```

SOM

*Self-Organizing Maps: Online Algorithm***Description**

Kohonen's Self-Organizing Maps are a crude form of multidimensional scaling.

**Usage**

```
SOM(data, grid = somgrid(), rlen = 10000, alpha, radii, init)
```

**Arguments**

|                    |                                                                                                                                                                                       |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>data</code>  | a matrix or data frame of observations, scaled so that Euclidean distance is appropriate.                                                                                             |
| <code>grid</code>  | A grid for the representatives: see <a href="#">somgrid</a> .                                                                                                                         |
| <code>rlen</code>  | the number of updates: used only in the defaults for <code>alpha</code> and <code>radii</code> .                                                                                      |
| <code>alpha</code> | the amount of change: one update is done for each element of <code>alpha</code> . Default is to decline linearly from 0.05 to 0 over <code>rlen</code> updates.                       |
| <code>radii</code> | the radii of the neighbourhood to be used for each update: must be the same length as <code>alpha</code> . Default is to decline linearly from 4 to 1 over <code>rlen</code> updates. |
| <code>init</code>  | the initial representatives. If missing, chosen (without replacement) randomly from <code>data</code> .                                                                               |

**Details**

`alpha` and `radii` can also be lists, in which case each component is used in turn, allowing two- or more phase training.

**Value**

An object of class "SOM" with components

|                    |                                         |
|--------------------|-----------------------------------------|
| <code>grid</code>  | the grid, an object of class "somgrid". |
| <code>codes</code> | a matrix of representatives.            |

## Examples

```
require(graphics)
data(crabs, package = "MASS")

lcrabs <- log(crabs[, 4:8])
crabs.grp <- factor(c("B", "b", "O", "o")[rep(1:4, rep(50,4))])
gr <- somgrid(topo = "hexagonal")
crabs.som <- SOM(lcrabs, gr)
plot(crabs.som)

## 2-phase training
crabs.som2 <- SOM(lcrabs, gr,
  alpha = list(seq(0.05, 0, len = 1e4), seq(0.02, 0, len = 1e5)),
  radii = list(seq(8, 1, len = 1e4), seq(4, 1, len = 1e5)))
plot(crabs.som2)
```

---

somgrid

*Plot SOM Fits*

---

## Description

Plotting functions for SOM results.

## Usage

```
somgrid(xdim = 8, ydim = 6, topo = c("rectangular", "hexagonal"))

## S3 method for class 'somgrid'
plot(x, type = "p", ...)

## S3 method for class 'SOM'
plot(x, ...)
```

## Arguments

|            |                                                     |
|------------|-----------------------------------------------------|
| xdim, ydim | dimensions of the grid                              |
| topo       | the topology of the grid.                           |
| x          | an object inheriting from class "somgrid" or "SOM". |
| type, ...  | graphical parameters.                               |

**Details**

The class "somgrid" records the coordinates of the grid to be used for (batch or on-line) SOM: this has a plot method.

The plot method for class "SOM" plots a [stars](#) plot of the representative at each grid point.

**Value**

For somgrid, an object of class "somgrid", a list with components

|                  |                                                           |
|------------------|-----------------------------------------------------------|
| pts              | a two-column matrix giving locations for the grid points. |
| xdim, ydim, topo | as in the arguments to somgrid.                           |

## Chapter 20

# The `cluster` package

---

`agnes`

*Agglomerative Nesting (Hierarchical Clustering)*

---

### Description

Computes agglomerative hierarchical clustering of the dataset.

### Usage

```
agnes(x, diss = inherits(x, "dist"), metric = "euclidean",
      stand = FALSE, method = "average", par.method,
      keep.diss = n < 100, keep.data = !diss, trace.lev = 0)
```

### Arguments

|                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>      | <p>data matrix or data frame, or dissimilarity matrix, depending on the value of the <code>diss</code> argument.</p> <p>In case of a matrix or data frame, each row corresponds to an observation, and each column corresponds to a variable. All variables must be numeric. Missing values (NAs) are allowed.</p> <p>In case of a dissimilarity matrix, <code>x</code> is typically the output of <code>daisy</code> or <code>dist</code>. Also a vector with length <math>n*(n-1)/2</math> is allowed (where <math>n</math> is the number of observations), and will be interpreted in the same way as the output of the above-mentioned functions. Missing values (NAs) are not allowed.</p> |
| <code>diss</code>   | <p>logical flag: if TRUE (default for <code>dist</code> or <code>dissimilarity</code> objects), then <code>x</code> is assumed to be a dissimilarity matrix. If FALSE, then <code>x</code> is treated as a matrix of observations by variables.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>metric</code> | <p>character string specifying the metric to be used for calculating dissimilarities between observations. The currently available options are "euclidean" and "manhattan". Euclidean distances are root sum-of-squares of differences, and manhattan distances are the sum of absolute differences. If <code>x</code> is already a dissimilarity matrix, then this argument will be ignored.</p>                                                                                                                                                                                                                                                                                               |
| <code>stand</code>  | <p>logical flag: if TRUE, then the measurements in <code>x</code> are standardized before calculating the dissimilarities. Measurements are standardized for each variable</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

|                                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-----------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                   | (column), by subtracting the variable's mean value and dividing by the variable's mean absolute deviation. If $x$ is already a dissimilarity matrix, then this argument will be ignored.                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>method</code>               | character string defining the clustering method. The six methods implemented are "average" (unweighted pair-group [arithMetic] average method, aka 'UPGMA'), "single" (single linkage), "complete" (complete linkage), "ward" (Ward's method), "weighted" (weighted average linkage, aka 'WPGMA'), its generalization "flexible" which uses (a constant version of) the Lance-Williams formula and the <code>par.method</code> argument, and "gaverage" a generalized "average" aka "flexible UPGMA" method also using the Lance-Williams formula and <code>par.method</code> .<br>The default is "average". |
| <code>par.method</code>           | If <code>method</code> is "flexible" or "gaverage", a numeric vector of length 1, 3, or 4, (with a default for "gaverage"), see in the details section.                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>keep.diss, keep.data</code> | logicals indicating if the dissimilarities and/or input data $x$ should be kept in the result. Setting these to FALSE can give much smaller results and hence even save memory allocation <i>time</i> .                                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>trace.lev</code>            | integer specifying a trace level for printing diagnostics during the algorithm. Default 0 does not print anything; higher values print increasingly more.                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

## Details

`agnes` is fully described in chapter 5 of Kaufman and Rousseeuw (1990). Compared to other agglomerative clustering methods such as `hclust`, `agnes` has the following features: (a) it yields the agglomerative coefficient (see `agnes.object`) which measures the amount of clustering structure found; and (b) apart from the usual tree it also provides the banner, a novel graphical display (see `plot.agnes`).

The `agnes`-algorithm constructs a hierarchy of clusterings.

At first, each observation is a small cluster by itself. Clusters are merged until only one large cluster remains which contains all the observations. At each stage the two *nearest* clusters are combined to form one larger cluster.

For `method="average"`, the distance between two clusters is the average of the dissimilarities between the points in one cluster and the points in the other cluster.

In `method="single"`, we use the smallest dissimilarity between a point in the first cluster and a point in the second cluster (nearest neighbor method).

When `method="complete"`, we use the largest dissimilarity between a point in the first cluster and a point in the second cluster (furthest neighbor method).

The `method="flexible"` allows (and requires) more details: The Lance-Williams formula specifies how dissimilarities are computed when clusters are agglomerated (equation (32) in K&R(1990), p.237). If clusters  $C_1$  and  $C_2$  are agglomerated into a new cluster, the dissimilarity between their union and another cluster  $Q$  is given by

$$D(C_1 \cup C_2, Q) = \alpha_1 * D(C_1, Q) + \alpha_2 * D(C_2, Q) + \beta * D(C_1, C_2) + \gamma * |D(C_1, Q) - D(C_2, Q)|,$$

where the four coefficients  $(\alpha_1, \alpha_2, \beta, \gamma)$  are specified by the vector `par.method`, either directly as vector of length 4, or (more conveniently) if `par.method` is of length 1, say  $= \alpha$ , `par.method` is extended to give the "Flexible Strategy" (K&R(1990), p.236 f) with Lance-Williams coefficients  $(\alpha_1 = \alpha_2 = \alpha, \beta = 1 - 2\alpha, \gamma = 0)$ .

Also, if `length(par.method) == 3`,  $\gamma = 0$  is set.

**Care** and expertise is probably needed when using `method = "flexible"` particularly for the case when `par.method` is specified of longer length than one. Since **cluster** version 2.0, choices leading to invalid merge structures now signal an error (from the C code already). The *weighted average* (`method = "weighted"`) is the same as `method = "flexible", par.method = 0.5`. Further, `method = "single"` is equivalent to `method = "flexible", par.method = c(.5, .5, 0, -.5)`, and `method = "complete"` is equivalent to `method = "flexible", par.method = c(.5, .5, 0, +.5)`.

The `method = "gaverage"` is a generalization of "average", aka "flexible UPGMA" method, and is (a generalization of the approach) detailed in Belbin et al. (1992). As "flexible", it uses the Lance-Williams formula above for dissimilarity updating, but with  $\alpha_1$  and  $\alpha_2$  not constant, but *proportional* to the sizes  $n_1$  and  $n_2$  of the clusters  $C_1$  and  $C_2$  respectively, i.e.,

$$\alpha_j = \alpha'_j \frac{n_1}{n_1 + n_2},$$

where  $\alpha'_1, \alpha'_2$  are determined from `par.method`, either directly as  $(\alpha_1, \alpha_2, \beta, \gamma)$  or  $(\alpha_1, \alpha_2, \beta)$  with  $\gamma = 0$ , or (less flexibly, but more conveniently) as follows:

Belbin et al proposed "flexible beta", i.e. the user would only specify  $\beta$  (as `par.method`), sensibly in

$$-1 \leq \beta < 1,$$

and  $\beta$  determines  $\alpha'_1$  and  $\alpha'_2$  as

$$\alpha'_j = 1 - \beta,$$

and  $\gamma = 0$ .

This  $\beta$  may be specified by `par.method` (as length 1 vector), and if `par.method` is not specified, a default value of -0.1 is used, as Belbin et al recommend taking a  $\beta$  value around -0.1 as a general agglomerative hierarchical clustering strategy.

Note that `method = "gaverage", par.method = 0` (or `par.method = c(1, 1, 0, 0)`) is equivalent to the `agnes()` default method "average".

## Value

an object of class "agnes" (which extends "twins") representing the clustering. See [agnes.object](#) for details, and methods applicable.

## BACKGROUND

Cluster analysis divides a dataset into groups (clusters) of observations that are similar to each other.

**Hierarchical methods** like `agnes`, `diana`, and `mona` construct a hierarchy of clusterings, with the number of clusters ranging from one to the number of observations.

**Partitioning methods** like `pam`, `clara`, and `fanny` require that the number of clusters be given by the user.

## Author(s)

Method "gaverage" has been contributed by Pierre Roudier, Landcare Research, New Zealand.

```
data(votes.repub)
agn1 <- agnes(votes.repub, metric = "manhattan", stand = TRUE)
agn1
plot(agn1)

op <- par(mfrow=c(2,2))
agn2 <- agnes(daisy(votes.repub), diss = TRUE, method = "complete")
plot(agn2)
## alpha = 0.625 ==> beta = -1/4 is "recommended" by some
agnS <- agnes(votes.repub, method = "flexible", par.meth = 0.625)
plot(agnS)
par(op)

## "show" equivalence of three "flexible" special cases
d.vr <- daisy(votes.repub)
a.wgt <- agnes(d.vr, method = "weighted")
a.sing <- agnes(d.vr, method = "single")
a.comp <- agnes(d.vr, method = "complete")
iC <- -(6:7) # not using 'call' and 'method' for comparisons
stopifnot(
  all.equal(a.wgt[iC], agnes(d.vr, method="flexible", par.method = 0.5)[iC]) ,
  all.equal(a.sing[iC], agnes(d.vr, method="flex", par.method= c(.5,.5,0, -.5))[iC]),
  all.equal(a.comp[iC], agnes(d.vr, method="flex", par.method= c(.5,.5,0, +.5))[iC]))

## Exploring the dendrogram structure
(d2 <- as.dendrogram(agn2)) # two main branches
d2[[1]] # the first branch
d2[[2]] # the 2nd one { 8 + 42 = 50 }
d2[[1]][[1]]# first sub-branch of branch 1 .. and shorter form
identical(d2[[c(1,1)]],
          d2[[1]][[1]])
## a "textual picture" of the dendrogram :
str(d2)

data(agriculture)
```

```
## Plot similar to Figure 7 in ref
## Not run: plot(agnes(agriculture), ask = TRUE)

data(animals)
aa.a <- agnes(animals) # default method = "average"
aa.ga <- agnes(animals, method = "gaverage")
op <- par(mfcol=1:2, mgp=c(1.5, 0.6, 0), mar=c(.1+ c(4,3,2,1)),
          cex.main=0.8)
plot(aa.a, which.plot = 2)
plot(aa.ga, which.plot = 2)
par(op)

## Show how "gaverage" is a "generalized average":
aa.ga.0 <- agnes(animals, method = "gaverage", par.method = 0)
stopifnot(all.equal(aa.ga.0[iC], aa.a[iC]))
```

---

agnes.object

*Agglomerative Nesting (AGNES) Object*

---

## Description

The objects of class "agnes" represent an agglomerative hierarchical clustering of a dataset.

## Value

A legitimate agnes object is a list with the following components:

|           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| order     | a vector giving a permutation of the original observations to allow for plotting, in the sense that the branches of a clustering tree will not cross.                                                                                                                                                                                                                                                                                                                                                                                                             |
| order.lab | a vector similar to order, but containing observation labels instead of observation numbers. This component is only available if the original observations were labelled.                                                                                                                                                                                                                                                                                                                                                                                         |
| height    | a vector with the distances between merging clusters at the successive stages.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| ac        | the agglomerative coefficient, measuring the clustering structure of the dataset. For each observation $i$ , denote by $m(i)$ its dissimilarity to the first cluster it is merged with, divided by the dissimilarity of the merger in the final step of the algorithm. The <code>ac</code> is the average of all $1 - m(i)$ . It can also be seen as the average width (or the percentage filled) of the banner plot. Because <code>ac</code> grows with the number of observations, this measure should not be used to compare datasets of very different sizes. |
| merge     | an $(n-1)$ by 2 matrix, where $n$ is the number of observations. Row $i$ of <code>merge</code> describes the merging of clusters at step $i$ of the clustering. If a number $j$ in the row is negative, then the single observation $ j $ is merged at this stage. If $j$ is positive, then the merger is with the cluster formed at stage $j$ of the algorithm.                                                                                                                                                                                                  |
| diss      | an object of class "dissimilarity" (see <a href="#">dissimilarity.object</a> ), representing the total dissimilarity matrix of the dataset.                                                                                                                                                                                                                                                                                                                                                                                                                       |
| data      | a matrix containing the original or standardized measurements, depending on the <code>stand</code> option of the function <code>agnes</code> . If a dissimilarity matrix was given as input structure, then this component is not available.                                                                                                                                                                                                                                                                                                                      |

GENERATION

This class of objects is returned from `agnes`.

METHODS

The "agnes" class has methods for the following generic functions: `print`, `summary`, `plot`, and `as.dendrogram`.  
In addition, `cutree(x, *)` can be used to “cut” the dendrogram in order to produce cluster assignments.

INHERITANCE

The class "agnes" inherits from "twins". Therefore, the generic functions `pltree` and `as.hclust` are available for agnes objects. After applying `as.hclust()`, all *its* methods are available, of course.

See Also

`agnes`, `diana`, `as.hclust`, `hclust`, `plot.agnes`, `twins.object`, `cutree`.

Examples

```
data(agriculture)
ag.ag <- agnes(agriculture)
class(ag.ag)
pltree(ag.ag) # the dendrogram

## cut the dendrogram -> get cluster assignments:
(ck3 <- cutree(ag.ag, k = 3))
(ch6 <- cutree(as.hclust(ag.ag), h = 6))
stopifnot(identical(unname(ch6), ck3))
```

---

|             |                                               |
|-------------|-----------------------------------------------|
| agriculture | <i>European Union Agricultural Workforces</i> |
|-------------|-----------------------------------------------|

---

Description

Gross National Product (GNP) per capita and percentage of the population working in agriculture for each country belonging to the European Union in 1993.

Usage

```
data(agriculture)
```

Format

A data frame with 12 observations on 2 variables:

|        |   |         |                           |
|--------|---|---------|---------------------------|
| [ , 1] | x | numeric | per capita GNP            |
| [ , 2] | y | numeric | percentage in agriculture |

The row names of the data frame indicate the countries.

**Details**

The data seem to show two clusters, the “more agricultural” one consisting of Greece, Portugal, Spain, and Ireland.

**Source**

Eurostat (European Statistical Agency, 1994): *Cijfers en feiten: Een statistisch portret van de Europese Unie*.

**References**

see those in [agnes](#).

**See Also**

[agnes](#), [daisy](#), [diana](#).

**Examples**

```
data(agriculture)

## Compute the dissimilarities using Euclidean metric and without
## standardization
daisy(agriculture, metric = "euclidean", stand = FALSE)

## 2nd plot is similar to Figure 3 in Struyf et al (1996)
plot(pam(agriculture, 2))

## Plot similar to Figure 7 in Struyf et al (1996)
## Not run: plot(agnes(agriculture), ask = TRUE)

## Plot similar to Figure 8 in Struyf et al (1996)
## Not run: plot(diana(agriculture), ask = TRUE)
```

---

animals

*Attributes of Animals*

---

**Description**

This data set considers 6 binary attributes for 20 animals.

**Usage**

```
data(animals)
```

**Format**

A data frame with 20 observations on 6 variables:

|        |     |                |
|--------|-----|----------------|
| [ , 1] | war | warm-blooded   |
| [ , 2] | fly | can fly        |
| [ , 3] | ver | vertebrate     |
| [ , 4] | end | endangered     |
| [ , 5] | gro | live in groups |
| [ , 6] | hai | have hair      |

All variables are encoded as 1 = 'no', 2 = 'yes'.

**Details**

This dataset is useful for illustrating monothetic (only a single variable is used for each split) hierarchical clustering.

**Source**

Leonard Kaufman and Peter J. Rousseeuw (1990): *Finding Groups in Data* (pp 297ff). New York: Wiley.

**References**

see Struyf, Hubert & Rousseeuw (1996), in [agnes](#).

**Examples**

```
data(animals)
apply(animals, 2, table) # simple overview

ma <- mona(animals)
ma
## Plot similar to Figure 10 in Struyf et al (1996)
plot(ma)
```

---

bannerplot

*Plot Banner (of Hierarchical Clustering)*

---

**Description**

Draws a “banner”, i.e. basically a horizontal [barplot](#) visualizing the (agglomerative or divisive) hierarchical clustering or an other binary dendrogram structure.

**Usage**

```
bannerplot(x, w = rev(x$height), fromLeft = TRUE,
           main=NULL, sub=NULL, xlab = "Height", adj = 0,
           col = c(2, 0), border = 0, axes = TRUE, frame.plot = axes,
           rev.xax = !fromLeft, xax.pretty = TRUE,
           labels = NULL, nmax.lab = 35, max.strlen = 5,
           yax.do = axes && length(x$order) <= nmax.lab,
           yaxRight = fromLeft, y.mar = 2.4 + max.strlen/2.5, ...)
```

**Arguments**

|                         |                                                                                                                                                                                   |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>          | a list with components <code>order</code> , <code>order.lab</code> and <code>height</code> when <code>w</code> , the next argument is not specified.                              |
| <code>w</code>          | non-negative numeric vector of bar widths.                                                                                                                                        |
| <code>fromLeft</code>   | logical, indicating if the banner is from the left or not.                                                                                                                        |
| <code>main, sub</code>  | main and sub titles, see <a href="#">title</a> .                                                                                                                                  |
| <code>xlab</code>       | x axis label (with ‘correct’ default e.g. for <code>plot.agnes</code> ).                                                                                                          |
| <code>adj</code>        | passed to <a href="#">title</a> ( <code>main, sub</code> ) for string adjustment.                                                                                                 |
| <code>col</code>        | vector of length 2, for two horizontal segments.                                                                                                                                  |
| <code>border</code>     | color for bar border; now defaults to background (no border).                                                                                                                     |
| <code>axes</code>       | logical indicating if axes (and labels) should be drawn at all.                                                                                                                   |
| <code>frame.plot</code> | logical indicating the banner should be framed; mainly used when <code>border = 0</code> (as per default).                                                                        |
| <code>rev.xax</code>    | logical indicating if the x axis should be reversed (as in <code>plot.diana</code> ).                                                                                             |
| <code>xax.pretty</code> | logical or integer indicating if <a href="#">pretty()</a> should be used for the x axis. <code>xax.pretty = FALSE</code> is mainly for back compatibility.                        |
| <code>labels</code>     | labels to use on y-axis; the default is constructed from <code>x</code> .                                                                                                         |
| <code>nmax.lab</code>   | integer indicating the number of labels which is considered too large for single-name labelling the banner plot.                                                                  |
| <code>max.strlen</code> | positive integer giving the length to which strings are truncated in banner plot labeling.                                                                                        |
| <code>yax.do</code>     | logical indicating if a y axis and banner labels should be drawn.                                                                                                                 |
| <code>yaxRight</code>   | logical indicating if the y axis is on the right or left.                                                                                                                         |
| <code>y.mar</code>      | positive number specifying the margin width to use when banners are labeled (along a y-axis). The default adapts to the string width and optimally would also depend on the font. |
| <code>...</code>        | graphical parameters (see <a href="#">par</a> ) may also be supplied as arguments to this function.                                                                               |

**Note**

This is mainly a utility called from [plot.agnes](#), [plot.diana](#) and [plot.mona](#).

**Author(s)**

Martin Maechler (from original code of Kaufman and Rousseeuw).

**Examples**

```
data(agriculture)
bannerplot(agnes(agriculture), main = "Bannerplot")
```

---

chorSub*Subset of C-horizon of Kola Data*

---

## Description

This is a small rounded subset of the C-horizon data [chorizon](#) from package **mvoutlier**.

## Usage

```
data(chorSub)
```

## Format

A data frame with 61 observations on 10 variables. The variables contain scaled concentrations of chemical elements.

## Details

This data set was produced from `chorizon` via these statements:

```
data(chorizon, package = "mvoutlier")
chorSub <- round(100*scale(chorizon[,101:110]))[190:250,]
storage.mode(chorSub) <- "integer"
colnames(chorSub) <- gsub("_.*", "", colnames(chorSub))
```

## Source

Kola Project (1993-1998)

## See Also

[chorizon](#) in package **mvoutlier** and other Kola data in the same package.

## Examples

```
data(chorSub)
summary(chorSub)
pairs(chorSub, gap= .1)# some outliers
```

|       |                               |
|-------|-------------------------------|
| clara | Clustering Large Applications |
|-------|-------------------------------|

---

**Description**

Computes a "clara" object, a `list` representing a clustering of the data into  $k$  clusters.

**Usage**

```
clara(x, k, metric = c("euclidean", "manhattan", "jaccard"),
      stand = FALSE, cluster.only = FALSE, samples = 5,
      sampsize = min(n, 40 + 2 * k), trace = 0, medoids.x = TRUE,
      keep.data = medoids.x, rngR = FALSE, pamLike = FALSE, correct.d = TRUE)
```

**Arguments**

- |                           |                                                                                                                                                                                                                                                                                                                                                                                                |
|---------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>            | data matrix or data frame, each row corresponds to an observation, and each column corresponds to a variable. All variables must be numeric. Missing values (NAs) are allowed.                                                                                                                                                                                                                 |
| <code>k</code>            | integer, the number of clusters. It is required that $0 < k < n$ where $n$ is the number of observations (i.e., $n = \text{nrow}(x)$ ).                                                                                                                                                                                                                                                        |
| <code>metric</code>       | character string specifying the metric to be used for calculating dissimilarities between observations. The currently available options are "euclidean", "manhattan", and "jaccard".<br>Euclidean distances are root sum-of-squares of differences, and manhattan distances are the sum of absolute differences.                                                                               |
| <code>stand</code>        | logical, indicating if the measurements in <code>x</code> are standardized before calculating the dissimilarities. Measurements are standardized for each variable (column), by subtracting the variable's mean value and dividing by the variable's mean absolute deviation.                                                                                                                  |
| <code>cluster.only</code> | logical; if true, only the clustering will be computed and returned, see details.                                                                                                                                                                                                                                                                                                              |
| <code>samples</code>      | integer, say $N$ , the number of samples to be drawn from the dataset. The default, $N = 5$ , is rather small for historical (and now back compatibility) reasons and we <i>recommend to set samples an order of magnitude larger</i> .                                                                                                                                                        |
| <code>sampsize</code>     | integer, say $j$ , the number of observations in each sample. <code>sampsize</code> should be higher than the number of clusters ( $k$ ) and at most the number of observations ( $n = \text{nrow}(x)$ ). While computational effort is proportional to $j^2$ , see note below, it may still be advisable to set $j = \text{sampsize}$ to a <i>larger</i> value than the (historical) default. |
| <code>trace</code>        | integer indicating a <i>trace level</i> for diagnostic output during the algorithm.                                                                                                                                                                                                                                                                                                            |
| <code>medoids.x</code>    | logical indicating if the medoids should be returned, identically to some rows of the input data <code>x</code> . If FALSE, <code>keep.data</code> must be false as well, and the medoid indices, i.e., row numbers of the medoids will still be returned ( <code>i.med</code> component), and the algorithm saves space by needing one copy less of <code>x</code> .                          |
| <code>keep.data</code>    | logical indicating if the ( <i>scaled</i> if <code>stand</code> is true) data should be kept in the result.<br>Setting this to FALSE saves memory (and hence time), but disables <code>clusplot()</code> ing of the result. Use <code>medoids.x = FALSE</code> to save even more memory.                                                                                                       |

|                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>rngR</code>      | logical indicating if R's random number generator should be used instead of the primitive <code>clara()</code> -builtin one. If true, this also means that each call to <code>clara()</code> returns a different result – though only slightly different in good situations.                                                                                                                                                                                                                                                 |
| <code>pamLike</code>   | logical indicating if the “swap” phase (see <a href="#">pam</a> , in C code) should use the same algorithm as <a href="#">pam()</a> . Note that from Kaufman and Rousseeuw's description this <i>should</i> have been true always, but as the original Fortran code and the subsequent port to C has always contained a small one-letter change (a typo according to Martin Maechler) with respect to PAM, the default, <code>pamLike = FALSE</code> has been chosen to remain back compatible rather than “PAM compatible”. |
| <code>correct.d</code> | logical or integer indicating that—only in the case of NAs present in <code>x</code> —the correct distance computation should be used instead of the wrong formula which has been present in the original Fortran code and been in use up to early 2016.<br>Because the new correct formula is not back compatible, for the time being, a warning is signalled in this case, unless the user explicitly specifies <code>correct.d</code> .                                                                                   |

### Details

`clara` is fully described in chapter 3 of Kaufman and Rousseeuw (1990). Compared to other partitioning methods such as `pam`, it can deal with much larger datasets. Internally, this is achieved by considering sub-datasets of fixed size (`sampsize`) such that the time and storage requirements become linear in  $n$  rather than quadratic.

Each sub-dataset is partitioned into  $k$  clusters using the same algorithm as in [pam](#).

Once  $k$  representative objects have been selected from the sub-dataset, each observation of the entire dataset is assigned to the nearest medoid.

The mean (equivalent to the sum) of the dissimilarities of the observations to their closest medoid is used as a measure of the quality of the clustering. The sub-dataset for which the mean (or sum) is minimal, is retained. A further analysis is carried out on the final partition.

Each sub-dataset is forced to contain the medoids obtained from the best sub-dataset until then. Randomly drawn observations are added to this set until `sampsize` has been reached.

When `cluster.only` is true, the result is simply a (possibly named) integer vector specifying the clustering, i.e.,

`clara(x, k, cluster.only=TRUE)` is the same as  
`clara(x, k)$clustering` but computed more efficiently.

### Value

If `cluster.only` is false (as by default), an object of class "`clara`" representing the clustering. See [clara.object](#) for details.

If `cluster.only` is true, the result is the "clustering", an integer vector of length  $n$  with entries from  $1:k$ .

### Note

By default, the random sampling is implemented with a *very* simple scheme (with period  $2^{16} = 65536$ ) inside the Fortran code, independently of R's random number generation, and as a matter of fact, deterministically. Alternatively, we recommend setting `rngR = TRUE` which uses R's random number generators. Then, `clara()` results are made reproducible typically by using [set.seed\(\)](#) before calling `clara`.

The storage requirement of clara computation (for small  $k$ ) is about  $O(n \times p) + O(j^2)$  where  $j = \text{sampsiz}$ e, and  $(n, p) = \text{dim}(x)$ . The CPU computing time (again assuming small  $k$ ) is about  $O(n \times p \times j^2 \times N)$ , where  $N = \text{samples}$ .

For “small” datasets, the function `pam` can be used directly. What can be considered *small*, is really a function of available computing power, both memory (RAM) and speed. Originally (1990), “small” meant less than 100 observations; in 1997, the authors said “*small (say with fewer than 200 observations)*”; as of 2006, you can use `pam` with several thousand observations.

### Author(s)

Kaufman and Rousseeuw (see `agnes`), originally. Metric “jaccard”: Kamil Kozłowski (@ownedoutcomes.com) and Kamil Jadeszko. All arguments from `trace` on, and most R documentation and all tests by Martin Maechler.

### See Also

`agnes` for background and references; `clara.object`, `pam`, `partition.object`, `plot.partition`.

### Examples

```
## generate 500 objects, divided into 2 clusters.
x <- rbind(cbind(rnorm(200,0,8), rnorm(200,0,8)),
           cbind(rnorm(300,50,8), rnorm(300,50,8)))
clarax <- clara(x, 2, samples=50)
clarax
clarax$clusinfo
## using pamLike=TRUE gives the same (apart from the 'call'):
all.equal(clarax[-8],
          clara(x, 2, samples=50, pamLike = TRUE)[-8])
plot(clarax)

## cluster.only = TRUE -- save some memory/time :
clclus <- clara(x, 2, samples=50, cluster.only = TRUE)
stopifnot(identical(clclus, clarax$clustering))

## 'xclara' is an artificial data set with 3 clusters of 1000 bivariate
## objects each.
data(xclara)
(clx3 <- clara(xclara, 3))
## "better" number of samples
cl.3 <- clara(xclara, 3, samples=100)
## but that did not change the result here:
stopifnot(cl.3$clustering == clx3$clustering)
## Plot similar to Figure 5 in Struyf et al (1996)
## Not run: plot(clx3, ask = TRUE)

## Try 100 times *different* random samples -- for reliability:
nSim <- 100
nCl <- 3 # = no.classes
set.seed(421) # (reproducibility)
cl <- matrix(NA, nrow(xclara), nSim)
for(i in 1:nSim)
  cl[,i] <- clara(xclara, nCl, medoids.x = FALSE, rngR = TRUE)$cluster
```

```

tcl <- apply(cl,1, tabulate, nbins = nCl)
## those that are not always in same cluster (5 out of 3000 for this seed):
(iDoubt <- which(apply(tcl,2, function(n) all(n < nSim))))
if(length(iDoubt)) { # (not for all seeds)
  tabD <- tcl[,iDoubt, drop=FALSE]
  dimnames(tabD) <- list(cluster = paste(1:nCl), obs = format(iDoubt))
  t(tabD) # how many times in which clusters
}

```

---

clara.object

---

*Clustering Large Applications (CLARA) Object*

---

## Description

The objects of class "clara" represent a partitioning of a large dataset into clusters and are typically returned from [clara](#).

## Value

A legitimate clara object is a list with the following components:

|            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| sample     | labels or case numbers of the observations in the best sample, that is, the sample used by the clara algorithm for the final partition.                                                                                                                                                                                                                                                                                                                                                                                                       |
| medoids    | the medoids or representative objects of the clusters. It is a matrix with in each row the coordinates of one medoid. Possibly NULL, namely when the object resulted from <code>clara(*, medoids.x=FALSE)</code> . Use the following <code>i.med</code> in that case.                                                                                                                                                                                                                                                                         |
| i.med      | the <i>indices</i> of the medoids above: <code>medoids &lt;- x[i.med, ]</code> where <code>x</code> is the original data matrix in <code>clara(x, *)</code> .                                                                                                                                                                                                                                                                                                                                                                                 |
| clustering | the clustering vector, see <a href="#">partition.object</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| objective  | the objective function for the final clustering of the entire dataset.                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| clusinfo   | matrix, each row gives numerical information for one cluster. These are the cardinality of the cluster (number of observations), the maximal and average dissimilarity between the observations in the cluster and the cluster's medoid. The last column is the maximal dissimilarity between the observations in the cluster and the cluster's medoid, divided by the minimal dissimilarity between the cluster's medoid and the medoid of any other cluster. If this ratio is small, the cluster is well-separated from the other clusters. |
| diss       | dissimilarity (maybe NULL), see <a href="#">partition.object</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| silinfo    | list with silhouette width information for the best sample, see <a href="#">partition.object</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| call       | generating call, see <a href="#">partition.object</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| data       | matrix, possibly standardized, or NULL, see <a href="#">partition.object</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

## Methods, Inheritance

The "clara" class has methods for the following generic functions: `print`, `summary`.

The class "clara" inherits from "partition". Therefore, the generic functions `plot` and `clusplot` can be used on a clara object.

---

clusGap

*Gap Statistic for Estimating the Number of Clusters*

---

**Description**

`clusGap()` calculates a goodness of clustering measure, the “gap” statistic. For each number of clusters  $k$ , it compares  $\log(W(k))$  with  $E^*[\log(W(k))]$  where the latter is defined via bootstrapping, i.e., simulating from a reference ( $H_0$ ) distribution, a uniform distribution on the hypercube determined by the ranges of  $x$ , after first centering, and then `svd` (aka ‘PCA’)-rotating them when (as by default) `spaceH0 = "scaledPCA"`.

`maxSE(f, SE.f)` determines the location of the **maximum** of  $f$ , taking a “1-SE rule” into account for the `*SE*` methods. The default method `"firstSEmax"` looks for the smallest  $k$  such that its value  $f(k)$  is not more than 1 standard error away from the first local maximum. This is similar but not the same as `"Tibs2001SEmax"`, Tibshirani et al’s recommendation of determining the number of clusters from the gap statistics and their standard deviations.

**Usage**

```
clusGap(x, FUNcluster, K.max, B = 100, d.power = 1,
        spaceH0 = c("scaledPCA", "original"),
        verbose = interactive(), ...)

maxSE(f, SE.f,
      method = c("firstSEmax", "Tibs2001SEmax", "globalSEmax",
                  "firstmax", "globalmax"),
      SE.factor = 1)

## S3 method for class 'clusGap'
print(x, method = "firstSEmax", SE.factor = 1, ...)

## S3 method for class 'clusGap'
plot(x, type = "b", xlab = "k", ylab = expression(Gap[k]),
     main = NULL, do.arrows = TRUE,
     arrowArgs = list(col="red3", length=1/16, angle=90, code=3), ...)
```

**Arguments**

|                         |                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>          | numeric matrix or <a href="#">data.frame</a> .                                                                                                                                                                                                                                                                                                                                                                  |
| <code>FUNcluster</code> | a <a href="#">function</a> which accepts as first argument a (data) matrix like <code>x</code> , second argument, say $k$ , $k \geq 2$ , the number of clusters desired, and returns a <a href="#">list</a> with a component named (or shortened to) <code>cluster</code> which is a vector of length $n = \text{nrow}(x)$ of integers in $1:k$ determining the clustering or grouping of the $n$ observations. |
| <code>K.max</code>      | the maximum number of clusters to consider, must be at least two.                                                                                                                                                                                                                                                                                                                                               |
| <code>B</code>          | integer, number of Monte Carlo (“bootstrap”) samples.                                                                                                                                                                                                                                                                                                                                                           |

|                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| d.power                | a positive integer specifying the power $p$ which is applied to the euclidean distances ( <code>dist</code> ) before they are summed up to give $W(k)$ . The default, <code>d.power = 1</code> , corresponds to the “historical” R implementation, whereas <code>d.power = 2</code> corresponds to what Tibshirani et al had proposed. This was found by Juan Gonzalez, in 2016-02.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| spaceH0                | a <code>character</code> string specifying the space of the $H_0$ distribution (of <i>no</i> cluster). Both <code>"scaledPCA"</code> and <code>"original"</code> use a uniform distribution in a hyper cube and had been mentioned in the reference; <code>"original"</code> been added after a proposal (including code) by Juan Gonzalez.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| verbose                | integer or logical, determining if “progress” output should be printed. The default prints one bit per bootstrap sample.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| ...                    | (for <code>clusGap()</code> ) optionally further arguments for <code>FUNcluster()</code> , see <code>kmeans</code> example below.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| f                      | numeric vector of ‘function values’, of length $K$ , whose (“1 SE respected”) maximum we want.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| SE.f                   | numeric vector of length $K$ of standard errors of <code>f</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| method                 | <p>character string indicating how the “optimal” number of clusters, <math>\hat{k}</math>, is computed from the gap statistics (and their standard deviations), or more generally how the location <math>\hat{k}</math> of the maximum of <math>f_k</math> should be determined.</p> <p><code>"globalmax"</code>: simply corresponds to the global maximum, i.e., is <code>which.max(f)</code></p> <p><code>"firstmax"</code>: gives the location of the first <i>local</i> maximum.</p> <p><code>"Tibs2001SEmax"</code>: uses the criterion, Tibshirani et al (2001) proposed: “the smallest <math>k</math> such that <math>f(k) \geq f(k+1) - s_{k+1}</math>”. Note that this chooses <math>k = 1</math> when all standard deviations are larger than the differences <math>f(k+1) - f(k)</math>.</p> <p><code>"firstSEmax"</code>: location of the first <math>f()</math> value which is not smaller than the first <i>local</i> maximum minus <code>SE.factor * SE.f[]</code>, i.e, within an “f S.E.” range of that maximum (see also <code>SE.factor</code>).</p> <p>This, the default, has been proposed by Martin Maechler in 2012, when adding <code>clusGap()</code> to the <b>cluster</b> package, after having seen the <code>"globalSEmax"</code> proposal (in code) and read the <code>"Tibs2001SEmax"</code> proposal.</p> <p><code>"globalSEmax"</code>: (used in Dudoit and Fridlyand (2002), supposedly following Tibshirani’s proposition): location of the first <math>f()</math> value which is not smaller than the <i>global</i> maximum minus <code>SE.factor * SE.f[]</code>, i.e, within an “f S.E.” range of that maximum (see also <code>SE.factor</code>).</p> <p>See the examples for a comparison in a simple case.</p> |
| SE.factor              | [When <code>method</code> contains <code>"SE"</code> ] Determining the optimal number of clusters, Tibshirani et al. proposed the “1 S.E.”-rule. Using an <code>SE.factor f</code> , the “f S.E.”-rule is used, more generally.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

## Details

The main result `<res>$Tab[, "gap"]` of course is from bootstrapping aka Monte Carlo simulation and hence random, or equivalently, depending on the initial random seed (see `set.seed()`). On the other hand, in our experience, using `B = 500` gives quite precise results such that the gap plot is basically unchanged after an another run.

## Value

`clusGap(.)` returns an object of S3 class `"clusGap"`, basically a list with components

|                         |                                                                                                                                                                                                                                                                                                                                                                    |

## Author(s)

This function is originally based on the functions `gap` of (Bioconductor) package **SAGx** by Per Broberg, `gapStat()` from former package **SLmisc** by Matthias Kohl and ideas from `gap()` and its methods of package **lga** by Justin Harrington.

The current implementation is by Martin Maechler.

The implementation of `spaceH0 = "original"` is based on code proposed by Juan Gonzalez.

gsP.Z <- clusGap(Z, FUN = pam1, K.max = 8, B = 200)
plot(gsP.Z, main = "clusGap(<iid_rnorm_p=3>) ==> k = 1 cluster is optimal")
gsP.Z

```

clusplot

*Bivariate Cluster Plot (of a Partitioning Object)*

## Description

Draws a 2-dimensional “clusplot” (clustering plot) on the current graphics device. The generic function has a default and a partition method.

## Usage

```

clusplot(x, ...)

## S3 method for class 'partition'
clusplot(x, main = NULL, dist = NULL, ...)

```

## Arguments

|                   |                                                                                                                                                                                                                                                                      |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>    | an R object, here, specifically an object of class "partition", e.g. created by one of the functions <a href="#">pam</a> , <a href="#">clara</a> , or <a href="#">fanny</a> .                                                                                        |
| <code>main</code> | title for the plot; when NULL (by default), a title is constructed, using <code>x\$call</code> .                                                                                                                                                                     |
| <code>dist</code> | when <code>x</code> does not have a <code>diss</code> nor a <code>data</code> component, e.g., for <a href="#">pam</a> ( <code>dist(*)</code> , <code>keep.diss=FALSE</code> ), <code>dist</code> must specify the dissimilarity for the clusplot.                   |
| <code>...</code>  | optional arguments passed to methods, notably the <a href="#">clusplot.default</a> method (except for the <code>diss</code> one) may also be supplied to this function. Many graphical parameters (see <a href="#">par</a> ) may also be supplied as arguments here. |

## Details

The `clusplot.partition()` method relies on [clusplot.default](#).

If the clustering algorithms [pam](#), [fanny](#) and [clara](#) are applied to a data matrix of observations-by-variables then a clusplot of the resulting clustering can always be drawn. When the data matrix contains missing values and the clustering is performed with [pam](#) or [fanny](#), the dissimilarity matrix will be given as input to `clusplot`. When the clustering algorithm [clara](#) was applied to a data matrix with NAs then `clusplot` will replace the missing values as described in [clusplot.default](#), because a dissimilarity matrix is not available.

**Value**

For the partition (and default) method: An invisible list with components `Distances` and `Shading`, as for `clusplot.default`, see there.

**Side Effects**

a 2-dimensional clusplot is created on the current graphics device.

**See Also**

`clusplot.default` for references; `partition.object`, `pam`, `pam.object`, `clara`, `clara.object`, `fanny`, `fanny.object`, `par`.

**Examples**

```
## For more, see ?clusplot.default

## generate 25 objects, divided into 2 clusters.
x <- rbind(cbind(rnorm(10,0,0.5), rnorm(10,0,0.5)),
           cbind(rnorm(15,5,0.5), rnorm(15,5,0.5)))
clusplot(pam(x, 2))
## add noise, and try again :
x4 <- cbind(x, rnorm(25), rnorm(25))
clusplot(pam(x4, 2))
```

|-------------------------------|---------------------------------------------------------|
| <code>clusplot.default</code> | <i>Bivariate Cluster Plot (clusplot) Default Method</i> |
|-------------------------------|---------------------------------------------------------|

---

**Description**

Creates a bivariate plot visualizing a partition (clustering) of the data. All observation are represented by points in the plot, using principal components or multidimensional scaling. Around each cluster an ellipse is drawn.

**Usage**

```
## Default S3 method:
clusplot(x, clus, diss = FALSE,
         s.x.2d = mkCheckX(x, diss), stand = FALSE,
         lines = 2, shade = FALSE, color = FALSE,
         labels = 0, plotchar = TRUE,
         col.p = "dark green", col.txt = col.p,
         col.clus = if(color) c(2, 4, 6, 3) else 5, cex = 1, cex.txt = cex,
         span = TRUE,
         add = FALSE,
         xlim = NULL, ylim = NULL,
         main = paste("CLUSPLOT(", deparse(substitute(x)), ")"),
         sub = paste("These two components explain",
                     round(100 * var.dec, digits = 2), "% of the point variability."),
         xlab = "Component 1", ylab = "Component 2",
         verbose = getOption("verbose"),
         ...)
```

## Arguments

|                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>      | <p>matrix or data frame, or dissimilarity matrix, depending on the value of the <code>diss</code> argument.</p> <p>In case of a matrix (alike), each row corresponds to an observation, and each column corresponds to a variable. All variables must be numeric. Missing values (NAs) are allowed. They are replaced by the median of the corresponding variable. When some variables or some observations contain only missing values, the function stops with a warning message.</p> <p>In case of a dissimilarity matrix, <code>x</code> is the output of <code>daisy</code> or <code>dist</code> or a symmetric matrix. Also, a vector of length <math>n * (n - 1) / 2</math> is allowed (where <math>n</math> is the number of observations), and will be interpreted in the same way as the output of the above-mentioned functions. Missing values (NAs) are not allowed.</p>                                                                                                                                                                               |
| <code>clus</code>   | <p>a vector of length <math>n</math> representing a clustering of <code>x</code>. For each observation the vector lists the number or name of the cluster to which it has been assigned. <code>clus</code> is often the clustering component of the output of <code>pam</code>, <code>fanny</code> or <code>clara</code>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <code>diss</code>   | <p>logical indicating if <code>x</code> will be considered as a dissimilarity matrix or a matrix of observations by variables (see <code>x</code> argument above).</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <code>s.x.2d</code> | <p>a <code>list</code> with components named <code>x</code> (a <math>n \times 2</math> matrix; typically something like principal components of original data), <code>labs</code> and <code>var.dec</code>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>stand</code>  | <p>logical flag: if true, then the representations of the <math>n</math> observations in the 2-dimensional plot are standardized.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>lines</code>  | <p>integer out of 0, 1, 2, used to obtain an idea of the distances between ellipses. The distance between two ellipses E1 and E2 is measured along the line connecting the centers <math>m1</math> and <math>m2</math> of the two ellipses.</p> <p>In case E1 and E2 overlap on the line through <math>m1</math> and <math>m2</math>, no line is drawn. Otherwise, the result depends on the value of <code>lines</code>: If</p> <p><b>lines = 0</b>, no distance lines will appear on the plot;</p> <p><b>lines = 1</b>, the line segment between <math>m1</math> and <math>m2</math> is drawn;</p> <p><b>lines = 2</b>, a line segment between the boundaries of E1 and E2 is drawn (along the line connecting <math>m1</math> and <math>m2</math>).</p>                                                                                                                                                                                                                                                                                                          |
| <code>shade</code>  | <p>logical flag: if TRUE, then the ellipses are shaded in relation to their density. The density is the number of points in the cluster divided by the area of the ellipse.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>color</code>  | <p>logical flag: if TRUE, then the ellipses are colored with respect to their density. With increasing density, the colors are light blue, light green, red and purple. To see these colors on the graphics device, an appropriate color scheme should be selected (we recommend a white background).</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>labels</code> | <p>integer code, currently one of 0,1,2,3,4 and 5. If</p> <p><b>labels= 0</b>, no labels are placed in the plot;</p> <p><b>labels= 1</b>, points and ellipses can be identified in the plot (see <code>identify</code>);</p> <p><b>labels= 2</b>, all points and ellipses are labelled in the plot;</p> <p><b>labels= 3</b>, only the points are labelled in the plot;</p> <p><b>labels= 4</b>, only the ellipses are labelled in the plot.</p> <p><b>labels= 5</b>, the ellipses are labelled in the plot, and points can be identified.</p> <p>The levels of the vector <code>clus</code> are taken as labels for the clusters. The labels of the points are the rownames of <code>x</code> if <code>x</code> is matrix like. Otherwise (<code>diss = TRUE</code>), <code>x</code> is a vector, point labels can be attached to <code>x</code> as a "Labels" attribute (<code>attr(x, "Labels")</code>), as is done for the output of <code>daisy</code>.</p> <p>A possible <code>names</code> attribute of <code>clus</code> will not be taken into account.</p> |

|              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| plotchar     | logical flag: if TRUE, then the plotting symbols differ for points belonging to different clusters.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| span         | logical flag: if TRUE, then each cluster is represented by the ellipse with smallest area containing all its points. (This is a special case of the minimum volume ellipsoid.)<br>If FALSE, the ellipse is based on the mean and covariance matrix of the same points. While this is faster to compute, it often yields a much larger ellipse.<br>There are also some special cases: When a cluster consists of only one point, a tiny circle is drawn around it. When the points of a cluster fall on a straight line, span=FALSE draws a narrow ellipse around it and span=TRUE gives the exact line segment. |
| add          | logical indicating if ellipses (and labels if labels is true) should be <i>added</i> to an already existing plot. If false, neither a <code>title</code> or sub title, see <code>sub</code> , is written.                                                                                                                                                                                                                                                                                                                                                                                                       |
| col.p        | color code(s) used for the observation points.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| col.txt      | color code(s) used for the labels (if labels >= 2).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| col.clus     | color code for the ellipses (and their labels); only one if color is false (as per default).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| cex, cex.txt | character <b>expansion</b> (size), for the point symbols and point labels, respectively.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| xlim, ylim   | numeric vectors of length 2, giving the x- and y- ranges as in <code>plot.default</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| main         | main title for the plot; by default, one is constructed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| sub          | sub title for the plot; by default, one is constructed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| xlab, ylab   | x- and y- axis labels for the plot, with defaults.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| verbose      | a logical indicating, if there should be extra diagnostic output; mainly for ‘debugging’.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| ...          | Further graphical parameters may also be supplied, see <code>par</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

### Details

clusplot uses function calls `princomp(*, cor = (ncol(x) > 2))` or `cmdscale(*, add=TRUE)`, respectively, depending on `diss` being false or true. These functions are data reduction techniques to represent the data in a bivariate plot.

Ellipses are then drawn to indicate the clusters. The further layout of the plot is determined by the optional arguments.

### Value

An invisible list with components:

|           |                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Distances | When <code>lines</code> is 1 or 2 we obtain a k by k matrix (k is the number of clusters). The element in <code>[i, j]</code> is the distance between ellipse i and ellipse j.<br>If <code>lines = 0</code> , then the value of this component is NA.                                                                                                                                                                  |
| Shading   | A vector of length k (where k is the number of clusters), containing the amount of shading per cluster. Let y be a vector where element i is the ratio between the number of points in cluster i and the area of ellipse i. When the cluster i is a line segment, y[i] and the density of the cluster are set to NA. Let z be the sum of all the elements of y without the NAs. Then we put shading = $y/z * 37 + 3$ . |

### Side Effects

a visual display of the clustering is plotted on the current graphics device.

**Note**

When we have 4 or fewer clusters, then the `color=TRUE` gives every cluster a different color. When there are more than 4 clusters, `clusplot` uses the function `pam` to cluster the densities into 4 groups such that ellipses with nearly the same density get the same color. `col.clus` specifies the colors used.

The `col.p` and `col.txt` arguments, added for R, are recycled to have length the number of observations. If `col.p` has more than one value, using `color = TRUE` can be confusing because of a mix of point and ellipse colors.

**Examples**

```
## plotting votes.diss(dissimilarity) in a bivariate plot and
## partitioning into 2 clusters
data(votes.repub)
votes.diss <- daisy(votes.repub)
pamv <- pam(votes.diss, 2, diss = TRUE)
clusplot(pamv, shade = TRUE)
## is the same as
votes.clus <- pamv$clustering
clusplot(votes.diss, votes.clus, diss = TRUE, shade = TRUE)
## Now look at components 3 and 2 instead of 1 and 2:
str(cMDS <- cmdscale(votes.diss, k=3, add=TRUE))
clusplot(pamv, s.x.2d = list(x=cMDS$points[, c(3,2)],
                           labs=rownames(votes.repub), var.dec=NA),
          shade = TRUE, col.p = votes.clus,
          sub="", xlab = "Component 3", ylab = "Component 2")

clusplot(pamv, col.p = votes.clus, labels = 4) # color points and label ellipses
# "simple" cheap ellipses: larger than minimum volume:
# here they are *added* to the previous plot:
clusplot(pamv, span = FALSE, add = TRUE, col.clus = "midnightblue")

## Setting a small *label* size:
clusplot(votes.diss, votes.clus, diss = TRUE, labels = 3, cex.txt = 0.6)

if(dev.interactive()) { # uses identify() *interactively* :
  clusplot(votes.diss, votes.clus, diss = TRUE, shade = TRUE, labels = 1)
  clusplot(votes.diss, votes.clus, diss = TRUE, labels = 5) # ident. only points
}
```

```
## plotting iris (data frame) in a 2-dimensional plot and partitioning
## into 3 clusters.
data(iris)
iris.x <- iris[, 1:4]
cl3 <- pam(iris.x, 3)$clustering
op <- par(mfrow= c(2,2))
clusplot(iris.x, cl3, color = TRUE)
U <- par("usr")
## zoom in :
rect(0,-1, 2,1, border = "orange", lwd=2)
clusplot(iris.x, cl3, color = TRUE, xlim = c(0,2), ylim = c(-1,1))
box(col="orange",lwd=2); mtext("sub region", font = 4, cex = 2)
## or zoom out :
clusplot(iris.x, cl3, color = TRUE, xlim = c(-4,4), ylim = c(-4,4))

coef.hclust

*Agglomerative / Divisive Coefficient for 'hclust' Objects*

## Description

Computes the “agglomerative coefficient” (aka “divisive coefficient” for [diana](#)), measuring the clustering structure of the dataset.

For each observation  $i$ , denote by  $m(i)$  its dissimilarity to the first cluster it is merged with, divided by the dissimilarity of the merger in the final step of the algorithm. The agglomerative coefficient is the average of all  $1 - m(i)$ . It can also be seen as the average width (or the percentage filled) of the banner plot.

`coefHier()` directly interfaces to the underlying C code, and “proves” that *only* `object$heights` is needed to compute the coefficient.

Because it grows with the number of observations, this measure should not be used to compare datasets of very different sizes.

## Usage

```
coefHier(object)
coef.hclust(object, ...)
## S3 method for class 'hclust'
coef(object, ...)
## S3 method for class 'twins'
coef(object, ...)
```

## Arguments

`object` an object of class “hclust” or “twins”, i.e., typically the result of `hclust(.)`, `agnes(.)`, or `diana(.)`.

Since `coef.hclust` only uses `object$heights`, and `object$merge`, `object` can be any list-like object with appropriate merge and heights components.

For `coefHier`, even only `object$heights` is needed.

... currently unused potential further arguments

### Value

a number specifying the *agglomerative* (or *divisive* for diana objects) coefficient as defined by Kaufman and Rousseeuw, see `agnes.object` \$ `ac` or `diana.object` \$ `dc`.

### Examples

```
data(agriculture)
aa <- agnes(agriculture)
coef(aa) # really just extracts aa$ac
coef(as.hclust(aa)) # recomputes
coefHier(aa) # ditto
```

---

daisy

Dissimilarity Matrix Calculation

---

### Description

Compute all the pairwise dissimilarities (distances) between observations in the data set. The original variables may be of mixed types. In that case, or whenever `metric = "gower"` is set, a generalization of Gower's formula is used, see 'Details' below.

### Usage

```
daisy(x, metric = c("euclidean", "manhattan", "gower"),
      stand = FALSE, type = list(), weights = rep.int(1, p),
      warnBin = warnType, warnAsym = warnType, warnConst = warnType,
      warnType = TRUE)
```

### Arguments

|                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>      | numeric matrix or data frame, of dimension $n \times p$ , say. Dissimilarities will be computed between the rows of <code>x</code> . Columns of mode <code>numeric</code> (i.e. all columns when <code>x</code> is a matrix) will be recognized as interval scaled variables, columns of class <code>factor</code> will be recognized as nominal variables, and columns of class <code>ordered</code> will be recognized as ordinal variables. Other variable types should be specified with the <code>type</code> argument. Missing values (NAs) are allowed.                                                                                                          |
| <code>metric</code> | character string specifying the metric to be used. The currently available options are "euclidean" (the default), "manhattan" and "gower". Euclidean distances are root sum-of-squares of differences, and manhattan distances are the sum of absolute differences.<br><br>"Gower's distance" is chosen by metric "gower" or automatically if some columns of <code>x</code> are not numeric. Also known as Gower's coefficient (1971), expressed as a dissimilarity, this implies that a particular standardisation will be applied to each variable, and the "distance" between two units is the sum of all the variable-specific distances, see the details section. |

|                                                                       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-----------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>stand</code>                                                    | <p>logical flag: if TRUE, then the measurements in <code>x</code> are standardized before calculating the dissimilarities. Measurements are standardized for each variable (column), by subtracting the variable's mean value and dividing by the variable's mean absolute deviation.</p> <p>If not all columns of <code>x</code> are numeric, <code>stand</code> will be ignored and Gower's standardization (based on the <code>range</code>) will be applied in any case, see argument <code>metric</code>, above, and the details section.</p>                                                                                                                      |
| <code>type</code>                                                     | <p>list for specifying some (or all) of the types of the variables (columns) in <code>x</code>. The list may contain the following components: <code>"ordratio"</code> (ratio scaled variables to be treated as ordinal variables), <code>"logratio"</code> (ratio scaled variables that must be logarithmically transformed), <code>"asymm"</code> (asymmetric binary) and <code>"symm"</code> (symmetric binary variables). Each component's value is a vector, containing the names or the numbers of the corresponding columns of <code>x</code>. Variables not mentioned in the <code>type</code> list are interpreted as usual (see argument <code>x</code>).</p> |
| <code>weights</code>                                                  | <p>an optional numeric vector of length <math>p(=n\text{col}(x))</math>; to be used in "case 2" (mixed variables, or <code>metric = "gower"</code>), specifying a weight for each variable (<code>x[, k]</code>) instead of 1 in Gower's original formula.</p>                                                                                                                                                                                                                                                                                                                                                                                                          |
| <code>warnBin</code> , <code>warnAsym</code> , <code>warnConst</code> | <p>logicals indicating if the corresponding type checking warnings should be signalled (when found).</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>warnType</code>                                                 | <p>logical indicating if <i>all</i> the type checking warnings should be active or not.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

## Details

The original version of `daisy` is fully described in chapter 1 of Kaufman and Rousseeuw (1990). Compared to `dist` whose input must be numeric variables, the main feature of `daisy` is its ability to handle other variable types as well (e.g. nominal, ordinal, (a)symmetric binary) even when different types occur in the same data set.

The handling of nominal, ordinal, and (a)symmetric binary data is achieved by using the general dissimilarity coefficient of Gower (1971). If `x` contains any columns of these data-types, both arguments `metric` and `stand` will be ignored and Gower's coefficient will be used as the metric. This can also be activated for purely numeric data by `metric = "gower"`. With that, each variable (column) is first standardized by dividing each entry by the range of the corresponding variable, after subtracting the minimum value; consequently the rescaled variable has range  $[0, 1]$ , exactly.

Note that setting the type to `symm` (symmetric binary) gives the same dissimilarities as using `nominal` (which is chosen for non-ordered factors) only when no missing values are present, and more efficiently.

Note that `daisy` signals a warning when 2-valued numerical variables do not have an explicit `type` specified, because the reference authors recommend to consider using `"asymm"`; the warning may be silenced by `warnBin = FALSE`.

In the `daisy` algorithm, missing values in a row of `x` are not included in the dissimilarities involving that row. There are two main cases,

1. If all variables are interval scaled (and `metric` is *not* `"gower"`), the metric is "euclidean", and  $n_g$  is the number of columns in which neither row  $i$  and  $j$  have NAs, then the dissimilarity  $d(i,j)$  returned is  $\sqrt{p/n_g}$  ( $p = n\text{col}(x)$ ) times the Euclidean distance between the two vectors of length  $n_g$  shortened to exclude NAs. The rule is similar for the "manhattan" metric, except that the coefficient is  $p/n_g$ . If  $n_g = 0$ , the dissimilarity is NA.
2. When some variables have a type other than interval scaled, or if `metric = "gower"` is specified, the dissimilarity between two rows is the weighted mean of the contributions of

each variable. Specifically,

$$d_{ij} = d(i, j) = \frac{\sum_{k=1}^p w_k \delta_{ij}^{(k)} d_{ij}^{(k)}}{\sum_{k=1}^p w_k \delta_{ij}^{(k)}}.$$

In other words,  $d_{ij}$  is a weighted mean of  $d_{ij}^{(k)}$  with weights  $w_k \delta_{ij}^{(k)}$ , where  $w_k = \text{weights}[k]$ ,  $\delta_{ij}^{(k)}$  is 0 or 1, and  $d_{ij}^{(k)}$ , the  $k$ -th variable contribution to the total distance, is a distance between  $x[i, k]$  and  $x[j, k]$ , see below.

The 0-1 weight  $\delta_{ij}^{(k)}$  becomes zero when the variable  $x[, k]$  is missing in either or both rows ( $i$  and  $j$ ), or when the variable is asymmetric binary and both values are zero. In all other situations it is 1.

The contribution  $d_{ij}^{(k)}$  of a nominal or binary variable to the total dissimilarity is 0 if both values are equal, 1 otherwise. The contribution of other variables is the absolute difference of both values, divided by the total range of that variable. Note that “standard scoring” is applied to ordinal variables, i.e., they are replaced by their integer codes  $1 : K$ . Note that this is not the same as using their ranks (since there typically are ties).

As the individual contributions  $d_{ij}^{(k)}$  are in  $[0, 1]$ , the dissimilarity  $d_{ij}$  will remain in this range.

If all weights  $w_k \delta_{ij}^{(k)}$  are zero, the dissimilarity is set to [NA](#).

## Value

an object of class "dissimilarity" containing the dissimilarities among the rows of  $x$ . This is typically the input for the functions `pam`, `fanny`, `agnes` or `diana`. For more details, see [dissimilarity.object](#).

## Background

Dissimilarities are used as inputs to cluster analysis and multidimensional scaling. The choice of metric may have a large impact.

## Author(s)

Anja Struyf, Mia Hubert, and Peter and Rousseeuw, for the original version.

Martin Maechler improved the [NA](#) handling and type specification checking, and extended functionality to `metric = "gower"` and the optional `weights` argument.

---

*Divisive ANALysis Clustering*

---

## Description

Computes a divisive hierarchical clustering of the dataset returning an object of class `diana`.

## Usage

```
diana(x, diss = inherits(x, "dist"), metric = "euclidean", stand = FALSE,
  stop.at.k = FALSE,
  keep.diss = n < 100, keep.data = !diss, trace.lev = 0)
```

## Arguments

|                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>      | <p>data matrix or data frame, or dissimilarity matrix or object, depending on the value of the <code>diss</code> argument.</p> <p>In case of a matrix or data frame, each row corresponds to an observation, and each column corresponds to a variable. All variables must be numeric. Missing values (NAs) <i>are</i> allowed.</p> <p>In case of a dissimilarity matrix, <code>x</code> is typically the output of <code>daisy</code> or <code>dist</code>. Also a vector of length <math>n*(n-1)/2</math> is allowed (where <math>n</math> is the number of observations), and will be interpreted in the same way as the output of the above-mentioned functions. Missing values (NAs) <i>are not</i> allowed.</p> |
| <code>diss</code>   | <p>logical flag: if TRUE (default for <code>dist</code> or dissimilarity objects), then <code>x</code> will be considered as a dissimilarity matrix. If FALSE, then <code>x</code> will be considered as a matrix of observations by variables.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>metric</code> | <p>character string specifying the metric to be used for calculating dissimilarities between observations.</p> <p>The currently available options are "euclidean" and "manhattan". Euclidean distances are root sum-of-squares of differences, and manhattan distances are the</p>                                                                                                                                                                                                                                                                                                                                                                                                                                    |

|                                   |                                                                                                                                                                                                                                                                                                                                             |
|-----------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                   | sum of absolute differences. If $x$ is already a dissimilarity matrix, then this argument will be ignored.                                                                                                                                                                                                                                  |
| <code>stand</code>                | logical; if true, the measurements in $x$ are standardized before calculating the dissimilarities. Measurements are standardized for each variable (column), by subtracting the variable's mean value and dividing by the variable's mean absolute deviation. If $x$ is already a dissimilarity matrix, then this argument will be ignored. |
| <code>stop.at.k</code>            | logical or integer, FALSE by default. Otherwise must be integer, say $k$ , in $\{1, 2, \dots, n\}$ , specifying that the <code>diana</code> algorithm should stop early.<br>Non-default NOT YET IMPLEMENTED.                                                                                                                                |
| <code>keep.diss, keep.data</code> | logicals indicating if the dissimilarities and/or input data $x$ should be kept in the result. Setting these to FALSE can give much smaller results and hence even save memory allocation <i>time</i> .                                                                                                                                     |
| <code>trace.lev</code>            | integer specifying a trace level for printing diagnostics during the algorithm. Default 0 does not print anything; higher values print increasingly more.                                                                                                                                                                                   |

## Details

`diana` is fully described in chapter 6 of Kaufman and Rousseeuw (1990). It is probably unique in computing a divisive hierarchy, whereas most other software for hierarchical clustering is agglomerative. Moreover, `diana` provides (a) the divisive coefficient (see `diana.object`) which measures the amount of clustering structure found; and (b) the banner, a novel graphical display (see `plot.diana`).

The `diana`-algorithm constructs a hierarchy of clusterings, starting with one large cluster containing all  $n$  observations. Clusters are divided until each cluster contains only a single observation.

At each stage, the cluster with the largest diameter is selected. (The diameter of a cluster is the largest dissimilarity between any two of its observations.)

To divide the selected cluster, the algorithm first looks for its most disparate observation (i.e., which has the largest average dissimilarity to the other observations of the selected cluster). This observation initiates the "splinter group". In subsequent steps, the algorithm reassigns observations that are closer to the "splinter group" than to the "old party". The result is a division of the selected cluster into two new clusters.

## Value

an object of class "`diana`" representing the clustering; this class has methods for the following generic functions: `print`, `summary`, `plot`.

Further, the class "`diana`" inherits from "`twins`". Therefore, the generic function `pltree` can be used on a `diana` object, and `as.hclust` and `as.dendrogram` methods are available.

A legitimate `diana` object is a list with the following components:

|                        |                                                                                                                                                                                         |
|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>order</code>     | a vector giving a permutation of the original observations to allow for plotting, in the sense that the branches of a clustering tree will not cross.                                   |
| <code>order.lab</code> | a vector similar to <code>order</code> , but containing observation labels instead of observation numbers. This component is only available if the original observations were labelled. |
| <code>height</code>    | a vector with the diameters of the clusters prior to splitting.                                                                                                                         |
| <code>dc</code>        | the divisive coefficient, measuring the clustering structure of the dataset. For each observation $i$ , denote by $d(i)$ the diameter of the last cluster to which it                   |

|                    |                                                                                                                                                                                                                                                                                                                                                                                                    |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                    | belongs (before being split off as a single observation), divided by the diameter of the whole dataset. The <code>dc</code> is the average of all $1 - d(i)$ . It can also be seen as the average width (or the percentage filled) of the banner plot. Because <code>dc</code> grows with the number of observations, this measure should not be used to compare datasets of very different sizes. |
| <code>merge</code> | an (n-1) by 2 matrix, where n is the number of observations. Row i of <code>merge</code> describes the split at step n-i of the clustering. If a number j in row r is negative, then the single observation  j  is split off at stage n-r. If j is positive, then the cluster that will be splitted at stage n-j (described by row j), is split off at stage n-r.                                  |
| <code>diss</code>  | an object of class "dissimilarity", representing the total dissimilarity matrix of the dataset.                                                                                                                                                                                                                                                                                                    |
| <code>data</code>  | a matrix containing the original or standardized measurements, depending on the <code>stand</code> option of the function <code>agnes</code> . If a dissimilarity matrix was given as input structure, then this component is not available.                                                                                                                                                       |

### See Also

`agnes` also for background and references; `cutree` (and `as.hclust`) for grouping extraction; `daisy`, `dist`, `plot.diana`, `twins.object`.

### Examples

```
data(votes.repub)
dv <- diana(votes.repub, metric = "manhattan", stand = TRUE)
print(dv)
plot(dv)

## Cut into 2 groups:
dv2 <- cutree(as.hclust(dv), k = 2)
table(dv2) # 8 and 42 group members
rownames(votes.repub)[dv2 == 1]

## For two groups, does the metric matter ?
dv0 <- diana(votes.repub, stand = TRUE) # default: Euclidean
dv.2 <- cutree(as.hclust(dv0), k = 2)
table(dv2 == dv.2) ## identical group assignments

str(as.dendrogram(dv0)) # {via as.dendrogram.twins() method}

data(agriculture)
## Plot similar to Figure 8 in ref
## Not run: plot(diana(agriculture), ask = TRUE)
```

---

dissimilarity.object

*Dissimilarity Matrix Object*

---

### Description

Objects of class "dissimilarity" representing the dissimilarity matrix of a dataset.

**Value**

The dissimilarity matrix is symmetric, and hence its lower triangle (column wise) is represented as a vector to save storage space. If the object, is called `do`, and `n` the number of observations, i.e., `n <- attr(do, "Size")`, then for  $i < j \leq n$ , the dissimilarity between (row)  $i$  and  $j$  is `do[n*(i-1) - i*(i-1)/2 + j-i]`. The length of the vector is  $n * (n - 1) / 2$ , i.e., of order  $n^2$ .

"dissimilarity" objects also inherit from class `dist` and can use `dist` methods, in particular, `as.matrix`, such that  $d_{ij}$  from above is just `as.matrix(do)[i, j]`.

The object has the following attributes:

|            |                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Size       | the number of observations in the dataset.                                                                                                                                                                                                                                                                                                                                                                                       |
| Metric     | the metric used for calculating the dissimilarities. Possible values are "euclidean", "manhattan", "mixed" (if variables of different types were present in the dataset), and "unspecified".                                                                                                                                                                                                                                     |
| Labels     | optionally, contains the labels, if any, of the observations of the dataset.                                                                                                                                                                                                                                                                                                                                                     |
| NA.message | optionally, if a dissimilarity could not be computed, because of too many missing values for some observations of the dataset.                                                                                                                                                                                                                                                                                                   |
| Types      | when a mixed metric was used, the types for each variable as one-letter codes (as in the book, e.g. p.54): <ul style="list-style-type: none"> <li><b>A</b> Asymmetric binary</li> <li><b>S</b> Symmetric binary</li> <li><b>N</b> Nominal (factor)</li> <li><b>O</b> Ordinal (ordered factor)</li> <li><b>I</b> Interval scaled (numeric)</li> <li><b>T</b> raTio to be log transformed (positive numeric)</li> <li>.</li> </ul> |

**GENERATION**

`daisy` returns this class of objects. Also the functions `pam`, `clara`, `fanny`, `agnes`, and `diana` return a dissimilarity object, as one component of their return objects.

**METHODS**

The "dissimilarity" class has methods for the following generic functions: `print`, `summary`.

**See Also**

`daisy`, `dist`, `pam`, `clara`, `fanny`, `agnes`, `diana`.

ellipsoidhull

*Compute the Ellipsoid Hull or Spanning Ellipsoid of a Point Set***Description**

Compute the “ellipsoid hull” or “spanning ellipsoid”, i.e. the ellipsoid of minimal volume (‘area’ in 2D) such that all given points lie just inside or on the boundary of the ellipsoid.

**Usage**

```
ellipsoidhull(x, tol=0.01, maxit=5000,
              ret.wt = FALSE, ret.sqdist = FALSE, ret.pr = FALSE)
## S3 method for class 'ellipsoid'
print(x, digits = max(1, getOption("digits") - 2), ...)
```

**Arguments**

**x** the  $n$   $p$ -dimensional points as numeric  $n \times p$  matrix.

**tol** convergence tolerance for Titterton’s algorithm. Setting this to much smaller values may drastically increase the number of iterations needed, and you may want to increase **maxit** as well.

**maxit** integer giving the maximal number of iteration steps for the algorithm.

**ret.wt, ret.sqdist, ret.pr** logicals indicating if additional information should be returned, **ret.wt** specifying the *weights*, **ret.sqdist** the *squared distances* and **ret.pr** the final **probabilities** in the algorithms.

**digits, ...** the usual arguments to `print` methods.

**Details**

The “spanning ellipsoid” algorithm is said to stem from Titterton(1976), in Pison et al (1999) who use it for `clusplot.default`.

The problem can be seen as a special case of the “Min.Vol.” ellipsoid of which a more flexible and general implementation is `cov.mve` in the MASS package.

**Value**

an object of class "ellipsoid", basically a `list` with several components, comprising at least

**cov**  $p \times p$  covariance matrix description the ellipsoid.

**loc**  $p$ -dimensional location of the ellipsoid center.

**d2** average squared radius. Further,  $d2 = t^2$ , where  $t$  is “the value of a t-statistic on the ellipse boundary” (from `ellipse` in the **ellipse** package), and hence, more usefully,  $d2 = qchisq(alpha, df = p)$ , where  $alpha$  is the confidence level for  $p$ -variate normally distributed data with location and covariance **loc** and **cov** to lie inside the ellipsoid.

**wt** the vector of weights iff **ret.wt** was true.

**sqdist** the vector of squared distances iff **ret.sqdist** was true.

**prob** the vector of algorithm probabilities iff **ret.pr** was true.

|                         |                                                                                                           |
|-------------------------|-----------------------------------------------------------------------------------------------------------|
| <code>it</code>         | number of iterations used.                                                                                |
| <code>tol, maxit</code> | just the input argument, see above.                                                                       |
| <code>eps</code>        | the achieved tolerance which is the maximal squared radius minus $p$ .                                    |
| <code>ierr</code>       | error code as from the algorithm; 0 means <i>ok</i> .                                                     |
| <code>conv</code>       | logical indicating if the converged. This is defined as <code>it &lt; maxit &amp;&amp; ierr == 0</code> . |

### Author(s)

Martin Maechler did the present class implementation; Rousseeuw et al did the underlying original code.

### See Also

`predict.ellipsoid` which is also the `predict` method for `ellipsoid` objects. `volume.ellipsoid` for an example of ‘manual’ `ellipsoid` object construction; further `ellipse` from package `ellipse` and `ellipsePoints` from package `sfsmisc`.

`chull` for the convex hull, `clusplot` which makes use of this; `cov.mve`.

### Examples

```
x <- rnorm(100)
xy <- unname(cbind(x, rnorm(100) + 2*x + 10))
exy. <- ellipsoidhull(xy)
exy. # >> calling print.ellipsoid()

plot(xy, main = "ellipsoidhull(<Gauss data>) -- 'spanning points'")
lines(predict(exy.), col="blue")
points(rbind(exy.$loc), col = "red", cex = 3, pch = 13)

exy <- ellipsoidhull(xy, tol = 1e-7, ret.wt = TRUE, ret.sq = TRUE)
str(exy) # had small 'tol', hence many iterations
(ii <- which(zapsmall(exy $ wt) > 1e-6))
## --> only about 4 to 6 "spanning ellipsoid" points
round(exy$wt[ii], 3); sum(exy$wt[ii]) # weights summing to 1
points(xy[ii,], pch = 21, cex = 2,
       col="blue", bg = adjustcolor("blue", 0.25))
```

## Description

Computes a fuzzy clustering of the data into  $k$  clusters.

## Usage

```
fanny(x, k, diss = inherits(x, "dist"), memb.exp = 2,
      metric = c("euclidean", "manhattan", "SqEuclidean"),
      stand = FALSE, iniMem.p = NULL, cluster.only = FALSE,
      keep.diss = !diss && !cluster.only && n < 100,
      keep.data = !diss && !cluster.only,
      maxit = 500, tol = 1e-15, trace.lev = 0)
```

## Arguments

|                       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>        | <p>data matrix or data frame, or dissimilarity matrix, depending on the value of the <code>diss</code> argument.</p> <p>In case of a matrix or data frame, each row corresponds to an observation, and each column corresponds to a variable. All variables must be numeric. Missing values (NAs) are allowed.</p> <p>In case of a dissimilarity matrix, <code>x</code> is typically the output of <code>daisy</code> or <code>dist</code>. Also a vector of length <math>n*(n-1)/2</math> is allowed (where <math>n</math> is the number of observations), and will be interpreted in the same way as the output of the above-mentioned functions. Missing values (NAs) are not allowed.</p> |
| <code>k</code>        | integer giving the desired number of clusters. It is required that $0 < k < n/2$ where $n$ is the number of observations.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>diss</code>     | logical flag: if TRUE (default for <code>dist</code> or dissimilarity objects), then <code>x</code> is assumed to be a dissimilarity matrix. If FALSE, then <code>x</code> is treated as a matrix of observations by variables.                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>memb.exp</code> | number $r$ strictly larger than 1 specifying the <i>membership exponent</i> used in the fit criterion; see the ‘Details’ below. Default: 2 which used to be hardwired inside FANNY.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>metric</code>   | <p>character string specifying the metric to be used for calculating dissimilarities between observations. Options are "euclidean" (default), "manhattan", and "SqEuclidean". Euclidean distances are root sum-of-squares of differences, and manhattan distances are the sum of absolute differences, and "SqEuclidean", the <i>squared</i> euclidean distances are sum-of-squares of differences. Using this last option is equivalent (but somewhat slower) to computing so called “fuzzy C-means”.</p> <p>If <code>x</code> is already a dissimilarity matrix, then this argument will be ignored.</p>                                                                                    |
| <code>stand</code>    | logical; if true, the measurements in <code>x</code> are standardized before calculating the dissimilarities. Measurements are standardized for each variable (column), by subtracting the variable’s mean value and dividing by the variable’s mean absolute deviation. If <code>x</code> is already a dissimilarity matrix, then this argument will be ignored.                                                                                                                                                                                                                                                                                                                             |

|                                   |                                                                                                                                                                                                                                                         |
|-----------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>iniMem.p</code>             | numeric $n \times k$ matrix or NULL (by default); can be used to specify a starting membership matrix, i.e., a matrix of non-negative numbers, each row summing to one.                                                                                 |
| <code>cluster.only</code>         | logical; if true, no silhouette information will be computed and returned, see details.                                                                                                                                                                 |
| <code>keep.diss, keep.data</code> | logicals indicating if the dissimilarities and/or input data $x$ should be kept in the result. Setting these to FALSE can give smaller results and hence also save memory allocation <i>time</i> .                                                      |
| <code>maxit, tol</code>           | maximal number of iterations and default tolerance for convergence (relative convergence of the fit criterion) for the FANNY algorithm. The defaults <code>maxit</code> = 500 and <code>tol</code> = $1e-15$ used to be hardwired inside the algorithm. |
| <code>trace.lev</code>            | integer specifying a trace level for printing diagnostics during the C-internal algorithm. Default 0 does not print anything; higher values print increasingly more.                                                                                    |

## Details

In a fuzzy clustering, each observation is “spread out” over the various clusters. Denote by  $u_{iv}$  the membership of observation  $i$  to cluster  $v$ .

The memberships are nonnegative, and for a fixed observation  $i$  they sum to 1. The particular method `fanny` stems from chapter 4 of Kaufman and Rousseeuw (1990) (see the references in [daisy](#)) and has been extended by Martin Maechler to allow user specified `memb.exp`, `iniMem.p`, `maxit`, `tol`, etc.

Fanny aims to minimize the objective function

$$\sum_{v=1}^k \frac{\sum_{i=1}^n \sum_{j=1}^n u_{iv}^r u_{jv}^r d(i, j)}{2 \sum_{j=1}^n u_{jv}^r}$$

where  $n$  is the number of observations,  $k$  is the number of clusters,  $r$  is the membership exponent `memb.exp` and  $d(i, j)$  is the dissimilarity between observations  $i$  and  $j$ .

Note that  $r \rightarrow 1$  gives increasingly crisper clusterings whereas  $r \rightarrow \infty$  leads to complete fuzzyness. K&R(1990), p.191 note that values too close to 1 can lead to slow convergence. Further note that even the default,  $r = 2$  can lead to complete fuzzyness, i.e., memberships  $u_{iv} \equiv 1/k$ . In that case a warning is signalled and the user is advised to chose a smaller `memb.exp` ( $= r$ ).

Compared to other fuzzy clustering methods, `fanny` has the following features: (a) it also accepts a dissimilarity matrix; (b) it is more robust to the spherical cluster assumption; (c) it provides a novel graphical display, the silhouette plot (see [plot.partition](#)).

## Value

an object of class "fanny" representing the clustering. See [fanny.object](#) for details.

## See Also

[agnes](#) for background and references; [fanny.object](#), [partition.object](#), [plot.partition](#), [daisy](#), [dist](#).

## Examples

```
## generate 10+15 objects in two clusters, plus 3 objects lying
## between those clusters.
x <- rbind(cbind(rnorm(10, 0, 0.5), rnorm(10, 0, 0.5)),
           cbind(rnorm(15, 5, 0.5), rnorm(15, 5, 0.5)),
           cbind(rnorm( 3,3.2,0.5), rnorm( 3,3.2,0.5)))
fannyx <- fanny(x, 2)
## Note that observations 26:28 are "fuzzy" (closer to # 2):
fannyx
summary(fannyx)
plot(fannyx)

(fan.x.15 <- fanny(x, 2, memb.exp = 1.5)) # 'crispier' for obs. 26:28
(fanny(x, 2, memb.exp = 3))               # more fuzzy in general

data(ruspini)
f4 <- fanny(ruspini, 4)
stopifnot(rle(f4$clustering)$lengths == c(20,23,17,15))
plot(f4, which = 1)
## Plot similar to Figure 6 in Stryuf et al (1996)
plot(fanny(ruspini, 5))
```

fanny.object

*Fuzzy Analysis (FANNY) Object*

## Description

The objects of class "fanny" represent a fuzzy clustering of a dataset.

## Value

A legitimate fanny object is a list with the following components:

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| membership  | matrix containing the memberships for each pair consisting of an observation and a cluster.                                                                                                                                                                                                                                                                                                                                                                                                               |
| memb.exp    | the membership exponent used in the fitting criterion.                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| coeff       | Dunn's partition coefficient $F(k)$ of the clustering, where $k$ is the number of clusters. $F(k)$ is the sum of all <i>squared</i> membership coefficients, divided by the number of observations. Its value is between $1/k$ and 1.<br>The normalized form of the coefficient is also given. It is defined as $(F(k) - 1/k)/(1 - 1/k)$ , and ranges between 0 and 1. A low value of Dunn's coefficient indicates a very fuzzy clustering, whereas a value close to 1 indicates a near-crisp clustering. |
| clustering  | the clustering vector of the nearest crisp clustering, see <a href="#">partition.object</a> .                                                                                                                                                                                                                                                                                                                                                                                                             |
| k.crisp     | integer ( $\leq k$ ) giving the number of <i>crisp</i> clusters; can be less than $k$ , where it's recommended to decrease memb.exp.                                                                                                                                                                                                                                                                                                                                                                      |
| objective   | named vector containing the minimal value of the objective function reached by the FANNY algorithm and the relative convergence tolerance tol used.                                                                                                                                                                                                                                                                                                                                                       |
| convergence | named vector with iterations, the number of iterations needed and converged indicating if the algorithm converged (in maxit iterations within convergence tolerance tol).                                                                                                                                                                                                                                                                                                                                 |

- diss            an object of class "dissimilarity", see [partition.object](#).
- call           generating call, see [partition.object](#).
- silinfo        list with silhouette information of the nearest crisp clustering, see [partition.object](#).
- data           matrix, possibly standardized, or NULL, see [partition.object](#).

**GENERATION**

These objects are returned from [fanny](#).

**METHODS**

The "fanny" class has methods for the following generic functions: `print`, `summary`.

**INHERITANCE**

The class "fanny" inherits from "partition". Therefore, the generic functions `plot` and `clusplot` can be used on a fanny object.

**See Also**

[fanny](#),    [print.fanny](#),    [dissimilarity.object](#),    [partition.object](#),  
[plot.partition](#).

---

|        |                               |
|--------|-------------------------------|
| flower | <i>Flower Characteristics</i> |
|--------|-------------------------------|

---

**Description**

8 characteristics for 18 popular flowers.

**Usage**

`data(flower)`

**Format**

A data frame with 18 observations on 8 variables:

|           |         |            |
|-----------|---------|------------|
| [ , "V1"] | factor  | winters    |
| [ , "V2"] | factor  | shadow     |
| [ , "V3"] | factor  | tubers     |
| [ , "V4"] | factor  | color      |
| [ , "V5"] | ordered | soil       |
| [ , "V6"] | ordered | preference |
| [ , "V7"] | numeric | height     |
| [ , "V8"] | numeric | distance   |

- V1** winters, is binary and indicates whether the plant may be left in the garden when it freezes.  
**V2** shadow, is binary and shows whether the plant needs to stand in the shadow.

- V3** tubers, is asymmetric binary and distinguishes between plants with tubers and plants that grow in any other way.
- V4** color, is nominal and specifies the flower's color (1 = white, 2 = yellow, 3 = pink, 4 = red, 5 = blue).
- V5** soil, is ordinal and indicates whether the plant grows in dry (1), normal (2), or wet (3) soil.
- V6** preference, is ordinal and gives someone's preference ranking going from 1 to 18.
- V7** height, is interval scaled, the plant's height in centimeters.
- V8** distance, is interval scaled, the distance in centimeters that should be left between the plants.

## References

```
lower.to.upper.tri.inds
```

*Permute Indices for Triangular Matrices*

---

## Description

Compute index vectors for extracting or reordering of lower or upper triangular matrices that are stored as contiguous vectors.

## Usage

```
lower.to.upper.tri.inds(n)
upper.to.lower.tri.inds(n)
```

## Arguments

**n** integer larger than 1.

## Value

integer vector containing a permutation of  $1:N$  where  $N = n(n-1)/2$ .

## See Also

[upper.tri](#), [lower.tri](#) with a related purpose.

## Examples

```
m5 <- matrix(NA, 5, 5)
m <- m5; m[lower.tri(m)] <- upper.to.lower.tri.inds(5); m
m <- m5; m[upper.tri(m)] <- lower.to.upper.tri.inds(5); m

stopifnot(lower.to.upper.tri.inds(2) == 1,
          lower.to.upper.tri.inds(3) == 1:3,
          upper.to.lower.tri.inds(3) == 1:3,
          sort(upper.to.lower.tri.inds(5)) == 1:10,
          sort(lower.to.upper.tri.inds(6)) == 1:15)
```

mona

*MONothetic Analysis Clustering of Binary Variables*

## Description

Returns a list representing a divisive hierarchical clustering of a dataset with binary variables only.

## Usage

```
mona(x, trace.lev = 0)
```

## Arguments

|                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>         | data matrix or data frame in which each row corresponds to an observation, and each column corresponds to a variable. All variables must be binary. A limited number of missing values (NAs) is allowed. Every observation must have at least one value different from <a href="#">NA</a> . No variable should have half of its values missing. There must be at least one variable which has no missing values. A variable with all its non-missing values identical is not allowed. |
| <code>trace.lev</code> | logical or integer indicating if (and how much) the algorithm should produce progress output.                                                                                                                                                                                                                                                                                                                                                                                         |

## Details

`mona` is fully described in chapter 7 of Kaufman and Rousseeuw (1990). It is “monothetic” in the sense that each division is based on a single (well-chosen) variable, whereas most other hierarchical methods (including `agnes` and `diana`) are “polythetic”, i.e. they use all variables together.

The `mona`-algorithm constructs a hierarchy of clusterings, starting with one large cluster. Clusters are divided until all observations in the same cluster have identical values for all variables.

At each stage, all clusters are divided according to the values of one variable. A cluster is divided into one cluster with all observations having value 1 for that variable, and another cluster with all observations having value 0 for that variable.

The variable used for splitting a cluster is the variable with the maximal total association to the other variables, according to the observations in the cluster to be splitted. The association between variables  $f$  and  $g$  is given by  $a(f,g)*d(f,g) - b(f,g)*c(f,g)$ , where  $a(f,g)$ ,  $b(f,g)$ ,  $c(f,g)$ , and  $d(f,g)$  are the numbers in the contingency table of  $f$  and  $g$ . [That is,  $a(f,g)$  (resp.  $d(f,g)$ ) is the number of observations for which  $f$  and  $g$  both have value 0 (resp. value 1);  $b(f,g)$  (resp.  $c(f,g)$ ) is the number of observations for which  $f$  has value 0 (resp. 1) and  $g$  has value 1 (resp. 0).] The total association of a variable  $f$  is the sum of its associations to all variables.

**Value**

an object of class "mona" representing the clustering. See [mona.object](#) for details.

**Missing Values (NAs)**

The mona-algorithm requires “pure” 0-1 values. However, `mona(x)` allows `x` to contain (not too many) NAs. In a preliminary step, these are “imputed”, i.e., all missing values are filled in. To do this, the same measure of association between variables is used as in the algorithm. When variable `f` has missing values, the variable `g` with the largest absolute association to `f` is looked up. When the association between `f` and `g` is positive, any missing value of `f` is replaced by the value of `g` for the same observation. If the association between `f` and `g` is negative, then any missing value of `f` is replaced by the value of `1-g` for the same observation.

**Note**

In **cluster** versions before 2.0.6, the algorithm entered an infinite loop in the boundary case of one variable, i.e., `ncol(x) == 1`, which currently signals an error (because the algorithm now in C, has not correctly taken account of this special case).

**See Also**

[agnes](#) for background and references; [mona.object](#), [plot.mona](#).

**Examples**

```
data(animals)
ma <- mona(animals)
ma
## Plot similar to Figure 10 in Struyf et al (1996)
plot(ma)

## One place to see if/how error messages are *translated* (to 'de' / 'pl'):
ani.NA <- animals; ani.NA[4,] <- NA
aniNA <- within(animals, { end[2:9] <- NA })
aniN2 <- animals; aniN2[cbind(1:6, c(3, 1, 4:6, 2))] <- NA
ani.non2 <- within(animals, end[7] <- 3 )
ani.idNA <- within(animals, end[!is.na(end)] <- 1 )
try( mona(ani.NA) ) ## error: .. object with all values missing
try( mona(aniNA) ) ## error: .. more than half missing values
try( mona(aniN2) ) ## error: all have at least one missing
try( mona(ani.non2) ) ## error: all must be binary
try( mona(ani.idNA) ) ## error: ditto
```

---

mona.object

---

*Monothetic Analysis (MONA) Object*

---

**Description**

The objects of class "mona" represent the divisive hierarchical clustering of a dataset with only binary variables (measurements). This class of objects is returned from [mona](#).

**Value**

A legitimate `mona` object is a list with the following components:

|                        |                                                                                                                                                                                         |
|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>data</code>      | matrix with the same dimensions as the original data matrix, but with factors coded as 0 and 1, and all missing values replaced.                                                        |
| <code>order</code>     | a vector giving a permutation of the original observations to allow for plotting, in the sense that the branches of a clustering tree will not cross.                                   |
| <code>order.lab</code> | a vector similar to <code>order</code> , but containing observation labels instead of observation numbers. This component is only available if the original observations were labelled. |
| <code>variable</code>  | vector of length <code>n-1</code> where <code>n</code> is the number of observations, specifying the variables used to separate the observations of <code>order</code> .                |
| <code>step</code>      | vector of length <code>n-1</code> where <code>n</code> is the number of observations, specifying the separation steps at which the observations of <code>order</code> are separated.    |

**METHODS**

The "mona" class has methods for the following generic functions: `print`, `summary`, `plot`.

**See Also**

[mona](#) for examples etc, [plot.mona](#).

---

|     |                                    |
|-----|------------------------------------|
| pam | <i>Partitioning Around Medoids</i> |
|-----|------------------------------------|

---

**Description**

Partitioning (clustering) of the data into `k` clusters “around medoids”, a more robust version of K-means.

**Usage**

```
pam(x, k, diss = inherits(x, "dist"),
    metric = c("euclidean", "manhattan"),
    medoids = if(is.numeric(nstart)) "random",
    nstart = if(variant == "faster") 1 else NA,
    stand = FALSE, cluster.only = FALSE,
    do.swap = TRUE,
    keep.diss = !diss && !cluster.only && n < 100,
    keep.data = !diss && !cluster.only,
    variant = c("original", "o_1", "o_2", "f_3", "f_4", "f_5", "faster"),
    pamonce = FALSE, trace.lev = 0)
```

## Arguments

|                                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-----------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>                    | <p>data matrix or data frame, or dissimilarity matrix or object, depending on the value of the <code>diss</code> argument.</p> <p>In case of a matrix or data frame, each row corresponds to an observation, and each column corresponds to a variable. All variables must be numeric. Missing values (NAs) are allowed—as long as every pair of observations has at least one case not missing.</p> <p>In case of a dissimilarity matrix, <code>x</code> is typically the output of <code>daisy</code> or <code>dist</code>. Also a vector of length <math>n*(n-1)/2</math> is allowed (where <math>n</math> is the number of observations), and will be interpreted in the same way as the output of the above-mentioned functions. Missing values (NAs) are <i>not</i> allowed.</p> |
| <code>k</code>                    | positive integer specifying the number of clusters, less than the number of observations.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <code>diss</code>                 | logical flag: if TRUE (default for <code>dist</code> or dissimilarity objects), then <code>x</code> will be considered as a dissimilarity matrix. If FALSE, then <code>x</code> will be considered as a matrix of observations by variables.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>metric</code>               | <p>character string specifying the metric to be used for calculating dissimilarities between observations.</p> <p>The currently available options are "euclidean" and "manhattan". Euclidean distances are root sum-of-squares of differences, and manhattan distances are the sum of absolute differences. If <code>x</code> is already a dissimilarity matrix, then this argument will be ignored.</p>                                                                                                                                                                                                                                                                                                                                                                               |
| <code>medoids</code>              | NULL (default) or length- <code>k</code> vector of integer indices (in $1:n$ ) specifying initial medoids instead of using the 'build' algorithm.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>nstart</code>               | used only when <code>medoids = "random"</code> : specifies the <i>number</i> of random "starts"; this argument corresponds to the one of <code>kmeans()</code> (from R's package <b>stats</b> ).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <code>stand</code>                | logical; if true, the measurements in <code>x</code> are standardized before calculating the dissimilarities. Measurements are standardized for each variable (column), by subtracting the variable's mean value and dividing by the variable's mean absolute deviation. If <code>x</code> is already a dissimilarity matrix, then this argument will be ignored.                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>cluster.only</code>         | logical; if true, only the clustering will be computed and returned, see details.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>do.swap</code>              | logical indicating if the <b>swap</b> phase should happen. The default, TRUE, correspond to the original algorithm. On the other hand, the <b>swap</b> phase is much more computer intensive than the <b>build</b> one for large $n$ , so can be skipped by <code>do.swap = FALSE</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>keep.diss, keep.data</code> | logicals indicating if the dissimilarities and/or input data <code>x</code> should be kept in the result. Setting these to FALSE can give much smaller results and hence even save memory allocation <i>time</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>pamonce</code>              | logical or integer in $0:6$ specifying algorithmic short cuts as proposed by Reynolds et al. (2006), and Schubert and Rousseeuw (2019, 2021) see below.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>variant</code>              | a <code>character</code> string denoting the variant of PAM algorithm to use; a more self-documenting version of <code>pamonce</code> which should be used preferably; note that "faster" not only uses <code>pamonce = 6</code> but also <code>nstart = 1</code> and hence <code>medoids = "random"</code> by default.                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>trace.lev</code>            | integer specifying a trace level for printing diagnostics during the build and swap phase of the algorithm. Default 0 does not print anything; higher values print increasingly more.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

## Details

The basic `pam` algorithm is fully described in chapter 2 of Kaufman and Rousseeuw(1990). Compared to the `k-means` approach in `kmeans`, the function `pam` has the following features: (a) it also accepts a dissimilarity matrix; (b) it is more robust because it minimizes a sum of dissimilarities instead of a sum of squared euclidean distances; (c) it provides a novel graphical display, the silhouette plot (see `plot.partition`) (d) it allows to select the number of clusters using `mean(silhouette(pr)[, "sil_width"])` on the result `pr <- pam(..)`, or directly its component `pr$silinfo$avg.width`, see also [pam.object](#).

When `cluster.only` is true, the result is simply a (possibly named) integer vector specifying the clustering, i.e.,

`pam(x, k, cluster.only=TRUE)` is the same as  
`pam(x, k)$clustering` but computed more efficiently.

The `pam`-algorithm is based on the search for  $k$  representative objects or medoids among the observations of the dataset. These observations should represent the structure of the data. After finding a set of  $k$  medoids,  $k$  clusters are constructed by assigning each observation to the nearest medoid. The goal is to find  $k$  representative objects which minimize the sum of the dissimilarities of the observations to their closest representative object.

By default, when medoids are not specified, the algorithm first looks for a good initial set of medoids (this is called the **build** phase). Then it finds a local minimum for the objective function, that is, a solution such that there is no single switch of an observation with a medoid (i.e. a ‘swap’) that will decrease the objective (this is called the **swap** phase).

When the medoids are specified (or randomly generated), their order does *not* matter; in general, the algorithms have been designed to not depend on the order of the observations.

The `pamonce` option, new in cluster 1.14.2 (Jan. 2012), has been proposed by Matthias Studer, University of Geneva, based on the findings by Reynolds et al. (2006) and was extended by Erich Schubert, TU Dortmund, with the FastPAM optimizations.

The default FALSE (or integer 0) corresponds to the original “swap” algorithm, whereas `pamonce = 1` (or TRUE), corresponds to the first proposal .... and `pamonce = 2` additionally implements the second proposal as well.

The key ideas of ‘FastPAM’ (Schubert and Rousseeuw, 2019) are implemented except for the linear approximate build as follows:

`pamonce = 3`: reduces the runtime by a factor of  $O(k)$  by exploiting that points cannot be closest to all current medoids at the same time.

`pamonce = 4`: additionally allows executing multiple swaps per iteration, usually reducing the number of iterations.

`pamonce = 5`: adds minor optimizations copied from the `pamonce = 2` approach, and is expected to be the fastest of the ‘FastPam’ variants included.

‘FasterPAM’ (Schubert and Rousseeuw, 2021) is implemented via

`pamonce = 6`: execute each swap which improves results immediately, and hence typically multiple swaps per iteration; this swapping algorithm runs in  $O(n^2)$  rather than  $O(n(n - k)k)$  time which is much faster for all but small  $k$ .

In addition, ‘FasterPAM’ uses *random* initialization of the medoids (instead of the ‘*build*’ phase) to avoid the  $O(n^2k)$  initialization cost of the build algorithm. In particular for large  $k$ , this yields a much faster algorithm, while preserving a similar result quality.

One may decide to use *repeated* random initialization by setting `nstart > 1`.

**Value**

an object of class "pam" representing the clustering. See `?pam.object` for details.

**Note**

For large datasets, pam may need too much memory or too much computation time since both are  $O(n^2)$ . Then, `clara()` is preferable, see its documentation.

There is hard limit currently,  $n \leq 65536$ , at  $2^{16}$  because for larger  $n$ ,  $n(n-1)/2$  is larger than the maximal integer (`.Machine$integer.max =  $2^{31} - 1$` ).

**Author(s)**

Kaufman and Rousseeuw's original Fortran code was translated to C and augmented in several ways, e.g. to allow `cluster.only=TRUE` or `do.swap=FALSE`, by Martin Maechler.  
Matthias Studer, Univ.Geneva provided the `pamonce` (1 and 2) implementation.  
Erich Schubert, TU Dortmund contributed the `pamonce` (3 to 6) implementation.

**Examples**

```
## generate 25 objects, divided into 2 clusters.
x <- rbind(cbind(rnorm(10,0,0.5), rnorm(10,0,0.5)),
           cbind(rnorm(15,5,0.5), rnorm(15,5,0.5)))
pamx <- pam(x, 2)
pamx # Medoids: '7' and '25' ...
summary(pamx)
plot(pamx)
## use obs. 1 & 16 as starting medoids -- same result (typically)
(p2m <- pam(x, 2, medoids = c(1,16)))
## no _build_ *and* no _swap_ phase: just cluster all obs. around (1, 16):
p2.s <- pam(x, 2, medoids = c(1,16), do.swap = FALSE)
p2.s

p3m <- pam(x, 3, trace = 2)
## rather stupid initial medoids:
(p3m. <- pam(x, 3, medoids = 3:1, trace = 1))

pam(daisy(x, metric = "manhattan"), 2, diss = TRUE)
```

```
data(ruspini)
## Plot similar to Figure 4 in Stryuf et al (1996)
## Not run: plot(pam(ruspini, 4), ask = TRUE)
```

pam.object

*Partitioning Around Medoids (PAM) Object***Description**

The objects of class "pam" represent a partitioning of a dataset into clusters.

**Value**

A legitimate pam object is a [list](#) with the following components:

|            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| medoids    | the medoids or representative objects of the clusters. If a dissimilarity matrix was given as input to pam, then a vector of numbers or labels of observations is given, else medoids is a <a href="#">matrix</a> with in each row the coordinates of one medoid.                                                                                                                                                                                                                                                    |
| id.med     | integer vector of <i>indices</i> giving the medoid observation numbers.                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| clustering | the clustering vector, see <a href="#">partition.object</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| objective  | the objective function after the first and second step of the pam algorithm.                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| isolation  | vector with length equal to the number of clusters, specifying which clusters are isolated clusters (L- or L*-clusters) and which clusters are not isolated. A cluster is an L*-cluster iff its diameter is smaller than its separation. A cluster is an L-cluster iff for each observation i the maximal dissimilarity between i and any other observation of the cluster is smaller than the minimal dissimilarity between i and any observation of another cluster. Clearly each L*-cluster is also an L-cluster. |
| clusinfo   | matrix, each row gives numerical information for one cluster. These are the cardinality of the cluster (number of observations), the maximal and average dissimilarity between the observations in the cluster and the cluster's medoid, the diameter of the cluster (maximal dissimilarity between two observations of the cluster), and the separation of the cluster (minimal dissimilarity between an observation of the cluster and an observation of another cluster).                                         |
| silinfo    | list with silhouette width information, see <a href="#">partition.object</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| diss       | dissimilarity (maybe NULL), see <a href="#">partition.object</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| call       | generating call, see <a href="#">partition.object</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| data       | (possibly standardized) see <a href="#">partition.object</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

**GENERATION**

These objects are returned from [pam](#).

**METHODS**

The "pam" class has methods for the following generic functions: `print`, `summary`.

## INHERITANCE

The class "pam" inherits from "partition". Therefore, the generic functions `plot` and `clusplot` can be used on a pam object.

## See Also

[pam](#), [dissimilarity.object](#), [partition.object](#), [plot.partition](#).

## Examples

```
## Use the silhouette widths for assessing the best number of clusters,
## following a one-dimensional example from Christian Hennig :
##
x <- c(rnorm(50), rnorm(50,mean=5), rnorm(30,mean=15))
asw <- numeric(20)
## Note that "k=1" won't work!
for (k in 2:20)
  asw[k] <- pam(x, k) $ silinfo $ avg.width
k.best <- which.max(asw)
cat("silhouette-optimal number of clusters:", k.best, "\n")

plot(1:20, asw, type="h", main = "pam() clustering assessment",
     xlab= "k  (# clusters)", ylab = "average silhouette width")
axis(1, k.best, paste("best",k.best,sep="\n"), col = "red", col.axis = "red")
```

---

partition.object      *Partitioning Object*

---

## Description

The objects of class "partition" represent a partitioning of a dataset into clusters.

## Value

a "partition" object is a list with the following (and typically more) components:

- |            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| clustering | the clustering vector. An integer vector of length $n$ , the number of observations, giving for each observation the number ('id') of the cluster to which it belongs.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| call       | the matched <a href="#">call</a> generating the object.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| silinfo    | <p>a list with all <i>silhouette</i> information, only available when the number of clusters is non-trivial, i.e., <math>1 &lt; k &lt; n</math> and then has the following components, see <a href="#">silhouette</a></p> <p><b>widths</b> an <math>(n \times 3)</math> matrix, as returned by <a href="#">silhouette()</a>, with for each observation <math>i</math> the cluster to which <math>i</math> belongs, as well as the neighbor cluster of <math>i</math> (the cluster, not containing <math>i</math>, for which the average dissimilarity between its observations and <math>i</math> is minimal), and the silhouette width <math>s(i)</math> of the observation.</p> <p><b>clus.avg.widths</b> the average silhouette width per cluster.</p> <p><b>avg.width</b> the average silhouette width for the dataset, i.e., simply the average of <math>s(i)</math> over all observations <math>i</math>.</p> |

|                        |                                                                                                                                                                                   |
|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                        | This information is also needed to construct a <i>silhouette plot</i> of the clustering, see <code>plot.partition</code> .                                                        |
|                        | Note that <code>avg.width</code> can be maximized over different clusterings (e.g. with varying number of clusters) to choose an <i>optimal</i> clustering.                       |
| <code>objective</code> | value of criterion maximized during the partitioning algorithm, may more than one entry for different stages.                                                                     |
| <code>diss</code>      | an object of class "dissimilarity", representing the total dissimilarity matrix of the dataset (or relevant subset, e.g. for <code>clara</code> ).                                |
| <code>data</code>      | a matrix containing the original or standardized data. This might be missing to save memory or when a dissimilarity matrix was given as input structure to the clustering method. |

## GENERATION

These objects are returned from `pam`, `clara` or `fanny`.

## METHODS

The "partition" class has a method for the following generic functions: `plot`, `clusplot`.

## INHERITANCE

The following classes inherit from class "partition": "pam", "clara" and "fanny".

See `pam.object`, `clara.object` and `fanny.object` for details.

## See Also

`pam`, `clara`, `fanny`.

|-------------|----------------------------------|
| plantTraits | <i>Plant Species Traits Data</i> |
|-------------|----------------------------------|

---

## Description

This dataset constitutes a description of 136 plant species according to biological attributes (morphological or reproductive)

## Usage

```
data(plantTraits)
```

## Format

A data frame with 136 observations on the following 31 variables.

`pdias` Diaspore mass (mg)

`longindex` Seed bank longevity

`durflow` Flowering duration

`height` Plant height, an ordered factor with levels 1 < 2 < ... < 8.

`begflow` Time of first flowering, an ordered factor with levels 1 < 2 < 3 < 4 < 5 < 6 < 7 < 8 < 9

mycor Mycorrhizas, an ordered factor with levels 0never < 1 sometimes< 2always

vegaer aerial vegetative propagation, an ordered factor with levels 0never < 1 present but limited< 2important.

vegsout underground vegetative propagation, an ordered factor with 3 levels identical to vegaer above.

autopoll selfing pollination, an ordered factor with levels 0never < 1rare < 2 often< the rule3

insects insect pollination, an ordered factor with 5 levels 0 < ... < 4.

wind wind pollination, an ordered factor with 5 levels 0 < ... < 4.

lign a binary factor with levels 0:1, indicating if plant is woody.

piq a binary factor indicating if plant is thorny.

ros a binary factor indicating if plant is rosette.

semiros semi-rosette plant, a binary factor (0: no; 1: yes).

leafy leafy plant, a binary factor.

suman summer annual, a binary factor.

winan winter annual, a binary factor.

monocarp monocarpic perennial, a binary factor.

polycarp polycarpic perennial, a binary factor.

seasaes seasonal aestival leaves, a binary factor.

seashiv seasonal hibernal leaves, a binary factor.

seasver seasonal vernal leaves, a binary factor.

everalw leaves always evergreen, a binary factor.

everparti leaves partially evergreen, a binary factor.

elaio fruits with an elaiosome (dispersed by ants), a binary factor.

endozoo endozoochorous fruits, a binary factor.

epizoo epizoochorous fruits, a binary factor.

aquat aquatic dispersal fruits, a binary factor.

windgl wind dispersed fruits, a binary factor.

unsp unspecialized mechanism of seed dispersal, a binary factor.

### Details

Most of factor attributes are not disjunctive. For example, a plant can be usually pollinated by insects but sometimes self-pollination can occurred.

## Examples

```
data(plantTraits)

## Calculation of a dissimilarity matrix
library(cluster)
dai.b <- daisy(plantTraits,
              type = list(ordratio = 4:11, symm = 12:13, asymm = 14:31))

## Hierarchical classification
agn.trts <- agnes(dai.b, method="ward")
plot(agn.trts, which.plots = 2, cex= 0.6)
plot(agn.trts, which.plots = 1)
cutree6 <- cutree(agn.trts, k=6)
cutree6

## Principal Coordinate Analysis
cmds dai.b <- cmdscale(dai.b, k=6)
plot(cmdsdai.b[, 1:2], asp = 1, col = cutree6)
```

---

plot.agnes

*Plots of an Agglomerative Hierarchical Clustering*

---

## Description

Creates plots for visualizing an agnes object.

## Usage

```
## S3 method for class 'agnes'
plot(x, ask = FALSE, which.plots = NULL, main = NULL,
      sub = paste("Agglomerative Coefficient = ", round(x$ac, digits = 2)),
      adj = 0, nmax.lab = 35, max.strlen = 5, xax.pretty = TRUE, ...)
```

## Arguments

|             |                                                                                                                                                                                                    |
|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x           | an object of class "agnes", typically created by <a href="#">agnes()</a> .                                                                                                                         |
| ask         | logical; if true and which.plots is NULL, plot.agnes operates in interactive mode, via <a href="#">menu</a> .                                                                                      |
| which.plots | integer vector or NULL (default), the latter producing both plots. Otherwise, which.plots must contain integers of 1 for a <i>banner</i> plot or 2 for a dendrogram or “clustering tree”.          |
| main, sub   | main and sub title for the plot, with convenient defaults. See documentation for these arguments in <a href="#">plot.default</a> .                                                                 |
| adj         | for label adjustment in <a href="#">bannerplot()</a> .                                                                                                                                             |
| nmax.lab    | integer indicating the number of labels which is considered too large for single-name labelling the banner plot.                                                                                   |
| max.strlen  | positive integer giving the length to which strings are truncated in banner plot labeling.                                                                                                         |
| xax.pretty  | logical or integer indicating if <a href="#">pretty()</a> ( <code>n = xax.pretty</code> ) should be used for the x axis. <code>xax.pretty = FALSE</code> is for back compatibility.                |
| ...         | graphical parameters (see <a href="#">par</a> ) may also be supplied and are passed to <a href="#">bannerplot()</a> or <a href="#">pltree()</a> (see <a href="#">pltree.twins</a> ), respectively. |

## Details

When `ask = TRUE`, rather than producing each plot sequentially, `plot.agnes` displays a menu listing all the plots that can be produced. If the menu is not desired but a pause between plots is still wanted one must set `par(ask= TRUE)` before invoking the plot command.

The banner displays the hierarchy of clusters, and is equivalent to a tree. See Rousseeuw (1986) or chapter 5 of Kaufman and Rousseeuw (1990). The banner plots distances at which observations and clusters are merged. The observations are listed in the order found by the `agnes` algorithm, and the numbers in the `height` vector are represented as bars between the observations.

The leaves of the clustering tree are the original observations. Two branches come together at the distance between the two clusters being merged.

For more customization of the plots, rather call `bannerplot` and `pltree()`, i.e., its method `pltree.twins`, respectively.

directly with corresponding arguments, e.g., `xlab` or `ylab`.

## Side Effects

Appropriate plots are produced on the current graphics device. This can be one or both of the following choices:

Banner  
Clustering tree

## Note

In the banner plot, observation labels are only printed when the number of observations is limited less than `nmax.lab` (35, by default), for readability. Moreover, observation labels are truncated to maximally `max.strlen` (5) characters.

For the dendrogram, more flexibility than via `pltree()` is provided by `dg <- as.dendrogram(x)` and plotting `dg` via `plot.dendrogram`.

| <code>main, sub</code>   | main and sub title for the plot, each with a convenient default. See documentation for these arguments in <code>plot.default</code> .                                                                  |
| <code>adj</code>         | for label adjustment in <code>bannerplot()</code> .                                                                                                                                                    |
| <code>nmax.lab</code>    | integer indicating the number of labels which is considered too large for single-name labelling the banner plot.                                                                                       |
| <code>max.strlen</code>  | positive integer giving the length to which strings are truncated in banner plot labeling.                                                                                                             |
| <code>xax.pretty</code>  | logical or integer indicating if <code>pretty(*, n = xax.pretty)</code> should be used for the x axis. <code>xax.pretty = FALSE</code> is for back compatibility.                                      |
| <code>...</code>         | graphical parameters (see <code>par</code> ) may also be supplied and are passed to <code>bannerplot()</code> or <code>pltree()</code> , respectively.                                                 |

## Details

When `ask = TRUE`, rather than producing each plot sequentially, `plot.diana` displays a menu listing all the plots that can be produced. If the menu is not desired but a pause between plots is still wanted one must set `par(ask = TRUE)` before invoking the plot command.

The banner displays the hierarchy of clusters, and is equivalent to a tree. See Rousseeuw (1986) or chapter 6 of Kaufman and Rousseeuw (1990). The banner plots the diameter of each cluster being splitted. The observations are listed in the order found by the `diana` algorithm, and the numbers in the `height` vector are represented as bars between the observations.

The leaves of the clustering tree are the original observations. A branch splits up at the diameter of the cluster being splitted.

### Side Effects

An appropriate plot is produced on the current graphics device. This can be one or both of the following choices:

Banner

Clustering tree

### Note

In the banner plot, observation labels are only printed when the number of observations is limited less than `nmax.lab` (35, by default), for readability. Moreover, observation labels are truncated to maximally `max.strlen` (5) characters.

```
example(diana)# -> dv <- diana(...)

plot(dv, which = 1, nmax.lab = 100)

## wider labels :
op <- par(mar = par("mar") + c(0, 2, 0, 0))
plot(dv, which = 1, nmax.lab = 100, max.strlen = 12)
par(op)
```

---

plot.mona

*Banner of Monothetic Divisive Hierarchical Clusterings*

---

### Description

Creates the banner of a `mona` object.

### Usage

```
## S3 method for class 'mona'
plot(x, main = paste("Banner of ", deparse(x$call)),
      sub = NULL, xlab = "Separation step",
      col = c(2, 0), axes = TRUE, adj = 0,
      nmax.lab = 35, max.strlen = 5, ...)
```

**Arguments**

|                         |                                                                                                              |
|-------------------------|--------------------------------------------------------------------------------------------------------------|
| <code>x</code>          | an object of class "mona", typically created by <code>mona ( . )</code> .                                    |
| <code>main, sub</code>  | main and sub titles for the plot, with convenient defaults. See documentation in <code>plot.default</code> . |
| <code>xlab</code>       | x axis label, see <code>title</code> .                                                                       |
| <code>col, adj</code>   | graphical parameters passed to <code>bannerplot ( )</code> .                                                 |
| <code>axes</code>       | logical, indicating if (labeled) axes should be drawn.                                                       |
| <code>nmax.lab</code>   | integer indicating the number of labels which is considered too large for labeling.                          |
| <code>max.strlen</code> | positive integer giving the length to which strings are truncated in labeling.                               |
| <code>...</code>        | further graphical arguments are passed to <code>bannerplot ( )</code> and <code>text</code> .                |

**Details**

Plots the separation step at which clusters are splitted. The observations are given in the order found by the `mona` algorithm, the numbers in the `step` vector are represented as bars between the observations.

When a long bar is drawn between two observations, those observations have the same value for each variable. See chapter 7 of Kaufman and Rousseeuw (1990).

**Side Effects**

A banner is plotted on the current graphics device.

**Note**

In the banner plot, observation labels are only printed when the number of observations is limited less than `nmax.lab` (35, by default), for readability. Moreover, observation labels are truncated to maximally `max.strlen` (5) characters.

**References**

see those in `plot.agnes`.

`mona`, `mona.object`, `par`.

---

`plot.partition`

*Plot of a Partition of the Data Set*

---

**Description**

Creates plots for visualizing a `partition` object.

## Usage

```
## S3 method for class 'partition'
plot(x, ask = FALSE, which.plots = NULL,
      nmax.lab = 40, max.strlen = 5, data = x$data, dist = NULL,
      stand = FALSE, lines = 2,
      shade = FALSE, color = FALSE, labels = 0, plotchar = TRUE,
      span = TRUE, xlim = NULL, ylim = NULL, main = NULL, ...)
```

## Arguments

|                                                                                        |                                                                                                                                                                                                                                   |
|----------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>                                                                         | an object of class "partition", typically created by the functions <a href="#">pam</a> , <a href="#">clara</a> , or <a href="#">fanny</a> .                                                                                       |
| <code>ask</code>                                                                       | logical; if true and <code>which.plots</code> is NULL, <code>plot.partition</code> operates in interactive mode, via <a href="#">menu</a> .                                                                                       |
| <code>which.plots</code>                                                               | integer vector or NULL (default), the latter producing both plots. Otherwise, <code>which.plots</code> must contain integers of 1 for a <i>clusplot</i> or 2 for <i>silhouette</i> .                                              |
| <code>nmax.lab</code>                                                                  | integer indicating the number of labels which is considered too large for single-name labeling the silhouette plot.                                                                                                               |
| <code>max.strlen</code>                                                                | positive integer giving the length to which strings are truncated in silhouette plot labeling.                                                                                                                                    |
| <code>data</code>                                                                      | numeric matrix with the scaled data; per default taken from the partition object <code>x</code> , but can be specified explicitly.                                                                                                |
| <code>dist</code>                                                                      | when <code>x</code> does not have a <code>diss</code> component as for <a href="#">pam</a> (*, keep.diss=FALSE), <code>dist</code> must be the dissimilarity if a <i>clusplot</i> is desired.                                     |
| <code>stand, lines, shade, color, labels, plotchar, span, xlim, ylim, main, ...</code> | All optional arguments available for the <a href="#">clusplot.default</a> function (except for the <code>diss</code> one) and graphical parameters (see <a href="#">par</a> ) may also be supplied as arguments to this function. |

## Details

When `ask=TRUE`, rather than producing each plot sequentially, `plot.partition` displays a menu listing all the plots that can be produced. If the menu is not desired but a pause between plots is still wanted, call `par(ask=TRUE)` before invoking the plot command.

The *clusplot* of a cluster partition consists of a two-dimensional representation of the observations, in which the clusters are indicated by ellipses (see [clusplot.partition](#) for more details).

The *silhouette plot* of a nonhierarchical clustering is fully described in Rousseeuw (1987) and in chapter 2 of Kaufman and Rousseeuw (1990). For each observation *i*, a bar is drawn, representing its silhouette width *s(i)*, see [silhouette](#) for details. Observations are grouped per cluster, starting with cluster 1 at the top. Observations with a large *s(i)* (almost 1) are very well clustered, a small *s(i)* (around 0) means that the observation lies between two clusters, and observations with a negative *s(i)* are probably placed in the wrong cluster.

A clustering can be performed for several values of *k* (the number of clusters). Finally, choose the value of *k* with the largest overall average silhouette width.

## Side Effects

An appropriate plot is produced on the current graphics device. This can be one or both of the following choices:

Clusplot  
Silhouette plot

### Note

In the silhouette plot, observation labels are only printed when the number of observations is less than `nmax.lab` (40, by default), for readability. Moreover, observation labels are truncated to maximally `max.strlen` (5) characters.

For more flexibility, use `plot(silhouette(x), ...)`, see [plot.silhouette](#).

[pam.object](#), [clara](#), [clara.object](#), [fanny](#), [fanny.object](#), [par](#).

### Examples

```
## generate 25 objects, divided into 2 clusters.
x <- rbind(cbind(rnorm(10,0,0.5), rnorm(10,0,0.5)),
           cbind(rnorm(15,5,0.5), rnorm(15,5,0.5)))
plot(pam(x, 2))

## Save space not keeping data in clus.object, and still clusplot() it:
data(xclara)
cx <- clara(xclara, 3, keep.data = FALSE)
cx$data # is NULL
plot(cx, data = xclara)
```

---

pltree

---

*Plot Clustering Tree of a Hierarchical Clustering*

---

### Description

`pltree()` Draws a clustering tree (“dendrogram”) on the current graphics device. We provide the `twins` method draws the tree of a `twins` object, i.e., hierarchical clustering, typically resulting from [agnes\(\)](#) or [diana\(\)](#).

### Usage

```
pltree(x, ...)
## S3 method for class 'twins'
pltree(x, main = paste("Dendrogram of ", deparse(x$call)),
       labels = NULL, ylab = "Height", ...)
```

## Arguments

|                     |                                                                                                                                                                                                 |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>      | in general, an R object for which a <code>pltree</code> method is defined; specifically, an object of class "twins", typically created by either <code>agnes()</code> or <code>diana()</code> . |
| <code>main</code>   | main title with a sensible default.                                                                                                                                                             |
| <code>labels</code> | labels to use; the default is constructed from <code>x</code> .                                                                                                                                 |
| <code>ylab</code>   | label for y-axis.                                                                                                                                                                               |
| <code>...</code>    | graphical parameters (see <code>par</code> ) may also be supplied as arguments to this function.                                                                                                |

## Details

Creates a plot of a clustering tree given a `twins` object. The leaves of the tree are the original observations. In case of an agglomerative clustering, two branches come together at the distance between the two clusters being merged. For a divisive clustering, a branch splits up at the diameter of the cluster being splitted.

Note that currently the method function simply calls `plot(as.hclust(x), ...)`, which dispatches to `plot.hclust(.)`. If more flexible plots are needed, consider `xx <- as.dendrogram(as.hclust(x))` and plotting `xx`, see `plot.dendrogram`.

## Value

a NULL value is returned.

## See Also

`agnes`, `agnes.object`, `diana`, `diana.object`, `hclust`, `par`, `plot.agnes`, `plot.diana`.

## Examples

```
data(votes.repub)
agn <- agnes(votes.repub)
pltree(agn)

dagn <- as.dendrogram(as.hclust(agn))
dagn2 <- as.dendrogram(as.hclust(agn), hang = 0.2)
op <- par(mar = par("mar") + c(0,0,0, 2)) # more space to the right
plot(dagn2, horiz = TRUE)
plot(dagn, horiz = TRUE, center = TRUE,
      nodePar = list(lab.cex = 0.6, lab.col = "forest green", pch = NA),
      main = deparse(agn$call))
par(op)
```

---

pluton

*Isotopic Composition Plutonium Batches*

---

## Description

The `pluton` data frame has 45 rows and 4 columns, containing percentages of isotopic composition of 45 Plutonium batches.

**Usage**

```
data(pluton)
```

**Format**

This data frame contains the following columns:

**Pu238** the percentages of  $^{238}\text{Pu}$ , always less than 2 percent.

**Pu239** the percentages of  $^{239}\text{Pu}$ , typically between 60 and 80 percent (from neutron capture of Uranium,  $^{238}\text{U}$ ).

**Pu240** percentage of the plutonium 240 isotope.

**Pu241** percentage of the plutonium 241 isotope.

**Details**

Note that the percentage of plutonium-242 can be computed from the other four percentages, see the examples.

In the reference below it is explained why it is very desirable to combine these plutonium patches in three groups of similar size.

**Source**

Available as ‘pluton.dat’ from the archive of the University of Antwerpen,  
 ‘.../datasets/clusplot-examples.tar.gz’, no longer available.

**References**

Rousseeuw, P.J. and Kaufman, L and Trauwaert, E. (1996) Fuzzy clustering using scatter matrices, *Computational Statistics and Data Analysis* **23**(1), 135–151.

**Examples**

```
data(pluton)

hist(apply(pluton,1,sum), col = "gray") # between 94% and 100%
pu5 <- pluton
pu5$Pu242 <- 100 - apply(pluton,1,sum) # the remaining isotope.
pairs(pu5)
```

---

predict.ellipsoid *Predict Method for Ellipsoid Objects*

---

**Description**

Compute points on the ellipsoid boundary, mostly for drawing.

**Usage**

```
predict.ellipsoid(object, n.out=201, ...)
## S3 method for class 'ellipsoid'
predict(object, n.out=201, ...)
ellipsoidPoints(A, d2, loc, n.half = 201)
```

## Arguments

|                            |                                                                                                                                                                         |
|----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code>        | an object of class <code>ellipsoid</code> , typically from <code>ellipsoidhull()</code> ; alternatively any list-like object with proper components, see details below. |
| <code>n.out, n.half</code> | half the number of points to create.                                                                                                                                    |
| <code>A, d2, loc</code>    | arguments of the auxiliary <code>ellipsoidPoints</code> , see below.                                                                                                    |
| <code>...</code>           | passed to and from methods.                                                                                                                                             |

## Details

Note `ellipsoidPoints` is the workhorse function of `predict.ellipsoid` a standalone function and method for `ellipsoid` objects, see `ellipsoidhull`. The class of `object` is not checked; it must solely have valid components `loc` (length  $p$ ), the  $p \times p$  matrix `cov` (corresponding to `A`) and `d2` for the center, the shape (“covariance”) matrix and the squared average radius (or distance) or `qchisq(*, p)` quantile.

Unfortunately, this is only implemented for  $p = 2$ , currently; contributions for  $p \geq 3$  are *very welcome*.

## Value

a numeric matrix of dimension  $2 * n.out$  times  $p$ .

## See Also

`ellipsoidhull`, `volume.ellipsoid`.

## Examples

```
## see also example(ellipsoidhull)

## Robust vs. L.S. covariance matrix

|-------------|---------------------------------------|
| print.agnes | <i>Print Method for AGNES Objects</i> |
|-------------|---------------------------------------|

---

**Description**

Prints the call, agglomerative coefficient, ordering of objects and distances between merging clusters ('Height') of an `agnes` object.

This is a method for the generic `print()` function for objects inheriting from class `agnes`, see `agnes.object`.

**Usage**

```
## S3 method for class 'agnes'
print(x, ...)
```

**Arguments**

|                  |                                                    |
|------------------|----------------------------------------------------|
| <code>x</code>   | an <code>agnes</code> object.                      |
| <code>...</code> | potential further arguments (required by generic). |

**See Also**

`summary.agnes` producing more output; `agnes`, `agnes.object`, `print`, `print.default`.

|-------------|---------------------------------------|
| print.clara | <i>Print Method for CLARA Objects</i> |
|-------------|---------------------------------------|

---

**Description**

Prints the best sample, medoids, clustering vector and objective function of `clara` object.

This is a method for the function `print()` for objects inheriting from class `clara`.

**Usage**

```
## S3 method for class 'clara'
print(x, ...)
```

**Arguments**

|                  |                                                   |
|------------------|---------------------------------------------------|
| <code>x</code>   | a <code>clara</code> object.                      |
| <code>...</code> | potential further arguments (require by generic). |

**See Also**

---

```
print.diana
```

---

*Print Method for DIANA Objects*

---

### Description

Prints the ordering of objects, diameters of splitted clusters, and divisive coefficient of a `diana` object.

This is a method for the function `print()` for objects inheriting from class `diana`.

### Usage

```
## S3 method for class 'diana'
print(x, ...)
```

### Arguments

`x`                      a `diana` object.  
`...`                    potential further arguments (require by generic).

### See Also

`diana`, `diana.object`, `print`, `print.default`.

---

```
print.dissimilarity
```

---

*Print and Summary Methods for Dissimilarity Objects*

---

### Description

Print or summarize the distances and the attributes of a `dissimilarity` object.

These are methods for the functions `print()` and `summary()` for `dissimilarity` objects. See `print`, `print.default`, or `summary` for the general behavior of these.

### Usage

```
## S3 method for class 'dissimilarity'
print(x, diag = NULL, upper = NULL,
      digits = getOption("digits"), justify = "none", right = TRUE, ...)
## S3 method for class 'dissimilarity'
summary(object,
         digits = max(3, getOption("digits") - 2), ...)
## S3 method for class 'summary.dissimilarity'
print(x, ...)
```

**Arguments**

`x, object` a dissimilarity object or a `summary.dissimilarity` one for `print.summary.dissimilarity()`.

`digits` the number of digits to use, see `print.default`.

`diag, upper, justify, right` optional arguments specifying how the triangular dissimilarity matrix is printed; see `print.dist`.

`...` potential further arguments (require by generic).

**See Also**

`daisy`, `dissimilarity.object`, `print`, `print.default`, `print.dist`.

**Examples**

```
## See example(daisy)

sd <- summary(daisy(matrix(rnorm(100), 20, 5)))
sd # -> print.summary.dissimilarity(.)
str(sd)
```

---

`print.fanny`

*Print and Summary Methods for FANNY Objects*

---

**Description**

Prints the objective function, membership coefficients and clustering vector of `fanny` object.

This is a method for the function `print()` for objects inheriting from class `fanny`.

**Usage**

```
## S3 method for class 'fanny'
print(x, digits = getOption("digits"), ...)
## S3 method for class 'fanny'
summary(object, ...)
## S3 method for class 'summary.fanny'
print(x, digits = getOption("digits"), ...)
```

**Arguments**

`x, object` a `fanny` object.

`digits` number of significant digits for printing, see `print.default`.

`...` potential further arguments (required by generic).

**See Also**

`fanny`, `fanny.object`, `print`, `print.default`.

---

`print.mona`*Print Method for MONA Objects*

---

**Description**

Prints the ordering of objects, separation steps, and used variables of a `mona` object.

This is a method for the function `print()` for objects inheriting from class `mona`.

**Usage**

```
## S3 method for class 'mona'
print(x, ...)
```

**Arguments**

|                  |                                                   |
|------------------|---------------------------------------------------|
| <code>x</code>   | a <code>mona</code> object.                       |
| <code>...</code> | potential further arguments (require by generic). |

**See Also**

`mona`, `mona.object`, `print`, `print.default`.

---

`print.pam`*Print Method for PAM Objects*

---

**Description**

Prints the medoids, clustering vector and objective function of `pam` object.

This is a method for the function `print()` for objects inheriting from class `pam`.

**Usage**

```
## S3 method for class 'pam'
print(x, ...)
```

**Arguments**

|                  |                                                   |
|------------------|---------------------------------------------------|
| <code>x</code>   | a <code>pam</code> object.                        |
| <code>...</code> | potential further arguments (require by generic). |

**See Also**

`pam`, `pam.object`, `print`, `print.default`.

---

`ruspini`*Ruspini Data*

---

**Description**

The Ruspini data set, consisting of 75 points in four groups that is popular for illustrating clustering techniques.

**Usage**

```
data(ruspini)
```

**Format**

A data frame with 75 observations on 2 variables giving the x and y coordinates of the points, respectively.

**Source**

E. H. Ruspini (1970) Numerical methods for fuzzy clustering. *Inform. Sci.* **2**, 319–350.

**References**

see those in [agnes](#).

**Examples**

```
data(ruspini)

## Plot similar to Figure 4 in Stryuf et al (1996)
## Not run: plot(pam(ruspini, 4), ask = TRUE)

## Plot similar to Figure 6 in Stryuf et al (1996)
plot(fanny(ruspini, 5))
```

---

`silhouette`*Compute or Extract Silhouette Information from Clustering*

---

**Description**

Compute silhouette information according to a given clustering in  $k$  clusters.

## Usage

```

silhouette(x, ...)
## Default S3 method:
  silhouette(x, dist, dmatrix, ...)
## S3 method for class 'partition'
silhouette(x, ...)
## S3 method for class 'clara'
silhouette(x, full = FALSE, subset = NULL, ...)

sortSilhouette(object, ...)
## S3 method for class 'silhouette'
summary(object, FUN = mean, ...)
## S3 method for class 'silhouette'
plot(x, nmax.lab = 40, max.strlen = 5,
     main = NULL, sub = NULL, xlab = expression("Silhouette width " * s[i]),
     col = "gray", do.col.sort = length(col) > 1, border = 0,
     cex.names = par("cex.axis"), do.n.k = TRUE, do.clus.stat = TRUE, ...)

```

## Arguments

|                                     |                                                                                                                                                                                                                                                                                                                                                                                        |
|-------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>                      | an object of appropriate class; for the default method an integer vector with $k$ different integer cluster codes or a list with such an <code>x\$clustering</code> component. Note that silhouette statistics are only defined if $2 \leq k \leq n - 1$ .                                                                                                                             |
| <code>dist</code>                   | a dissimilarity object inheriting from class <code>dist</code> or coercible to one. If not specified, <code>dmatrix</code> must be.                                                                                                                                                                                                                                                    |
| <code>dmatrix</code>                | a symmetric dissimilarity matrix ( $n \times n$ ), specified instead of <code>dist</code> , which can be more efficient.                                                                                                                                                                                                                                                               |
| <code>full</code>                   | logical or number in $[0, 1]$ specifying if a <i>full</i> silhouette should be computed for <code>clara</code> object. When a number, say $f$ , for a random <code>sample.int(n, size = f*n)</code> of the data the silhouette values are computed. This requires $O((f*n)^2)$ memory, since the full dissimilarity of the (sub)sample (see <code>daisy</code> ) is needed internally. |
| <code>subset</code>                 | a subset from $1:n$ , specified instead of <code>full</code> to specify the indices of the observations to be used for the silhouette computations.                                                                                                                                                                                                                                    |
| <code>object</code>                 | an object of class <code>silhouette</code> .                                                                                                                                                                                                                                                                                                                                           |
| <code>...</code>                    | further arguments passed to and from methods.                                                                                                                                                                                                                                                                                                                                          |
| <code>FUN</code>                    | function used to summarize silhouette widths.                                                                                                                                                                                                                                                                                                                                          |
| <code>nmax.lab</code>               | integer indicating the number of labels which is considered too large for single-name labeling the silhouette plot.                                                                                                                                                                                                                                                                    |
| <code>max.strlen</code>             | positive integer giving the length to which strings are truncated in silhouette plot labeling.                                                                                                                                                                                                                                                                                         |
| <code>main, sub, xlab</code>        | arguments to <code>title</code> ; have a sensible non-NULL default here.                                                                                                                                                                                                                                                                                                               |
| <code>col, border, cex.names</code> | arguments passed <code>barplot()</code> ; note that the default used to be <code>col = heat.colors(n), border = par("fg")</code> instead.<br><code>col</code> can also be a color vector of length $k$ for clusterwise coloring, see also <code>do.col.sort</code> :                                                                                                                   |

`do.col.sort` logical indicating if the colors `col` should be sorted “along” the silhouette; this is useful for casewise or clusterwise coloring.

`do.n.k` logical indicating if  $n$  and  $k$  “title text” should be written.

`do.clus.stat` logical indicating if cluster size and averages should be written right to the silhouettes.

## Details

For each observation  $i$ , the *silhouette width*  $s(i)$  is defined as follows:

Put  $a(i)$  = average dissimilarity between  $i$  and all other points of the cluster to which  $i$  belongs (if  $i$  is the *only* observation in its cluster,  $s(i) := 0$  without further calculations). For all *other* clusters  $C$ , put  $d(i, C)$  = average dissimilarity of  $i$  to all observations of  $C$ . The smallest of these  $d(i, C)$  is  $b(i) := \min_C d(i, C)$ , and can be seen as the dissimilarity between  $i$  and its “neighbor” cluster, i.e., the nearest one to which it does *not* belong. Finally,

$$s(i) := \frac{b(i) - a(i)}{\max(a(i), b(i))}.$$

`silhouette.default()` is now based on C code donated by Romain Francois (the R version being still available as `cluster::silhouette.default.R`).

Observations with a large  $s(i)$  (almost 1) are very well clustered, a small  $s(i)$  (around 0) means that the observation lies between two clusters, and observations with a negative  $s(i)$  are probably placed in the wrong cluster.

## Value

`silhouette()` returns an object, `sil`, of class `silhouette` which is an  $n \times 3$  matrix with attributes. For each observation  $i$ , `sil[i, ]` contains the cluster to which  $i$  belongs as well as the neighbor cluster of  $i$  (the cluster, not containing  $i$ , for which the average dissimilarity between its observations and  $i$  is minimal), and the silhouette width  $s(i)$  of the observation. The `colnames` correspondingly are `c("cluster", "neighbor", "sil_width")`.

`summary(sil)` returns an object of class `summary.silhouette`, a list with components

`si.summary`: numerical `summary` of the individual silhouette widths  $s(i)$ .

`clus.avg.widths`: numeric (rank 1) array of clusterwise *means* of silhouette widths where `mean = FUN` is used.

`avg.width`: the total mean `FUN(s)` where  $s$  are the individual silhouette widths.

`clus.sizes`: `table` of the  $k$  cluster sizes.

`call`: if available, the `call` creating `sil`.

`Ordered`: logical identical to `attr(sil, "Ordered")`, see below.

`sortSilhouette(sil)` orders the rows of `sil` as in the silhouette plot, by cluster (increasingly) and decreasing silhouette width  $s(i)$ .

`attr(sil, "Ordered")` is a logical indicating if `sil` is ordered as by `sortSilhouette()`. In that case, `rownames(sil)` will contain case labels or numbers, and `attr(sil, "iOrd")` the ordering index vector.

## Note

While `silhouette()` is *intrinsic* to the `partition` clusterings, and hence has a (trivial) method for these, it is straightforward to get silhouettes from hierarchical clusterings from `silhouette.default()` with `cutree()` and distance as input.

By default, for `clara()` partitions, the silhouette is just for the best random *subset* used. Use `full = TRUE` to compute (and later possibly plot) the full silhouette.

## Examples

```
data(ruspini)
pr4 <- pam(ruspini, 4)
str(si <- silhouette(pr4))
(ssi <- summary(si))
plot(si) # silhouette plot
plot(si, col = c("red", "green", "blue", "purple")) # with cluster-wise coloring

si2 <- silhouette(pr4$clustering, dist(ruspini, "canberra"))
summary(si2) # has small values: "canberra"'s fault
plot(si2, nmax= 80, cex.names=0.6)

op <- par(mfrow= c(3,2), oma= c(0,0, 3, 0),
          mgp= c(1.6, .8, 0), mar= .1+c(4,2,2,2))
for(k in 2:6)
  plot(silhouette(pam(ruspini, k=k)), main = paste("k = ",k), do.n.k=FALSE)
mtext("PAM(Ruspini) as in Kaufman & Rousseeuw, p.101",
      outer = TRUE, font = par("font.main"), cex = par("cex.main")); frame()

## the same with cluster-wise colours:
c6 <- c("tomato", "forest green", "dark blue", "purple2", "goldenrod4", "gray20")
for(k in 2:6)
  plot(silhouette(pam(ruspini, k=k)), main = paste("k = ",k), do.n.k=FALSE,
       col = c6[1:k])
par(op)

## clara(): standard silhouette is just for the best random subset
data(xclara)
set.seed(7)
str(xclk <- xclara[ sample(nrow(xclara), size = 1000) ,]) # rownames == indices
cl3 <- clara(xclk, 3)
plot(silhouette(cl3)) # only of the "best" subset of 46
## The full silhouette: internally needs large (36 MB) dist object:
sf <- silhouette(cl3, full = TRUE) ## this is the same as
s.full <- silhouette(cl3$clustering, daisy(xclk))
stopifnot(all.equal(sf, s.full, check.attributes = FALSE, tolerance = 0))
## color dependent on original "3 groups of each 1000": % __FIXME ??__
```

```

plot(sf, col = 2+ as.integer(names(cl3$clustering) ) %% 1000,
     main ="plot(silhouette(clara(.), full = TRUE))")

## Silhouette for a hierarchical clustering:
ar <- agnes(ruspini)
si3 <- silhouette(cutree(ar, k = 5), # k = 4 gave the same as pam() above
                 daisy(ruspini))
plot(si3, nmax = 80, cex.names = 0.5)
## 2 groups: Agnes() wasn't too good:
si4 <- silhouette(cutree(ar, k = 2), daisy(ruspini))
plot(si4, nmax = 80, cex.names = 0.5)

```

sizeDiss

*Sample Size of Dissimilarity Like Object***Description**

Returns the number of observations (*sample size*) corresponding to a dissimilarity like object, or equivalently, the number of rows or columns of a matrix when only the lower or upper triangular part (without diagonal) is given.

It is nothing else but the inverse function of  $f(n) = n(n-1)/2$ .

**Usage**

```
sizeDiss(d)
```

**Arguments**

`d` any R object with length (typically)  $n(n-1)/2$ .

**Value**

a number;  $n$  if `length(d) == n(n-1)/2`, NA otherwise.

**See Also**

[dissimilarity.object](#) and also [as.dist](#) for class dissimilarity and dist objects which have a `Size` attribute.

**Examples**

```

sizeDiss(1:10) # 5, since 10 == 5 * (5 - 1) / 2
sizeDiss(1:9) # NA

n <- 1:100
stopifnot(n == sapply( n*(n-1)/2, function(n) sizeDiss(logical(n))))

```

---

`summary.agnes`*Summary Method for 'agnes' Objects*

---

**Description**

Returns (and prints) a summary list for an `agnes` object. Printing gives more output than the corresponding `print.agnes` method.

**Usage**

```
## S3 method for class 'agnes'
summary(object, ...)
## S3 method for class 'summary.agnes'
print(x, ...)
```

**Arguments**

`x, object`      a `agnes` object.  
`...`            potential further arguments (require by generic).

**See Also**

`agnes`, `agnes.object`.

**Examples**

```
data(agriculture)
summary(agnes(agriculture))
```

---

`summary.clara`*Summary Method for 'clara' Objects*

---

**Description**

Returns (and prints) a summary list for a `clara` object. Printing gives more output than the corresponding `print.clara` method.

**Usage**

```
## S3 method for class 'clara'
summary(object, ...)
## S3 method for class 'summary.clara'
print(x, ...)
```

**Arguments**

`x, object`      a `clara` object.  
`...`            potential further arguments (require by generic).

**See Also**

[clara.object](#)

**Examples**

```
## generate 2000 objects, divided into 5 clusters.
set.seed(47)
x <- rbind(cbind(rnorm(400, 0,4), rnorm(400, 0,4)),
           cbind(rnorm(400,10,8), rnorm(400,40,6)),
           cbind(rnorm(400,30,4), rnorm(400, 0,4)),
           cbind(rnorm(400,40,4), rnorm(400,20,2)),
           cbind(rnorm(400,50,4), rnorm(400,50,4))
)
clx5 <- clara(x, 5)
## Mis'classification' table:

table(rep(1:5, rep(400,5)), clx5$clust) # -> 1 "error"
summary(clx5)

## Graphically:
par(mfrow = c(3,1), mgp = c(1.5, 0.6, 0), mar = par("mar") - c(0,0,2,0))

plot(x, col = rep(2:6, rep(400,5)))
plot(clx5)
```

---

summary.diana

*Summary Method for 'diana' Objects*

---

**Description**

Returns (and prints) a summary list for a diana object.

**Usage**

```
## S3 method for class 'diana'
summary(object, ...)
## S3 method for class 'summary.diana'
print(x, ...)
```

**Arguments**

`x, object`      a [diana](#) object.

`...`            potential further arguments (require by generic).

**See Also**

[diana](#), [diana.object](#).

---

`summary.mona`*Summary Method for 'mona' Objects*

---

### Description

Returns (and prints) a summary list for a `mona` object.

### Usage

```
## S3 method for class 'mona'
summary(object, ...)
## S3 method for class 'summary.mona'
print(x, ...)
```

### Arguments

`x, object`      a [mona](#) object.  
`...`            potential further arguments (require by generic).

`summary.pam`*Summary Method for PAM Objects*

---

### Description

Summarize a [pam](#) object and return an object of class `summary.pam`. There's a [print](#) method for the latter.

### Usage

```
## S3 method for class 'pam'
summary(object, ...)
## S3 method for class 'summary.pam'
print(x, ...)
```

### Arguments

`x, object`      a [pam](#) object.  
`...`            potential further arguments (require by generic).

### See Also

[pam](#), [pam.object](#).

---

|              |                                       |
|--------------|---------------------------------------|
| twins.object | <i>Hierarchical Clustering Object</i> |
|--------------|---------------------------------------|

---

**Description**

The objects of class "twins" represent an agglomerative or divisive (polythetic) hierarchical clustering of a dataset.

**Value**

See [agnes.object](#) and [diana.object](#) for details.

**GENERATION**

This class of objects is returned from `agnes` or `diana`.

**METHODS**

The "twins" class has a method for the following generic function: `pltree`.

**INHERITANCE**

The following classes inherit from class "twins": "agnes" and "diana".

**See Also**

[agnes,diana](#).

---

|                  |                                             |
|------------------|---------------------------------------------|
| volume.ellipsoid | <i>Compute the Volume (of an Ellipsoid)</i> |
|------------------|---------------------------------------------|

---

**Description**

Compute the volume of geometric R object. This is a generic function and has a method for `ellipsoid` objects (typically resulting from [ellipsoidhull\(\)](#)).

**Usage**

```
volume(object, ...)
## S3 method for class 'ellipsoid'
volume(object, log = FALSE, ...)
```

**Arguments**

|        |                                                                                                                                                                     |
|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object | an R object the volume of which is wanted; for the <code>ellipsoid</code> method, an object of that class (see <a href="#">ellipsoidhull</a> or the example below). |
| log    | <a href="#">logical</a> indicating if the volume should be returned in log scale. Maybe needed in largish dimensions.                                               |
| ...    | potential further arguments of methods, e.g. <code>log</code> .                                                                                                     |

**Value**

a number, the volume  $V$  (or  $\log(V)$  if `log = TRUE`) of the given object.

**Author(s)**

Martin Maechler (2002, extracting from former `clusplot` code); Keefe Murphy (2019) provided code for dimensions  $d > 2$ .

**See Also**

`ellipsoidhull` for spanning ellipsoid computation.

**Examples**

```
## example(ellipsoidhull) # which defines 'ellipsoid' object <namefoo>

myEl <- structure(list(cov = rbind(c(3,1),1:2), loc = c(0,0), d2 = 10),
                    class = "ellipsoid")
volume(myEl) # i.e. "area" here (d = 2)
myEl # also mentions the "volume"

set.seed(1)
d5 <- matrix(rt(500, df=3), 100, 5)
e5 <- ellipsoidhull(d5)
```

---

votes.repub

*Votes for Republican Candidate in Presidential Elections*

---

**Description**

A data frame with the percents of votes given to the republican candidate in presidential elections from 1856 to 1976. Rows represent the 50 states, and columns the 31 elections.

**Usage**

```
data(votes.repub)
```

**Source**

S. Peterson (1973): *A Statistical History of the American Presidential Elections*. New York: Frederick Ungar Publishing Co.

Data from 1964 to 1976 is from R. M. Scammon, *American Votes 12*, Congressional Quarterly.

xclara

*Bivariate Data Set with 3 Clusters***Description**

An artificial data set consisting of 3000 points in 3 quite well-separated clusters.

**Usage**

```
data(xclara)
```

**Format**

A data frame with 3000 observations on 2 numeric variables (named V1 and V2) giving the  $x$  and  $y$  coordinates of the points, respectively.

**Note**

Our version of the `xclara` is slightly more rounded than the one from `read.table("xclara.dat")` and the relative difference measured by `all.equal` is  $1.15\text{e-}7$  for V1 and  $1.17\text{e-}7$  for V2 which suggests that our version has been the result of a `options(digits = 7)` formatting.

Previously (before May 2017), it was claimed the three cluster were each of size 1000, which is clearly wrong. `pam(*, 3)` gives cluster sizes of 899, 1149, and 952, which apart from seven “outliers” (or “mislabellings”) correspond to observation indices  $\{1 : 900\}$ ,  $\{901 : 2050\}$ , and  $\{2051 : 3000\}$ , see the example.

**Source**

Sample data set accompanying the reference below (file ‘`xclara.dat`’ in side ‘`clus_examples.tar.gz`’).

**Examples**

```
## Visualization: Assuming groups are defined as {1:1000}, {1001:2000}, {2001:3000}
plot(xclara, cex = 3/4, col = rep(1:3, each=1000))
p.ID <- c(78, 1411, 2535) ## PAM's medoid indices == pam(xclara, 3)$id.med
text(xclara[p.ID,], labels = 1:3, cex=2, col=1:3)

px <- pam(xclara, 3) ## takes ~2 seconds
cxcl <- px$clustering ; iCl <- split(seq_along(cxcl), cxcl)
boxplot(iCl, range = 0.7, horizontal=TRUE,
        main = "Indices of the 3 clusters of pam(xclara, 3)")

## Look more closely now:
bxCl <- boxplot(iCl, range = 0.7, plot=FALSE)
## We see 3 + 2 + 2 = 7 clear "outlier"s or "wrong group" observations:
with(bxCl, rbind(out, group))
```

```
## out    1038 1451 1610    30  327  562  770
## group   1     1     1     2     2     3     3
## Apart from these, what are the robust ranges of indices? -- Robust range:
t(iR <- bxCl$stats[c(1,5),])
##      1  900
##    901 2050
##   2051 3000
gc <- adjustcolor("gray20",1/2)
abline(v = iR, col = gc, lty=3)
axis(3, at = c(0, iR[2,]), padj = 1.2, col=gc, col.axis=gc)
```

## Chapter 21

# The codetools package

---

checkUsage

*Check R Code for Possible Problems*

---

### Description

Check R code for possible problems.

### Usage

```
checkUsage(fun, name = "<anonymous>", report = cat, all = FALSE,
           suppressLocal = FALSE, suppressParamAssigns = !all,
           suppressParamUnused = !all, suppressFundefMismatch = FALSE,
           suppressLocalUnused = FALSE, suppressNoLocalFun = !all,
           skipWith = FALSE, suppressUndefined = dfltSuppressUndefined,
           suppressPartialMatchArgs = TRUE)
checkUsageEnv(env, ...)
checkUsagePackage(pack, ...)
```

### Arguments

|                      |                                                           |
|----------------------|-----------------------------------------------------------|
| fun                  | closure.                                                  |
| name                 | character; name of closure.                               |
| env                  | environment containing closures to check.                 |
| pack                 | character naming package to check.                        |
| ...                  | options to be passed to checkUsage.                       |
| report               | function to use to report possible problems.              |
| all                  | logical; report all possible problems if TRUE.            |
| suppressLocal        | suppress all local variable warnings.                     |
| suppressParamAssigns | suppress warnings about assignments to formal parameters. |
| suppressParamUnused  | suppress warnings about unused formal parameters.         |

```

suppressFundefMismatch
    suppress warnings about multiple local function definitions with different formal
    argument lists
suppressLocalUnused
    suppress warnings about unused local variables
suppressNoLocalFun
    suppress warnings about using local variables as functions with no apparent
    local function definition
skipWith      logical; if true, do not examine code portion of with expressions.
suppressUndefined
    suppress warnings about undefined global functions and variables.
suppressPartialMatchArgs
    suppress warnings about partial argument matching

```

### Details

`checkUsage` checks a single R closure. Options control which possible problems to report. The default settings are moderately verbose. A first pass might use `suppressLocal=TRUE` to suppress all information related to local variable usage. The `suppressXYZ` values can either be scalar logicals or character vectors; then they are character vectors they only suppress problem reports for the variables with names in the vector.

`checkUsageEnv` and `checkUsagePackage` are convenience functions that apply `checkUsage` to all closures in an environment or a package. `checkUsagePackage` requires that the package be loaded. If the package has a name space then the internal name space frame is checked.

### Author(s)

Luke Tierney

### Examples

```

checkUsage(checkUsage)
checkUsagePackage("codetools", all=TRUE)
## Not run: checkUsagePackage("base", suppressLocal=TRUE)

```

---

codetools

*Low Level Code Analysis Tools for R*

---

### Description

These functions provide some tools for analysing R code. Mainly intended to support the other tools in this package and byte code compilation.

### Usage

```

collectLocals(e, collect)
collectUsage(fun, name = "<anonymous>", ...)
constantFold(e, env = NULL, fail = NULL)
findFuncLocals(formals, body)
findLocals(e, envir = .BaseEnv)

```

```
findLocalsList(elist, envir = .BaseEnv)
flattenAssignment(e)
getAssignedVar(e)
isConstantValue(v, w)
makeCodeWalker(..., handler, call, leaf)
makeLocalsCollector(..., leaf, handler, isLocal, exit, collect)
makeUsageCollector(fun, ..., name, enterLocal, enterGlobal, enterInternal,
                   startCollectLocals, finishCollectLocals, warn,
                   signal)
walkCode(e, w = makeCodeWalker())
```

### Arguments

|                     |                                 |
|---------------------|---------------------------------|
| e                   | R expression.                   |
| elist               | list of R expressions.          |
| v                   | R object.                       |
| fun                 | closure.                        |
| formals             | formal arguments of a closure.  |
| body                | body of a closure.              |
| name                | character.                      |
| env                 | character.                      |
| envir               | environment.                    |
| w                   | code walker.                    |
| ...                 | extra elements for code walker. |
| collect             | function.                       |
| fail                | function.                       |
| handler             | function.                       |
| call                | function.                       |
| leaf                | function.                       |
| isLocal             | function.                       |
| exit                | function.                       |
| enterLocal          | function.                       |
| enterGlobal         | function.                       |
| enterInternal       | function.                       |
| startCollectLocals  | function.                       |
| finishCollectLocals | function.                       |
| warn                | function.                       |
| signal              | function.                       |

### Author(s)

Luke Tierney

---

|             |                                                              |
|-------------|--------------------------------------------------------------|
| findGlobals | <i>Find Global Functions and Variables Used by a Closure</i> |
|-------------|--------------------------------------------------------------|

---

**Description**

Finds global functions and variables used by a closure.

**Usage**

```
findGlobals(fun, merge = TRUE)
```

**Arguments**

|       |                                     |
|-------|-------------------------------------|
| fun   | function object; usually a closure. |
| merge | logical                             |

**Details**

The result is an approximation. R semantics only allow variables that might be local to be identified (and event that assumes no use of `assign` and `rm`).

**Value**

Character vector if `merge` is true; otherwise, a list with `functions` and `variables` character vector components. Character vectors are of length zero For non-closures.

**Author(s)**

Luke Tierney

**Examples**

```
findGlobals(findGlobals)
findGlobals(findGlobals, merge = FALSE)
```

---

|          |                                                        |
|----------|--------------------------------------------------------|
| showTree | <i>Print Lisp-Style Representation of R Expression</i> |
|----------|--------------------------------------------------------|

---

**Description**

Prints a Lisp-style representation of R expression. This can be useful for understanding how some things are parsed.

**Usage**

```
showTree(e, write = cat)
```

**Arguments**

|       |                                               |
|-------|-----------------------------------------------|
| e     | R expression.                                 |
| write | function of one argument to write the result. |

**Author(s)**

Luke Tierney

**Examples**

```
showTree(quote(-3))  
showTree(quote("x"<-1))  
showTree(quote("f"(x)))
```

## Chapter 22

# The foreign package

---

`lookup.xport`

*Lookup Information on a SAS XPORT Format Library*

---

### Description

Scans a file as a SAS XPORT format library and returns a list containing information about the SAS library.

### Usage

```
lookup.xport (file)
```

### Arguments

|                   |                                                                                             |
|-------------------|---------------------------------------------------------------------------------------------|
| <code>file</code> | character variable with the name of the file to read. The file must be in SAS XPORT format. |
|-------------------|---------------------------------------------------------------------------------------------|

### Value

A list with one component for each dataset in the XPORT format library.

### Author(s)

Saikat DebRoy

### References

SAS Technical Support document TS-140: “The Record Layout of a Data Set in SAS Transport (XPORT) Format” available as <https://support.sas.com/techsup/technote/ts140.pdf>.

```
## Not run: ## no XPORT file is installed.
lookup.xport("test.xpt")

## End(Not run)
```

---

read.arff

*Read Data from ARFF Files*

---

**Description**

Reads data from Weka Attribute-Relation File Format (ARFF) files.

**Usage**

```
read.arff(file)
```

**Arguments**

`file` a character string with the name of the ARFF file to read from, or a [connection](#) which will be opened if necessary, and if so closed at the end of the function call.

**Value**

A data frame containing the data from the ARFF file.

**References**

Attribute-Relation File Format [https://waikato.github.io/weka-wiki/formats\\_and\\_processing/arff/](https://waikato.github.io/weka-wiki/formats_and_processing/arff/).

**See Also**

[write.arff](#); functions `write.arff` and `read.arff` in package **RWeka** which provide some support for logicals via conversion to or from factors.

---

read.dbf

*Read a DBF File*

---

**Description**

The function reads a DBF file into a data frame, converting character fields to factors, and trying to respect NULL fields.

The DBF format is documented but not much adhered to. There is no guarantee this will read all DBF files.

**Usage**

```
read.dbf(file, as.is = FALSE)
```

## Arguments

|                    |                                                       |
|--------------------|-------------------------------------------------------|
| <code>file</code>  | name of input file                                    |
| <code>as.is</code> | should character vectors not be converted to factors? |

## Details

DBF is the extension used for files written for the 'XBASE' family of database languages, 'covering the dBase, Clipper, FoxPro, and their Windows equivalents Visual dBase, Visual Objects, and Visual FoxPro, plus some older products' (<https://www.clicketyclick.dk/databases/xbase/format/>). Most of these follow the file structure used by Ashton-Tate's dBase II, III or 4 (later owned by Borland).

`read.dbf` is based on C code from <http://shapelib.maptools.org/> which implements the 'XBASE' specification. It can convert fields of type "L" (logical), "N" and "F" (numeric and float) and "D" (dates): all other field types are read as-is as character vectors. A numeric field is read as an R integer vector if it is encoded to have no decimals, otherwise as a numeric vector. However, if the numbers are too large to fit into an integer vector, it is changed to numeric. Note that is possible to read integers that cannot be represented exactly even as doubles: this sometimes occurs if IDs are incorrectly coded as numeric.

## Value

A data frame of data from the DBF file; note that the field names are adjusted to use in R using `make.names` (`unique=TRUE`).

There is an attribute "data\_type" giving the single-character dBase types for each field.

## Note

Not to be able to read a particular 'DBF' file is not a bug: this is a convenience function especially for shapefiles.

## Author(s)

Nicholas Lewin-Koh and Roger Bivand; shapelib by Frank Warmerdam

## References

<http://shapelib.maptools.org/>.

`write.dbf`

## Examples

```
x <- read.dbf(system.file("files/sids.dbf", package="foreign"))[1:]
str(x)
summary(x)
```

read.dta

*Read Stata Binary Files***Description**

Reads a file in Stata version 5–12 binary format into a data frame.

Frozen: will not support Stata formats after 12.

**Usage**

```
read.dta(file, convert.dates = TRUE, convert.factors = TRUE,
         missing.type = FALSE,
         convert.underscore = FALSE, warn.missing.labels = TRUE)
```

**Arguments**

`file` a filename or URL as a character string.

`convert.dates` Convert Stata dates to Date class, and date-times to POSIXct class?

`convert.factors` Use Stata value labels to create factors? (Version 6.0 or later).

`missing.type` For version 8 or later, store information about different types of missing data?

`convert.underscore` Convert "\_" in Stata variable names to "." in R names?

`warn.missing.labels` Warn if a variable is specified with value labels and those value labels are not present in the file.

**Details**

If the filename appears to be a URL (of schemes 'http:', 'ftp:' or 'https:') the URL is first downloaded to a temporary file and then read. ('https:' is only supported on some platforms.)

The variables in the Stata data set become the columns of the data frame. Missing values are correctly handled. The data label, variable labels, timestamp, and variable/dataset characteristics are stored as attributes of the data frame.

By default Stata dates (%d and %td formats) are converted to R's Date class, and variables with Stata value labels are converted to factors. Ordinarily, `read.dta` will not convert a variable to a factor unless a label is present for every level. Use `convert.factors = NA` to override this. In any case the value label and format information is stored as attributes on the returned data frame. Stata's date formats are sketchily documented: if necessary use `convert.dates = FALSE` and examine the attributes to work out how to post-process the dates.

Stata 8 introduced a system of 27 different missing data values. If `missing.type` is TRUE a separate list is created with the same variable names as the loaded data. For string variables the list value is NULL. For other variables the value is NA where the observation is not missing and 0–26 when the observation is missing. This is attached as the "missing" attribute of the returned value.

The default file format for Stata 13, `format-115`, is substantially different from those for Stata 5–12.

**Value**

A data frame with attributes. These will include "datalabel", "time.stamp", "formats", "types", "val.labels", "var.labels" and "version" and may include "label.table" and "expansion.table". Possible versions are 5, 6, 7, -7 (Stata 7SE, 'format-111'), 8 (Stata 8 and 9, 'format-113'), 10 (Stata 10 and 11, 'format-114'), and 12 (Stata 12, 'format-115').

The value labels in attribute "val.labels" name a table for each variable, or are an empty string. The tables are elements of the named list attribute "label.table": each is an integer vector with names.

**Author(s)**

Thomas Lumley and R-core members: support for value labels by Brian Quistorff.

**References**

Stata Users Manual (versions 5 & 6), Programming manual (version 7), or online help (version 8 and later) describe the format of the files. Different approaches are available in package **memisc** (see its help for `Stata.file`), function `read_dta` in package **haven** and package **readstata13**.

`write.dta`, `attributes`, `Date`, `factor`

**Examples**

```
write.dta(swiss, swissfile <- tempfile())
read.dta(swissfile)
```

---

`read.epiinfo`*Read Epi Info Data Files*

---

**Description**

Reads data files in the .REC format used by Epi Info versions 6 and earlier and by EpiData. Epi Info is a public domain database and statistics package produced by the US Centers for Disease Control and EpiData is a freely available data entry and validation system.

**Usage**

```
read.epiinfo(file, read.deleted = FALSE, guess.broken.dates = FALSE,
             thisyear = NULL, lower.case.names = FALSE)
```

## Arguments

|                                 |                                                                               |
|---------------------------------|-------------------------------------------------------------------------------|
| <code>file</code>               | A filename, URL, or connection.                                               |
| <code>read.deleted</code>       | Deleted records are read if TRUE, omitted if FALSE or replaced with NA if NA. |
| <code>guess.broken.dates</code> | Attempt to convert dates with 0 or 2 digit year information (see 'Details').  |
| <code>thisyear</code>           | A 4-digit year to use for dates with no year. Defaults to the current year.   |
| <code>lower.case.names</code>   | Convert variable names to lowercase?                                          |

## Details

Epi Info allows dates to be specified with no year or with a 2 or 4 digits. Dates with four-digit years are always converted to `Date` class. With the `guess.broken.dates` option the function will attempt to convert two-digit years using the operating system's default method (see [Date](#)) and will use the current year or the `thisyear` argument for dates with no year information.

If `read.deleted` is TRUE the "deleted" attribute of the data frame indicates the deleted records.

## Value

A data frame.

## Note

Some later versions of Epi Info use the Microsoft Access file format to store data. That may be readable with the **RODBC** package.

## Examples

```
## Not run: ## That file is not available
read.epiinfo("oswego.rec", guess.broken.dates = TRUE, thisyear = "1972")

## End(Not run)
```

---

`read.mtp`*Read a Minitab Portable Worksheet*

---

## Description

Return a list with the data stored in a file as a Minitab Portable Worksheet.

## Usage

```
read.mtp(file)
```

## Arguments

|                   |                                                                                                              |
|-------------------|--------------------------------------------------------------------------------------------------------------|
| <code>file</code> | character variable with the name of the file to read. The file must be in Minitab Portable Worksheet format. |
|-------------------|--------------------------------------------------------------------------------------------------------------|

## Value

A list with one component for each column, matrix, or constant stored in the Minitab worksheet.

## Note

This function was written around 1990 for the format current then. Later versions of Minitab appear to have added to the format.

## Examples

```
## Not run:  
read.mtp("ex1-10.mtp")  
  
## End (Not run)
```

---

read.octave

*Read Octave Text Data Files*

---

### Description

Read a file in Octave text data format into a list.

### Usage

```
read.octave(file)
```

### Arguments

`file` a character string with the name of the file to read.

### Details

This function is used to read in files in Octave text data format, as created by `save -text` in Octave. It knows about most of the common types of variables, including the standard atomic (real and complex scalars, matrices, and  $N$ -d arrays, strings, ranges, and boolean scalars and matrices) and recursive (structs, cells, and lists) ones, but has no guarantee to read all types. If a type is not recognized, a warning indicating the unknown type is issued, it is attempted to skip the unknown entry, and `NULL` is used as its value. Note that this will give incorrect results, and maybe even errors, in the case of unknown recursive data types.

As Octave can read MATLAB binary files, one can make the contents of such files available to R by using Octave's load and save (as text) facilities as an intermediary step.

### Value

A list with one named component for each variable in the file.

read.spss

*Read an SPSS Data File*

---

### Description

`read.spss` reads a file stored by the SPSS `save` or `export` commands.

This was originally written in 2000 and has limited support for changes in SPSS formats since (which have not been many).

## Usage

```
read.spss(file, use.value.labels = TRUE, to.data.frame = FALSE,
          max.value.labels = Inf, trim.factor.names = FALSE,
          trim_values = TRUE, reencode = NA, use.missings = to.data.frame,
          sub = ".", add.undeclared.levels = c("sort", "append", "no"),
          duplicated.value.labels = c("append", "condense"),
          duplicated.value.labels.infix = "_duplicated_", ...)
```

## Arguments

|                                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|--------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>file</code>                    | character string: the name of the file or URL to read.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <code>use.value.labels</code>        | logical: convert variables with value labels into R factors with those levels? This is only done if there are at least as many labels as values of the variable (when values without a matching label are returned as NA).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <code>to.data.frame</code>           | logical: return a data frame?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>max.value.labels</code>        | logical: only variables with value labels and at most this many unique values will be converted to factors if TRUE.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>trim.factor.names</code>       | logical: trim trailing spaces from factor levels?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| <code>reencode</code>                | logical: should character strings be re-encoded to the current locale. The default, NA, means to do so in UTF-8 or latin-1 locales, only. Alternatively a character string specifying an encoding to assume for the file.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>use.missings</code>            | logical: should information on user-defined missing values be used to set the corresponding values to NA?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>sub</code>                     | character string: If not NA it is used by <code>iconv</code> to replace any non-convertible bytes in character/factor input. Default is ".". For back compatibility with <b>foreign</b> versions <= 0.8-68 use <code>sub=NA</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <code>add.undeclared.levels</code>   | character: specify how to handle variables with at least one value label and further non-missing values that have no value label (like a factor levels in R). For "sort" (the default) it adds undeclared factor levels to the already declared levels (and labels) and sort them according to level, for "append" it appends undeclared factor levels to declared levels (and labels) without sorting, and for "no" this does not convert to factor in case of numeric SPSS levels (not labels), and still converts to factor if the SPSS levels are characters and <code>to.data.frame=TRUE</code> . For back compatibility with <b>foreign</b> versions <= 0.8-68 use <code>add.undeclared.levels="no"</code> (not recommended as this may convert some values with missing corresponding value labels to NA). |
| <code>duplicated.value.labels</code> | character: what to do with duplicated value labels for different levels. For "append" (the default), the first original value label is kept while further duplicated labels are renamed to <code>paste0(label, duplicated.value.labels.infix, level)</code> , for "condense", all levels with identical labels are condensed into exactly the first of these levels in R. Back compatibility with <b>foreign</b> versions <= 0.8-68 is not given as R versions >= 3.4.0 no longer support duplicated factor labels.                                                                                                                                                                                                                                                                                               |

```

duplicated.value.labels.infix
    character: the infix used for labels of factor levels with du-
                plicated value labels in SPSS (default "_duplicated_") if
                duplicated.value.labels="append".
...
    passed to as.data.frame if to.data.frame = TRUE.

```

## Details

This uses modified code from the PSPP project (<http://www.gnu.org/software/pspp/> for reading the SPSS formats.

If the filename appears to be a URL (of schemes 'http:', 'ftp:' or 'https:') the URL is first downloaded to a temporary file and then read. ('https:' is supported where supported by `download.file` with its current default method.)

Occasionally in SPSS, value labels will be added to some values of a continuous variable (e.g. to distinguish different types of missing data), and you will not want these variables converted to factors. By setting `max.value.labels` you can specify that variables with a large number of distinct values are not converted to factors even if they have value labels.

If SPSS variable labels are present, they are returned as the `"variable.labels"` attribute of the answer.

Fixed length strings (including value labels) are padded on the right with spaces by SPSS, and so are read that way by R. The default argument `trim_values=TRUE` causes trailing spaces to be ignored when matching to value labels, as examples have been seen where the strings and the value labels had different amounts of padding. See the examples for `sub` for ways to remove trailing spaces in character data.

URL <https://docs.microsoft.com/en-us/windows/win32/intl/code-page-identifiers> provides a list of translations from Windows codepage numbers to encoding names that `iconv` is likely to know about and so suitable values for `reencode`. Automatic re-encoding is attempted for apparent codepages of 200 or more in a UTF-8 or latin-1 locale: some other high-numbered codepages can be re-encoded on most systems, but the encoding names are platform-dependent (see `iconvlist`).

## Value

A list (or optionally a data frame) with one component for each variable in the saved data set.

If what looks like a Windows codepage was recorded in the SPSS file, it is attached (as a number) as attribute `"codepage"` to the result.

There may be attributes `"label.table"` and `"variable.labels"`. Attribute `"label.table"` is a named list of value labels with one element per variable, either `NULL` or a named character vector. Attribute `"variable.labels"` is a named character vector with names the short variable names and elements the long names.

If there are user-defined missing values, there will be a attribute `"Missings"`. This is a named list with one list element per variable. Each element has an element `type`, a length-one character vector giving the type of missingness, and may also have an element `value` with the values corresponding to missingness. This is a complex subject (where the R and C source code for `read.spss` is the main documentation), but the simplest cases are types `"one"`, `"two"` and `"three"` with a corresponding number of (real or string) values whose labels can be found from the `"label.table"` attribute. Other possibilities are a finite or semi-infinite range, possibly plus a single value. See also [http://www.gnu.org/software/pspp/manual/html\\_node/Missing-Observations.html#Missing-Observations](http://www.gnu.org/software/pspp/manual/html_node/Missing-Observations.html#Missing-Observations).

**Note**

If SPSS value labels are converted to factors the underlying numerical codes will not in general be the same as the SPSS numerical values, since the numerical codes in R are always 1, 2, 3, ...

You may see warnings about the file encoding for SPSS save files: it is possible such files contain non-ASCII character data which need re-encoding. The most common occurrence is Windows codepage 1252, a superset of Latin-1. The encoding is recorded (as an integer) in attribute "codepage" of the result if it looks like a Windows codepage. Automatic re-encoding is done only in UTF-8 and latin-1 locales: see argument `reencode`.

**Author(s)**

Saikat DebRoy and the R-core team

**See Also**

A different interface also based on the PSPP codebase is available in package **memisc**: see its help for `spss.system.file`.

**Examples**

```
(sav <- system.file("files", "electric.sav", package = "foreign"))
dat <- read.spss(file=sav)
str(dat)    # list structure with attributes

dat <- read.spss(file=sav, to.data.frame=TRUE)
str(dat)    # now a data.frame

### Now we use an example file that is not very well structured and
### hence may need some special treatment with appropriate argument settings.
### Expect lots of warnings as value labels (corresponding to R factor labels) are uncom
### and an unsupported long string variable is present in the data
(sav <- system.file("files", "testdata.sav", package = "foreign"))

### Examples for add.undeclared.levels:
## add.undeclared.levels = "sort" (default):
x.sort <- read.spss(file=sav, to.data.frame = TRUE)
## add.undeclared.levels = "append":
x.append <- read.spss(file=sav, to.data.frame = TRUE,
  add.undeclared.levels = "append")
## add.undeclared.levels = "no":
x.no <- read.spss(file=sav, to.data.frame = TRUE,
  add.undeclared.levels = "no")

levels(x.sort$factor_n_undeclared)
levels(x.append$factor_n_undeclared)
str(x.no$factor_n_undeclared)

### Examples for duplicated.value.labels:
## duplicated.value.labels = "append" (default)
x.append <- read.spss(file=sav, to.data.frame=TRUE)
## duplicated.value.labels = "condense"
x.condense <- read.spss(file=sav, to.data.frame=TRUE,
  duplicated.value.labels = "condense")
```

```

levels(x.append$factor_n_duplicated)
levels(x.condense$factor_n_duplicated)

as.numeric(x.append$factor_n_duplicated)
as.numeric(x.condense$factor_n_duplicated)

## Long Strings (>255 chars) are imported in consecutive separate variables
## (see warning about subtype 14):
x <- read.spss(file=sav, to.data.frame=TRUE, stringsAsFactors=FALSE)

cat.long.string <- function(x, w=70) cat(paste(strwrap(x, width=w), "\n"))

## first part: x$string_500:
cat.long.string(x$string_500)
## second part: x$STRIN0:
cat.long.string(x$STRIN0)
## complete long string:
long.string <- apply(x[,c("string_500", "STRIN0")], 1, paste, collapse="")
cat.long.string(long.string)

```

---

read.ssd

---

*Obtain a Data Frame from a SAS Permanent Dataset, via read.xport*

---

## Description

Generates a SAS program to convert the ssd contents to SAS transport format and then uses read.xport to obtain a data frame.

## Usage

```

read.ssd(libname, sectionnames,
         tmpXport=tempfile(), tmpProgLoc=tempfile(), sascmd="sas")

```

## Arguments

|              |                                                                                                                                                                                                                                      |
|--------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| libname      | character string defining the SAS library (usually a directory reference)                                                                                                                                                            |
| sectionnames | character vector giving member names. These are files in the libname directory. They will usually have a .ssd0x or .sas7bdat extension, which should be omitted. Use of ASCII names of at most 8 characters is strongly recommended. |
| tmpXport     | character string: location where temporary xport format archive should reside – defaults to a randomly named file in the session temporary directory, which will be removed.                                                         |
| tmpProgLoc   | character string: location where temporary conversion SAS program should reside – defaults to a randomly named file in session temporary directory, which will be removed on successful operation.                                   |
| sascmd       | character string giving full path to SAS executable.                                                                                                                                                                                 |

## Details

Creates a SAS program and runs it.

Error handling is primitive.

## Value

A data frame if all goes well, or `NULL` with warnings and some enduring side effects (log file for auditing)

## Note

**This requires SAS to be available.** If you have a SAS dataset without access to SAS you will need another product to convert it to a format such as `.csv`, for example ‘Stat/Transfer’ or ‘DBMS/Copy’ or the ‘SAS System Viewer’ (Windows only).

SAS requires section names to be no more than 8 characters. This is worked by the use of symbolic links: these are barely supported on Windows.

## Author(s)

For Unix: VJ Carey <stvjc@channing.harvard.edu>

[read.xport](#)

## Examples

```
## if there were some files on the web we could get a real
## runnable example
## Not run:
R> list.files("trialdata")
[1] "baseline.sas7bdat" "form11.sas7bdat" "form12.sas7bdat"
[4] "form13.sas7bdat" "form22.sas7bdat" "form23.sas7bdat"
[7] "form3.sas7bdat" "form4.sas7bdat" "form48.sas7bdat"
[10] "form50.sas7bdat" "form51.sas7bdat" "form71.sas7bdat"
[13] "form72.sas7bdat" "form8.sas7bdat" "form9.sas7bdat"
[16] "form90.sas7bdat" "form91.sas7bdat"
R> baseline <- read.ssd("trialdata", "baseline")
R> form90 <- read.ssd("trialdata", "form90")

## Or for a Windows example
sashome <- "/Program Files/SAS/SAS 9.1"
read.ssd(file.path(sashome, "core", "sashelp"), "retail",
         sascmd = file.path(sashome, "sas.exe"))

## End(Not run)
```

---

`read.systat`*Obtain a Data Frame from a Systat File*

---

### Description

`read.systat` reads a rectangular data file stored by the Systat `SAVE` command as (legacy) `*.sys` or more recently `*.syd` files.

### Usage

```
read.systat(file, to.data.frame = TRUE)
```

### Arguments

|                            |                                                      |
|----------------------------|------------------------------------------------------|
| <code>file</code>          | character variable with the name of the file to read |
| <code>to.data.frame</code> | return a data frame (otherwise a list)               |

### Details

The function only reads those Systat files that are rectangular data files (`mtype = 1`), and warns when files have non-standard variable name codings. The files tested were produced on MS-DOS and Windows: files for the Mac version of Systat have a completely different format.

The C code was originally written for an add-on module for Systat described in Bivand (1992 paper). Variable names retain the trailing dollar in the list returned when `to.data.frame` is `FALSE`, and in that case character variables are returned as is and filled up to 12 characters with blanks on the right. The original function was limited to reading Systat files with up to 256 variables (a Systat limitation); it will now read up to 8192 variables.

If there is a user comment in the header this is returned as attribute `"comment"`. Such comments are always a multiple of 72 characters (with a maximum of 720 chars returned), normally padded with trailing spaces.

### Value

A data frame (or list) with one component for each variable in the saved data set.

### Author(s)

Roger Bivand

**Examples**

```
summary(iris)
iris.s <- read.systat(system.file("files/Iris.syd", package="foreign")[1])
str(iris.s)
summary(iris.s)
```

read.xport

*Read a SAS XPORT Format Library***Description**

Reads a file as a SAS XPORT format library and returns a list of data.frames.

**Usage**

```
read.xport(file, ...)
```

**Arguments**

|      |                                                                                             |
|------|---------------------------------------------------------------------------------------------|
| file | character variable with the name of the file to read. The file must be in SAS XPORT format. |
| ...  | passed to <code>as.data.frame</code> when creating the data frames.                         |

**Value**

If there is a more than one dataset in the XPORT format library, a named list of data frames, otherwise a data frame. The columns of the data frames will be either numeric (corresponding to numeric in SAS) or factor (corresponding to character in SAS). All SAS numeric missing values (including special missing values represented by .\_, .A to .Z by SAS) are mapped to R NA.

Trailing blanks are removed from character columns before conversion to a factor. Some sources claim that character missing values in SAS are represented by ' ' or ' ': these are not treated as R missing values.

```
## Not run: ## no XPORT file is installed
read.xport("test.xpt")

## End(Not run)
```

---

S3 read functions    *Read an S3 Binary or data.dump File*

---

**Description**

Reads binary data files or `data.dump` files that were produced in S version 3.

**Usage**

```
data.restore(file, print = FALSE, verbose = FALSE, env = .GlobalEnv)
read.S(file)
```

**Arguments**

|                      |                                                                   |
|----------------------|-------------------------------------------------------------------|
| <code>file</code>    | the filename of the S-PLUS <code>data.dump</code> or binary file. |
| <code>print</code>   | whether to print the name of each object as read from the file.   |
| <code>verbose</code> | whether to print the name of every subitem within each object.    |
| <code>env</code>     | environment within which to create the restored object(s).        |

**Details**

`read.S` can read the binary files produced in some older versions of S-PLUS on either Windows (versions 3.x, 4.x, 2000) or Unix (version 3.x with 4 byte integers). It automatically detects whether the file was produced on a big- or little-endian machine and adapts itself accordingly.

`data.restore` can read a similar range of files produced by `data.dump` and for newer versions of S-PLUS, those from `data.dump(..., oldStyle=TRUE)`.

Not all S3 objects can be handled in the current version. The most frequently encountered exceptions are functions and expressions; you will also have trouble with objects that contain model formulas. In particular, comments will be lost from function bodies, and the argument lists of functions will often be changed.

**Value**

For `read.S`, an R version of the S3 object.

For `data.restore`, the name of the file.

**Author(s)**

Duncan Murdoch

**Examples**

```
## if you have an S-PLUS _Data file containing 'myobj'
## Not run: read.S(file.path("_Data", "myobj"))
data.restore("dumpdata", print = TRUE)

## End(Not run)
```

---

`write.arff`*Write Data into ARFF Files*

---

## Description

Writes data into Weka Attribute-Relation File Format (ARFF) files.

## Usage

```
write.arff(x, file, eol = "\n", relation = deparse(substitute(x)))
```

## Arguments

|                       |                                                                                                                  |
|-----------------------|------------------------------------------------------------------------------------------------------------------|
| <code>x</code>        | the data to be written, preferably a matrix or data frame. If not, coercion to a data frame is attempted.        |
| <code>file</code>     | either a character string naming a file, or a connection. "" indicates output to the standard output connection. |
| <code>eol</code>      | the character(s) to print at the end of each line (row).                                                         |
| <code>relation</code> | The name of the relation to be written in the file.                                                              |

## Details

`relation` will be passed through `make.names` before writing to the file, in an attempt to it them acceptable to Weka, and column names what do not start with an alphabetic character will have `x` prepended.

However, the references say that ARFF files are ASCII files, and that encoding is not enforced.

## See Also

`read.arff`; functions `write.arff` and `read.arff` in package **RWeka** which provide some support for logicals via conversion to or from factors.

## Examples

```
write.arff(iris, file = "")
```

---

|           |                         |
|-----------|-------------------------|
| write.dbf | <i>Write a DBF File</i> |
|-----------|-------------------------|

---

## Description

The function tries to write a data frame to a DBF file.

## Usage

```
write.dbf(dataframe, file, factor2char = TRUE, max_nchar = 254)
```

## Arguments

|             |                                                                                                                                         |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| dataframe   | a data frame object.                                                                                                                    |
| file        | a file name to be written to.                                                                                                           |
| factor2char | logical, default TRUE, convert factor columns to character: otherwise they are written as the internal integer codes.                   |
| max_nchar   | The maximum number of characters allowed in a character field. Strings which exceed this will be truncated with a warning. See Details. |

## Details

Dots in column names are replaced by underlines in the DBF file, and names are truncated to 11 characters.

Only vector columns of classes "logical", "numeric", "integer", "character", "factor" and "Date" can be written. Other columns should be converted to one of these.

Maximum precision (number of digits including minus sign and decimal sign) for numeric is 19 - scale (digits after the decimal sign) which is calculated internally based on the number of digits before the decimal sign.

The original DBASE format limited character fields to 254 bytes. It is said that Clipper and FoxPro can read up to 32K, and it is possible to write a reader that could accept up to 65535 bytes. (The documentation suggests that only ASCII characters can be assumed to be supported.) Readers expecting the older standard (which includes Excel 2003, Access 2003 and OpenOffice 2.0) will truncate the field to the maximum width modulo 256, so increase `max_nchar` only if you are sure the intended reader supports wider character fields.

## Value

Invisible NULL.

## Note

Other applications have varying abilities to read the data types used here. Microsoft Access reads "numeric", "integer", "character" and "Date" fields, including recognizing missing values, but not "logical" (read as 0, -1). Microsoft Excel understood all possible types but did not interpret missing values in character fields correctly (showing them as character nuls).

---

write.dta

*Write Files in Stata Binary Format*

---

## Description

Writes the data frame to file in the Stata binary format. Does not write array variables unless they can be [drop](#)-ed to a vector.

Frozen: will not support Stata formats after 10 (also used by Stata 11).

## Usage

```
write.dta(dataframe, file, version = 7L,
          convert.dates = TRUE, tz = "GMT",
          convert.factors = c("labels", "string", "numeric", "codes"))
```

## Arguments

|                 |                                                                                       |
|-----------------|---------------------------------------------------------------------------------------|
| dataframe       | a data frame.                                                                         |
| file            | character string giving filename.                                                     |
| version         | integer: Stata version: 6, 7, 8 and 10 are supported, and 9 is mapped to 8, 11 to 10. |
| convert.dates   | logical: convert Date and POSIXct objects: see section ‘Dates’.                       |
| tz              | timezone for date conversion.                                                         |
| convert.factors | how to handle factors.                                                                |

## Details

The major difference between supported file formats in Stata versions is that version 7.0 and later allow 32-character variable names (5 and 6 were restricted to 8-character names). The `abbreviate` function is used to trim variable names to the permitted length. A warning is given if this is needed and it is an error for the abbreviated names not to be unique. Each version of Stata is claimed to be able to read all earlier formats.

The columns in the data frame become variables in the Stata data set. Missing values are handled correctly.

There are four options for handling factors. The default is to use Stata 'value labels' for the factor levels. With `convert.factors = "string"`, the factor levels are written as strings (the name of the value label is taken from the `"val.labels"` attribute if it exists or the variable name otherwise). With `convert.factors = "numeric"` the numeric values of the levels are written, or NA if they cannot be coerced to numeric. Finally, `convert.factors = "codes"` writes the underlying integer codes of the factors. This last used to be the only available method and is provided largely for backwards compatibility.

If the `"label.table"` attribute contains value labels with names not already attached to a variable (not the variable name or name from `"val.labels"`) then these will be written out as well.

If the `"datalabel"` attribute contains a string, it is written out as the dataset label otherwise the dataset label is `"Written by R."`.

If the `"expansion.table"` attribute exists expansion fields are written. This attribute should contain a `list` where each element is a `character` vector of length three. The first vector element contains the name of a variable or `"_dta"` (meaning the dataset). The second element contains the characteristic name. The third contains the associated data.

If the `"val.labels"` attribute contains a `character` vector with a string label for each value then this is written as the value labels. Otherwise the variable names are used.

If the `"var.labels"` attribute contains a `character` vector with a string label for each variable then this is written as the variable labels. Otherwise the variable names are repeated as variable labels.

For Stata 8 or later use the default `version = 7` – the only advantage of Stata 8 format over 7 is that it can represent multiple different missing value types, and R doesn't have them. Stata 10/11 allows longer format lists, but R does not make use of them.

Note that the Stata formats are documented to use ASCII strings – R does not enforce this, but use of non-ASCII character strings will not be portable as the encoding is not recorded. Up to 244 bytes are allowed in character data, and longer strings will be truncated with a warning.

Stata uses some large numerical values to represent missing values. This function does not currently check, and hence integers greater than 2147483620 and doubles greater than  $8.988e+307$  may be misinterpreted by Stata.

## Value

NULL

## Dates

Unless disabled by argument `convert.dates = FALSE`, R date and date-time objects (`POSIXt` classes) are converted into the Stata date format, the number of days since 1960-01-01. (For date-time objects this may lose information.) Stata can be told that these are dates by

```
format xdate %td;
```

It is possible to pass objects of class `POSIXct` to Stata to be treated as one of its versions of date-times. Stata uses the number of milliseconds since 1960-01-01, either excluding (format `%tc`) or counting (format `%tC`) leap seconds. So either an object of class `POSIXct` can be passed to Stata with `convert.dates = FALSE` and converted in Stata, or 315619200 should be added and then multiplied by 1000 before passing to `write.dta` and assigning format `%tc`. Stata's comments on the first route are at <https://www.stata.com/manuals13/ddatetime.pdf>, but at the time of writing were wrong: R uses POSIX conventions and hence does not count leap seconds.

read.dta(swissfile)
```

---

write.foreign

*Write Text Files and Code to Read Them*

---

### Description

This function exports simple data frames to other statistical packages by writing the data as free-format text and writing a separate file of instructions for the other package to read the data.

### Usage

```
write.foreign(df, datafile, codefile,
              package = c("SPSS", "Stata", "SAS"), ...)
```

### Arguments

|                       |                                                                        |
|-----------------------|------------------------------------------------------------------------|
| <code>df</code>       | A data frame                                                           |
| <code>datafile</code> | Name of file for data output                                           |
| <code>codefile</code> | Name of file for code output                                           |
| <code>package</code>  | Name of package                                                        |
| <code>...</code>      | Other arguments for the individual <code>writeForeign</code> functions |

## Details

The work for this function is done by `foreign::writeForeignStata`, `foreign::writeForeignSAS` and `foreign::writeForeignSPSS`. To add support for another package, eg Systat, create a function `writeForeignSystat` with the same first three arguments as `write.foreign`. This will be called from `write.foreign` when `package="Systat"`.

Numeric variables and factors are supported for all packages: dates and times (`Date`, `dates`, `date`, and `POSIXt` classes) and logical vectors are also supported for SAS and characters are supported for SPSS.

For `package="SAS"` there are optional arguments `dataname = "rdata"` taking a string that will be the SAS data set name, `validvarname` taking either `"V6"` or `"V7"`, and `libpath = NULL` taking a string that will be the directory where the target SAS dataset will be written when the generated SAS code been run.

For `package="SPSS"` there is an optional argument `maxchars = 32L` taking an integer that causes the variable names (not variable labels) to be abbreviated to not more than `maxchars` chars. For compatibility with SPSS version 12 and before, change this to `maxchars = 8L`. In single byte locales with SPSS versions 13 or later, this can be set to `maxchars = 64L`.

For `package="SPSS"`, as a side effect, the decimal indicator is always set by `SET DECIMAL=DOT.` which may override user settings of the indicator or its default derived from the current locale.

## Value

Invisible `NULL`.

## Author(s)

Thomas Lumley and Stephen Weigand

## Examples

```
## Not run:
datafile <- tempfile()
codefile <- tempfile()
write.foreign(esoph, datafile, codefile, package="SPSS")
file.show(datafile)
file.show(codefile)
unlink(datafile)
unlink(codefile)

## End(Not run)
```

## Chapter 23

# The `lattice` package

---

A\_01\_Lattice

*Lattice Graphics*

---

### Description

The **lattice** add-on package is an implementation of Trellis graphics for R. It is a powerful and elegant high-level data visualization system with an emphasis on multivariate data. It is designed to meet most typical graphics needs with minimal tuning, but can also be easily extended to handle most nonstandard requirements.

### Details

Trellis Graphics, originally developed for S and S-PLUS at the Bell Labs, is a framework for data visualization developed by R. A. Becker, W. S. Cleveland, et al, extending ideas presented in Cleveland's 1993 book *Visualizing Data*. The Lattice API is based on the original design in S, but extends it in many ways.

The Lattice user interface primarily consists of several 'high-level' generic functions (listed below in the "See Also" section), each designed to create a particular type of display by default. Although the functions produce different output, they share many common features, reflected in several common arguments that affect the resulting displays in similar ways. These arguments are extensively (sometimes only) documented in the help page for `xyplot`, which also includes a discussion of the important topics of *conditioning* and control of the Trellis layout. Features specific to other high-level functions are documented in their respective help pages.

Lattice employs an extensive system of user-controllable settings to determine the look and feel of the displays it produces. To learn how to use and customize the graphical parameters used by lattice, see `trellis.par.set`. For other settings, see `lattice.options`. The default graphical settings are (potentially) different for different graphical devices. To learn how to initialize new devices with the desired settings or change the settings of the current device, see `trellis.device`.

It is usually unnecessary, but sometimes important to be able to plot multiple lattice plots on a single page. Such capabilities are described in the `print.trellis` help page. See `update.trellis` to learn about manipulating a "trellis" object. Tools to augment lattice plots after they are drawn (including *locator*-like functionality) are described in the `trellis.focus` help page.

The online documentation accompanying the package is complete, and effort has been made to present the help pages in a logical sequence, so that one can learn how to use lattice by reading the

PDF reference manual available at <https://cran.r-project.org/package=lattice>. However, the format in which the online documentation is written and the breadth of topics covered necessarily makes it somewhat terse and less than ideal as a first introduction. For a more gentle introduction, a book on lattice is available as part of Springer's 'Use R' series; see the "References" section below.

### Note

High-level **lattice** functions like `xyplot` are different from traditional R graphics functions in that they do not perform any plotting themselves. Instead, they return an object, of class "trellis", which has to be then `print`-ed or `plot`-ted to create the actual plot. Due to R's automatic printing rule, it is usually not necessary to explicitly carry out the second step, and **lattice** functions appear to behave like their traditional counterparts. However, the automatic plotting is suppressed when the high-level functions are called inside another function (most often `source`) or in other contexts where automatic printing is suppressed (e.g., `for` or `while` loops). In such situations, an explicit call to `print` or `plot` is required.

The **lattice** package is based on the Grid graphics engine and requires the **grid** add-on package. One consequence of this is that it is not (readily) compatible with traditional R graphics tools. In particular, changing `par()` settings usually has no effect on Lattice plots; **lattice** provides its own interface for querying and modifying an extensive set of graphical and non-graphical settings.

### See Also

The following is a list of high-level functions in the **lattice** package and their default displays. In all cases, the actual display is produced by the so-called "panel" function, which has a suitable default, but can be substituted by an user defined function to create customized displays. In many cases, the default panel function will itself have many optional arguments to customize its output. The default panel functions are named as "panel." followed by the name of the corresponding high-level function; i.e., the default panel function for `xyplot` is `panel.xyplot`, the one for `histogram` is `panel.histogram`, etc. Each default panel function has a separate help page, linked from the help pages of the corresponding high-level function. Although documented separately, arguments to these panel functions can be supplied directly to the high-level functions, which will pass on the arguments appropriately.

#### Univariate:

`barchart`: Bar plots.

`bwplot`: Box-and-whisker plots.  
`densityplot`: Kernel density estimates.  
`dotplot`: Cleveland dot plots.  
`histogram`: Histograms.  
`qqmath`: Theretical quantile plots.  
`stripplot`: One-dimensional scatterplots.

#### **Bivariate:**

`qq`: Quantile plots for comparing two distributions.  
`xyplot`: Scatterplots and time-series plots (and potentially a lot more).

#### **Trivariate:**

`levelplot`: Level plots (similar to `image` plots).  
`contourplot`: Contour plots.  
`cloud`: Three-dimensional scatter plots.  
`wireframe`: Three-dimensional surface plots (similar to `persp` plots).

#### **Hypervariate:**

`splom`: Scatterplot matrices.  
`parallel`: Parallel coordinate plots.

#### **Miscellaneous:**

`rfs`: Residual and fitted value plots (also see `oneway`).  
`tmd`: Tukey Mean-Difference plots.

In addition, there are several panel functions that do little by themselves, but can be useful components of custom panel functions. These are documented in `panel.functions`. Lattice also provides a collection of convenience functions that correspond to the traditional graphics primitives `lines`, `points`, etc. These are implemented using Grid graphics, but try to be as close to the traditional versions as possible in terms of their argument list. These functions have names like `llines` or `panel.lines` and are often useful when writing (or porting from S-PLUS code) nontrivial panel functions.

Finally, many useful enhancements that extend the Lattice system are available in the **latticeExtra** package.

### **Examples**

```
## Not run:

## Show brief history of changes to lattice, including
## a summary of new features.

RShowDoc("NEWS", package = "lattice")

## End(Not run)
```

## Description

This help page documents several commonly used high-level Lattice functions. `xyplot` produces bivariate scatterplots or time-series plots, `bwplot` produces box-and-whisker plots, `dotplot` produces Cleveland dot plots, `barchart` produces bar plots, and `stripplot` produces one-dimensional scatterplots. All these functions, along with other high-level Lattice functions, respond to a common set of arguments that control conditioning, layout, aspect ratio, legends, axis annotation, and many other details in a consistent manner. These arguments are described extensively in this help page, and should be used as the reference for other high-level functions as well.

For control and customization of the actual display in each panel, the help page of the respective default panel function will often be more informative. In particular, these help pages describe many arguments commonly used when calling the corresponding high-level function but are specific to them.

## Usage

```
xyplot(x, data, ...)
dotplot(x, data, ...)
barchart(x, data, ...)
stripplot(x, data, ...)
bwplot(x, data, ...)

## S3 method for class 'formula'
xyplot(x,
  data,

  outer = !is.null(groups),
  auto.key = FALSE,
  aspect = "fill",
  panel = lattice.getOption("panel.xyplot"),
  prepanel = NULL,
  scales = list(),
  strip = TRUE,
  groups = NULL,
  xlab,
  xlim,
  ylab,
  ylim,
  drop.unused.levels = lattice.getOption("drop.unused.levels"),
  ...,
  lattice.options = NULL,
  default.scales,
  default.prepanel = lattice.getOption("prepanel.default.xyplot"),
  subscripts = !is.null(groups),
  subset = TRUE)

## S3 method for class 'formula'
```

```

dotplot(x,
        data,
        panel = lattice.getOption("panel.dotplot"),
        default.prepanel = lattice.getOption("prepanel.default.dotplot"),
        ...)

## S3 method for class 'formula'
barchart(x,
         data,
         panel = lattice.getOption("panel.barchart"),
         default.prepanel = lattice.getOption("prepanel.default.barchart"),
         box.ratio = 2,
         ...)

## S3 method for class 'formula'
stripplot(x,
          data,
          panel = lattice.getOption("panel.stripplot"),
          default.prepanel = lattice.getOption("prepanel.default.stripplot"),
          ...)

## S3 method for class 'formula'
bwplot(x,
       data,
       allow.multiple = is.null(groups) || outer,
       outer = FALSE,
       auto.key = FALSE,
       aspect = "fill",
       panel = lattice.getOption("panel.bwplot"),
       prepanel = NULL,
       scales = list(),
       strip = TRUE,
       groups = NULL,
       xlab,
       xlim,
       ylab,
       ylim,
       box.ratio = 1,
       horizontal = NULL,
       drop.unused.levels = lattice.getOption("drop.unused.levels"),
       ...,
       lattice.options = NULL,
       default.scales,
       default.prepanel = lattice.getOption("prepanel.default.bwplot"),
       subscripts = !is.null(groups),
       subset = TRUE)

```

## Arguments

**x** All high-level function in **lattice** are generic. **x** is the object on which method dispatch is carried out.  
For the "formula" methods, **x** must be a formula describing the primary vari-

ables (used for the per-panel display) and the optional conditioning variables (which define the subsets plotted in different panels) to be used in the plot. Conditioning is described in the “Details” section below.

For the functions documented here, the formula is generally of the form  $y \sim x \mid g1 * g2 * \dots$  (or equivalently,  $y \sim x \mid g1 + g2 + \dots$ ), indicating that plots of  $y$  (on the y-axis) versus  $x$  (on the x-axis) should be produced conditional on the variables  $g1, g2, \dots$ . Here  $x$  and  $y$  are the primary variables, and  $g1, g2, \dots$  are the conditioning variables. The conditioning variables may be omitted to give a formula of the form  $y \sim x$ , in which case the plot will consist of a single panel with the full dataset. The formula can also involve expressions, e.g., `sqrt()`, `log()`, etc. See the `data` argument below for rules regarding evaluation of the terms in the formula.

With the exception of `xyplot`, the functions documented here may also be supplied a formula of the form  $\sim x \mid g1 * g2 * \dots$ . In that case,  $y$  defaults to `names(x)` if  $x$  is named, and a factor with a single level otherwise.

Cases where  $x$  is not a formula is handled by appropriate methods. The numeric methods are equivalent to a call with no left hand side and no conditioning variables in the formula. For `barchart` and `dotplot`, non-trivial methods exist for tables and arrays, documented at [barchart.table](#).

The conditioning variables  $g1, g2, \dots$  must be either factors or shingles. Shingles provide a way of using numeric variables for conditioning; see the help page of [shingle](#) for details. Like factors, they have a “levels” attribute, which is used in producing the conditional plots. If necessary, numeric conditioning variables are converted to shingles using the `shingle` function; however, using `equal.count` may be more appropriate in many cases. Character variables are coerced to factors.

**Extended formula interface:** As a useful extension of the interface described above, the primary variable terms (both the LHS  $y$  and RHS  $x$ ) may consist of multiple terms separated by a ‘+’ sign, e.g.,  $y1 + y2 \sim x \mid a * b$ . This formula would be taken to mean that the user wants to plot both  $y1 \sim x \mid a * b$  and  $y2 \sim x \mid a * b$ , but with the  $y1 \sim x$  and  $y2 \sim x$  superposed in each panel. The two groups will be distinguished by different graphical parameters. This is essentially what the `groups` argument (see below) would produce, if  $y1$  and  $y2$  were concatenated to produce a longer vector, with the `groups` argument being an indicator of which rows come from which variable. In fact, this is exactly what is done internally using the `reshape` function. This feature cannot be used in conjunction with the `groups` argument.

To interpret  $y1 + y2$  as a sum, one can either set `allow.multiple=FALSE` or use `I(y1+y2)`.

A variation on this feature is when the `outer` argument is set to `TRUE`. In that case, the plots are not superposed in each panel, but instead separated into different panels (as if a new conditioning variable had been added).

**Primary variables:** The  $x$  and  $y$  variables should both be numeric in `xyplot`, and an attempt is made to coerce them if not. However, if either is a factor, the levels of that factor are used as axis labels. In the other four functions documented here, exactly one of  $x$  and  $y$  should be numeric, and the other a factor or shingle. Which of these will happen is determined by the `horizontal` argument — if `horizontal=TRUE`, then  $y$  will be coerced to be a factor or shingle, otherwise  $x$ . The default value of `horizontal` is `FALSE` if  $x$  is a factor or shingle, `TRUE` otherwise. (The functionality provided by `horizontal=FALSE` is not S-compatible.)

Note that the `x` argument used to be called `formula` in earlier versions (when the high-level functions were not generic and the `formula` method was essentially the only method). This is no longer allowed. It is recommended that this argument not be named in any case, but instead be the first (unnamed) argument.

`data` For the `formula` methods, a data frame (or more precisely, anything that is a valid `envir` argument in `eval`, e.g., a list or an environment) containing values for any variables in the formula, as well as `groups` and `subset` if applicable. If not found in `data`, or if `data` is unspecified, the variables are looked for in the environment of the formula. For other methods (where `x` is not a formula), `data` is usually ignored, often with a warning if it is explicitly specified.

`allow.multiple`

Logical flag specifying whether the extended formula interface described above should be in effect. Defaults to `TRUE` whenever sensible.

`outer`

Logical flag controlling what happens with formulas using the extended interface described above (see the entry for `x` for details). Defaults to `FALSE`, except when `groups` is explicitly specified or grouping does not make sense for the default panel function.

`box.ratio`

Applicable to `barchart` and `bwplot`. Specifies the ratio of the width of the rectangles to the inter-rectangle space. See also the `box.width` argument in the respective default panel functions.

`horizontal`

Logical flag applicable to `bwplot`, `dotplot`, `barchart`, and `stripplot`. Determines which of `x` and `y` is to be a factor or shingle (`y` if `TRUE`, `x` otherwise). Defaults to `FALSE` if `x` is a factor or shingle, `TRUE` otherwise. This argument is used to process the arguments to these high-level functions, but more importantly, it is passed as an argument to the panel function, which is expected to use it as appropriate.

A potentially useful component of `scales` in this case may be `abbreviate = TRUE`, in which case long labels which would usually overlap will be abbreviated. `scales` could also contain a `minlength` argument in this case, which would be passed to the `abbreviate` function.

**Common arguments:** The following arguments are common to all the functions documented here, as well as most other high-level Trellis functions. These are not documented elsewhere, except to override the usage given here.

`panel`

Once the subset of rows defined by each unique combination of the levels of the grouping variables are obtained (see “Details”), the corresponding `x` and `y` variables (or other variables, as appropriate, in the case of other high-level functions) are passed on to be plotted in each panel. The actual plotting is done by the function specified by the `panel` argument. The argument may be a function object or a character string giving the name of a predefined function. Each high-level function has its own default panel function, named as “`panel.`” followed by the name of the corresponding high-level function (e.g., `panel.xyplot`, `panel.barchart`, etc).

Much of the power of Trellis Graphics comes from the ability to define customized panel functions. A panel function appropriate for the functions described here would usually expect arguments named `x` and `y`, which would be provided by the conditioning process. It can also have other arguments. It is useful to know in this context that all arguments passed to a high-level Lattice function (such as `xyplot`) that are not recognized by it are passed through to the panel function. It is thus generally good practice when defining panel functions to allow a `...` argument. Such extra arguments typically control graphical

parameters, but other uses are also common. See documentation for individual panel functions for specifics.

Note that unlike in S-PLUS, it is not guaranteed that panel functions will be supplied only numeric vectors for the `x` and `y` arguments; they can be factors as well (but not shingles). Panel functions need to handle this case, which in most cases can be done by simply coercing them to numeric.

Technically speaking, panel functions must be written using Grid graphics functions. However, knowledge of Grid is usually not necessary to construct new custom panel functions, as there are several predefined panel functions which can help; for example, `panel.grid`, `panel.loess`, etc. There are also some grid-compatible replacements of commonly used traditional graphics functions useful for this purpose. For example, `lines` can be replaced by `llines` (or equivalently, `panel.lines`). Note that traditional graphics functions like `lines` will not work in a lattice panel function.

One case where a bit more is required of the panel function is when the `groups` argument is not `NULL`. In that case, the panel function should also accept arguments named `groups` and `subscripts` (see below for details). A useful panel function predefined for use in such cases is `panel.superpose`, which can be combined with different `panel.groups` functions to determine what is plotted for each group. See the “Examples” section for an interaction plot constructed in this way. Several other panel functions can also handle the `groups` argument, including the default ones for `xyplot`, `barchart`, `dotplot`, and `stripplot`.

Even when `groups` is not present, the panel function can have `subscripts` as a formal argument. In either case, the `subscripts` argument passed to the panel function are the indices of the `x` and `y` data for that panel in the original data, BEFORE taking into account the effect of the `subset` argument. Note that `groups` remains unaffected by any subsetting operations, so `groups[subscripts]` gives the values of `groups` that correspond to the data in that panel.

This interpretation of `subscripts` does not hold when the extended formula interface is in use (i.e., when `allow.multiple` is in effect). A comprehensive description would be too complicated (details can be found in the source code of the function `latticeParseFormula`), but in short, the extended interface works by creating an artificial grouping variable that is longer than the original data frame, and consequently, `subscripts` needs to refer to rows beyond those in the original data. To further complicate matters, the artificial grouping variable is created after any effect of `subset`, in which case `subscripts` may have no relationship with corresponding rows in the original data frame.

One can also use functions called `panel.number` and `packet.number`, representing panel order and packet order respectively, inside the panel function (as well as the `strip` function or while interacting with a lattice display using `trellis.focus` etc). Both provide a simple integer index indicating which panel is currently being drawn, but differ in how the count is calculated. The panel number is a simple incremental counter that starts with 1 and is incremented each time a panel is drawn. The packet number on the other hand indexes the combination of levels of the conditioning variables that is represented by that panel. The two indices coincide unless the order of conditioning variables is permuted and/or the plotting order of levels within one or more conditioning variables is altered (using `perm.cond` and `index.cond` respectively), in which case `packet.number` gives the index corresponding to the ‘natural’

ordering of that combination of levels of the conditioning variables.

`panel.xyplot` has an argument called `type` which is worth mentioning here because it is quite frequently used (and as mentioned above, can be passed to `xyplot` directly). In the event that a `groups` variable is used, `panel.xyplot` calls `panel.superpose`, arguments of which can also be passed directly to `xyplot`. Panel functions for `bwplot` and friends should have an argument called `horizontal` to account for the cases when `x` is the factor or shingle.

`aspect`

This argument controls the physical aspect ratio of the panels, which is usually the same for all the panels. It can be specified as a ratio (vertical size/horizontal size) or as a character string. In the latter case, legitimate values are `"fill"` (the default) which tries to make the panels as big as possible to fill the available space; `"xy"`, which computes the aspect ratio based on the 45 degree banking rule (see `banking`); and `"iso"` for isometric scales, where the relation between physical distance on the device and distance in the data scale are forced to be the same for both axes.

If a `prepanel` function is specified and it returns components `dx` and `dy`, these are used for banking calculations. Otherwise, values from the default `prepanel` function are used. Not all default `prepanel` functions produce sensible banking calculations.

`groups`

A variable or expression to be evaluated in `data`, expected to act as a grouping variable within each panel, typically used to distinguish different groups by varying graphical parameters like color and line type. Formally, if `groups` is specified, then `groups` along with `subscripts` is passed to the panel function, which is expected to handle these arguments. For high level functions where grouping is appropriate, the default panel functions can handle grouping.

It is very common to use a key (legend) when a grouping variable is specified. See entries for `key`, `auto.key` and `simpleKey` for how to draw a key.

`auto.key`

A logical, or a list containing components to be used as arguments to `simpleKey`. `auto.key=TRUE` is equivalent to `auto.key=list()`, in which case `simpleKey` is called with a set of default arguments (which may depend on the relevant high-level function). Most valid components to the `key` argument can be specified in this manner, as `simpleKey` will simply add unrecognized arguments to the list it produces.

`auto.key` is typically used to automatically produce a suitable legend in conjunction with a grouping variable. If `auto.key=TRUE`, a suitable legend will be drawn if a `groups` argument is also provided, and not otherwise. In list form, `auto.key` will modify the default legend thus produced. For example, `auto.key=list(columns=2)` will create a legend split into two columns (`columns` is documented in the entry for `key`).

More precisely, if `auto.key` is not `FALSE`, `groups` is non-null, and there is no `key` or `legend` argument specified in the call, a key is created with `simpleKey` with `levels(groups)` as the first (`text`) argument. (Note: this may not work in all high-level functions, but it does work for the ones where grouping makes sense with the default panel function). If `auto.key` is provided as a list and includes a `text` component, then that is used instead as the text labels in the key, and the key is drawn even if `groups` is not specified.

Note that `simpleKey` uses the default settings (see `trellis.par.get`) to determine the graphical parameters in the key, so the resulting legend will be meaningful only if the same settings are used in the plot as well. The

`par.settings` argument, possibly in conjunction with [simpleTheme](#), may be useful to temporarily modify the default settings for this purpose.

One disadvantage to using `key` (or even `simpleKey`) directly is that the graphical parameters used in the key are absolutely determined at the time when the "trellis" object is created. Consequently, if a plot once created is re-plotted with different settings, the original parameter settings will be used for the key even though the new settings are used for the actual display. However, with `auto.key`, the key is actually created at plotting time, so the settings will match.

`prepanel`

A function that takes the same arguments as the `panel` function and returns a list, possibly containing components named `xlim`, `ylim`, `dx`, and `dy` (and less frequently, `xat` and `yat`). The return value of a user-supplied `prepanel` function need not contain all these components; in case some are missing, they are replaced by the component-wise defaults.

The `xlim` and `ylim` components are similar to the high level `xlim` and `ylim` arguments (i.e., they are usually a numeric vector of length 2 defining a range, or a character vector representing levels of a factor). If the `xlim` and `ylim` arguments are not explicitly specified (possibly as components in `scales`) in the high-level call, then the actual limits of the panels are guaranteed to include the limits returned by the `prepanel` function. This happens globally if the `relation` component of `scales` is "same", and on a per-panel basis otherwise.

The `dx` and `dy` components are used for banking computations in case `aspect` is specified as "xy". See documentation of [banking](#) for details.

If `xlim` or `ylim` is a character vector (which is appropriate when the corresponding variable is a factor), this implicitly indicates that the scale should include the first `n` integers, where `n` is the length of `xlim` or `ylim`, as the case may be. The elements of the character vector are used as the default labels for these `n` integers. Thus, to make this information consistent between panels, the `xlim` or `ylim` values should represent all the levels of the corresponding factor, even if some are not used within that particular panel.

In such cases, an additional component `xat` or `yat` may be returned by the `prepanel` function, which should be a subset of `1:n`, indicating which of the `n` values (levels) are actually represented in the panel. This is useful when calculating the limits with `relation="free"` or `relation="sliced"` in `scales`.

The `prepanel` function is responsible for providing a meaningful return value when the `x`, `y` (etc.) variables are zero-length vectors. When nothing else is appropriate, values of NA should be returned for the `xlim` and `ylim` components.

`strip`

A logical flag or function. If `FALSE`, strips are not drawn. Otherwise, strips are drawn using the `strip` function, which defaults to `strip.default`. See documentation of [strip.default](#) to see the arguments that are available to the `strip` function. This description also applies to the `strip.left` argument (see . . . below), which can be used to draw strips on the left of each panel (useful for wide short panels, e.g., in time-series plots).

`xlab`

Character or expression (or a "grob") giving label(s) for the x-axis. Generally defaults to the expression for `x` in the formula defining the plot. Can be specified as `NULL` to omit the label altogether. Finer control is possible, as described in the entry for `main`, with the modification that if the `label` component is omitted from the list, it is replaced by the default `xlab`.

**ylab** Character or expression (or "grob") giving label for the y-axis. Generally defaults to the expression for *y* in the formula defining the plot. Finer control is possible, see entries for *main* and *xlab*.

**scales** Generally a list determining how the x- and y-axes (tick marks and labels) are drawn. The list contains parameters in *name=value* form, and may also contain two other lists called *x* and *y* of the same form (described below). Components of *x* and *y* affect the respective axes only, while those in *scales* affect both. When parameters are specified in both lists, the values in *x* or *y* are used. Note that certain high-level functions have defaults that are specific to a particular axis (e.g., *bwplot* has *alternating=FALSE* for the categorical axis only); these can only be overridden by an entry in the corresponding component of *scales*.

As a special exception, *scales* (or its *x* and *y* components) can also be a character string, in which case it is interpreted as the *relation* component.

The possible components are :

**relation** A character string that determines how axis limits are calculated for each panel. Possible values are "same" (default), "free" and "sliced". For *relation="same"*, the same limits, usually large enough to encompass all the data, are used for all the panels. For *relation="free"*, limits for each panel is determined by just the points in that panel. Behavior for *relation="sliced"* is similar, except that the length (max - min) of the scales are constrained to remain the same across panels.

The determination of what axis limits are suitable for each panel can be controlled by the *prepanel* function, which can be overridden by *xlim*, *ylim* or *scales\$limits* (except when *relation="sliced"*, in which case explicitly specified limits are ignored with a warning). When *relation* is "free", *xlim* or *ylim* can be a list, in which case it is treated as if its components were the limit values obtained from the *prepanel* calculations for each panel (after being replicated if necessary).

**tick.number** An integer, giving the suggested number of intervals between ticks. This is ignored for a factor, shingle, or character vector, for in these cases there is no natural rule for leaving out some of the labels. But see *xlim*.

**draw** A logical flag, defaulting to TRUE, that determines whether to draw the axis (i.e., tick marks and labels) at all.

**alternating** Usually a logical flag specifying whether axis labels should alternate from one side of the group of panels to the other. For finer control, *alternating* can also be a vector (replicated to be as long as the number of rows or columns per page) consisting of the following numbers

- 0: do not draw tick labels
- 1: bottom/left
- 2: top/right
- 3: both.

*alternating* applies only when *relation="same"*. The default is TRUE, or equivalently, *c(1, 2)*

**limits** Same as *xlim* and *ylim*.

**at** The location of tick marks along the axis (in native coordinates), or a list as long as the number of panels describing tick locations for each panel.

**labels** Vector of labels (characters or expressions) to go along with *at*. Can also be a list like *at*.

- cex** A numeric multiplier to control character sizes for axis labels. Can be a vector of length 2, to control left/bottom and right/top labels separately.
- font, fontface, fontfamily** Specifies the font to be used for axis labels.
- lineheight** Specifies the line height parameter (height of line as a multiple of the size of text); relevant for multi-line labels. (This is currently ignored for `cloud`.)
- tck** Usually a numeric scalar controlling the length of tick marks. Can also be a vector of length 2, to control the length of left/bottom and right/top tick marks separately.
- col** Color of tick marks and labels.
- rot** Angle (in degrees) by which the axis labels are to be rotated. Can be a vector of length 2, to control left/bottom and right/top axes separately.
- abbreviate** A logical flag, indicating whether to abbreviate the labels using the `abbreviate` function. Can be useful for long labels (e.g., in factors), especially on the x-axis.
- minlength** Argument passed to `abbreviate` if `abbreviate=TRUE`.
- log** Controls whether the corresponding variable (x or y) will be log transformed before being passed to the panel function. Defaults to `FALSE`, in which case the data are not transformed. Other possible values are any number that works as a base for taking logarithm, `TRUE` (which is equivalent to 10), and `"e"` (for the natural logarithm). As a side effect, the corresponding axis is labeled differently. Note that this is in reality a transformation of the data, not the axes. Other than the axis labeling, using this feature is no different than transforming the data in the formula; e.g., `scales=list(x = list(log = 2))` is equivalent to  $y \sim \log_2(x)$ . See entry for `equispaced.log` below for details on how to control axis labeling.
- equispaced.log** A logical flag indicating whether tick mark locations should be equispaced when 'log scales' are in use. Defaults to `TRUE`. Tick marks are always labeled in the original (untransformed) scale, but this makes the choice of tick mark locations nontrivial. If `equispaced.log` is `FALSE`, the choice made is similar to how log scales are annotated in traditional graphics. If `TRUE`, tick mark locations are chosen as 'pretty' equispaced values in the transformed scale, and labeled in the form `"base^loc"`, where `base` is the base of the logarithm transformation, and `loc` are the locations in the transformed scale. See also `xscale.components.logpower` in the **latticeExtra** package.
- format** The format to use for POSIXct variables. See `strptime` for description of valid values.
- axis** A character string, `"r"` (default) or `"i"`. In the latter case, the axis limits are calculated as the exact data range, instead of being padded on either side. (May not always work as expected.)

Note that much of the function of `scales` is accomplished by `pscales` in `splom`.

- subscripts** A logical flag specifying whether or not a vector named `subscripts` should be passed to the panel function. Defaults to `FALSE`, unless `groups` is specified, or if the panel function accepts an argument named `subscripts`. This argument is useful if one wants the subscripts to be passed on even if these conditions do not hold; a typical example is when one wishes to augment a Lattice plot after it has been drawn, e.g., using `panel.identify`.

|                                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|---------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>subset</code>             | An expression that evaluates to a logical or integer indexing vector. Like groups, it is evaluated in data. Only the resulting rows of data are used for the plot. If <code>subscripts</code> is <code>TRUE</code> , the subscripts provided to the panel function will be indices referring to the rows of data prior to the subsetting. Whether levels of factors in the data frame that are unused after the subsetting will be dropped depends on the <code>drop.unused.levels</code> argument.                                                                                                                                                                                                                                                                                        |
| <code>xlim</code>               | Normally a numeric vector (or a <code>DateTime</code> object) of length 2 giving left and right limits for the x-axis, or a character vector, expected to denote the levels of <code>x</code> . The latter form is interpreted as a range containing <code>c(1, length(xlim))</code> , with the character vector determining labels at tick positions <code>1:length(xlim)</code> .<br><br><code>xlim</code> could also be a list, with as many components as the number of panels (recycled if necessary), with each component as described above. This is meaningful only when <code>scales\$x\$relation</code> is <code>"free"</code> , in which case these are treated as if they were the corresponding limit components returned by <code>prepanel</code> calculations.              |
| <code>ylim</code>               | Similar to <code>xlim</code> , applied to the y-axis.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>drop.unused.levels</code> | A logical flag indicating whether the unused levels of factors will be dropped, usually relevant when a subsetting operation is performed or an <a href="#">interaction</a> is created. Unused levels are usually dropped, but it is sometimes appropriate to suppress dropping to preserve a useful layout. For finer control, this argument could also be list containing components <code>cond</code> and <code>data</code> , both logical, indicating desired behavior for conditioning variables and primary variables respectively. The default is given by <code>lattice.getOption("drop.unused.levels")</code> , which is initially set to <code>TRUE</code> for both components. Note that this argument does not control dropping of levels of the <code>groups</code> argument. |
| <code>default.scales</code>     | A list giving the default values of <code>scales</code> for a particular high-level function. This is rarely of interest to the end-user, but may be helpful when defining other functions that act as a wrapper to one of the high-level Lattice functions.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>default.prepanel</code>   | A function or character string giving the name of a function that serves as the (component-wise) fallback <code>prepanel</code> function when the <code>prepanel</code> argument is not specified, or does not return all necessary components. The main purpose of this argument is to enable the defaults to be overridden through the use of <a href="#">lattice.options</a> .                                                                                                                                                                                                                                                                                                                                                                                                          |
| <code>lattice.options</code>    | A list that could be supplied to <a href="#">lattice.options</a> . These options are applied temporarily for the duration of the call, after which the settings revert back to what they were before. The options are retained along with the object and reused during plotting. This enables the user to attach options settings to the trellis object itself rather than change the settings globally. See also the <code>par.settings</code> argument described below for a similar treatment of graphical settings.                                                                                                                                                                                                                                                                    |
| <code>...</code>                | Further arguments, usually not directly processed by the high-level functions documented here, but instead passed on to other functions. Such arguments can be broadly categorized into two types: those that affect all high-level Lattice functions in a similar manner, and those that are meant for the specific panel function being used.<br><br>The first group of arguments are processed by a common, unexported function called <code>trellis.skeleton</code> . These arguments affect all high-level functions,                                                                                                                                                                                                                                                                 |

but are only documented here (except to override the behaviour described here). All other arguments specified in a high-level call, specifically those neither described here nor in the help page of the relevant high-level function, are passed unchanged to the panel function used. By convention, the default panel function used for any high-level function is named as “panel.” followed by the name of the high-level function; for example, the default panel function for `bwplot` is `panel.bwplot`. In practical terms, this means that in addition to the help page of the high-level function being used, the user should also consult the help page of the corresponding panel function for arguments that may be specified in the high-level call.

The effect of the first group of common arguments are as follows:

**as.table:** A logical flag that controls the order in which panels should be displayed: if `FALSE` (the default), panels are drawn left to right, bottom to top (as in a graph); if `TRUE`, left to right, top to bottom (as in a table).

**between:** A list with components `x` and `y` (both usually 0 by default), numeric vectors specifying the space between the panels (units are character heights). `x` and `y` are repeated to account for all panels in a page and any extra components are ignored. The result is used for all pages in a multi page display. In other words, it is not possible to use different `between` values for different pages.

**key:** A list that defines a legend to be drawn on the plot. This list is used as an argument to the `draw.key` function, which produces a “grob” (grid object) eventually plotted by the print method for “trellis” objects. The structure of the legend is constrained in the ways described below.

Although such a list can be and often is created explicitly, it is also possible to generate such a list using the `simpleKey` function; the latter is more convenient but less flexible. The `auto.key` argument can be even more convenient for the most common situation where legends are used, namely, in conjunction with a grouping variable. To use more than one legend, or to have arbitrary legends not constrained by the structure imposed by `key`, use the `legend` argument.

The position of the key can be controlled in either of two possible ways. If a component called `space` is present, the key is positioned outside the plot region, in one of the four sides, determined by the value of `space`, which can be one of “top”, “bottom”, “left” and “right”. Alternatively, the key can be positioned inside the plot region by specifying components `x`, `y` and `corner`. `x` and `y` determine the location of the corner of the key given by `corner`, which is usually one of `c(0, 0)`, `c(1, 0)`, `c(1, 1)` and `c(0, 1)`, which denote the corners of the unit square. Fractional values are also allowed, in which case `x` and `y` determine the position of an arbitrary point inside (or outside for values outside the unit interval) the key.

`x` and `y` should be numbers between 0 and 1, giving coordinates with respect to the “display area”. Depending on the value of the “`legend.bbox`” option (see `lattice.getOption`), this can be either the full figure region (“full”), or just the region that bounds the panels and strips (“panel”).

The key essentially consists of a number of columns, possibly divided into blocks, each containing some rows. The contents of the key are determined by (possibly repeated) components named “`rectangles`”, “`lines`”, “`points`” or “`text`”. Each of these must be lists with relevant graphical parameters (see later) controlling their appearance. The `key` list itself

can contain graphical parameters, these would be used if relevant graphical components are omitted from the other components.

The length (number of rows) of each such column (except "text"s) is taken to be the largest of the lengths of the graphical components, including the ones specified outside (see the entry for `rep` below for details on this). The "text" component must have a character or expression vector as its first component, to be used as labels. The length of this vector determines the number of rows.

The graphical components that can be included in `key` and also in the components named "text", "lines", "points" and "rectangles" (as appropriate) are:

- `cex=1` (text, lines, points)
- `col="black"` (text, rectangles, lines, points)
- `alpha=1` (text, rectangles, lines, points)
- `fill="transparent"` (lines, points)
- `lty=1` (lines)
- `lwd=1` (lines, points)
- `font=1` (text, points)
- `fontface` (text, points)
- `fontfamily` (text, points)
- `pch=8` (lines, points)
- `adj=0` (text)
- `type="l"` (lines)
- `size=5` (rectangles, lines)
- `height=1` (rectangles)
- `lineheight=1` (text)
- `angle=0` (rectangles, but ignored)
- `density=-1` (rectangles, but ignored)

In addition, the component `border` can be included inside the "rect" component to control the border color of the rectangles; when specified at the top level, `border` controls the border of the entire key (see below).

`angle` and `density` are unimplemented. `size` determines the width of columns of rectangles and lines in character widths. `type` is relevant for lines; "l" denotes a line, "p" denotes a point, and "b" and "o" both denote both together. `height` gives heights of rectangles as a fraction of the default.

Other possible components of `key` are:

`reverse.rows` Logical flag, defaulting to FALSE. If TRUE, all components are reversed *after* being replicated (the details of which may depend on the value of `rep`). This is useful in certain situations, e.g., with a grouped barchart with `stack = TRUE` with the categorical variable on the vertical axis, where the bars in the plot will usually be ordered from bottom to top, but the corresponding legend will have the levels from top to bottom unless `reverse.rows = TRUE`. Note that in this case, unless all columns have the same number of rows, they will no longer be aligned.

`between` Numeric vector giving the amount of space (character widths) surrounding each column (split equally on both sides).

`title` String or expression giving a title for the key.

- `rep` Logical flag, defaults to `TRUE`. By default, it is assumed that all columns in the key (except the "text"s) will have the same number of rows, and all components are replicated to be as long as the longest. This can be suppressed by specifying `rep=FALSE`, in which case the length of each column will be determined by components of that column alone.
- `cex.title` Zoom factor for the title.
- `lines.title` The amount of vertical space to be occupied by the title in lines (in multiples of itself). Defaults to 2.
- `padding.text` The amount of space (padding) to be used above and below each row containing text, in multiples of the default, which is currently  $0.2 * \text{"lines"}$ . This padding is in addition to the normal height of any row that contains text, which is the minimum amount necessary to contain all the text entries.
- `background` Background color for the legend. Defaults to the global background color.
- `alpha.background` An alpha transparency value between 0 and 1 for the background.
- `border` Either a color for the border, or a logical flag. In the latter case, the border color is black if `border` is `TRUE`, and no border is drawn if it is `FALSE` (the default).
- `transparent=FALSE` Logical flag, whether legend should have a transparent background.
- `just` A character or numeric vector of length one or two giving horizontal and vertical justification for the placement of the legend. See [grid.layout](#) for more precise details.
- `columns` The number of column-blocks (drawn side by side) the legend is to be divided into.
- `between.columns` Space between column blocks, in addition to between.
- `divide` Number of point symbols to divide each line when `type` is "b" or "o" in lines.
- legend:** The legend argument can be useful if one wants to place more than one key. It also allows the use of arbitrary "grob"s (grid objects) as legends.
- If used, `legend` must be a list, with an arbitrary number of components. Each component must be named one of "left", "right", "top", "bottom", or "inside". The name "inside" can be repeated, but not the others. This name will be used to determine the location for that component, and is similar to the `space` component of `key`. If `key` (or `colorkey` for [levelplot](#) and [wireframe](#)) is specified, their `space` component must not conflict with the name of any component of `legend`. Each component of `legend` must have a component called `fun`. This can be a "grob", or a function (or the name of a function) that produces a "grob" when called. If this function expects any arguments, they must be supplied as a list in another component called `args`. For components named "inside", there can be additional components called `x`, `y` and `corner`, which work in the same way as for `key`.
- page:** A function of one argument (page number) to be called after drawing each page. The function must be 'grid-compliant', and is called with the whole display area as the default viewport.

`xlab.top`, `ylab.right`: Labels for the x-axis on top, and y-axis on the right. Similar to `xlab` and `ylab`, but less commonly used.

`main`: Typically a character string or expression describing the main title to be placed on top of each page. Defaults to `NULL`.

`main` (as well as `xlab`, `ylab` and `sub`) is usually a character string or an expression that gets used as the label, but can also be a list that controls further details. Expressions are treated as specification of LaTeX-like markup as described in [plotmath](#). The label can be a vector, in which case the components will be spaced out horizontally (or vertically for `ylab`). This feature can be used to provide column or row labels rather than a single axis label.

When `main` (etc.) is a list, the actual label should be specified as the `label` component (which may be unnamed if it is the first component). The label can be missing, in which case the default will be used (`xlab` and `ylab` usually have defaults, but `main` and `sub` do not). Further named arguments are passed on to `textGrob`; this can include arguments controlling positioning like `just` and `rot` as well as graphical parameters such as `col` and `font` (see [gpar](#) for a full list).

`main`, `sub`, `xlab`, `ylab`, `xlab.top`, and `ylab.right` can also be arbitrary "grob"s (grid graphical objects).

`sub`: Character string or expression (or a list or "grob") for a subtitle to be placed at the bottom of each page. See entry for `main` for finer control options.

`par.strip.text`: A list of parameters to control the appearance of strip text. Notable components are `col`, `cex`, `font`, and `lines`. The first three control graphical parameters while the last is a means of altering the height of the strips. This can be useful, for example, if the strip labels (derived from factor levels, say) are double height (i.e., contains "`\n`"-s) or if the default height seems too small or too large.

Additionally, the `lineheight` component can control the space between multiple lines. The labels can be abbreviated when shown by specifying `abbreviate = TRUE`, in which case the components `minlength` and `dot` (passed along to the [abbreviate](#) function) can be specified to control the details of how this is done.

`layout`: In general, a conditioning plot in Lattice consists of several panels arranged in a rectangular array, possibly spanning multiple pages. `layout` determines this arrangement.

`layout` is a numeric vector of length 2 or 3 giving the number of columns, rows, and pages (optional) in a multipanel display. By default, the number of columns is the number of levels of the first conditioning variable and the number of rows is the number of levels of the second conditioning variable. If there is only one conditioning variable, the default layout vector is `c(0, n)`, where `n` is the number of levels of the given vector. Any time the first value in the layout vector is 0, the second value is used as the desired number of panels per page and the actual layout is computed from this, taking into account the aspect ratio of the panels and the device dimensions (via `par("din")`). If `NA` is specified for the number of rows or columns (but not both), that dimension will be filled out according to the number of panels.

The number of pages is by default set to as many as is required to plot all the panels, and so rarely needs to be specified. However, in certain situations the default calculation may be incorrect, and in that case the number of

pages needs to be specified explicitly.

**skip:** A logical vector (default `FALSE`), replicated to be as long as the number of panels (spanning all pages). For elements that are `TRUE`, the corresponding panel position is skipped; i.e., nothing is plotted in that position. The panel that was supposed to be drawn there is now drawn in the next available panel position, and the positions of all the subsequent panels are bumped up accordingly. This may be useful for arranging plots in an informative manner.

**strip.left:** `strip.left` can be used to draw strips on the left of each panel, which can be useful for wide short panels, as in time-series (or similar) plots. See the entry for `strip` for detailed usage.

**xlab.default, ylab.default:** Fallback default for `xlab` and `ylab` when they are not specified. If `NULL`, the defaults are parsed from the Trellis formula. This is rarely useful for the end-user, but can be helpful when developing new Lattice functions.

**xscale.components, yscale.components:** Functions that determine axis annotation for the x and y axes respectively. See documentation for `xscale.components.default`, the default values of these arguments, to learn more.

**axis:** Function responsible for drawing axis annotation. See documentation for `axis.default`, the default value of this argument, to learn more.

**perm.cond:** An integer vector, a permutation of `1:n`, where `n` is the number of conditioning variables. By default, the order in which panels are drawn depends on the order of the conditioning variables specified in the formula. `perm.cond` can modify this order. If the trellis display is thought of as an `n`-dimensional array, then during printing, its dimensions are permuted using `perm.cond` as the `perm` argument does in `aperm`.

**index.cond:** Whereas `perm.cond` permutes the dimensions of the multi-dimensional array of panels, `index.cond` can be used to subset (or reorder) margins of that array. `index.cond` can be a list or a function, with behavior in each case described below.

The panel display order within each conditioning variable depends on the order of their levels. `index.cond` can be used to choose a ‘subset’ (in the R sense) of these levels, which is then used as the display order for that variable. If `index.cond` is a list, it has to be as long as the number of conditioning variables, and the `i`-th component has to be a valid indexing vector for `levels(g_i)`, where `g_i` is the `i`-th conditioning variable in the plot (note that these levels may not contain all levels of the original variable, depending on the effects of the `subset` and `drop.unused.levels` arguments). In particular, this indexing may repeat levels, or drop some altogether. The result of this indexing determines the order of panels within that conditioning variable. To keep the order of a particular variable unchanged, the corresponding component must be set to `TRUE`.

Note that the components of `index.cond` are interpreted in the order of the conditioning variables in the original call, and is not affected by `perm.cond`.

Another possibility is to specify `index.cond` as a function. In this case, this function is called once for each panel, potentially with all arguments that are passed to the panel function for that panel. (More specifically, if this function has a `...` argument, then all panel arguments are passed, otherwise, only named arguments that match are passed.) If there is only one conditioning variable, the levels of that variable are then sorted so that

these values are in ascending order. For multiple conditioning variables, the order for each variable is determined by first taking the average over all other conditioning variables.

Although they can be supplied in high-level function calls directly, it is more typical to use `perm.cond` and `index.cond` to update an existing "trellis" object, thus allowing it to be displayed in a different arrangement without re-calculating the data subsets that go into each panel. In the `update.trellis` method, both can be set to `NULL`, which reverts these back to their defaults.

`par.settings`: A list that could be supplied to `trellis.par.set`. When the resulting object is plotted, these options are applied temporarily for the duration of the plotting, after which the settings revert back to what they were before. This enables the user to attach some display settings to the trellis object itself rather than change the settings globally. See also the `lattice.options` argument described above for a similar treatment of non-graphical options.

`plot.args`: A list containing possible arguments to `plot.trellis`, which will be used by the `plot` or `print` methods when drawing the object, unless overridden explicitly. This enables the user to attach such arguments to the trellis object itself. Partial matching is not performed.

## Details

The high-level functions documented here, as well as other high-level Lattice functions, are generic, with the `formula` method usually doing the most substantial work. The structure of the plot that is produced is mostly controlled by the formula (implicitly in the case of the non-formula methods). For each unique combination of the levels of the conditioning variables `g1, g2, . . .`, a separate "packet" is produced, consisting of the points  $(x, y)$  for the subset of the data defined by that combination. The display can be thought of as a three-dimensional array of panels, consisting of one two-dimensional matrix per page. The dimensions of this array are determined by the `layout` argument. If there are no conditioning variables, the plot produced consists of a single packet. Each packet usually corresponds to one panel, but this is not strictly necessary (see the entry for `index.cond` above).

The coordinate system used by **lattice** by default is like a graph, with the origin at the bottom left, with axes increasing to the right and top. In particular, panels are by default drawn starting from the bottom left corner, going right and then up, unless `as.table = TRUE`, in which case panels are drawn from the top left corner, going right and then down. It is possible to set a global preference for the table-like arrangement by changing the default to `as.table=TRUE`; this can be done by setting `lattice.options(default.args = list(as.table = TRUE))`. Default values can be set in this manner for the following arguments: `as.table`, `aspect`, `between`, `page`, `main`, `sub`, `par.strip.text`, `layout`, `skip` and `strip`. Note that these global defaults are sometimes overridden by individual functions.

The order of the panels depends on the order in which the conditioning variables are specified, with `g1` varying fastest, followed by `g2`, and so on. Within a conditioning variable, the order depends on the order of the levels (which for factors is usually in alphabetical order). Both of these orders can be modified using the `index.cond` and `perm.cond` arguments, possibly using the `update` (and other related) method(s).

## Value

The high-level functions documented here, as well as other high-level Lattice functions, return an object of class "trellis". The `update` method can be used to subsequently update components

of the object, and the `print` method (usually called by default) will plot it on an appropriate plotting device.

### Note

Most of the arguments documented here are also applicable for the other high-level functions in the **lattice** package. These are not described in any detail elsewhere unless relevant, and this should be considered the canonical documentation for such arguments.

Any arguments passed to these functions and not recognized by them will be passed to the panel function. Most predefined panel functions have arguments that customize its output. These arguments are described only in the help pages for these panel functions, but can usually be supplied as arguments to the high-level plot.

### Examples

```
require(stats)

## Tonga Trench Earthquakes

Depth <- equal.count(quakes$depth, number=8, overlap=.1)
xyplot(lat ~ long | Depth, data = quakes)
update(trellis.last.object(),
       strip = strip.custom(strip.names = TRUE, strip.levels = TRUE),
       par.strip.text = list(cex = 0.75),
       aspect = "iso")

## Examples with data from 'Visualizing Data' (Cleveland, 1993) obtained
## from http://cm.bell-labs.com/cm/ms/departments/sia/wsc/

EE <- equal.count(ethanol$E, number=9, overlap=1/4)

## Constructing panel functions on the fly; prepanel
xyplot(NOx ~ C | EE, data = ethanol,
       prepanel = function(x, y) prepanel.loess(x, y, span = 1),
       xlab = "Compression Ratio", ylab = "NOx (micrograms/J)",
       panel = function(x, y) {
         panel.grid(h = -1, v = 2)
         panel.xyplot(x, y)
         panel.loess(x, y, span=1)
       })
```

```

    },
    aspect = "xy")

## Extended formula interface

xyplot(Sepal.Length + Sepal.Width ~ Petal.Length + Petal.Width | Species,
       data = iris, scales = "free", layout = c(2, 2),
       auto.key = list(x = .6, y = .7, corner = c(0, 0)))

## user defined panel functions

states <- data.frame(state.x77,
                     state.name = dimnames(state.x77)[[1]],
                     state.region = state.region)
xyplot(Murder ~ Population | state.region, data = states,
       groups = state.name,
       panel = function(x, y, subscripts, groups) {
         ltext(x = x, y = y, labels = groups[subscripts], cex=1,
              fontfamily = "HersheySans")
       })

## Stacked bar chart

barchart(yield ~ variety | site, data = barley,
         groups = year, layout = c(1,6), stack = TRUE,
         auto.key = list(space = "right"),
         ylab = "Barley Yield (bushels/acre)",
         scales = list(x = list(rot = 45)))

bwplot(voice.part ~ height, data=singer, xlab="Height (inches)")

dotplot(variety ~ yield | year * site, data=barley)

## Grouped dot plot showing anomaly at Morris

dotplot(variety ~ yield | site, data = barley, groups = year,
       key = simpleKey(levels(barley$year), space = "right"),
       xlab = "Barley Yield (bushels/acre) ",
       aspect=0.5, layout = c(1,6), ylab=NULL)

stripplot(voice.part ~ jitter(height), data = singer, aspect = 1,
          jitter.data = TRUE, xlab = "Height (inches)")

## Interaction Plot

xyplot(decrease ~ treatment, OrchardSprays, groups = rowpos,
       type = "a",
       auto.key =
       list(space = "right", points = FALSE, lines = TRUE))

## longer version with no x-ticks

## Not run:
bwplot(decrease ~ treatment, OrchardSprays, groups = rowpos,
       panel = "panel.superpose",
       panel.groups = "panel.linejoin",

```

```

xlab = "treatment",
key = list(lines = Rows(trellis.par.get("superpose.line"),
  c(1:7, 1)),
  text = list(lab = as.character(unique(OrchardSprays$rowpos))),
  columns = 4, title = "Row position"))

## End(Not run)

```

B\_01\_xyplot.ts

*Time series plotting methods*

## Description

This function handles time series plotting, including cut-and-stack plots. Examples are given of superposing, juxtaposing and styling different time series.

## Usage

```

## S3 method for class 'ts'
xyplot(x, data = NULL,
  screens = if (superpose) 1 else colnames(x),
  ...,
  superpose = FALSE,
  cut = FALSE,
  type = "l",
  col = NULL,
  lty = NULL,
  lwd = NULL,
  pch = NULL,
  cex = NULL,
  fill = NULL,
  auto.key = superpose,
  panel = if (superpose) "panel.superpose"
    else "panel.superpose.plain",
  par.settings = list(),
  layout = NULL, as.table = TRUE,
  xlab = "Time", ylab = NULL,
  default.scales = list(y = list(relation =
    if (missing(cut)) "free" else "same")))

```

## Arguments

|         |                                                                                                                                                                                                                                   |
|---------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x       | an object of class <code>ts</code> , which may be multi-variate, i.e. have a matrix structure with multiple columns.                                                                                                              |
| data    | not used, and must be left as <code>NULL</code> .                                                                                                                                                                                 |
| ...     | additional arguments passed to <code>xyplot</code> , which may pass them on to <code>panel.xyplot</code> .                                                                                                                        |
| screens | factor (or coerced to factor) whose levels specify which panel each series is to be plotted in. <code>screens = c(1, 2, 1)</code> would plot series 1, 2 and 3 in panels 1, 2 and 1. May also be a named list, see Details below. |

|                                                  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|--------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>superpose</code>                           | overlays all series in one panel (via <code>screens = 1</code> ) and uses grouped style settings (from <code>trellis.par.get("superpose.line")</code> , etc). Note that this is just a convenience argument: its only action is to change the default values of other arguments.                                                                                                                                                                                                                                                                                                                                  |
| <code>cut</code>                                 | defines a cut-and-stack plot. <code>cut</code> can be a list of arguments to the function <code>equal.count</code> , i.e. <code>number</code> (number of intervals to divide into) and <code>overlap</code> (the fraction of overlap between cuts, default 0.5). If <code>cut</code> is numeric this is passed as the <code>number</code> argument.<br><br><code>cut = TRUE</code> tries to choose an appropriate number of cuts (up to a maximum of 6), using <code>banking</code> , and assuming a square plot region. This should have the effect of minimising wasted space when <code>aspect = "xy"</code> . |
| <code>type, col, lty, lwd, pch, cex, fill</code> | graphical arguments, which are processed and eventually passed to <code>panel.xyplot</code> . These arguments can also be vectors or (named) lists, see Details for more information.                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>auto.key</code>                            | a logical, or a list describing how to draw a key. See the <code>auto.key</code> entry in <code>xyplot</code> . The default here is to draw lines, not points, and any specified style arguments should show up automatically.                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>panel</code>                               | the panel function. It is recommended to leave this alone, but one can pass a <code>panel.groups</code> argument which is handled by <code>panel.superpose</code> for each series.                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>par.settings</code>                        | style settings beyond the standard <code>col, lty, lwd</code> , etc; see <code>trellis.par.set</code> and <code>simpleTheme</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <code>layout</code>                              | numeric vector of length 2 specifying number of columns and rows in the plot. The default is to fill columns with up to 6 rows.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>as.table</code>                            | to draw panels from top to bottom. The order is determined by the order of columns in <code>x</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <code>xlab, ylab</code>                          | X axis and Y axis labels; see <code>xyplot</code> . Note in particular that <code>ylab</code> may be a character vector, in which case the labels are spaced out equally, to correspond to the panels; but <i>NOTE</i> in this case the vector should be reversed OR the argument <code>as.table</code> set to <code>FALSE</code> .                                                                                                                                                                                                                                                                               |
| <code>default.scales</code>                      | scales specification. The default is set to have "free" Y axis scales unless <code>cut</code> is given. Note, users should pass the <code>scales</code> argument rather than <code>default.scales</code> .                                                                                                                                                                                                                                                                                                                                                                                                        |

## Details

The handling of several graphical parameters is more flexible for multivariate series. These parameters can be vectors of the same length as the number of series plotted or are recycled if shorter. They can also be (partially) named list, e.g., `list(A = c(1, 2), c(3, 4))` in which `c(3, 4)` is the default value and `c(1, 2)` the value only for series A. The `screens` argument can be specified in a similar way.

Some examples are given below.

## Value

An object of class "trellis". The `update` method can be used to update components of the object and the `print` method (usually called by default) will plot it on an appropriate plotting device.

**Author(s)**

Gabor Grothendieck, Achim Zeileis, Deepayan Sarkar and Felix Andrews  
<felix@nfrac.org>.

The first two authors developed `xyplot.ts` in their **zoo** package, including the `screens` approach. The third author developed a different `xyplot.ts` for cut-and-stack plots in the **lattice-Extra** package. The final author fused these together.

**References**

Sarkar, Deepayan (2008) *Lattice: Multivariate Data Visualization with R*, Springer. <http://lmdvr.r-forge.r-project.org/> (cut-and-stack plots)

**See Also**

`xyplot`, `panel.xyplot`, `plot.ts`, `ts`, `xyplot.zoo` in the **zoo** package.

**Examples**

```
xyplot(ts(c(1:10,10:1)))

### Figure 14.1 from Sarkar (2008)
xyplot(sunspot.year, aspect = "xy",
       strip = FALSE, strip.left = TRUE,
       cut = list(number = 4, overlap = 0.05))

### A multivariate example; first juxtaposed, then superposed
xyplot(EuStockMarkets, scales = list(y = "same"))
xyplot(EuStockMarkets, superpose = TRUE, aspect = "xy", lwd = 2,
       type = c("l","g"), ylim = c(0, max(EuStockMarkets)))

### Examples using screens (these two are identical)
xyplot(EuStockMarkets, screens = c(rep("Continental", 3), "UK"))
xyplot(EuStockMarkets, screens = list(FTSE = "UK", "Continental"))

### Automatic group styles
xyplot(EuStockMarkets, screens = list(FTSE = "UK", "Continental"),
       superpose = TRUE)

xyplot(EuStockMarkets, screens = list(FTSE = "UK", "Continental"),
       superpose = TRUE, xlim = extendrange(1996:1998),
       par.settings = standard.theme(color = FALSE))

### Specifying styles for series by name
xyplot(EuStockMarkets, screens = list(FTSE = "UK", "Continental"),
       col = list(DAX = "red", FTSE = "blue", "black"), auto.key = TRUE)

xyplot(EuStockMarkets, screens = list(FTSE = "UK", "Continental"),
       col = list(DAX = "red"), lty = list(SMI = 2), lwd = 1:2,
       auto.key = TRUE)

### Example with simpler data, few data points
set.seed(1)
z <- ts(cbind(a = 1:5, b = 11:15, c = 21:25) + rnorm(5))
xyplot(z, screens = 1)
xyplot(z, screens = list(a = "primary (a)", "other (b & c)"),
```

```
type = list(a = c("p", "h"), b = c("p", "s"), "o"),
pch = list(a = 2, c = 3), auto.key = list(type = "o"))
```

---

B\_02\_barchart.table

*table methods for barchart and dotplot*

---

## Description

Contingency tables are often displayed using bar charts and dot plots. These methods operate directly on tables, bypassing the need to convert them to data frames for use with the formula interface. Matrices and arrays are also supported, by coercing them to tables.

## Usage

```
## S3 method for class 'table'
barchart(x, data, groups = TRUE,
         origin = 0, stack = TRUE, ..., horizontal = TRUE)

## S3 method for class 'array'
barchart(x, data, ...)

## S3 method for class 'matrix'
barchart(x, data, ...)

## S3 method for class 'table'
dotplot(x, data, groups = TRUE, ..., horizontal = TRUE)

## S3 method for class 'array'
dotplot(x, data, ...)

## S3 method for class 'matrix'
dotplot(x, data, ...)
```

## Arguments

|               |                                                                                                                           |
|---------------|---------------------------------------------------------------------------------------------------------------------------|
| x             | A table, array or matrix object.                                                                                          |
| data          | Should not be specified. If specified, will be ignored with a warning.                                                    |
| groups        | A logical flag, indicating whether to use the last dimension as a grouping variable in the display.                       |
| origin, stack | Arguments to <a href="#">panel.barchart</a> . The defaults for the table method are different.                            |
| horizontal    | Logical flag, indicating whether the plot should be horizontal (with the categorical variable on the y-axis) or vertical. |
| ...           | Other arguments, passed to the underlying formula method.                                                                 |

do.breaks(endpoints, nint)

```

## Arguments

**x** The object on which method dispatch is carried out.

For the `formula` method, `x` can be a formula of the form `~ x | g1 * g2 * ...`, indicating that histograms or kernel density estimates of the `x` variable should be produced conditioned on the levels of the (optional) variables `g1`, `g2`, .... `x` should be numeric (or possibly a factor in the case of `histogram`), and each of `g1`, `g2`, ... should be either factors or shingles.

As a special case, the right hand side of the formula can contain more than one

term separated by '+' signs (e.g.,  $\sim x_1 + x_2 \mid g_1 * g_2$ ). What happens in this case is described in the documentation for [xyplot](#). Note that in either form, all the terms in the formula must have the same length after evaluation.

For the `numeric` and `factor` methods, `x` is the variable whose histogram or Kernel density estimate is drawn. Conditioning is not allowed in these cases.

|                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>data</code>      | For the <code>formula</code> method, an optional data source (usually a data frame) in which variables are to be evaluated (see <a href="#">xyplot</a> for details). <code>data</code> should not be specified for the other methods, and is ignored with a warning if it is.                                                                                                                                                                  |
| <code>type</code>      | A character string indicating the type of histogram that is to be drawn. "percent" and "count" give relative frequency and frequency histograms respectively, and can be misleading when breakpoints are not equally spaced. "density" produces a density histogram.<br><br>type defaults to "density" when the breakpoints are unequally spaced, and when <code>breaks</code> is <code>NULL</code> or a function, and to "percent" otherwise. |
| <code>nint</code>      | An integer specifying the number of histogram bins, applicable only when <code>breaks</code> is unspecified or <code>NULL</code> in the call. Ignored when the variable being plotted is a factor.                                                                                                                                                                                                                                             |
| <code>endpoints</code> | A numeric vector of length 2 indicating the range of <code>x</code> -values that is to be covered by the histogram. This applies only when <code>breaks</code> is unspecified and the variable being plotted is not a factor. In <code>do.breaks</code> , this specifies the interval that is to be divided up.                                                                                                                                |
| <code>breaks</code>    | Usually a numeric vector of length (number of bins + 1) defining the breakpoints of the bins. Note that when breakpoints are not equally spaced, the only value of <code>type</code> that makes sense is <code>density</code> .<br><br>When <code>breaks</code> is unspecified, the value of <code>lattice.getOption("histogram.breaks")</code> is first checked. If this value is <code>NULL</code> , then the default is to use              |

```
breaks = seq_len(1 + nlevels(x)) - 0.5
```

when `x` is a factor, and

```
breaks = do.breaks(endpoints, nint)
```

otherwise. Breakpoints calculated in such a manner are used in all panels. If the retrieved value is not `NULL`, or if `breaks` is explicitly specified, it affects the display in each panel independently. Valid values are those accepted as the `breaks` argument in [hist](#). In particular, this allows specification of `breaks` as an integer giving the number of bins (similar to `nint`), as a character string denoting a method, or as a function.

When specified explicitly, a special value of `breaks` is `NULL`, in which case the number of bins is determined by `nint` and then breakpoints are chosen according to the value of `equal.widths`.

|                           |                                                                                                                                                                                                                                          |
|---------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>equal.widths</code> | A logical flag, relevant only when <code>breaks=NULL</code> . If <code>TRUE</code> , equally spaced bins will be selected, otherwise, approximately equal area bins will be selected (typically producing unequally spaced breakpoints). |
| <code>n</code>            | Integer, giving the number of points at which the kernel density is to be evaluated. Passed on as an argument to <a href="#">density</a> .                                                                                               |

|                                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>panel</code>                 | A function, called once for each panel, that uses the packet (subset of panel variables) corresponding to the panel to create a display. The default panel functions <code>panel.histogram</code> and <code>panel.densityplot</code> are documented separately, and have arguments that can be used to customize its output in various ways. Such arguments can usually be directly supplied to the high-level function.                                                                                                           |
| <code>allow.multiple, outer</code> | See <code>xyplot</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <code>auto.key</code>              | See <code>xyplot</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <code>aspect</code>                | See <code>xyplot</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| <code>weights</code>               | <p>numeric vector of weights for the density calculations, evaluated in the non-standard manner used for <code>groups</code> and terms in the formula, if any. If this is specified, it is subsetted using <code>subscripts</code> inside the panel function to match it to the corresponding <code>x</code> values.</p> <p>At the time of writing, <code>weights</code> do not work in conjunction with an extended formula specification (this is not too hard to fix, so just bug the maintainer if you need this feature).</p> |
| <code>bw, adjust, width</code>     | Arguments controlling bandwidth. Passed on as arguments to <code>density</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <code>kernel, window</code>        | The choice of kernel. Passed on as arguments to <code>density</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>give.Rkern</code>            | Logical flag, passed on as argument to <code>density</code> . This argument is made available only for ease of implementation, and will produce an error if TRUE.                                                                                                                                                                                                                                                                                                                                                                  |
| <code>from, to, cut</code>         | Controls range over which density is evaluated. Passed on as arguments to <code>density</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>na.rm</code>                 | Logical flag specifying whether NA values should be ignored. Passed on as argument to <code>density</code> , but unlike in <code>density</code> , the default is TRUE.                                                                                                                                                                                                                                                                                                                                                             |
| <code>...</code>                   | Further arguments. See corresponding entry in <code>xyplot</code> for non-trivial details.                                                                                                                                                                                                                                                                                                                                                                                                                                         |

## Details

`histogram` draws Conditional Histograms, and `densityplot` draws Conditional Kernel Density Plots. The default panel function uses the `density` function to compute the density estimate, and all arguments accepted by `density` can be specified in the call to `densityplot` to control the output. See documentation of `density` for details.

These and all other high level Trellis functions have several arguments in common. These are extensively documented only in the help page for `xyplot`, which should be consulted to learn more detailed usage.

`do.breaks` is an utility function that calculates breakpoints given an interval and the number of pieces to break it into.

## Value

An object of class "trellis". The `update` method can be used to update components of the object and the `print` method (usually called by default) will plot it on an appropriate plotting device.

## Note

The form of the arguments accepted by the default panel function `panel.histogram` is different from that in S-PLUS. Whereas S-PLUS calculates the heights inside `histogram` and passes only the breakpoints and the heights to the panel function, **lattice** simply passes along the original variable `x` along with the breakpoints. This approach is more flexible; see the example below with an estimated density superimposed over the histogram.

## Examples

```
require(stats)
histogram( ~ height | voice.part, data = singer, nint = 17,
           endpoints = c(59.5, 76.5), layout = c(2,4), aspect = 1,
           xlab = "Height (inches)")

histogram( ~ height | voice.part, data = singer,
           xlab = "Height (inches)", type = "density",
           panel = function(x, ...) {
             panel.histogram(x, ...)
             panel.mathdensity(dmath = dnorm, col = "black",
                               args = list(mean=mean(x), sd=sd(x)))
           })
```

```
densityplot( ~ height | voice.part, data = singer, layout = c(2, 4),
             xlab = "Height (inches)", bw = 5)
```

B\_04\_qqmath

*Q-Q Plot with Theoretical Distribution*

## Description

Draw quantile-Quantile plots of a sample against a theoretical distribution, possibly conditioned on other variables.

## Usage

```
qqmath(x, data, ...)

## S3 method for class 'formula'
qqmath(x,
       data,
       allow.multiple = is.null(groups) || outer,
       outer = !is.null(groups),

## S3 method for class 'numeric'
qqmath(x, data = NULL, ylab, ...)
```

## Arguments

- |              |                                                                                                                                                                                                                                                                                                                                                           |
|--------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x            | The object on which method dispatch is carried out.<br>For the "formula" method, x should be a formula of the form <code>~ x   g1 * g2 * ...</code> , where x should be a numeric variable. For the "numeric" method, x should be a numeric vector.                                                                                                       |
| data         | For the formula method, an optional data source (usually a data frame) in which variables are to be evaluated (see <a href="#">xyplot</a> for details). data should not be specified for the other methods, and is ignored with a warning if it is.                                                                                                       |
| distribution | A quantile function that takes a vector of probabilities as argument and produces the corresponding quantiles from a theoretical distribution. Possible values are <a href="#">qnorm</a> , <a href="#">qunif</a> , etc. Distributions with other required arguments need to be provided as user-defined functions (see example with <a href="#">qt</a> ). |

|                                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>f.value</code>               | <p>An optional numeric vector of probabilities, quantiles corresponding to which should be plotted. This can also be a function of a single integer (representing sample size) that returns such a numeric vector. A typical value for this argument is the function <code>ppoints</code>, which is also the S-PLUS default. If specified, the probabilities generated by this function is used for the plotted quantiles, through the <code>quantile</code> function for the sample, and the function specified as the <code>distribution</code> argument for the theoretical distribution.</p> <p><code>f.value</code> defaults to <code>NULL</code>, which has the effect of using <code>ppoints</code> for the quantiles of the theoretical distribution, but the exact data values for the sample. This is similar to what happens for <code>qqnorm</code>, but different from the S-PLUS default of <code>f.value=ppoints</code>.</p> <p>For large <code>x</code>, this argument can be used to restrict the number of points plotted. See also the <code>tails.n</code> argument in <code>panel.qqmath</code>.</p> |
| <code>panel</code>                 | <p>A function, called once for each panel, that uses the <code>packet</code> (subset of panel variables) corresponding to the panel to create a display. The default panel function <code>panel.qqmath</code> is documented separately, and has arguments that can be used to customize its output in various ways. Such arguments can usually be directly supplied to the high-level function.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

## Details

`qqmath` produces Q-Q plots of the given sample against a theoretical distribution. The default behaviour of `qqmath` is different from the corresponding S-PLUS function, but is similar to `qqnorm`. See the entry for `f.value` for specifics.

The implementation details are also different from S-PLUS. In particular, all the important calculations are done by the `panel` (and `prepanel` function) and not `qqmath` itself. In fact, both the

arguments `distribution` and `f.value` are passed unchanged to the panel and prepanel function. This allows, among other things, display of grouped Q-Q plots, which are often useful. See the help page for [panel.qqmath](#) for further details.

This and all other high level Trellis functions have several arguments in common. These are extensively documented only in the help page for [xyplot](#), which should be consulted to learn more detailed usage.

### Value

An object of class "trellis". The [update](#) method can be used to update components of the object and the [print](#) method (usually called by default) will plot it on an appropriate plotting device.

### Examples

```
qqmath(~ rnorm(100), distribution = function(p) qt(p, df = 10))
qqmath(~ height | voice.part, aspect = "xy", data = singer,
       prepanel = prepanel.qqmathline,
       panel = function(x, ...) {
         panel.qqmathline(x, ...)
         panel.qqmath(x, ...)
       })
vp.comb <-
  factor(sapply(strsplit(as.character(singer$voice.part), split = " "),
               "[", 1),
         levels = c("Bass", "Tenor", "Alto", "Soprano"))
vp.group <-
  factor(sapply(strsplit(as.character(singer$voice.part), split = " "),
               "[", 2))
qqmath(~ height | vp.comb, data = singer,
       groups = vp.group, auto.key = list(space = "right"),
       aspect = "xy",
       prepanel = prepanel.qqmathline,
       panel = function(x, ...) {
         panel.qqmathline(x, ...)
         panel.qqmath(x, ...)
       })
```

### Description

Quantile-Quantile plots for comparing two Distributions

**Usage**

```
qq(x, data, ...)

## S3 method for class 'formula'
qq(x, data, aspect = "fill",
   panel = lattice.getOption("panel.qq"),
   prepanel, scales, strip,
   groups, xlab, xlim, ylab, ylim, f.value = NULL,
   drop.unused.levels = lattice.getOption("drop.unused.levels"),
   ...,
   lattice.options = NULL,
   qtype = 7,
   default.scales = list(),
   default.prepanel = lattice.getOption("prepanel.default.qq"),
   subscripts,
   subset)
```

**Arguments**

- |          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x        | <p>The object on which method dispatch is carried out.</p> <p>For the "formula" method, x should be a formula of the form <math>y \sim x \mid g1 * g2 * \dots</math>, where x should be a numeric variable, and y a factor, shingle, character, or numeric variable, with the restriction that there must be exactly two levels of y, which divide the values of x into two groups. Quantiles for these groups will be plotted against each other along the two axes.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| data     | <p>For the formula method, an optional data source (usually a data frame) in which variables are to be evaluated (see <a href="#">xyplot</a> for details).</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| f.value  | <p>An optional numeric vector of probabilities, quantiles corresponding to which should be plotted. This can also be a function of a single integer (representing sample size) that returns such a numeric vector. A typical value for this argument is the function <code>ppoints</code>, which is also the S-PLUS default. If specified, the probabilities generated by this function is used for the plotted quantiles, through the <code>quantile</code> function.</p> <p>f.value defaults to NULL, which is equivalent to</p> <pre>f.value = function(n) ppoints(n, a = 1)</pre> <p>This has the effect of including the minimum and maximum data values in the computed quantiles. This is similar to what happens for <code>qqplot</code> but different from the default behaviour of <code>qq</code> in S-PLUS.</p> <p>For large x, this argument can be used to restrict the number of quantiles plotted.</p> |
| panel    | <p>A function, called once for each panel, that uses the packet (subset of panel variables) corresponding to the panel to create a display. The default panel function <a href="#">panel.qq</a> is documented separately, and has arguments that can be used to customize its output in various ways. Such arguments can usually be directly supplied to the high-level function.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| qtype    | <p>The type argument for <a href="#">quantile</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

## Details

`qq` produces Q-Q plots of two samples. The default behaviour of `qq` is different from the corresponding S-PLUS function. See the entry for `f.value` for specifics.

This and all other high level Trellis functions have several arguments in common. These are extensively documented only in the help page for `xyplot`, which should be consulted to learn more detailed usage.

## Value

An object of class `"trellis"`. The [update](#) method can be used to update components of the object and the [print](#) method (usually called by default) will plot it on an appropriate plotting device.

## Author(s)

## Examples

```
qq(voice.part ~ height, aspect = 1, data = singer,
   subset = (voice.part == "Bass 2" | voice.part == "Tenor 1"))
```

B\_06\_levelplot

*Level plots and contour plots***Description**

Draws false color level plots and contour plots.

**Usage**

```

levelplot(x, data, ...)
contourplot(x, data, ...)

## S3 method for class 'formula'
levelplot(x,
  data,
  allow.multiple = is.null(groups) || outer,
  outer = TRUE,
  aspect = "fill",
  panel = if (useRaster) lattice.getOption("panel.levelplot.raster")
    else lattice.getOption("panel.levelplot"),

  alpha.regions,
  subset = TRUE)

## S3 method for class 'formula'
contourplot(x,
  data,
  panel = lattice.getOption("panel.contourplot"),
  default.prepanel =
    lattice.getOption("prepanel.default.contourplot"),

```

```

cuts = 7,
labels = TRUE,
contour = TRUE,
pretty = TRUE,
region = FALSE,
...)

## S3 method for class 'table'
levelplot(x, data = NULL, aspect = "iso", ..., xlim, ylim)

## S3 method for class 'table'
contourplot(x, data = NULL, aspect = "iso", ..., xlim, ylim)

## S3 method for class 'matrix'
levelplot(x, data = NULL, aspect = "iso",
..., xlim, ylim,
row.values = seq_len(nrow(x)),
column.values = seq_len(ncol(x)))

## S3 method for class 'matrix'
contourplot(x, data = NULL, aspect = "iso",
..., xlim, ylim,
row.values = seq_len(nrow(x)),
column.values = seq_len(ncol(x)))

## S3 method for class 'array'
levelplot(x, data = NULL, ...)

## S3 method for class 'array'
contourplot(x, data = NULL, ...)

```

## Arguments

**x** for the formula method, a formula of the form  $z \sim x * y \mid g1 * g2 * \dots$ , where  $z$  is a numeric response, and  $x, y$  are numeric values evaluated on a rectangular grid.  $g1, g2, \dots$  are optional conditional variables, and must be either factors or shingles if present.

Calculations are based on the assumption that all  $x$  and  $y$  values are evaluated on a grid (defined by their unique values). The function will not return an error if this is not true, but the display might not be meaningful. However, the  $x$  and  $y$  values need not be equally spaced.

Both `levelplot` and `wireframe` have methods for `matrix`, `array`, and `table` objects, in which case  $x$  provides the  $z$  vector described above, while its rows and columns are interpreted as the  $x$  and  $y$  vectors respectively. This is similar to the form used in `filled.contour` and `image`. For higher-dimensional arrays and tables, further dimensions are used as conditioning variables. Note that the `dimnames` may be duplicated; this is handled by calling `make.unique` to make the names unique (although the original labels are used for the  $x$ - and  $y$ -axes).

| <code>data</code>                      | For the formula methods, an optional data frame in which variables in the formula (as well as groups and subset, if any) are to be evaluated. Usually ignored with a warning in other cases.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <code>row.values, column.values</code> | Optional vectors of values that define the grid when <code>x</code> is a matrix. <code>row.values</code> and <code>column.values</code> must have the same lengths as <code>nrow(x)</code> and <code>ncol(x)</code> respectively. By default, row and column numbers.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>panel</code>                     | panel function used to create the display, as described in <a href="#">xyplot</a>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>aspect</code>                    | For the matrix methods, the default aspect ratio is chosen to make each cell square. The usual default is <code>aspect="fill"</code> , as described in <a href="#">xyplot</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>at</code>                        | A numeric vector giving breakpoints along the range of <code>z</code> . Contours (if any) will be drawn at these heights, and the regions in between would be colored using <code>col.regions</code> . In the latter case, values outside the range of <code>at</code> will not be drawn at all. This serves as a way to limit the range of the data shown, similar to what a <code>zlim</code> argument might have been used for. However, this also means that when supplying <code>at</code> explicitly, one has to be careful to include values outside the range of <code>z</code> to ensure that all the data are shown.<br><code>at</code> can have length one only if <code>region=FALSE</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>col.regions</code>               | color vector to be used if regions is TRUE. The general idea is that this should be a color vector of moderately large length (longer than the number of regions. By default this is 100). It is expected that this vector would be gradually varying in color (so that nearby colors would be similar). When the colors are actually chosen, they are chosen to be equally spaced along this vector. When there are more regions than colors in <code>col.regions</code> , the colors are recycled. The actual color assignment is performed by <a href="#">level.colors</a> , which is documented separately.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>alpha.regions</code>             | numeric, specifying alpha transparency (works only on some devices)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>colorkey</code>                  | logical specifying whether a color key is to be drawn alongside the plot, or a list describing the color key. The list may contain the following components:<br><code>space</code> : location of the colorkey, can be one of "left", "right", "top" and "bottom". Defaults to "right".<br><code>x, y</code> : location, currently unused<br><code>col</code> : A color ramp specification, as in the <code>col.regions</code> argument in <a href="#">level.colors</a><br><code>at</code> : numeric vector specifying where the colors change. must be of length 1 more than the col vector.<br><code>tri.lower, tri.upper</code> : Logical or numeric controlling whether the first and last intervals should be triangular instead of rectangular. With the default value (NA), this happens only if the corresponding extreme <code>at</code> values are <code>-Inf</code> or <code>Inf</code> respectively, and the triangles occupy 5% of the total length of the color key. If numeric and between 0 and 0.25, these give the corresponding fraction, which is again 5% when specified as TRUE.<br><code>labels</code> : a character vector for labelling the <code>at</code> values, or more commonly, a list describing characteristics of the labels. This list may include components <code>labels</code> , <code>at</code> , <code>cex</code> , <code>col</code> , <code>rot</code> , <code>font</code> , <code>fontface</code> and <code>fontfamily</code> .<br><code>tick.number</code> : The approximate number of ticks desired.<br><code>tck</code> : A (scalar) multiplier for tick lengths. |

|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                                                                                                                                                                                                                                 | <p><b>corner:</b> Interacts with <code>x</code>, <code>y</code>; currently unimplemented</p> <p><b>width:</b> The width of the key</p> <p><b>height:</b> The length of key as a fraction of the appropriate side of plot.</p> <p><b>raster:</b> A logical flag indicating whether the colorkey should be rendered as a raster image using <code>grid.raster</code>. See also <code>panel.levelplot.raster</code>.</p> <p><b>interpolate:</b> Logical flag, passed to <code>rasterGrob</code> when <code>raster=TRUE</code>.</p> <p><b>axis.line:</b> A list giving graphical parameters for the color key boundary and tick marks. Defaults to <code>trellis.par.get("axis.line")</code>.</p> <p><b>axis.text:</b> A list giving graphical parameters for the tick mark labels on the color key. Defaults to <code>trellis.par.get("axis.text")</code>.</p> |
| <code>contour</code>                                                                                                                                                                                                                            | A logical flag, indicating whether to draw contour lines.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>cuts</code>                                                                                                                                                                                                                               | The number of levels the range of <code>z</code> would be divided into.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>labels</code>                                                                                                                                                                                                                             | Typically a logical indicating whether contour lines should be labelled, but other possibilities for more sophisticated control exists. Details are documented in the help page for <code>panel.levelplot</code> , to which this argument is passed on unchanged. That help page also documents the <code>label.style</code> argument, which affects how the labels are rendered.                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>pretty</code>                                                                                                                                                                                                                             | A logical flag, indicating whether to use pretty cut locations and labels.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

Some are processed by <code>levelplot</code> or <code>contourplot</code> , and those that are unrecognized are passed on to the panel function.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <code>useRaster</code>                                                                                                                                                                                                                          | <p>A logical flag indicating whether raster representations should be used, both for the false color image and the color key (if present). Effectively, setting this to <code>TRUE</code> changes the default panel function from <code>panel.levelplot</code> to <code>panel.levelplot.raster</code>, and sets the default value of <code>colorkey\$raster</code> to <code>TRUE</code>.</p> <p>Note that <code>panel.levelplot.raster</code> provides only a subset of the features of <code>panel.levelplot</code>, but setting <code>useRaster=TRUE</code> will not check whether any of the additional features have been requested.</p> <p>Not all devices support raster images. For devices that appear to lack support, <code>useRaster=TRUE</code> will be ignored with a warning.</p>                                                             |

## Details

These and all other high level Trellis functions have several arguments in common. These are extensively documented only in the help page for `xyplot`, which should be consulted to learn more detailed usage.

Other useful arguments are mentioned in the help page for the default panel function `panel.levelplot` (these are formally arguments to the panel function, but can be specified in the high level calls directly).

**Value**

An object of class "trellis". The `update` method can be used to update components of the object and the `print` method (usually called by default) will plot it on an appropriate plotting device.

**Author(s)**

Deepayan Sarkar <Deepayan.Sarkar@R-project.org>

**References**

Sarkar, Deepayan (2008) *Lattice: Multivariate Data Visualization with R*, Springer. <http://lmdvr.r-forge.r-project.org/>

**Examples**

```
x <- seq(pi/4, 5 * pi, length.out = 100)
y <- seq(pi/4, 5 * pi, length.out = 100)
r <- as.vector(sqrt(outer(x^2, y^2, "+")))
grid <- expand.grid(x=x, y=y)
grid$z <- cos(r^2) * exp(-r/(pi^3))
levelplot(z ~ x * y, grid, cuts = 50, scales=list(log="e"), xlab="",
          ylab="", main="Weird Function", sub="with log scales",
          colorkey = FALSE, region = TRUE)
## triangular end-points in color key
levelplot(z ~ x * y, grid, col.regions = topo.colors(10),
          at = c(-Inf, seq(-0.8, 0.8, by = 0.2), Inf))

#S-PLUS example
require(stats)
attach(environmental)
ozo.m <- loess((ozone^(1/3)) ~ wind * temperature * radiation,
              parametric = c("radiation", "wind"), span = 1, degree = 2)
w.marginal <- seq(min(wind), max(wind), length.out = 50)
t.marginal <- seq(min(temperature), max(temperature), length.out = 50)
r.marginal <- seq(min(radiation), max(radiation), length.out = 4)
wtr.marginal <- list(wind = w.marginal, temperature = t.marginal,
                    radiation = r.marginal)
grid <- expand.grid(wtr.marginal)
grid[, "fit"] <- c(predict(ozo.m, grid))
contourplot(fit ~ wind * temperature | radiation, data = grid,
            cuts = 10, region = TRUE,
            xlab = "Wind Speed (mph)",
            ylab = "Temperature (F)",
            main = "Cube Root Ozone (cube root ppb)")
detach()
```

## Description

Generic functions to draw 3d scatter plots and surfaces. The "formula" methods do most of the actual work.

## Usage

```
cloud(x, data, ...)
wireframe(x, data, ...)

## S3 method for class 'formula'
cloud(x,
      data,
      allow.multiple = is.null(groups) || outer,
      outer = FALSE,
      auto.key = FALSE,
      aspect = c(1,1),
      panel.aspect = 1,
      panel = lattice.getOption("panel.cloud"),
      prepanel = NULL,
      scales = list(),
      strip = TRUE,
      groups = NULL,
      xlab,
      ylab,
      zlab,
      xlim = if (is.factor(x)) levels(x) else range(x, finite = TRUE),
      ylim = if (is.factor(y)) levels(y) else range(y, finite = TRUE),
      zlim = if (is.factor(z)) levels(z) else range(z, finite = TRUE),
      at,
      drape = FALSE,
      pretty = FALSE,
      drop.unused.levels,
      ...,
      lattice.options = NULL,
      default.scales =
        list(distance = c(1, 1, 1),
              arrows = TRUE,
              axs = axs.default),
      default.prepanel = lattice.getOption("prepanel.default.cloud"),
      colorkey,
      col.regions,
      alpha.regions,
      cuts = 70,
      subset = TRUE,
      axs.default = "r")

## S3 method for class 'formula'
```

```

wireframe(x,
          data,
          panel = lattice.getOption("panel.wireframe"),
          default.prepanel = lattice.getOption("prepanel.default.wireframe"),
          ...)

## S3 method for class 'matrix'
cloud(x, data = NULL, type = "h",
      zlab = deparse(substitute(x)), aspect, ...,
      xlim, ylim, row.values, column.values)

## S3 method for class 'table'
cloud(x, data = NULL, groups = FALSE,
      zlab = deparse(substitute(x)),
      type = "h", ...)

## S3 method for class 'matrix'
wireframe(x, data = NULL,
          zlab = deparse(substitute(x)), aspect, ...,
          xlim, ylim, row.values, column.values)

|----------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x                                                                                      | <p>The object on which method dispatch is carried out.</p> <p>For the "formula" methods, a formula of the form <math>z \sim x * y \mid g1 * g2 * \dots</math>, where <math>z</math> is a numeric response, and <math>x, y</math> are numeric values. <math>g1, g2, \dots</math>, if present, are conditioning variables used for conditioning, and must be either factors or shingles. In the case of <code>wireframe</code>, calculations are based on the assumption that the <math>x</math> and <math>y</math> values are evaluated on a rectangular grid defined by their unique values. The grid points need not be equally spaced.</p> <p>For <code>wireframe</code>, <math>x, y</math> and <math>z</math> may also be matrices (of the same dimension), in which case they are taken to represent a 3-D surface parametrized on a 2-D grid (e.g., a sphere). Conditioning is not possible with this feature. See details below.</p> <p>Missing values are allowed, either as NA values in the <math>z</math> vector, or missing rows in the data frame (note however that in that case the <math>X</math> and <math>Y</math> grids will be determined only by the available values). For a grouped display (producing multiple surfaces), missing rows are not allowed, but NA-s in <math>z</math> are.</p> <p>Both <code>wireframe</code> and <code>cloud</code> have methods for <code>matrix</code> objects, in which case <math>x</math> provides the <math>z</math> vector described above, while its rows and columns are interpreted as the <math>x</math> and <math>y</math> vectors respectively. This is similar to the form used in <code>persp</code>.</p> |
| data                                                                                   | <p>for the "formula" methods, an optional data frame in which variables in the formula (as well as <code>groups</code> and <code>subset</code>, if any) are to be evaluated. <code>data</code> should not be specified except when using the "formula" method.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| row.values, column.values                                                              | <p>Optional vectors of values that define the grid when <math>x</math> is a matrix. <code>row.values</code> and <code>column.values</code> must have the same lengths as <code>nrow(x)</code> and <code>ncol(x)</code> respectively. By default, row and column numbers.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| allow.multiple, outer, auto.key, prepanel, strip, groups, xlab, xlim, ylab, ylim, drop | <p>These arguments are documented in the help page for <a href="#">xyplot</a>. For the <code>cloud.table</code> method, <code>groups</code> must be a logical indicating whether the last</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

|                      | dimension should be used as a grouping variable as opposed to a conditioning variable. This is only relevant if the table has more than 2 dimensions.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| type                 | type of display in <code>cloud</code> (see <a href="#">panel.3dscatter</a> for details). Defaults to "h" for the <code>matrix</code> method.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| aspect, panel.aspect | <p>Unlike other high level functions, <code>aspect</code> is taken to be a numeric vector of length 2, giving the relative aspects of the y-size/x-size and z-size/x-size of the enclosing cube. The usual role of the <code>aspect</code> argument in determining the aspect ratio of the panel (see <a href="#">xyplot</a> for details) is played by <code>panel.aspect</code>, except that it can only be a numeric value.</p> <p>For the <code>matrix</code> methods, the default y/x aspect is <code>ncol(x) / nrow(x)</code> and the z/x aspect is the smaller of the y/x aspect and 1.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| panel                | panel function used to create the display. See <a href="#">panel.cloud</a> for (non-trivial) details.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| default.prepanel     | Fallback prepanel function. See <a href="#">xyplot</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| scales               | <p>a list describing the scales. As with other high level functions (see <a href="#">xyplot</a> for details), this list can contain parameters in name=value form. It can also contain components with the special names <code>x</code>, <code>y</code> and <code>z</code>, which can be similar lists with axis-specific values overriding the ones specified in <code>scales</code>.</p> <p>The most common use for this argument is to set <code>arrows=FALSE</code>, which causes tick marks and labels to be used instead of arrows being drawn (the default). Both can be suppressed by <code>draw=FALSE</code>. Another special component is <code>distance</code>, which specifies the relative distance of the axis label from the bounding box. If specified as a component of <code>scales</code> (as opposed to one of <code>scales\$z</code> etc), this can be (and is recycled if not) a vector of length 3, specifying distances for the <code>x</code>, <code>y</code> and <code>z</code> labels respectively.</p> <p>Other components that work in the <code>scales</code> argument of <code>xyplot</code> etc. should also work here (as long as they make sense), including explicit specification of tick mark locations and labels. (Not everything is implemented yet, but if you find something that should work but does not, feel free to bug the maintainer.)</p> <p>Note, however, that for these functions <code>scales</code> cannot contain information that is specific to particular panels. If you really need that, consider using the <code>scales.3d</code> argument of <code>panel.cloud</code>.</p> |
| axs.default          | Unlike 2-D display functions, <code>cloud</code> does not expand the bounding box to slightly beyond the range of the data, even though it should. This is primarily because this is the natural behaviour in <code>wireframe</code> , which uses the same code. <code>axs.default</code> is intended to provide a different default for <code>cloud</code> . However, this feature has not yet been implemented.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| zlab                 | Specifies a label describing the <code>z</code> variable in ways similar to <code>xlab</code> and <code>ylab</code> (i.e. "grob", character string, expression or list) in other high level functions. Additionally, if <code>zlab</code> (and <code>xlab</code> and <code>ylab</code> ) is a list, it can contain a component called <code>rot</code> , controlling the rotation for the label                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| zlim                 | limits for the <code>z</code> -axis. Similar to <code>xlim</code> and <code>ylim</code> in other high level functions                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| drape                | logical, whether the wireframe is to be draped in color. If <code>TRUE</code> , the height of a facet is used to determine its color in a manner similar to the coloring scheme used in <a href="#">levelplot</a> . Otherwise, the background color is used to color the facets. This argument is ignored if <code>shade = TRUE</code> (see <a href="#">panel.3dwire</a> ).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

|                                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| <code>...</code>                            | Any number of other arguments can be specified, and are passed to the panel function. In particular, the arguments <code>distance</code> , <code>perspective</code> , <code>screen</code> and <code>R.mat</code> are very important in determining the 3-D display. The argument <code>shade</code> can be useful for <code>wireframe</code> calls, and controls shading of the rendered surface. These arguments are described in detail in the help page for <code>panel.cloud</code> .<br><br>Additionally, an argument called <code>zoom</code> may be specified, which should be a numeric scalar to be interpreted as a scale factor by which the projection is magnified. This can be useful to get the variable names into the plot. This argument is actually only used by the default <code>prepanel</code> function. |

## Details

These functions produce three dimensional plots in each panel (as long as the default panel functions are used). The orientation is obtained as follows: the data are scaled to fall within a bounding box that is contained in the  $[-0.5, 0.5]$  cube (even smaller for non-default values of `aspect`). The viewing direction is given by a sequence of rotations specified by the `screen` argument, starting from the positive Z-axis. The viewing point (camera) is located at a distance of  $1/\text{distance}$  from the origin. If `perspective=FALSE`, `distance` is set to 0 (i.e., the viewing point is at an infinite distance).

`cloud` draws a 3-D Scatter Plot, while `wireframe` draws a 3-D surface (usually evaluated on a grid). Multiple surfaces can be drawn by `wireframe` using the `groups` argument (although this is of limited use because the display is incorrect when the surfaces intersect). Specifying `groups` with `cloud` results in a `panel.superpose`-like effect (via `panel.3dscatter`).

`wireframe` can optionally render the surface as being illuminated by a light source (no shadows though). Details can be found in the help page for `panel.3dwire`. Note that although arguments controlling these are actually arguments for the panel function, they can be supplied to `cloud` and `wireframe` directly.

For single panel plots, `wireframe` can also plot parametrized 3-D surfaces (i.e., functions of the form  $f(u,v) = (x(u,v), y(u,v), z(u,v))$ , where values of  $(u,v)$  lie on a rectangle. The simplest example of this sort of surface is a sphere parametrized by latitude and longitude. This can be achieved by calling `wireframe` with a formula `x` of the form `z~x*y`, where `x`, `y` and `z` are all matrices of the same dimension, representing the values of  $x(u,v)$ ,  $y(u,v)$  and  $z(u,v)$  evaluated on a discrete rectangular grid (the actual values of  $(u,v)$  are irrelevant).

When this feature is used, the heights used to calculate drape colors or shading colors are no longer the  $z$  values, but the distances of  $(x, y, z)$  from the origin.

Note that this feature does not work with `groups`, `subscripts`, `subset`, etc. Conditioning variables are also not supported in this case.

The algorithm for identifying which edges of the bounding box are ‘behind’ the points doesn’t work in some extreme situations. Also, `panel.cloud` tries to figure out the optimal location of the arrows and axis labels automatically, but can fail on occasion (especially when the view is from ‘below’ the data). This can be manually controlled by the `scpos` argument in `panel.cloud`.

These and all other high level Trellis functions have several other arguments in common. These are extensively documented only in the help page for `xyplot`, which should be consulted to learn more detailed usage.

### Value

An object of class "trellis". The `update` method can be used to update components of the object and the `print` method (usually called by default) will plot it on an appropriate plotting device.

### Note

There is a known problem with grouped wireframe displays when the (x, y) coordinates represented in the data do not represent the full evaluation grid. The problem occurs whether the grouping is specified through the `groups` argument or through the formula interface, and currently causes memory access violations. Depending on the circumstances, this is manifested either as a meaningless plot or a crash. To work around the problem, it should be enough to have a row in the data frame for each grid point, with an NA response (z) in rows that were previously missing.

## Details

`splom` produces Scatter Plot Matrices. The role usually played by `panel` is taken over by `superpanel`, which takes a data frame subset and is responsible for plotting it. It is called with the coordinate system set up to have both `x`- and `y`-limits from `0.5` to `ncol(z) + 0.5`. The only built-in option currently available is [panel.pairs](#), which calls a further `panel` function for each pair  $(i, j)$  of variables in `z` inside a rectangle of unit width and height centered at  $c(i, j)$  (see [panel.pairs](#) for details).

Many of the finer customizations usually done via arguments to high level function like `xyplot` are instead done by `panel.pairs` for `splom`. These include control of axis limits, tick locations and `prepanel` calculations. If you are trying to fine-tune your `splom` plot, definitely look at the [panel.pairs](#) help page. The `scales` argument is usually not very useful in `splom`, and trying to change it may have undesired effects.

[parallelplot](#) draws Parallel Coordinate Plots. (Difficult to describe, see example.)

These and all other high level Trellis functions have several arguments in common. These are extensively documented only in the help page for `xyplot`, which should be consulted to learn more detailed usage.

**Value**

An object of class "trellis". The `update` method can be used to update components of the object and the `print` method (usually called by default) will plot it on an appropriate plotting device.

**Examples**

```
super.sym <- trellis.par.get("superpose.symbol")
splom(~iris[1:4], groups = Species, data = iris,
      panel = panel.superpose,
      key = list(title = "Three Varieties of Iris",
                 columns = 3,
                 points = list(pch = super.sym$pch[1:3],
                               col = super.sym$col[1:3]),
                 text = list(c("Setosa", "Versicolor", "Virginica"))))
splom(~iris[1:3] | Species, data = iris,
      layout=c(2,2), pscales = 0,
      varnames = c("Sepal\nLength", "Sepal\nWidth", "Petal\nLength"),
      page = function(...) {
        ltext(x = seq(.6, .8, length.out = 4),
              y = seq(.9, .6, length.out = 4),
              labels = c("Three", "Varieties", "of", "Iris"),
              cex = 2)
      })
parallelplot(~iris[1:4] | Species, iris)
parallelplot(~iris[1:4], iris, groups = Species,
             horizontal.axis = FALSE, scales = list(x = list(rot = 90)))
```

**Description**

`tmd` Creates Tukey Mean-Difference Plots from a trellis object returned by `xyplot`, `qq` or `qqmath`. The `prepanel` and `panel` functions are used as appropriate. The `formula` method for `tmd` is provided for convenience, and simply calls `tmd` on the object created by calling `xyplot` on that formula.

**Usage**

```
tmd(object, ...)

## S3 method for class 'trellis'
tmd(object,
     xlab = "mean",
```

```

        ylab = "difference",
        panel,
        prepanel,
        ...)

prepanel.tmd.qqmath(x,
                    f.value = NULL,
                    distribution = qnorm,
                    qtype = 7,
                    groups = NULL,
                    subscripts, ...)
panel.tmd.qqmath(x,
                 f.value = NULL,
                 distribution = qnorm,
                 qtype = 7,
                 groups = NULL,
                 subscripts, ...,
                 identifier = "tmd")
panel.tmd.default(x, y, groups = NULL, ...,
                  identifier = "tmd")
prepanel.tmd.default(x, y, ...)

```

| <code>identifier</code>                   | A character string that is prepended to the names of grobs that are created by this panel function.     |

### Details

The Tukey Mean-difference plot is produced by modifying the (x,y) values of each panel as follows: the new coordinates are given by  $x = (x+y) / 2$  and  $y = y - x$ , which are then plotted. The default panel function(s) add a reference line at  $y=0$  as well.

`tmd` acts on the a "trellis" object, not on the actual plot this object would have produced. As such, it only uses the arguments supplied to the panel function in the original call, and completely ignores what the original panel function might have done with this data. `tmd` uses these panel arguments to set up its own scales (using its `prepanel` argument) and display (using `panel`). It is thus important to provide suitable `prepanel` and `panel` functions to `tmd` depending on the original call.

Such functions currently exist for `xyplot`, `qq` (the ones with `default` in their name) and `qqmath`, as listed in the usage section above. These assume the default displays for the corresponding high-level call. If unspecified, the `prepanel` and `panel` arguments default to suitable choices.

`tmd` uses the `update` method for "trellis" objects, which processes all extra arguments supplied to `tmd`.

### Value

An object of class "trellis". The `update` method can be used to update components of the object and the `print` method (usually called by default) will plot it on an appropriate plotting device.

Description

Fits a One-way model to univariate data grouped by a factor, the result often being displayed using `rfs`

Usage

```
oneway(formula, data, location=mean, spread=function(x) sqrt(var(x)))
```

Arguments

- |                       |                                                                                                                                                              |
|-----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>formula</code>  | formula of the form $y \sim x$ where $y$ is the numeric response and $x$ is the grouping factor                                                              |
| <code>data</code>     | data frame in which the model is to be evaluated                                                                                                             |
| <code>location</code> | function or numeric giving the location statistic to be used for centering the observations, e.g. <code>median</code> , <code>0</code> (to avoid centering). |
| <code>spread</code>   | function or numeric giving the spread statistic to be used for scaling the observations, e.g. <code>sd</code> , <code>1</code> (to avoid scaling).           |

Value

- A list with components
- |                               |                                            |
|-------------------------------|--------------------------------------------|
| <code>location</code>         | vector of locations for each group.        |
| <code>spread</code>           | vector of spreads for each group.          |
| <code>fitted.values</code>    | vector of locations for each observation.  |
| <code>residuals</code>        | residuals ( $y - \text{fitted.values}$ ).  |
| <code>scaled.residuals</code> | residuals scaled by spread for their group |

C\_01\_trellis.device

*Initializing Trellis Displays*

---

**Description**

Initialization of a display device with appropriate graphical parameters.

**Usage**

```
trellis.device(device = getOption("device"),
               color = !(dev.name == "postscript"),
               theme = lattice.getOption("default.theme"),
               new = TRUE,
               retain = FALSE,
               ...)

standard.theme(name, color)
canonical.theme(name, color)
col.whitebg()
```

**Arguments**

|        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| device | function (or the name of one as a character string) that starts a device. Admissible values depend on the platform and how R was compiled (see <a href="#">Devices</a> ), but usually "pdf", "postscript", "png", "jpeg" and at least one of "X11", "windows" and "quartz" will be available.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| color  | logical, whether the initial settings should be color or black and white. Defaults to FALSE for postscript devices, TRUE otherwise. Note that this only applies to the initial choice of colors, which can be overridden using <a href="#">theme</a> or subsequent calls to <a href="#">trellis.par.set</a> (and by arguments supplied directly in high level calls for some settings).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| theme  | list of components that changes the settings of the device opened, or, a function that when called produces such a list. The function name can be supplied as a quoted string. These settings are only used to modify the default settings (determined by other arguments), and need not contain all possible parameters. A possible use of this argument is to change the default settings by specifying <code>lattice.options(default.theme = "col.whitebg")</code> . For back-compatibility, this is initially (when <code>lattice</code> is loaded) set to <code>getOption(lattice.theme)</code> .<br><br>If <code>theme</code> is a function, it will not be supplied any arguments, however, it is guaranteed that a device will already be open when it is called, so one may use <code>.Device</code> inside the function to ascertain what device has been opened. |

|                     |                                                                                                                                                                                                                                                               |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>new</code>    | logical flag indicating whether a new device should be started. If <code>FALSE</code> , the options for the current device are changed to the defaults determined by the other arguments.                                                                     |
| <code>retain</code> | logical. If <code>TRUE</code> and a setting for this device already exists, then that is used instead of the defaults for this device. By default, pre-existing settings are overwritten (and lost).                                                          |
| <code>name</code>   | name of the device for which the setting is required, as returned by <code>.Device</code>                                                                                                                                                                     |
| <code>...</code>    | additional parameters to be passed to the <code>device</code> function, most commonly <code>file</code> for non-screen devices, as well as <code>height</code> , <code>width</code> , etc. See the help file for individual devices for admissible arguments. |

## Details

Trellis Graphics functions obtain the default values of various graphical parameters (colors, line types, fonts, etc.) from a customizable “settings” list. This functionality is analogous to `par` for standard R graphics and, together with `lattice.options`, mostly supplants it (`par` settings are mostly ignored by Lattice). Unlike `par`, Trellis settings can be controlled separately for each different device type (but not concurrently for different instances of the same device). `standard.theme` and `col.whitebg` produce predefined settings (a.k.a. themes), while `trellis.device` provides a high level interface to control which “theme” will be in effect when a new device is opened. `trellis.device` is called automatically when a “trellis” object is plotted, and the defaults can be used to provide sufficient control, so in a properly configured system it is rarely necessary for the user to call `trellis.device` explicitly.

The `standard.theme` function is intended to provide device specific settings (e.g. light colors on a grey background for screen devices, dark colors or black and white for print devices) which were used as defaults prior to R 2.3.0. However, these defaults are not always appropriate, due to the variety of platforms and hardware settings on which R is used, as well as the fact that a plot created on a particular device may be subsequently used in many different ways. For this reason, a “safe” default is used for all devices from R 2.3.0 onwards. The old behaviour can be reinstated by setting `standard.theme` as the default `theme` argument, e.g. by putting `lattice.options(default.theme = "standard.theme")` in a startup script (see the entry for `theme` above for details).

## Value

`standard.theme` returns a list of components defining graphical parameter settings for Lattice displays. It is used internally in `trellis.device`, and can also be used as the `theme` argument to `trellis.par.set`, or even as `theme` in `trellis.device` to use the defaults for another device. `canonical.theme` is an alias for `standard.theme`.

`col.whitebg` returns a similar (but smaller) list that is suitable as the `theme` argument to `trellis.device` and `trellis.par.set`. It contains settings values which provide colors suitable for plotting on a white background. Note that the name `col.whitebg` is somewhat of a misnomer, since it actually sets the background to transparent rather than white.

## Note

Earlier versions of `trellis.device` had a `bg` argument to set the background color, but this is no longer supported. If supplied, the `bg` argument will be passed on to the device function; however, this will have no effect on the Trellis settings. It is rarely meaningful to change the background alone; if you feel the need to change the background, consider using the `theme` argument instead.

[trellis.par.get](#) and [trellis.par.set](#) can be used to query and modify the settings *after* a device has been initialized. The `par.settings` argument to high level functions, described in [xyplot](#), can be used to attach transient settings to a "trellis" object.

---

C\_02\_trellis.par.get

*Graphical Parameters for Trellis Displays*

---

**Description**

Functions used to query, display and modify graphical parameters for fine control of Trellis displays. Modifications are made to the settings for the currently active device only.

**Usage**

```
trellis.par.set(name, value, ..., theme, warn = TRUE, strict = FALSE)
trellis.par.get(name = NULL)
show.settings(x = NULL)
```

**Arguments**

|       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| name  | A character string giving the name of a component. If unspecified in <code>trellis.par.get()</code> , the return value is a named list containing all the current settings (this can be used to get the valid values for <code>name</code> ).                                                                                                                                                                                                                                                                                                           |
| value | a list giving the desired value of the component. Components that are already defined as part of the current settings but are not mentioned in <code>value</code> will remain unchanged.                                                                                                                                                                                                                                                                                                                                                                |
| theme | a list describing how to change the settings, similar to what is returned by <code>trellis.par.get()</code> . This is purely for convenience, allowing multiple calls to <code>trellis.par.set</code> to be condensed into one. The name of each component must be a valid name as described above, with the corresponding value a valid value as described above.<br><br>As in <a href="#">trellis.device</a> , <code>theme</code> can also be a function that produces such a list when called. The function name can be supplied as a quoted string. |
| ...   | Multiple settings can be specified in <code>name = value</code> form. Equivalent to calling with <code>theme = list(...)</code>                                                                                                                                                                                                                                                                                                                                                                                                                         |

|        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| warn   | A logical flag, indicating whether a warning should be issued when <code>trellis.par.get</code> is called when no graphics device is open.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| strict | Usually a logical flag, indicating whether the <code>value</code> should be interpreted strictly. Usually, assignment of value to the corresponding named component is fuzzy in the sense that sub-components that are absent from <code>value</code> but not currently <code>NULL</code> are retained. By specifying <code>strict = TRUE</code> , such values will be removed.<br><br>An even stricter interpretation is allowed by specifying <code>strict</code> as a numeric value larger than 1. In that case, top-level components not specified in the call will also be removed. This is primarily for internal use. |
| x      | optional list of components that change the settings (any valid value of <code>theme</code> ). These are used to modify the current settings (obtained by <code>trellis.par.get</code> ) before they are displayed.                                                                                                                                                                                                                                                                                                                                                                                                          |

## Details

The various graphical parameters (color, line type, background etc) that control the look and feel of Trellis displays are highly customizable. Also, R can produce graphics on a number of devices, and it is expected that a different set of parameters would be more suited to different devices. These parameters are stored internally in a variable named `lattice.theme`, which is a list whose components define settings for particular devices. The components are identified by the name of the device they represent (as obtained by `.Device`), and are created as and when new devices are opened for the first time using `trellis.device` (or Lattice plots are drawn on a device for the first time in that session).

The initial settings for each device defaults to values appropriate for that device. In practice, this boils down to three distinct settings, one for screen devices like `x11` and `windows`, one for black and white plots (mostly useful for `postscript`) and one for color printers (`color postscript`, `pdf`).

Once a device is open, its settings can be modified. When another instance of the same device is opened later using `trellis.device`, the settings for that device are reset to its defaults, unless otherwise specified in the call to `trellis.device`. But settings for different devices are treated separately, i.e., opening a `postscript` device will not alter the `x11` settings, which will remain in effect whenever an `x11` device is active.

The functions `trellis.par.*` are meant to be interfaces to the global settings. They always apply on the settings for the currently `ACTIVE` device.

`trellis.par.get`, called without any arguments, returns the full list of settings for the active device. With the `name` argument present, it returns that component only. `trellis.par.get` sets the value of the `name` component of the current active device settings to `value`.

`trellis.par.get` is usually used inside `trellis` functions to get graphical parameters before plotting. Modifications by users via `trellis.par.set` is traditionally done as follows:

```
add.line <- trellis.par.get("add.line")
add.line$col <- "red"
trellis.par.set("add.line", add.line)
```

More convenient (but not S compatible) ways to do this are

```
trellis.par.set(list(add.line = list(col = "red")))
and
trellis.par.set(add.line = list(col = "red"))
```

The actual list of the components in `trellis.settings` has not been finalized, so I'm not attempting to list them here. The current value can be obtained by `print(trellis.par.get())`. Most names should be self-explanatory.

`show.settings` provides a graphical display summarizing some of the values in the current settings.

### Value

`trellis.par.get` returns a list giving parameters for that component. If `name` is missing, it returns the full list.

Most of the settings are graphical parameters that control various elements of a lattice plot. For details, see the examples below. The more unusual settings are described here.

**grid.pars** Grid graphical parameters that are in effect globally unless overridden by specific settings.

**fontsize** A list of two components (each a numeric scalar), `text` and `points`, for text and symbols respectively.

**clip** A list of two components (each a character string, either "on" or "off"), `panel` and `strip`.

**axis.components**

**layout.heights**

**layout.widths**

### Note

In some ways, `trellis.par.get` and `trellis.par.set` together are a replacement for the `par` function used in traditional R graphics. In particular, changing `par` settings has little (if any) effect on lattice output. Since lattice plots are implemented using Grid graphics, its parameter system *does* have an effect unless overridden by a suitable lattice parameter setting. Such parameters can be specified as part of a lattice theme by including them in the `grid.pars` component (see [gpar](#) for a list of valid parameter names).

### Examples

```
show.settings()

tp <- trellis.par.get()

unusual <- c("grid.pars", "fontsize", "clip", "axis.components",
            "layout.heights", "layout.widths")

for (u in unusual) tp[[u]] <- NULL
names.tp <- lapply(tp, names)
unames <- sort(unique(unlist(names.tp)))
```

```

ans <- matrix(0, nrow = length(names.tp), ncol = length(unames))
rownames(ans) <- names(names.tp)
colnames(ans) <- unames
for (i in seq(along = names.tp))
  ans[i, ] <- as.numeric(unames %in% names.tp[[i]])
ans <- ans[, order(-colSums(ans))]
ans <- ans[order(rowSums(ans)), ]
ans[ans == 0] <- NA

levelplot(t(ans), colorkey = FALSE,
  scales = list(x = list(rot = 90)),
  panel = function(x, y, z, ...) {
    panel.abline(v = unique(as.numeric(x)),
      h = unique(as.numeric(y)),
      col = "darkgrey")
    panel.xyplot(x, y, pch = 16 * z, ...)
  },
  xlab = "Graphical parameters",
  ylab = "Setting names")

```

---

C\_03\_simpleTheme      *Function to generate a simple theme*

---

## Description

Simple interface to generate a list appropriate as a theme, typically used as the `par.settings` argument in a high level call

## Usage

```

simpleTheme(col, alpha,
  cex, pch, lty, lwd, font, fill, border,
  col.points, col.line,
  alpha.points, alpha.line)

```

## Arguments

`col, col.points, col.line`

A color specification. `col` is used for components `"plot.symbol"`, `"plot.line"`, `"plot.polygon"`, `"superpose.symbol"`, `"superpose.line"`, and `"superpose.polygon"`. `col.points` overrides `col`, but is used only for `"plot.symbol"` and `"superpose.symbol"`. Similarly, `col.line` overrides `col` for `"plot.line"` and `"superpose.line"`. The arguments can be vectors, but only the first component is used for scalar targets (i.e., the ones without `"superpose"` in their name).

`alpha, alpha.points, alpha.line`

A numeric alpha transparency specification. The same rules as `col`, etc., apply.

`cex, pch, font`

Parameters for points. Applicable for components `plot.symbol` (for which only the first component is used) and `superpose.symbol` (for which the arguments can be vectors).

|                       |                                                                                                                                                                                               |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>lty, lwd</code> | Parameters for lines. Applicable for components <code>plot.line</code> (for which only the first component is used) and <code>superpose.line</code> (for which the arguments can be vectors). |
| <code>fill</code>     | fill color, applicable for components <code>plot.symbol</code> , <code>plot.polygon</code> , <code>superpose.symbol</code> , and <code>superpose.polygon</code> .                             |
| <code>border</code>   | border color, applicable for components <code>plot.polygon</code> and <code>superpose.polygon</code> .                                                                                        |

### Details

The appearance of a lattice display depends partly on the “theme” active when the display is plotted (see `trellis.device` for details). This theme is used to obtain defaults for various graphical parameters, and in particular, the `auto.key` argument works on the premise that the same source is used for both the actual graphical encoding and the legend. The easiest way to specify custom settings for a particular display is to use the `par.settings` argument, which is usually tedious to construct as it is a nested list. The `simpleTheme` function can be used in such situations as a wrapper that generates a suitable list given parameters in `simple name=value` form, with the nesting made implicit. This is less flexible, but straightforward and sufficient in most situations.

### Value

A list that would work as the `theme` argument to `trellis.device` and `trellis.par.set`, or as the `par.settings` argument to any high level lattice function such as `xyplot`.

### Author(s)

Deepayan Sarkar <Deepayan.Sarkar@R-project.org>, based on a suggestion from John Maindonald.

### See Also

`trellis.device`, `xyplot`, `Lattice`

### Examples

```
str(simpleTheme(pch = 16))

dotplot(variety ~ yield | site, data = barley, groups = year,
        auto.key = list(space = "right"),
        par.settings = simpleTheme(pch = 16),
        xlab = "Barley Yield (bushels/acre) ",
        aspect=0.5, layout = c(1,6))
```

### Description

Functions to handle settings used by lattice. Their main purpose is to make code maintenance easier, and users normally should not need to use these functions. However, fine control at this level maybe useful in certain cases.

## Usage

```
lattice.options(...)
lattice.getOption(name)
```

## Arguments

|      |                                                                                                                                                                                                                                                                                             |
|------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| name | character giving the name of a setting                                                                                                                                                                                                                                                      |
| ...  | new options can be defined, or existing ones modified, using one or more arguments of the form <code>name = value</code> or by passing a list of such tagged values. Existing values can be retrieved by supplying the names (as character strings) of the components as unnamed arguments. |

## Details

These functions are modeled on `options` and `getOption`, and behave similarly for the most part. Some of the available components are documented here, but not all. The purpose of the ones not documented are either fairly obvious, or not of interest to the end-user.

`panel.error` A function, or `NULL`. If the former, every call to the `panel` function will be wrapped inside `tryCatch` with the specified function as an error handler. The default is to use the `panel.error` function. This prevents the plot from failing due to errors in a single panel, and leaving the grid operations in an unmanageable state. If set to `NULL`, errors in panel functions will not be caught using `tryCatch`.

`save.object` Logical flag indicating whether a "trellis" object should be saved when plotted for subsequent retrieval and further manipulation. Defaults to `TRUE`.

`layout.widths`, `layout.heights` Controls details of the default space allocation in the grid layout created in the course of plotting a "trellis" object. Each named component is a list of arguments to the `grid` function `unit` (`x`, `units`, and optionally `data`).

Usually not of interest to the end-user, who should instead use the similarly named component in the graphical settings, modifiable using `trellis.par.set`.

`drop.unused.levels` A list of two components named `cond` and `data`, both logical flags. The flags indicate whether the unused levels of factors (conditioning variables and primary variables respectively) will be dropped, which is usually relevant when a subsetting operation is performed or an 'interaction' is created. See `xyplot` for more details. Note that this does not control dropping of levels of the 'groups' argument.

`legend.bbox` A character string, either "full" or "panel". This determines the interpretation of `x` and `y` when `space="inside"` in `key` (determining the legend; see `xyplot`): either the full figure region ("full"), or just the region that bounds the panels and strips ("panel").

`default.args` A list giving default values for various standard arguments: `as.table`, `aspect`, `between`, `skip`, `strip`, `xscale.components`, `yscale.components`, and `axis`.

`highlight.gpar` A list giving arguments to `gpar` used to highlight a viewport chosen using `trellis.focus`.

`banking` The banking function. See `banking`.

`axis.padding` List with components named "numeric" and "factor", both scalar numbers. Panel limits are extended by this amount, to provide padding for numeric and factor scales respectively. The value for numeric is multiplicative, whereas factor is additive.

`skip.boundary.labels` Numeric scalar between 0 and 1. Tick marks that are too close to the limits are not drawn unless explicitly requested. The limits are contracted by this proportion, and anything outside is skipped.

`interaction.sep` The separator for creating interactions with the extended formula interface (see [xyplot](#)).

`axis.units` List determining default units for axis components. Should not be of interest to the end-user.

In addition, there is an option for the default prepanel and panel function for each high-level function; e.g., `panel.xyplot` and `prepanel.default.xyplot` for [xyplot](#). The options for the others have similarly patterned names.

### Value

`lattice.getOption` returns the value of a single component, whereas `lattice.options` always returns a list with one or more named components. When changing the values of components, the old values of the modified components are returned by `lattice.options`. If called without any arguments, the full list is returned.

### Examples

```
names(lattice.options())
str(lattice.getOption("layout.widths"), max.level = 2)
```

---

C\_05\_print.trellis *Plot and Summarize Trellis Objects*

---

### Description

The `print` and `plot` methods produce a graph from a "trellis" object. The `print` method is necessary for automatic plotting. `plot` method is essentially an alias, provided for convenience. The `summary` method gives a textual summary of the object. `dim` and `dimnames` describe the cross-tabulation induced by conditioning. `panel.error` is the default handler used when an error occurs while executing the panel function.

### Usage

```
## S3 method for class 'trellis'
plot(x, position, split,
     more = FALSE, newpage = TRUE,
     packet.panel = packet.panel.default,
     draw.in = NULL,
     panel.height = lattice.getOption("layout.heights")$panel,
     panel.width = lattice.getOption("layout.widths")$panel,
```

```

        save.object = lattice.getOption("save.object"),
        panel.error = lattice.getOption("panel.error"),
        prefix,
        ...)
## S3 method for class 'trellis'
print(x, ...)

## S3 method for class 'trellis'
summary(object, ...)

## S3 method for class 'trellis'
dim(x)
## S3 method for class 'trellis'
dimnames(x)

panel.error(e)

```

### Arguments

|                                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|----------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x, object</code>                 | an object of class "trellis"                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>position</code>                  | a vector of 4 numbers, typically <code>c(xmin, ymin, xmax, ymax)</code> that give the lower-left and upper-right corners of a rectangle in which the Trellis plot of <code>x</code> is to be positioned. The coordinate system for this rectangle is [0-1] in both the <code>x</code> and <code>y</code> directions.                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>split</code>                     | a vector of 4 integers, <code>c(x,y,nx,ny)</code> , that says to position the current plot at the <code>x,y</code> position in a regular array of <code>nx</code> by <code>ny</code> plots. (Note: this has origin at top left)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <code>more</code>                      | A logical specifying whether more plots will follow on this page.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>newpage</code>                   | A logical specifying whether the plot should be on a new page. This option is specific to lattice, and is useful for including lattice plots in an arbitrary grid viewport (see the details section).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <code>packet.panel</code>              | a function that determines which packet (data subset) is plotted in which panel. Panels are always drawn in an order such that columns vary the fastest, then rows and then pages. This function determines, given the column, row and page and other relevant information, the packet (if any) which should be used in that panel. By default, the association is determined by matching panel order with packet order, which is determined by varying the first conditioning variable the fastest, then the second, and so on. This association rule is encoded in the default, namely the function <code>packet.panel.default</code> , whose help page details the arguments supplied to whichever function is specified as the <code>packet.panel</code> argument. |
| <code>draw.in</code>                   | An optional (grid) viewport (used as the <code>name</code> argument in <code>downViewport</code> ) in which the plot is to be drawn. If specified, the <code>newpage</code> argument is ignored. This feature is not well-tested.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>panel.width, panel.height</code> | lists with 2 components, that should be valid <code>x</code> and <code>units</code> arguments to <code>unit()</code> (the <code>data</code> argument cannot be specified currently, but can be considered for addition if needed). The resulting <code>unit</code> object will be the width/height of each panel in the Lattice plot. These arguments can be used to explicitly control the dimensions of the panel, rather than letting them expand to maximize                                                                                                                                                                                                                                                                                                       |

|                          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|--------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                          | available space. Vector widths are allowed, and can specify unequal lengths across rows or columns.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|                          | Note that this option should not be used in conjunction with non-default values of the <code>aspect</code> argument in the original high level call (no error will be produced, but the resulting behaviour is undefined).                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>save.object</code> | logical, specifying whether the object being printed is to be saved. The last object thus saved can be subsequently retrieved. This is an experimental feature that should allow access to a panel's data after the plot is done, making it possible to enhance the plot after the fact. This also allows the user to invoke the <code>update</code> method on the current plot, even if it was not assigned to a variable explicitly. For more details, see <a href="#">trellis.focus</a> .                                                                                                                                                                                                         |
| <code>panel.error</code> | a function, or a character string naming a function, that is to be executed when an error occurs during the execution of the panel function. The error is caught (using <code>tryCatch</code> ) and supplied as the only argument to <code>panel.error</code> . The default behaviour (implemented as the <code>panel.error</code> function) is to print the corresponding error message in the panel and continue. To stop execution on error, use <code>panel.error = stop</code> .<br><br>Normal error recovery and debugging tools are unhelpful when <code>tryCatch</code> is used. <code>tryCatch</code> can be completely bypassed by setting <code>panel.error</code> to <code>NULL</code> . |
| <code>prefix</code>      | A character string acting as a prefix identifying the plot of a "trellis" object, primarily used in constructing viewport and grob names, to distinguish similar viewports if a page contains multiple plots. The default is based on the serial number of the current plot on the current page (specifically, "plot_01", "plot_02", etc.). If supplied explicitly, this must be a valid R symbol name (briefly, it must start with a letter or a period followed by a letter) and must not contain the grid path separator (currently " : ").                                                                                                                                                       |
| <code>e</code>           | an error condition caught by <code>tryCatch</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>...</code>         | extra arguments, ignored by the <code>print</code> method. All arguments to the <code>plot</code> method are passed on to the <code>print</code> method.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

## Details

This is the default print method for objects of class "trellis", produced by calls to functions like `xyplot`, `bwplot` etc. It is usually called automatically when a trellis object is produced. It can also be called explicitly to control plot positioning by means of the arguments `split` and `position`.

When `newpage = FALSE`, the current grid viewport is treated as the plotting area, making it possible to embed a Lattice plot inside an arbitrary grid viewport. The `draw.in` argument provides an alternative mechanism that may be simpler to use.

The print method uses the information in `x` (the object to be printed) to produce a display using the Grid graphics engine. At the heart of the plot is a grid layout, of which the entries of most interest to the user are the ones containing the display panels.

Unlike in older versions of Lattice (and Grid), the grid display tree is retained after the plot is produced, making it possible to access individual viewport locations and make additions to the plot. For more details and a lattice level interface to these viewports, see [trellis.focus](#).

## Note

Unlike S-PLUS, trying to position a multipage display (using `position` and/or `split`) will mess things up.

**Examples**

```
p11 <- histogram( ~ height | voice.part, data = singer, xlab="Height")
p12 <- densityplot( ~ height | voice.part, data = singer, xlab = "Height")
p2 <- histogram( ~ height, data = singer, xlab = "Height")

## simple positioning by split
print(p11, split=c(1,1,1,2), more=TRUE)
print(p2, split=c(1,2,1,2))

## Combining split and position:
print(p11, position = c(0,0,.75,.75), split=c(1,1,1,2), more=TRUE)
print(p12, position = c(0,0,.75,.75), split=c(1,2,1,2), more=TRUE)
print(p2, position = c(.5,.75,1,1), more=FALSE)

## Using seekViewport

## repeat same plot, with different polynomial fits in each panel
xyplot(Armed.Forces ~ Year, longley, index.cond = list(rep(1, 6)),
       layout = c(3, 2),
       panel = function(x, y, ...)
       {
         panel.xyplot(x, y, ...)
         fm <- lm(y ~ poly(x, panel.number()))
         llines(x, predict(fm))
       })

## Not run:

C\_06\_update.trellis

*Retrieve and Update Trellis Object*

---

## Description

Update method for objects of class "trellis", and a way to retrieve the last printed trellis object (that was saved).

## Usage

```
## S3 method for class 'trellis'
update(object,
        panel,
        aspect,
        as.table,
        between,
        key,
        auto.key,
        legend,
        layout,
        main,
        page,
        par.strip.text,
        prepanel,
        scales,
        skip,
        strip,
        strip.left,
        sub,
        xlab,
        ylab,
        xlab.top,
        ylab.right,
        xlim,
        ylim,
        xscale.components,
        yscale.components,
        axis,
        par.settings,
        plot.args,
        lattice.options,
        index.cond,
        perm.cond,
        ...)

## S3 method for class 'trellis'
```

```
t(x)

## S3 method for class 'trellis'
x[i, j, ..., drop = FALSE]

trellis.last.object(..., prefix)
```

### Arguments

|                                                                                                     |                                                                                                                                                                                                                                                                        |
|-----------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object, x</code>                                                                              | The object to be updated, of class "trellis".                                                                                                                                                                                                                          |
| <code>i, j</code>                                                                                   | indices to be used. Names are not currently allowed.                                                                                                                                                                                                                   |
| <code>drop</code>                                                                                   | logical, whether dimensions with only one level are to be dropped. Currently ignored, behaves as if it were FALSE.                                                                                                                                                     |
| <code>panel, aspect, as.table, between, key, auto.key, legend, layout, main, page, par.strip</code> | arguments that will be used to update <code>object</code> . See details below.                                                                                                                                                                                         |
| <code>prefix</code>                                                                                 | A character string acting as a prefix identifying the plot of a "trellis" object. Only relevant when a particular page is occupied by more than one plot. Defaults to the value appropriate for the last "trellis" object printed. See <a href="#">trellis.focus</a> . |

### Details

All high level lattice functions such as `xyplot` produce an object of (S3) class "trellis", which is usually displayed by its `print` method. However, the object itself can be manipulated and modified to a large extent using the `update` method, and then re-displayed as needed.

Most arguments to high level functions can also be supplied to the `update` method as well, with some exceptions. Generally speaking, anything that would need to change the data within each panel is a no-no (this includes the `formula`, `data`, `groups`, `subscripts` and `subset`). Everything else is technically game, though might not be implemented yet. If you find something missing that you wish to have, feel free to make a request.

Not all arguments accepted by a Lattice function are processed by `update`, but the ones listed above should work. The purpose of these arguments are described in the help page for [xyplot](#). Any other argument is added to the list of arguments to be passed to the `panel` function. Because of their somewhat special nature, updates to objects produced by `cloud` and `wireframe` do not work very well yet.

The `"["` method is a convenient shortcut for updating `index.cond`. The `t` method is a convenient shortcut for updating `perm.cond` in the special (but frequent) case where there are exactly two conditioning variables, when it has the effect of switching ('transposing') their order.

The `print` method for "trellis" objects optionally saves the object after printing it. If this feature is enabled, `trellis.last.object` can retrieve it. By default, the last object plotted is retrieved, but if multiple objects are plotted on the current page, then others can be retrieved using the appropriate `prefix` argument. If [trellis.last.object](#) is called with arguments, these are used to update the retrieved object before returning it.

### Value

An object of class `trellis`, by default plotted by `print.trellis`. `trellis.last.object` returns NULL if no saved object is available.

C\_07\_shingles

*shingles*

---

**Description**

Functions to handle shingles

**Usage**

```
shingle(x, intervals=sort(unique(x)))
equal.count(x, ...)
as.shingle(x)
is.shingle(x)

## S3 method for class 'shingle'
plot(x, panel, xlab, ylab, ...)

## S3 method for class 'shingle'
print(x, showValues = TRUE, ...)

## S3 method for class 'shingleLevel'
as.character(x, ...)

## S3 method for class 'shingleLevel'
print(x, ...)

## S3 method for class 'shingle'
summary(object, showValues = FALSE, ...)

## S3 method for class 'shingle'
x[subset, drop = FALSE]
as.factorOrShingle(x, subset, drop)
```

**Arguments**

|                                |                                                                                                                                                                                                                                     |
|--------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>                 | numeric variable or R object, <code>shingle</code> in <code>plot.shingle</code> and <code>x[]</code> . An object (list of intervals) of class "shingleLevel" in <code>print.shingleLevel</code>                                     |
| <code>object</code>            | shingle object to be summarized                                                                                                                                                                                                     |
| <code>showValues</code>        | logical, whether to print the numeric part. If FALSE, only the intervals are printed                                                                                                                                                |
| <code>intervals</code>         | numeric vector or matrix with 2 columns                                                                                                                                                                                             |
| <code>subset</code>            | logical vector                                                                                                                                                                                                                      |
| <code>drop</code>              | whether redundant shingle levels are to be dropped                                                                                                                                                                                  |
| <code>panel, xlab, ylab</code> | standard Trellis arguments (see <a href="#">xyplot</a> )                                                                                                                                                                            |
| <code>...</code>               | other arguments, passed down as appropriate. For example, extra arguments to <code>equal.count</code> are passed on to <code>co.intervals</code> . graphical parameters can be passed as arguments to the <code>plot</code> method. |

**Details**

A shingle is a data structure used in Trellis, and is a generalization of factors to ‘continuous’ variables. It consists of a numeric vector along with some possibly overlapping intervals. These intervals are the ‘levels’ of the shingle. The `levels` and `nlevels` functions, usually applicable to factors, also work on shingles. The implementation of shingles is slightly different from S.

There are print methods for shingles, as well as for printing the result of `levels()` applied to a shingle. For use in labelling, the `as.character` method can be used to convert levels of a shingle to character strings.

`equal.count` converts `x` to a shingle using the equal count algorithm. This is essentially a wrapper around `co.intervals`. All arguments are passed to `co.intervals`.

`shingle` creates a shingle using the given `intervals`. If `intervals` is a vector, these are used to form 0 length intervals.

`as.shingle` returns `shingle(x)` if `x` is not a shingle.

`is.shingle` tests whether `x` is a shingle.

`plot.shingle` displays the ranges of shingles via rectangles. `print.shingle` and `summary.shingle` describe the shingle object.

**Value**

`x$intervals` for `levels.shingle(x)`, logical for `is.shingle`, an object of class "trellis" for `plot` (printed by default by `print.trellis`), and an object of class "shingle" for the others.

**Author(s)**

Deepayan Sarkar <Deepayan.Sarkar@R-project.org>

**See Also**

[xyplot](#), [co.intervals](#), [Lattice](#)

**Examples**

```
z <- equal.count(rnorm(50))
plot(z)
print(z)
print(levels(z))
```

---

|                 |                                                   |
|-----------------|---------------------------------------------------|
| D_draw.colorkey | <i>Produce a colorkey typically for levelplot</i> |
|-----------------|---------------------------------------------------|

---

**Description**

Creates (and optionally draws) a grid frame grob representing a color key that can be placed in other grid-based plots. Primarily used by `levelplot` when a color key is requested.

**Usage**

```
draw.colorkey(key, draw = FALSE, vp = NULL)
```

**Arguments**

|      |                                                                                                                                                                  |
|------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| key  | A list determining the key. See documentation for <code>levelplot</code> , in particular the section describing the <code>colorkey</code> argument, for details. |
| draw | A scalar logical, indicating whether the grob is to be drawn.                                                                                                    |
| vp   | The viewport in which to draw the grob, if applicable.                                                                                                           |

**Value**

A grid frame object (that inherits from "grob")

### Description

Calculates false colors from a numeric variable (including factors, using their numeric codes) given a color scheme and breakpoints.

### Usage

```
level.colors(x, at, col.regions, colors = TRUE, ...)
```

**Arguments**

|                          |                                                                                                                                                                                                                                                                       |
|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>           | A numeric or <code>factor</code> variable.                                                                                                                                                                                                                            |
| <code>at</code>          | A numeric variable of breakpoints defining intervals along the range of <code>x</code> .                                                                                                                                                                              |
| <code>col.regions</code> | A specification of the colors to be assigned to each interval defined by <code>at</code> . This could be either a vector of colors, or a function that produces a vector of colors when called with a single argument giving the number of colors. See details below. |
| <code>colors</code>      | logical indicating whether colors should be computed and returned. If <code>FALSE</code> , only the indices representing which interval (among those defined by <code>at</code> ) each value in <code>x</code> falls into is returned.                                |
| <code>...</code>         | Extra arguments, ignored.                                                                                                                                                                                                                                             |

**Details**

If `at` has length `n`, then it defines `n-1` intervals. Values of `x` outside the range of `at` are not assigned to an interval, and the return value is `NA` for such values.

Colors are chosen by assigning a color to each of the `n-1` intervals. If `col.regions` is a palette function (such as `topo.colors`, or the result of calling `colorRampPalette`), it is called with `n-1` as an argument to obtain the colors. Otherwise, if there are exactly `n-1` colors in `col.regions`, these get assigned to the intervals. If there are fewer than `n-1` colors, `col.regions` gets recycled. If there are more, a more or less equally spaced (along the length of `col.regions`) subset is chosen.

**Value**

A vector of the same length as `x`. Depending on the `colors` argument, this could be either a vector of colors (in a form usable by `R`), or a vector of integer indices representing which interval the values of `x` fall in.

**Examples**

```
depth.col <-
  with(quakes,
    level.colors(depth, at = do.breaks(range(depth), 30),
      col.regions = terrain.colors))

xyplot(lat ~ long | equal.count(stations), quakes,
  strip = strip.custom(var.name = "Stations"),
  colours = depth.col,
  panel = function(x, y, colours, subscripts, ...) {
    panel.xyplot(x, y, pch = 21, col = "transparent",
      fill = colours[subscripts], ...)
  })
```

---

`D_make.groups`*Grouped data from multiple vectors*

---

**Description**

Combines two or more vectors, possibly of different lengths, producing a data frame with a second column indicating which of these vectors that row came from. This is mostly useful for getting data into a form suitable for use in high level Lattice functions.

**Usage**

```
make.groups(...)
```

**Arguments**

`...` one or more vectors of the same type (coercion is attempted if not), or one or more data frames with similar columns, with possibly differing number of rows.

**Value**

When all the input arguments are vectors, a data frame with two columns

`data` all the vectors supplied, concatenated

`which` factor indicating which vector the corresponding data value came from

When all the input arguments are data frames, the result of `rbind` applied to them, along with an additional `which` column as described above.

[Lattice](#)

**Examples**

```
sim.dat <-  
  make.groups(uniform = runif(200),  
              exponential = rexp(175),  
              lognormal = rlnorm(150),  
              normal = rnorm(125))  
qqmath( ~ data | which, sim.dat, scales = list(y = "free"))
```

---

D\_simpleKey

Function to generate a simple key

---

## Description

Simple interface to generate a list appropriate for `draw.key`

## Usage

```
simpleKey(text, points = TRUE,
         rectangles = FALSE,
         lines = FALSE,
         col, cex, alpha, font,
         fontface, fontfamily,
         lineheight, ...)
```

## Arguments

|                                                                      |                                                                                                                                                       |
|----------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>text</code>                                                    | character or expression vector, to be used as labels for levels of the grouping variable                                                              |
| <code>points</code>                                                  | logical                                                                                                                                               |
| <code>rectangles</code>                                              | logical                                                                                                                                               |
| <code>lines</code>                                                   | logical                                                                                                                                               |
| <code>col, cex, alpha, font, fontface, fontfamily, lineheight</code> | Used as top-level components of the list produced, to be used for the text labels. Defaults to the values in <code>trellis.par.get("add.text")</code> |
| <code>...</code>                                                     | further arguments added to the list, eventually passed to <code>draw.key</code>                                                                       |

## Details

A lattice plot can include a legend (key) if an appropriate list is specified as the `key` argument to a high level Lattice function such as `xyplot`. This key can be very flexible, but that flexibility comes at a cost: this list needs to be fairly complicated even in simple situations. `simpleKey` is designed as a useful shortcut in the common case of a key drawn in conjunction with a grouping variable, using the default graphical settings.

The `simpleKey` function produces a suitable `key` argument using a simpler interface. The resulting list will use the `text` argument as a text component, along with at most one set each of points, rectangles, and lines. The number of entries (rows) in the key will be the length of the `text` component. The graphical parameters for the additional components will be derived from the default graphical settings (wherein lies the simplification, as otherwise these would have to be provided explicitly).

Calling `simpleKey` directly is usually unnecessary. It is most commonly invoked (during the plotting of the "trellis" object) when the `auto.key` argument is supplied in a high-level plot with a `groups` argument. In that case, the `text` argument of `simpleKey` defaults to `levels(groups)`, and the defaults for the other arguments depend on the relevant high-level function. Note that these defaults can be overridden by supplying `auto.key` as a list containing the replacement values.

**Value**

A list that would work as the `key` argument to `xyplot`, etc.

**Author(s)**

|                 |                                       |
|-----------------|---------------------------------------|
| D_strip.default | <i>Default Trellis Strip Function</i> |
|-----------------|---------------------------------------|

---

**Description**

`strip.default` is the function that draws the strips by default in Trellis plots. Users can write their own strip functions, but most commonly this involves calling `strip.default` with a slightly different arguments. `strip.custom` provides a convenient way to obtain new strip functions that differ from `strip.default` only in the default values of certain arguments.

**Usage**

```
strip.default(which.given,
              which.panel,
              var.name,
              factor.levels,
              shingle.intervals,
              strip.names = c(FALSE, TRUE),
              strip.levels = c(TRUE, FALSE),
              sep = " : ",
              style = 1,
              horizontal = TRUE,
              bg = trellis.par.get("strip.background")$col[which.given],
              fg = trellis.par.get("strip.shingle")$col[which.given],
              par.strip.text = trellis.par.get("add.text"))
strip.custom(...)
```

**Arguments**

|                          |                                                                                                                                                                                                                                                                                                                                                                |
|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>which.given</code> | integer index specifying which of the conditioning variables this strip corresponds to.                                                                                                                                                                                                                                                                        |
| <code>which.panel</code> | vector of integers as long as the number of conditioning variables. The contents are indices specifying the current levels of each of the conditioning variables (thus, this would be unique for each distinct packet). This is identical to the return value of <code>which.packet</code> , which is a more accurate name.                                    |
| <code>var.name</code>    | vector of character strings or expressions as long as the number of conditioning variables. The contents are interpreted as names for the conditioning variables. Whether they are shown on the strip depends on the values of <code>strip.names</code> and <code>style</code> (see below). By default, the names are shown for shingles, but not for factors. |

|                                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|--------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>factor.levels</code>     | vector of character strings or expressions giving the levels of the conditioning variable currently being drawn. For more than one conditioning variable, this will vary with <code>which.given</code> . Whether these levels are shown on the strip depends on the values of <code>strip.levels</code> and <code>style</code> (see below). <code>factor.levels</code> may be specified for both factors and shingles (despite the name), but by default they are shown only for factors. If shown, the labels may optionally be abbreviated by specifying suitable components in <code>par.strip.text</code> (see <code>xyplot</code> )                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <code>shingle.intervals</code> | if the current strip corresponds to a shingle, this should be a 2-column matrix giving the levels of the shingle. (of the form that would be produced by <code>printing.levels(shingle)</code> ). Otherwise, it should be <code>NULL</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>strip.names</code>       | a logical vector of length 2, indicating whether or not the name of the conditioning variable that corresponds to the strip being drawn is to be written on the strip. The two components give the values for factors and shingles respectively. This argument is ignored for a factor when <code>style</code> is not one of 1 and 3.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>strip.levels</code>      | a logical vector of length 2, indicating whether or not the level of the conditioning variable that corresponds to the strip being drawn is to be written on the strip. The two components give the values for factors and shingles respectively.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>sep</code>               | character or expression, serving as a separator if the name and level are both to be shown.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>style</code>             | integer, with values 1, 2, 3, 4 and 5 currently supported, controlling how the current level of a factor is encoded. Ignored for shingles (actually, when <code>shingle.intervals</code> is non-null.<br><br>The best way to find out what effect the value of <code>style</code> has is to try them out. Here is a short description: for a style value of 1, the strip is colored in the background color with the strip text (as determined by other arguments) centered on it. A value of 3 is the same, except that a part of the strip is colored in the foreground color, indicating the current level of the factor. For styles 2 and 4, the part corresponding to the current level remains colored in the foreground color, however, for style = 2, the remaining part is not colored at all, whereas for 4, it is colored with the background color. For both these, the names of all the levels of the factor are placed on the strip from left to right. Styles 5 and 6 produce the same effect (they are subtly different in S, this implementation corresponds to 5), they are similar to style 1, except that the strip text is not centered, it is instead positioned according to the current level.<br><br>Note that unlike S-PLUS, the default value of <code>style</code> is 1. <code>strip.names</code> and <code>strip.levels</code> have no effect if <code>style</code> is not 1 or 3. |
| <code>horizontal</code>        | logical, specifying whether the labels etc should be horizontal. <code>horizontal=FALSE</code> is useful for strips on the left of panels using <code>strip.left=TRUE</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>par.strip.text</code>    | list with parameters controlling the text on each strip, with components <code>col</code> , <code>cex</code> , <code>font</code> , etc.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| <code>...</code>               | arguments to be passed on to <code>strip.default</code> , overriding whatever value it would have normally assumed                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

**Details**

default strip function for trellis functions. Useful mostly because of the `style` argument — non-default styles are often more informative, especially when the names of the levels of the factor `x` are small. Traditional use is as `strip = function(...) strip.default(style=2,...)`, though this can be simplified by the use of `strip.custom`.

**Value**

`strip.default` is called for its side-effect, which is to draw a strip appropriate for multi-panel Trellis conditioning plots. `strip.custom` returns a function that is similar to `strip.default`, but with different defaults for the arguments specified in the call.

**See Also**

`xyplot`, `Lattice`

**Examples**

```
## Traditional use
xyplot(Petal.Length ~ Petal.Width | Species, iris,
       strip = function(..., style) strip.default(..., style = 4))

## equivalent call using strip.custom
xyplot(Petal.Length ~ Petal.Width | Species, iris,
       strip = strip.custom(style = 4))

xyplot(Petal.Length ~ Petal.Width | Species, iris,
       strip = FALSE,
       strip.left = strip.custom(style = 4, horizontal = FALSE))
```

D\_trellis.object     *A Trellis Plot Object*

---

**Description**

This class of objects is returned by high level lattice functions, and is usually plotted by default by its `print` method.

**Details**

A trellis object, as returned by high level lattice functions like `xyplot`, is a list with the "class" attribute set to "trellis". Many of the components of this list are simply the arguments to the high level function that produced the object. Among them are: `as.table`, `layout`, `page`, `panel`, `prepanel`, `main`, `sub`, `par.strip.text`, `strip`, `skip`, `xlab` `ylab`, `par.settings`, `lattice.options` and `plot.args`. Some other typical components are:

`formula` the Trellis formula used in the call

`index.cond` list with index for each of the conditioning variables

`perm.cond` permutation of the order of the conditioning variables  
`aspect.fill` logical, whether aspect is "fill"  
`aspect.ratio` numeric, aspect ratio to be used if `aspect.fill` is FALSE  
`call` call that generated the object.  
`condlevels` list with levels of the conditioning variables  
`legend` list describing the legend(s) to be drawn  
`panel.args` a list as long as the number of panels, each element being a list itself, containing the arguments in named form to be passed to the panel function in that panel.  
`panel.args.common` a list containing the arguments common to all the panel functions in name=value form  
`x.scales` list describing x-scale, can consist of several other lists, paralleling `panel.args`, if x-relation is not "same"  
`y.scales` list describing y-scale, similar to `x.scales`  
`x.between` numeric vector of interpanel x-space  
`y.between` numeric vector of interpanel y-space  
`x.limits` numeric vector of length 2 or list, giving x-axis limits  
`y.limits` similar to `x.limits`  
`packet.sizes` array recording the number of observations in each packet

E\_interaction

*Functions to Interact with Lattice Plots*

---

**Description**

The classic Trellis paradigm is to plot the whole object at once, without the possibility of interacting with it afterwards. However, by keeping track of the grid viewports where the panels and strips are drawn, it is possible to go back to them afterwards and enhance them one panel at a time. These functions provide convenient interfaces to help in this. Note that these are still experimental and the exact details may change in future.

**Usage**

```

panel.identify(x, y = NULL,
               subscripts = seq_along(x),
               labels = subscripts,
               n = length(x), offset = 0.5,
               threshold = 18, ## in points, roughly 0.25 inches
               panel.args = trellis.panelArgs(),
               ...)

```

```

panel.identify.qqmath(x, distribution, groups, subscripts, labels,
                      panel.args = trellis.panelArgs(),
                      ...)
panel.identify.cloud(x, y, z, subscripts,
                    perspective, distance,
                    xlim, ylim, zlim,
                    screen, R.mat, aspect, scales.3d,
                    ...,
                    panel.3d.identify,
                    n = length(subscripts),
                    offset = 0.5,
                    threshold = 18,
                    labels = subscripts,
                    panel.args = trellis.panelArgs())
panel.link.splom(threshold = 18, verbose = getOption("verbose"), ...)
panel.brush.splom(threshold = 18, verbose = getOption("verbose"), ...)

### Arguments

|                         |                                                                                                                   |
|-------------------------|-------------------------------------------------------------------------------------------------------------------|
| <code>x, y, z</code>    | variables defining the contents of the panel. In the case of <code>trellis.panelArgs</code> , a "trellis" object. |
| <code>n</code>          | the number of points to identify by default (overridden by a right click)                                         |
| <code>subscripts</code> | an optional vector of integer indices associated with each point. See details below.                              |

|                                                                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| distribution, groups                                                      | typical panel arguments of <code>panel.qqmath</code> . These will usually be obtained from <code>panel.args</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| offset                                                                    | the labels are printed either below, above, to the left or to the right of the identified point, depending on the relative location of the mouse click. The <code>offset</code> specifies (in "char" units) how far from the identified point the labels should be printed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| threshold                                                                 | threshold in grid's "points" units. Points further than these from the mouse click position are not considered                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| panel.args                                                                | list that contains components names <code>x</code> (and usually <code>y</code> ), to be used if <code>x</code> is missing. Typically, when called after <code>trellis.focus</code> , this would appropriately be the arguments passed to that panel.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| perspective, distance, xlim, ylim, zlim, screen, R.mat, aspect, scales.3d | arguments as passed to <code>panel.cloud</code> . These are required to recompute the relevant three-dimensional projections in <code>panel.identify.cloud</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| panel.3d.identify                                                         | the function that is responsible for the actual interaction once the data rescaling and rotation computations have been done. By default, an internal function similar to <code>panel.identify</code> is used.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| name                                                                      | <p>A character string indicating which viewport or grob we are looking for. Although these do not necessarily provide access to all viewports and grobs created by a lattice plot, they cover most of the ones that end-users may find interesting. <code>trellis.vpname</code> and <code>trellis.focus</code> deal with viewport names only, and only accept the values explicitly listed above. <code>trellis.grobname</code> is meant to create names for grobs, and can currently accept any value.</p> <p>If <code>name</code>, as well as <code>column</code> and <code>row</code> is missing in a call to <code>trellis.focus</code>, the user can click inside a panel (or an associated strip) to focus on that panel. Note however that this assumes equal width and height for each panel, and may not work when this is not true.</p> <p>When <code>name</code> is "panel", "strip", or "strip.left", <code>column</code> and <code>row</code> must also be specified. When <code>name</code> is "legend", <code>side</code> must also be specified.</p> |
| column, row                                                               | integers, indicating position of the panel or strip that should be assigned focus in the Trellis layout. Rows are usually calculated from the bottom up, unless the plot was created with <code>as.table=TRUE</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| guess                                                                     | logical. If TRUE, and the display has only one panel, that panel will be automatically selected by a call to <code>trellis.focus</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| side                                                                      | character string, relevant only for legends (i.e., when <code>name="legend"</code> ), indicating their position. Partial specification is allowed, as long as it is unambiguous.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| clip.off                                                                  | logical, whether clipping should be off, relevant when <code>name</code> is "panel" or "strip". This is necessary if axes are to be drawn outside the panel or strip. Note that setting <code>clip.off=FALSE</code> does not necessarily mean that clipping is on; that is determined by conditions in effect during printing.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| type                                                                      | <p>A character string specifying whether the grob is specific to a particular panel or strip.</p> <p>When <code>type</code> is "panel", "strip", or "strip.left", information about the panel is added to the grob name.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

|                                       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| <code>group</code>                    | <p>An integer specifying whether the grob is specific to a particular group within the plot.</p> <p>When <code>group</code> is greater than zero, information about the group is added to the grob name.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>which.given, which.panel</code> | <p>integers, indicating which conditional variable is being represented (within a strip) and the current levels of the conditional variables.</p> <p>When <code>which.panel</code> has length greater than 1, and the type is "strip" or "strip.left", information about the conditional variable is added to the grob name.</p>                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>prefix</code>                   | <p>A character string acting as a prefix identifying the plot of a "trellis" object, primarily used to distinguish otherwise equivalent viewports in different plots. This only becomes relevant when a particular page is occupied by more than one plot. Defaults to the value appropriate for the last "trellis" object printed, as determined by the <code>prefix</code> argument in <code>print.trellis</code>.</p> <p>Users should not usually need to supply a value for this argument except to interact with an existing plot other than the one plotted last.</p> <p>For <code>switchFocus</code>, ignored except when it does not match the prefix of the currently active plot, in which case an error occurs.</p> |
| <code>highlight</code>                | <p>logical, whether the viewport being assigned focus should be highlighted. For <code>trellis.focus</code>, the default is TRUE in interactive mode, and <code>trellis.switchFocus</code> by default preserves the setting currently active.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <code>packet.number</code>            | <p>integer, which panel to get data from. See <code>packet.number</code> for details on how this is calculated</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>verbose</code>                  | <p>whether details will be printed</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>...</code>                      | <p>For <code>panel.identify.qqmath</code>, extra parameters are passed on to <code>panel.identify</code>. For <code>panel.identify</code>, extra arguments are treated as graphical parameters and are used for labelling. For <code>trellis.focus</code> and <code>trellis.switchFocus</code>, these are used (in combination with <code>lattice.options</code>) for highlighting the chosen viewport if so requested. Graphical parameters can be supplied for <code>panel.link.splom</code>.</p>                                                                                                                                                                                                                            |

## Details

`panel.identify` is similar to `identify`. When called, it waits for the user to identify points (in the panel being drawn) via mouse clicks. Clicks other than left-clicks terminate the procedure. Although it is possible to call it as part of the panel function, it is more typical to use it to identify points after plotting the whole object, in which case a call to `trellis.focus` first is necessary.

`panel.link.splom` is meant for use with `spлом`, and requires a panel to be chosen using `trellis.focus` before it is called. Clicking on a point causes that and the corresponding projections in other pairwise scatter plots to be highlighted. `panel.brush.splom` is a (misnamed) alias for `panel.link.splom`, retained for back-compatibility.

`panel.identify.qqmath` is a specialized wrapper meant for use with the display produced by `qqmath`. `panel.identify.cloud` is a specialized wrapper meant for use with the display produced by `cloud`. It would be unusual to call them except in a context where default panel function arguments are available through `trellis.panelArgs` (see below).

One way in which `panel.identify` etc. are different from `identify` is in how it uses the `subscripts` argument. In general, when one identifies points in a panel, one wants to identify the origin in the data frame used to produce the plot, and not within that particular panel.

This information is available to the panel function, but only in certain situations. One way to ensure that `subscripts` is available is to specify `subscripts = TRUE` in the high level call such as `xyplot`. If `subscripts` is not explicitly specified in the call to `panel.identify`, but is available in `panel.args`, then those values will be used. Otherwise, they default to `seq_along(x)`. In either case, the final return value will be the `subscripts` that were marked.

The process of printing (plotting) a Trellis object builds up a grid layout with named viewports which can then be accessed to modify the plot further. While full flexibility can only be obtained by using grid functions directly, a few lattice functions are available for the more common tasks.

`trellis.focus` can be used to move to a particular panel or strip, identified by its position in the array of panels. It can also be used to focus on the viewport corresponding to one of the labels or a legend, though such usage would be less useful. The exact viewport is determined by the `name` along with the other arguments, not all of which are relevant for all names. Note that when more than one object is plotted on a page, `trellis.focus` will always go to the plot that was created last. For more flexibility, use grid functions directly (see note below).

After a successful call to `trellis.focus`, the desired viewport (typically panel or strip area) will be made the 'current' viewport (plotting area), which can then be enhanced by calls to standard lattice panel functions as well as grid functions.

It is quite common to have the layout of panels chosen when a "trellis" object is drawn, and not before then. Information on the layout (specifically, how many rows and columns, and which packet belongs in which position in this layout) is retained for the last "trellis" object plotted, and is available through `trellis.currentLayout`.

`trellis.unfocus` unsets the focus, and makes the top level viewport the current viewport.

`trellis.switchFocus` is a convenience function to switch from one viewport to another, while preserving the current `row` and `column`. Although the rows and columns only make sense for panels and strips, they would be preserved even when the user switches to some other viewport (where row/column is irrelevant) and then switches back.

Once a panel or strip is in focus, `trellis.panelArgs` can be used to retrieve the arguments that were available to the panel function at that position. In this case, it can be called without arguments as

```
trellis.panelArgs()
```

This usage is also allowed when a "trellis" object is being printed, e.g. inside the panel functions or the axis function (but not inside the `prepanel` function). `trellis.panelArgs` can also retrieve the panel arguments from any "trellis" object. Note that for this usage, one needs to specify the `packet.number` (as described under the `panel` entry in [xyplot](#)) and not the position in the layout, because a layout determines the panel only **after** the object has been printed.

It is usually not necessary to call `trellis.vpname` and `trellis.grobname` directly. However, they can be useful in generating appropriate names in a portable way when using grid functions to interact with the plots directly, as described in the note below.

## Value

`panel.identify` returns an integer vector containing the subscripts of the identified points (see details above). The equivalent of `identify` with `pos=TRUE` is not yet implemented, but can be considered for addition if requested.

`trellis.panelArgs` returns a named list of arguments that were available to the panel function for the chosen panel.

`trellis.vpname` and `trellis.grobname` return character strings.

`trellis.focus` has a meaningful return value only if it has been used to focus on a panel interactively, in which case the return value is a list with components `col` and `row` giving the column and row positions respectively of the chosen panel, unless the choice was cancelled (by a right click), in which case the return value is `NULL`. If click was outside a panel, both `col` and `row` are set to 0.

### Note

The viewports created by `lattice` are accessible to the user through `trellis.focus` as described above. Functions from the `grid` package can also be used directly. For example, `current.vpTree` can be used to inspect the current viewport tree and `seekViewport` or `downViewport` can be used to navigate to these viewports. For such usage, `trellis.vpname` and `trellis.grobname` provides a portable way to access the appropriate viewports and grobs by name.

### Author(s)

Deepayan Sarkar <Deepayan.Sarkar@R-project.org>. Felix Andrews provided initial implementations of `panel.identify.qqmath` and support for focusing on panels interactively.

### Examples

```
## Not run:
xyplot(1:10 ~ 1:10)
trellis.focus("panel", 1, 1)
panel.identify()

## End(Not run)

xyplot(Petal.Length ~ Sepal.Length | Species, iris, layout = c(2, 2))
Sys.sleep(1)

trellis.focus("panel", 1, 1)
do.call("panel.lmline", trellis.panelArgs())
Sys.sleep(0.5)
trellis.unfocus()

trellis.focus("panel", 2, 1)
do.call("panel.lmline", trellis.panelArgs())
Sys.sleep(0.5)
trellis.unfocus()

trellis.focus("panel", 1, 2)
do.call("panel.lmline", trellis.panelArgs())
Sys.sleep(0.5)
trellis.unfocus()

## choosing loess smoothing parameter

p <- xyplot(dist ~ speed, cars)
```

```

panel.loessresid <-
  function(x = panel.args$x,
           y = panel.args$y,
           span,
           panel.args = trellis.panelArgs())
{
  fm <- loess(y ~ x, span = span)
  xgrid <- do.breaks(current.panel.limits()$xlim, 50)
  ygrid <- predict(fm, newdata = data.frame(x = xgrid))
  panel.lines(xgrid, ygrid)
  pred <- predict(fm)
  ## center residuals so that they fall inside panel
  resids <- y - pred + mean(y)
  fm.resid <- loess.smooth(x, resids, span = span)
  ##panel.points(x, resids, col = 1, pch = 4)
  panel.lines(fm.resid, col = 1)
}

spans <- c(0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8)
update(p, index.cond = list(rep(1, length(spans))))
panel.locs <- trellis.currentLayout()

i <- 1

for (row in 1:nrow(panel.locs))
  for (column in 1:ncol(panel.locs))
    if (panel.locs[row, column] > 0)
    {
      trellis.focus("panel", row = row, column = column,
                    highlight = FALSE)
      panel.loessresid(span = spans[i])
      grid::grid.text(paste("span = ", spans[i]),
                      x = 0.25,
                      y = 0.75,
                      default.units = "npc")
      trellis.unfocus()
      i <- i + 1
    }
}

F\_1\_panel.barchart *Default Panel Function for barchart*

---

## Description

Default panel function for barchart.

## Usage

```

panel.barchart(x, y, box.ratio = 1, box.width,
               horizontal = TRUE,

```

```

origin = NULL, reference = TRUE,
stack = FALSE,
groups = NULL,
col = if (is.null(groups)) plot.polygon$col
      else superpose.polygon$col,
border = if (is.null(groups)) plot.polygon$border
      else superpose.polygon$border,
lty = if (is.null(groups)) plot.polygon$lty
      else superpose.polygon$lty,
lwd = if (is.null(groups)) plot.polygon$lwd
      else superpose.polygon$lwd,
..., identifier = "barchart")

```

### Arguments

|                                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>                     | Extent of Bars. By default, bars start at left of panel, unless <code>origin</code> is specified, in which case they start there.                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>y</code>                     | Horizontal location of bars. Possibly a factor.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>box.ratio</code>             | Ratio of bar width to inter-bar space.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>box.width</code>             | Thickness of bars in absolute units; overrides <code>box.ratio</code> . Useful for specifying thickness when the categorical variable is not a factor, as use of <code>box.ratio</code> alone cannot achieve a thickness greater than 1.                                                                                                                                                                                                                                                                                                                    |
| <code>horizontal</code>            | Logical flag. If <code>FALSE</code> , the plot is ‘transposed’ in the sense that the behaviours of <code>x</code> and <code>y</code> are switched. <code>x</code> is now the ‘factor’. Interpretation of other arguments change accordingly. See documentation of <a href="#">bwplot</a> for a fuller explanation.                                                                                                                                                                                                                                          |
| <code>origin</code>                | The origin for the bars. For grouped displays with <code>stack = TRUE</code> , this argument is ignored and the origin set to 0. Otherwise, defaults to <code>NULL</code> , in which case bars start at the left (or bottom) end of a panel. This choice is somewhat unfortunate, as it can be misleading, but is the default for historical reasons. For tabular (or similar) data, <code>origin = 0</code> is usually more appropriate; if not, one should reconsider the use of a bar chart in the first place (dot plots are often a good alternative). |
| <code>reference</code>             | Logical, whether a reference line is to be drawn at the origin.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>stack</code>                 | logical, relevant when <code>groups</code> is non-null. If <code>FALSE</code> (the default), bars for different values of the grouping variable are drawn side by side, otherwise they are stacked.                                                                                                                                                                                                                                                                                                                                                         |
| <code>groups</code>                | Optional grouping variable.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <code>col, border, lty, lwd</code> | Graphical parameters for the bars. By default, the trellis parameter <code>plot.polygon</code> is used if there is no grouping variable, otherwise <code>superpose.polygon</code> is used. <code>col</code> gives the fill color, <code>border</code> the border color, and <code>lty</code> and <code>lwd</code> the line type and width of the borders.                                                                                                                                                                                                   |
| <code>...</code>                   | Extra arguments will be accepted but ignored.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>identifier</code>            | A character string that is prepended to the names of grobs that are created by this panel function.                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

### Details

A barchart is drawn in the panel. Note that most arguments controlling the display can be supplied to the high-level `barchart` call directly.

**Examples**

```
barchart(yield ~ variety | site, data = barley,
         groups = year, layout = c(1,6), origin = 0,
         ylab = "Barley Yield (bushels/acre)",
         scales = list(x = list(abbreviate = TRUE,
                                minlength = 5)))
```

---

F\_1\_panel.bwplot      *Default Panel Function for bwplot*

---

**Description**

This is the default panel function for bwplot.

**Usage**

```
panel.bwplot(x, y, box.ratio = 1,
             box.width = box.ratio / (1 + box.ratio),
             horizontal = TRUE,
             pch, col, alpha, cex,
             font, fontfamily, fontface,
             fill, varwidth = FALSE,
             notch = FALSE, notch.frac = 0.5,
             ...,
             levels.fos,
             stats = boxplot.stats,
             coef = 1.5,
             do.out = TRUE,
             identifier = "bwplot")
```

**Arguments**

|                         |                                                                                                                                                                                                                                                                                                               |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x, y</code>       | numeric vector or factor. Boxplots drawn for each unique value of <code>y</code> ( <code>x</code> ) if <code>horizontal</code> is <code>TRUE</code> ( <code>FALSE</code> )                                                                                                                                    |
| <code>box.ratio</code>  | ratio of box thickness to inter box space                                                                                                                                                                                                                                                                     |
| <code>box.width</code>  | thickness of box in absolute units; overrides <code>box.ratio</code> . Useful for specifying thickness when the categorical variable is not a factor, as use of <code>box.ratio</code> alone cannot achieve a thickness greater than 1.                                                                       |
| <code>horizontal</code> | logical. If <code>FALSE</code> , the plot is ‘transposed’ in the sense that the behaviours of <code>x</code> and <code>y</code> are switched. <code>x</code> is now the ‘factor’. Interpretation of other arguments change accordingly. See documentation of <a href="#">bwplot</a> for a fuller explanation. |

|                                                               |                                                                                                                                                                                                                                                                                                                                                                                          |
|---------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>pch, col, alpha, cex, font, fontfamily, fontface</code> | graphical parameters controlling the dot. <code>pch=" "</code> is treated specially, by replacing the dot with a line (similar to <code>boxplot</code> )                                                                                                                                                                                                                                 |
| <code>fill</code>                                             | color to fill the boxplot                                                                                                                                                                                                                                                                                                                                                                |
| <code>varwidth</code>                                         | logical. If TRUE, widths of boxplots are proportional to the number of points used in creating it.                                                                                                                                                                                                                                                                                       |
| <code>notch</code>                                            | if <code>notch</code> is TRUE, a notch is drawn in each side of the boxes. If the notches of two plots do not overlap this is 'strong evidence' that the two medians differ (Chambers et al., 1983, p. 62). See <code>boxplot.stats</code> for the calculations used.                                                                                                                    |
| <code>notch.frac</code>                                       | numeric in (0,1). When <code>notch=TRUE</code> , the fraction of the box width that the notches should use.                                                                                                                                                                                                                                                                              |
| <code>stats</code>                                            | a function, defaulting to <code>boxplot.stats</code> , that accepts a numeric vector and returns a list similar to the return value of <code>boxplot.stats</code> . The function must accept arguments <code>coef</code> and <code>do.out</code> even if they do not use them (a <code>...</code> argument is good enough). This function is used to determine the box and whisker plot. |
| <code>coef, do.out</code>                                     | passed to <code>stats</code>                                                                                                                                                                                                                                                                                                                                                             |
| <code>levels.fos</code>                                       | numeric values corresponding to positions of the factor or shingle variable. For internal use.                                                                                                                                                                                                                                                                                           |
| <code>...</code>                                              | further arguments, ignored.                                                                                                                                                                                                                                                                                                                                                              |
| <code>identifier</code>                                       | A character string that is prepended to the names of grobs that are created by this panel function.                                                                                                                                                                                                                                                                                      |

### Details

Creates Box and Whisker plot of `x` for every level of `y` (or the other way round if `horizontal=FALSE`). By default, the actual boxplot statistics are calculated using `boxplot.stats`. Note that most arguments controlling the display can be supplied to the high-level `bwplot` call directly.

Although the graphical parameters for the dot representing the median can be controlled by optional arguments, many others can not. These parameters are obtained from the relevant settings parameters ("`box.rectangle`" for the box, "`box.umbrella`" for the whiskers and "`plot.symbol`" for the outliers).

### Examples

```
bwplot(voice.part ~ height, data = singer,
       xlab = "Height (inches)",
       panel = function(...) {
         panel.grid(v = -1, h = 0)
         panel.bwplot(...)
       },
```

```

par.settings = list(plot.symbol = list(pch = 4))

bwplot(voice.part ~ height, data = singer,
       xlab = "Height (inches)",
       notch = TRUE, pch = "|")

```

F\_1\_panel.cloud

*Default Panel Function for cloud*

## Description

These are default panel functions controlling cloud and wireframe displays.

## Usage

```

panel.cloud(x, y, subscripts, z,
            groups = NULL,
            perspective = TRUE,
            distance = if (perspective) 0.2 else 0,
            xlim, ylim, zlim,
            panel.3d.cloud = "panel.3dscatter",
            panel.3d.wireframe = "panel.3dwire",
            screen = list(z = 40, x = -60),
            R.mat = diag(4), aspect = c(1, 1),
            par.box = NULL,
            xlab, ylab, zlab,
            xlab.default, ylab.default, zlab.default,
            scales.3d,
            proportion = 0.6,
            wireframe = FALSE,
            scpos,
            ...,
            at,
            identifier = "cloud")
panel.wireframe(...)
panel.3dscatter(x, y, z, rot.mat, distance,
               groups, type = "p",
               xlim, ylim, zlim,
               xlim.scaled, ylim.scaled, zlim.scaled,

### Arguments

|                          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|--------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x, y, z</code>     | <p>numeric (or possibly factors) vectors representing the data to be displayed. The interpretation depends on the context. For <code>panel.cloud</code> these are essentially the same as the data passed to the high level plot (except if <code>formula</code> was a matrix, the appropriate <code>x</code> and <code>y</code> vectors are generated). By the time they are passed to <code>panel.3dscatter</code> and <code>panel.3dwire</code>, they have been appropriately subsetting (using <code>subscripts</code>) and scaled (to lie inside a bounding box, usually the <code>[-0.5, 0.5]</code> cube).</p> <p>Further, for <code>panel.3dwire</code>, <code>x</code> and <code>y</code> are shorter than <code>z</code> and represent the sorted locations defining a rectangular grid. Also in this case, <code>z</code> may be a matrix if the display is grouped, with each column representing one surface.</p> <p>In <code>panel.cloud</code> (called from <code>wireframe</code>) and <code>panel.3dwire</code>, <code>x</code>, <code>y</code> and <code>z</code> could also be matrices (of the same dimension) when they represent a 3-D surface parametrized on a 2-D grid.</p> |
| <code>subscripts</code>  | index specifying which points to draw. The same <code>x</code> , <code>y</code> and <code>z</code> values (representing the whole data) are passed to <code>panel.cloud</code> for each panel. <code>subscripts</code> specifies the subset of rows to be used for the particular panel.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>groups</code>      | specification of a grouping variable, passed down from the high level functions.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>perspective</code> | logical, whether to plot a perspective view. Setting this to <code>FALSE</code> is equivalent to setting <code>distance</code> to 0                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <code>distance</code>    | numeric, between 0 and 1, controls amount of perspective. The distance of the viewing point from the origin (in the transformed coordinate system) is <code>1 / distance</code> . This is described in a little more detail in the documentation for <a href="#">cloud</a>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>screen</code>      | A list determining the sequence of rotations to be applied to the data before being plotted. The initial position starts with the viewing point along the positive <code>z</code> -axis, and the <code>x</code> and <code>y</code> axes in the usual position. Each component of the list should be named one of " <code>x</code> ", " <code>y</code> " or " <code>z</code> " (repetitions are allowed), with their values indicating the amount of rotation about that axis in degrees.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>R.mat</code>       | initial rotation matrix in homogeneous coordinates, to be applied to the data before <code>screen</code> rotates the view further.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>par.box</code>     | graphical parameters for box, namely, <code>col</code> , <code>lty</code> and <code>lwd</code> . By default obtained from the parameter <code>box.3d</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

|                                                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| <code>xlim, ylim, zlim</code>                      | limits for the respective axes. As with other lattice functions, these could each be a numeric 2-vector or a character vector indicating levels of a factor.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>panel.3d.cloud, panel.3d.wireframe</code>    | functions that draw the data-driven part of the plot (as opposed to the bounding box and scales) in <code>cloud</code> and <code>wireframe</code> . This function is called after the 'back' of the bounding box is drawn, but before the 'front' is drawn.<br>Any user-defined custom display would probably want to change these functions. The intention is to pass as much information to this function as might be useful (not all of which are used by the defaults). In particular, these functions can expect arguments called <code>xlim</code> , <code>ylim</code> , <code>zlim</code> which give the bounding box ranges in the original data scale and <code>xlim.scaled</code> , <code>ylim.scaled</code> , <code>zlim.scaled</code> which give the bounding box ranges in the transformed scale. More arguments can be considered on request. |

| <code>scpos</code>                                 | A list with three components x, y and z (each a scalar integer), describing which of the 12 sides of the cube the scales should be drawn. The defaults should be OK. Valid values are x: 1, 3, 9, 11; y: 8, 5, 7, 6 and z: 4, 2, 10, 12. (See comments in the source code of <code>panel.cloud</code> to see the details of this enumeration.)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <code>wireframe</code>                             | logical, indicating whether this is a wireframe plot                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <code>drape</code>                                 | logical, whether the facets will be colored by height, in a manner similar to <code>levelplot</code> . This is ignored if <code>shade=TRUE</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>at, col.regions, alpha.regions</code>        | deals with specification of colors when <code>drape=TRUE</code> in <code>wireframe</code> . <code>at</code> can be a numeric vector, <code>col.regions</code> a vector of colors, and <code>alpha.regions</code> a numeric scalar controlling transparency. The resulting behaviour is similar to <code>levelplot</code> , <code>at</code> giving the breakpoints along the z-axis where colors change, and the other two determining the colors of the facets that fall in between.                                                                                                                                                                                                                                                                                                                                                                        |
| <code>rot.mat</code>                               | 4x4 transformation matrix in homogeneous coordinates. This gives the rotation matrix combining the screen and <code>R.mat</code> arguments to <code>panel.cloud</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>type</code>                                  | Character vector, specifying type of cloud plot. Can include one or more of "p", "l", "h" or "b". "p" and "l" mean 'points' and 'lines' respectively, and "b" means 'both'. "h" stands for 'histogram', and causes a line to be drawn from each point to the X-Y plane (i.e., the plane representing $z = 0$ ), or the lower (or upper) bounding box face, whichever is closer.                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>xlim.scaled, ylim.scaled, zlim.scaled</code> | axis limits (after being scaled to the bounding box)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

|                                                                  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>zero.scaled</code>                                         | z-axis location (after being scaled to the bounding box) of the X-Y plane in the original data scale, to which lines will be dropped (if within range) from each point when <code>type = "h"</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <code>cross</code>                                               | <p>logical, defaults to TRUE if <code>pch = "+"</code>. <code>panel.3dscatter</code> can represent each point by a 3d 'cross' of sorts (it's much easier to understand looking at an example than from a description). This is different from the usual <code>pch</code> argument, and reflects the depth of the points and the orientation of the axes. This argument indicates whether this feature will be used.</p> <p>This is useful for two reasons. It can be set to FALSE to use "+" as the plotting character in the regular sense. It can also be used to force this feature in grouped displays.</p>                                                                                                                                      |
| <code>shade</code>                                               | logical, indicating whether the surface is to be colored using an illumination model with a single light source                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>shade.colors.palette</code>                                | <p>a function (or the name of one) that is supposed to calculate the color of a facet when shading is being used. Three pieces of information are available to the function: first, the cosine of the angle between the incident light ray and the normal to the surface (representing foreshortening); second, the cosine of half the angle between the reflected ray and the viewing direction (useful for non-Lambertian surfaces); and third, the scaled (average) height of that particular facet with respect to the total plot z-axis limits.</p> <p>All three numbers should be between 0 and 1. The <code>shade.colors.palette</code> function should return a valid color. The default function is obtained from the trellis settings.</p> |
| <code>light.source</code>                                        | a 3-vector representing (in cartesian coordinates) the light source. This is relative to the viewing point being (0, 0, 1/distance) (along the positive z-axis), keeping in mind that all observations are bounded within the [-0.5, 0.5] cube                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <code>polynum</code>                                             | quadrilateral faces are drawn in batches of <code>polynum</code> at a time. Drawing too few at a time increases the total number of calls to the underlying <code>grid.polygon</code> function, which affects speed. Trying to draw too many at once may be unnecessarily memory intensive. This argument controls the trade-off.                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>col.groups</code>                                          | colors for different groups                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <code>col, col.point, col.line, lty, lwd, cex, pch, alpha</code> | Graphical parameters. Some other arguments (such as <code>lex</code> for line width) may also be passed through the <code>...</code> argument.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <code>...</code>                                                 | other parameters, passed down when appropriate                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <code>.scale</code>                                              | Logical flag, indicating whether x, y, and z should be assumed to be in the original data scale and hence scaled before being plotted. x, y, and z are usually already scaled. However, setting <code>.scale=TRUE</code> may be helpful for calls to <code>panel.3dscatter</code> and <code>panel.3dwire</code> in user-supplied panel functions.                                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>identifier</code>                                          | A character string that is prepended to the names of grobs that are created by this panel function.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

## Details

These functions together are responsible for the content drawn inside each panel in `cloud` and `wireframe`. `panel.wireframe` is a wrapper to `panel.cloud`, which does the actual work. `panel.cloud` is responsible for drawing the content that does not depend on the data, namely, the bounding box, the arrows/scales, etc. At some point, depending on whether `wireframe` is TRUE,

it calls either `panel.3d.wireframe` or `panel.3d.cloud`, which draws the data-driven part of the plot.

The arguments accepted by these two functions are different, since they have essentially different purposes. For `cloud`, the data is unstructured, and `x`, `y` and `z` are all passed to the `panel.3d.cloud` function. For `wireframe`, on the other hand, `x` and `y` are increasing vectors with unique values, defining a rectangular grid. `z` must be a matrix with `length(x) * length(y)` rows, and as many columns as the number of groups.

`panel.3dscatter` is the default `panel.3d.cloud` function. It has a `type` argument similar to `panel.xyplot`, and supports grouped displays. It tries to honour depth ordering, i.e., points and lines closer to the camera are drawn later, overplotting more distant ones. (Of course there is no absolute ordering for line segments, so an ad hoc ordering is used. There is no hidden point removal.)

`panel.3dwire` is the default `panel.3d.wireframe` function. It calculates polygons corresponding to the facets one by one, but waits till it has collected information about `polynum` facets, and draws them all at once. This avoids the overhead of drawing `grid.polygon` repeatedly, speeding up the rendering considerably. If `shade = TRUE`, these attempt to color the surface as being illuminated from a light source at `light.source`. `palette.shade` is a simple function that provides the default shading colors

Multiple surfaces are drawn if `groups` is non-null in the call to `wireframe`, however, the algorithm is not sophisticated enough to render intersecting surfaces correctly.

F\_1\_panel.densityplot

*Default Panel Function for densityplot*

---

### Description

This is the default panel function for `densityplot`.

### Usage

```
panel.densityplot(x, darg, plot.points = "jitter", ref = FALSE,
                  groups = NULL, weights = NULL,
                  jitter.amount, type, ...,
                  identifier = "density")
```

### Arguments

|                   |                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>    | data points for which density is to be estimated                                                                                                                                                                                                                                                                                                                                                                                |
| <code>darg</code> | list of arguments to be passed to the <code>density</code> function. Typically, this should be a list with zero or more of the following components : <code>bw</code> , <code>adjust</code> , <code>kernel</code> , <code>window</code> , <code>width</code> , <code>give.Rkern</code> , <code>n</code> , <code>from</code> , <code>to</code> , <code>cut</code> , <code>na.rm</code> (see <a href="#">density</a> for details) |

|                            |                                                                                                                                                                                                                                                                                                                                                                                          |
|----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>plot.points</code>   | logical specifying whether or not the data points should be plotted along with the estimated density. Alternatively, a character string specifying how the points should be plotted. Meaningful values are "rug", in which case <code>panel.rug</code> is used to plot a 'rug', and "jitter", in which case the points are jittered vertically to better distinguish overlapping points. |
| <code>ref</code>           | logical, whether to draw x-axis                                                                                                                                                                                                                                                                                                                                                          |
| <code>groups</code>        | an optional grouping variable. If present, <code>panel.superpose</code> will be used instead to display each subgroup                                                                                                                                                                                                                                                                    |
| <code>weights</code>       | numeric vector of weights for the density calculations. If this is specified, the <code>...</code> part must also include a <code>subscripts</code> argument that matches the weights to <code>x</code> .                                                                                                                                                                                |
| <code>jitter.amount</code> | when <code>plot.points="jitter"</code> , the value to use as the <code>amount</code> argument to <code>jitter</code> .                                                                                                                                                                                                                                                                   |
| <code>type</code>          | type argument used to plot points, if requested. This is not expected to be useful, it is available mostly to protect a <code>type</code> argument, if specified, from affecting the density curve.                                                                                                                                                                                      |
| <code>...</code>           | extra graphical parameters. Note that additional arguments to <code>panel.rug</code> cannot be passed on through <code>panel.densityplot</code> .                                                                                                                                                                                                                                        |
| <code>identifier</code>    | A character string that is prepended to the names of grobs that are created by this panel function.                                                                                                                                                                                                                                                                                      |

F\_1\_panel.dotplot    *Default Panel Function for dotplot*

---

**Description**

Default panel function for `dotplot`.

**Usage**

```
panel.dotplot(x, y, horizontal = TRUE,
              pch, col, lty, lwd,
              col.line, levels.fos,
              groups = NULL,
              ...,
              identifier = "dotplot")
```

**Arguments**

|                                           |                                                                                                                                                                                                                                                                                                               |
|-------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x, y</code>                         | variables to be plotted in the panel. Typically <code>y</code> is the ‘factor’                                                                                                                                                                                                                                |
| <code>horizontal</code>                   | logical. If <code>FALSE</code> , the plot is ‘transposed’ in the sense that the behaviours of <code>x</code> and <code>y</code> are switched. <code>x</code> is now the ‘factor’. Interpretation of other arguments change accordingly. See documentation of <a href="#">bwplot</a> for a fuller explanation. |
| <code>pch, col, lty, lwd, col.line</code> | graphical parameters                                                                                                                                                                                                                                                                                          |
| <code>levels.fos</code>                   | locations where reference lines will be drawn                                                                                                                                                                                                                                                                 |
| <code>groups</code>                       | grouping variable (affects graphical parameters)                                                                                                                                                                                                                                                              |
| <code>...</code>                          | extra parameters, passed to <code>panel.xyplot</code> which is responsible for drawing the foreground points ( <code>panel.dotplot</code> only draws the background reference lines).                                                                                                                         |
| <code>identifier</code>                   | A character string that is prepended to the names of grobs that are created by this panel function.                                                                                                                                                                                                           |

**Details**

Creates (possibly grouped) Dotplot of `x` against `y` or vice versa

F\_1\_panel.histogram

*Default Panel Function for histogram*

---

**Description**

This is the default panel function for histogram.

**Usage**

```
panel.histogram(x,
                breaks,
                equal.widths = TRUE,
                type = "density",
                nint = round(log2(length(x)) + 1),
                alpha, col, border, lty, lwd,
                ...,
                identifier = "histogram")
```

**Arguments**

|                                           |                                                                                                     |
|-------------------------------------------|-----------------------------------------------------------------------------------------------------|
| <code>x</code>                            | The data points for which the histogram is to be drawn                                              |
| <code>breaks</code>                       | The breakpoints for the histogram                                                                   |
| <code>equal.widths</code>                 | logical used when <code>breaks==NULL</code>                                                         |
| <code>type</code>                         | Type of histogram, possible values being "percent", "density" and "count"                           |
| <code>nint</code>                         | Number of bins for the histogram                                                                    |
| <code>alpha, col, border, lty, lwd</code> | graphical parameters for bars; defaults are obtained from the <code>plot.polygon</code> settings.   |
| <code>...</code>                          | other arguments, passed to <code>hist</code> when deemed appropriate                                |
| <code>identifier</code>                   | A character string that is prepended to the names of grobs that are created by this panel function. |

F\_1\_panel.levelplot

*Panel Functions for levelplot and contourplot*

---

**Description**

These are the default panel functions for `levelplot` and `contourplot`. Also documented is an alternative raster-based panel function for use with `levelplot`.

**Usage**

```
panel.levelplot(x, y, z,
               subscripts,
               at = pretty(z),
               shrink,
               labels,
               label.style = c("mixed", "flat", "align"),
               contour = FALSE,
               region = TRUE,
               col = add.line$col,
               lty = add.line$lty,
               lwd = add.line$lwd,
               border = "transparent",
               border.lty = 1,
               border.lwd = 0.1,
               ...,
               col.regions = regions$col,
```

```

        alpha.regions = regions$alpha,
        identifier = "levelplot")
panel.contourplot(...)

panel.levelplot.raster(x, y, z,
                      subscripts,
                      at = pretty(z),
                      ...,
                      col.regions = regions$col,
                      alpha.regions = regions$alpha,
                      interpolate = FALSE,
                      identifier = "levelplot")

```

### Arguments

|                                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x, y, z</code>                | Variables defining the plot.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>subscripts</code>             | Integer vector indicating what subset of <code>x</code> , <code>y</code> and <code>z</code> to draw.                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <code>at</code>                     | Numeric vector giving breakpoints along the range of <code>z</code> . See <a href="#">levelplot</a> for details.                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <code>shrink</code>                 | Either a numeric vector of length 2 (meant to work as both <code>x</code> and <code>y</code> components), or a list with components <code>x</code> and <code>y</code> which are numeric vectors of length 2. This allows the rectangles to be scaled proportional to the <code>z</code> -value. The specification can be made separately for widths ( <code>x</code> ) and heights ( <code>y</code> ). The elements of the length 2 numeric vector gives the minimum and maximum proportion of shrinkage (corresponding to min and max of <code>z</code> ). |
| <code>labels</code>                 | Either a logical scalar indicating whether the labels are to be drawn, or a character or expression vector giving the labels associated with the <code>at</code> values. Alternatively, <code>labels</code> can be a list with the following components:<br><br><code>labels</code> : a character or expression vector giving the labels. This can be omitted, in which case the defaults will be used.<br><code>col, cex, alpha</code> : graphical parameters for label texts<br><code>fontfamily, fontface, font</code> : font used for the labels        |
| <code>label.style</code>            | Controls how label positions and rotation are determined. A value of <code>"flat"</code> causes the label to be positioned where the contour is flattest, and the label is not rotated. A value of <code>"align"</code> causes the label to be drawn as far from the boundaries as possible, and the label is rotated to align with the contour at that point. The default is to mix these approaches, preferring the flattest location unless it is too close to the boundaries.                                                                           |
| <code>contour</code>                | A logical flag, specifying whether contour lines should be drawn.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>region</code>                 | A logical flag, specifying whether inter-contour regions should be filled with appropriately colored rectangles.                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <code>col, lty, lwd</code>          | Graphical parameters for contour lines.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>border</code>                 | Border color for rectangles used when <code>region=TRUE</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
