indMatrix-class

---

*Index Matrices*

---

### Description

The "indMatrix" class is the class of index matrices, stored as 1-based integer index vectors. An index matrix is a matrix with exactly one non-zero entry per row. Index matrices are useful for mapping observations to unique covariate values, for example.

Matrix (vector) multiplication with index matrices is equivalent to replicating and permuting rows, or "sampling rows with replacement", and is implemented that way in the **Matrix** package, see the 'Details' below.

## Details

Matrix (vector) multiplication with index matrices from the left is equivalent to replicating and permuting rows of the matrix on the right hand side. (Similarly, matrix multiplication with the transpose of an index matrix from the right corresponds to selecting *columns*.) The crossproduct of an index matrix  $M$  with itself is a diagonal matrix with the number of entries in each column of  $M$  on the diagonal, i.e.,  $M'M = \text{Diagonal}(x = \text{table}(M@perm))$ .

Permutation matrices (of class `pMatrix`) are special cases of index matrices: They are square, of dimension, say,  $n \times n$ , and their index vectors contain exactly all of  $1:n$ .

While “row-indexing” (of more than one row *or* using `drop=FALSE`) stays within the “indMatrix” class, all other subsetting/indexing operations (“column-indexing”, including, `diag`) on “indMatrix” objects treats them as nonzero-pattern matrices (“ngTMatrix” specifically), such that non-matrix subsetting results in `logical` vectors. Sub-assignment (`M[i, j] <- v`) is not sensible and hence an error for these matrices.

## Objects from the Class

Objects can be created by calls of the form `new("indMatrix", ...)` or by coercion from an integer index vector, see below.

## Slots

**perm:** An integer, 1-based index vector, i.e. an integer vector of length `Dim[1]` whose elements are taken from `1:Dim[2]`.

**Dim:** `integer` vector of length two. In some applications, the matrix will be skinny, i.e., with at least as many rows as columns.

**Dimnames:** a `list` of length two where each component is either `NULL` or a `character` vector of length equal to the corresponding `Dim` element.

## Extends

Class “`sparseMatrix`” and “`generalMatrix`”, directly.

## Methods

`%*%` signature (`x = "matrix", y = "indMatrix"`) and other signatures (use `showMethods("%*%", class = "indMatrix")`): ...

**coerce** signature (`from = "integer", to = "indMatrix"`): This enables typical “indMatrix” construction, given an index vector from elements in `1:Dim[2]`, see the first example.

**coerce** signature (`from = "numeric", to = "indMatrix"`): a user convenience, to allow `as(perm, "indMatrix")` for numeric `perm` with integer values.

**coerce** signature (`from = "list", to = "indMatrix"`): The list must have two (integer-valued) entries: the first giving the index vector with elements in `1:Dim[2]`, the second giving `Dim[2]`. This allows “indMatrix” construction for cases in which the values represented by the rightmost column(s) are not associated with any observations, i.e., in which the index does not contain values `Dim[2], Dim[2]-1, Dim[2]-2, ...`

**coerce** signature (`from = "indMatrix", to = "matrix"`): coercion to a traditional FALSE/TRUE `matrix` of mode `logical`.

**coerce** signature (`from = "indMatrix", to = "ngTMatrix"`): coercion to sparse logical matrix of class `ngTMatrix`.

**t** signature(x = "indMatrix"): return the transpose of the index matrix (which is no longer an indMatrix, but of class [ngTMatrix](#)).

**colSums, colMeans, rowSums, rowMeans** signature(x = "indMatrix"): return the column or row sums or means.

**rbind2** signature(x = "indMatrix", y = "indMatrix"): a fast method for rowwise catenation of two index matrices (with the same number of columns).

**kronecker** signature(X = "indMatrix", Y = "indMatrix"): return the kronecker product of two index matrices, which corresponds to the index matrix of the interaction of the two.

### Author(s)

Fabian Scheipl, Uni Muenchen, building on existing ["pMatrix"](#), after a nice hike's conversation with Martin Maechler; diverse tweaks by the latter. The [crossprod\(x, y\)](#) and [kronecker\(x, y\)](#) methods when both arguments are ["indMatrix"](#) have been made considerably faster thanks to a suggestion by Boris Vaillant.

### See Also

The permutation matrices [pMatrix](#) are special index matrices. The “pattern” matrices, [nMatrix](#) and its subclasses.

### Examples

```
p1 <- as(c(2,3,1), "pMatrix")
(sm1 <- as(rep(c(2,3,1), e=3), "indMatrix"))
stopifnot(all(sm1 == p1[rep(1:3, each=3),]))

row-indexing of a <pMatrix> turns it into an <indMatrix>:
class(p1[rep(1:3, each=3),])

set.seed(12) # so we know '10' is in sample
random index matrix for 30 observations and 10 unique values:
(s10 <- as(sample(10, 30, replace=TRUE), "indMatrix"))

Sample rows of a numeric matrix :
(mm <- matrix(1:10, nrow=10, ncol=3))
s10 %*% mm

set.seed(27)
IM1 <- as(sample(1:20, 100, replace=TRUE), "indMatrix")
IM2 <- as(sample(1:18, 100, replace=TRUE), "indMatrix")
(c12 <- crossprod(IM1, IM2))
same as cross-tabulation of the two index vectors:
stopifnot(all(c12 - unclass(table(IM1@perm, IM2@perm)) == 0))

3 observations, 4 implied values, first does not occur in sample:
as(2:4, "indMatrix")
3 observations, 5 values, first and last do not occur in sample:
as(list(2:4, 5), "indMatrix")

as(sm1, "ngTMatrix")
s10[1:7, 1:4] # gives an "ngTMatrix" (most economic!)
s10[1:4,] # preserves "indMatrix"-class
```

```
I1 <- as(c(5:1,6:4,7:3), "indMatrix")
I2 <- as(7:1, "pMatrix")
(I12 <- suppressWarnings(rBind(I1, I2)))
stopifnot(is(I12, "indMatrix"),
 if(getRversion() >= "3.2.0") identical(I12, rbind(I1, I2)) else TRUE,
 colSums(I12) == c(2L,2:4,4:2))
```

invPerm

*Inverse Permutation Vector*

## Description

From a permutation vector *p*, compute its *inverse* permutation vector.

## Usage

```
invPerm(p, zero.p = FALSE, zero.res = FALSE)
```

## Arguments

|                 |                                                                                                                                       |
|-----------------|---------------------------------------------------------------------------------------------------------------------------------------|
| <i>p</i>        | an integer vector of length, say, <i>n</i> .                                                                                          |
| <i>zero.p</i>   | logical indicating if <i>p</i> contains values 0:( <i>n</i> -1) or rather (by default, <i>zero.p</i> = FALSE) 1: <i>n</i> .           |
| <i>zero.res</i> | logical indicating if the result should contain values 0:( <i>n</i> -1) or rather (by default, <i>zero.res</i> = FALSE) 1: <i>n</i> . |

## Value

an integer vector of the same length (*n*) as *p*. By default, (*zero.p* = FALSE, *zero.res* = FALSE), `invPerm(p)` is the same as `order(p)` or `sort.list(p)` and for that case, the function is equivalent to `invPerm. <-function(p) { p[p] <-seq_along(p) ; p }`.

## Author(s)

Martin Maechler

## See Also

the class of permutation matrices, `pMatrix`.

## Examples

```
p <- sample(10) # a random permutation vector
ip <- invPerm(p)
p[ip] # == 1:10
they are indeed inverse of each other:
stopifnot(
 identical(p[ip], 1:10),
 identical(ip[p], 1:10),
 identical(invPerm(ip), p)
)
```

is.na-methods

*is.na(), is.infinite() Methods for 'Matrix' Objects***Description**

Methods for function `is.na()`, `is.finite()`, and `is.infinite()` for all Matrices (objects extending the `Matrix` class):

`x = "denseMatrix"` returns a `nMatrix` object of same dimension as `x`, with TRUE's whenever `x` is `NA`, finite, or infinite, respectively.

`x = "sparseMatrix"` ditto.

**Usage**

```
S4 method for signature 'sparseMatrix'
is.na(x)
S4 method for signature 'dsparseMatrix'
is.finite(x)
S4 method for signature 'ddenseMatrix'
is.infinite(x)
...
and for other classes

S4 method for signature 'xMatrix'
anyNA(x)
S4 method for signature 'nsparseMatrix'
anyNA(x)
S4 method for signature 'sparseVector'
anyNA(x)
S4 method for signature 'nsparseVector'
anyNA(x)
```

**Arguments**

`x` sparse or dense matrix or sparse vector (here; any R object in general).

**See Also**

`NA`, `is.na`; `is.finite`, `is.infinite`; `nMatrix`, `denseMatrix`, `sparseMatrix`.

The `sparseVector` class.

**Examples**

```
M <- Matrix(1:6, nrow=4, ncol=3,
 dimnames = list(c("a", "b", "c", "d"), c("A", "B", "C")))
stopifnot(all(!is.na(M)))
M[2:3,2] <- NA
is.na(M)
if(exists("anyNA", mode="function"))
 anyNA(M)

A <- spMatrix(10,20, i = c(1,3:8),
```

```
j = c(2,9,6:10),
x = 7 * (1:7))
stopifnot(all(!is.na(A)))

A[2,3] <- A[1,2] <- A[5, 5:9] <- NA
inA <- is.na(A)
stopifnot(sum(inA) == 1+1+5)
```

---

`is.null.DN`*Are the Dimnames dn NULL-like ?*

---

## Description

Are the `dimnames` `dn` `NULL`-like?

`is.null.DN(dn)` is less strict than `is.null(dn)`, because it is also true (`TRUE`) when the `dimnames dn` are “like” `NULL`, or `list(NULL, NULL)`, as they can easily be for the traditional R matrices (`matrix`) which have no formal `class` definition, and hence much freedom in how their `dimnames` look like.

## Usage

```
is.null.DN(dn)
```

## Arguments

`dn`                    `dimnames()` of a `matrix`-like R object.

## Value

logical `TRUE` or `FALSE`.

## Note

This function is really to be used on “traditional” matrices rather than those inheriting from `Matrix`, as the latter will always have `dimnames list(NULL, NULL)` exactly, in such a case.

## Author(s)

Martin Maechler

## See Also

`is.null`, `dimnames`, `matrix`.

**Examples**

```

m <- matrix(round(100 * rnorm(6)), 2,3); m1 <- m2 <- m3 <- m4 <- m
dimnames(m1) <- list(NULL, NULL)
dimnames(m2) <- list(NULL, character())
dimnames(m3) <- rev(dimnames(m2))
dimnames(m4) <- rep(list(character()),2)

m4 ## prints absolutely identically to m

stopifnot(m == m1, m1 == m2, m2 == m3, m3 == m4,
 identical(capture.output(m) -> cm,
 capture.output(m1)),
 identical(cm, capture.output(m2)),
 identical(cm, capture.output(m3)),
 identical(cm, capture.output(m4)))

```

---

isSymmetric-methods

*Methods for Function isSymmetric in Package 'Matrix'*

---

**Description**

isSymmetric(M) returns a **logical** indicating if M is a symmetric matrix. This (now) is a **base** function with a default method for the traditional matrices of **class** "matrix". Methods here are defined for virtual Matrix classes such that it works for all objects inheriting from class **Matrix**.

**See Also**

[forceSymmetric](#), [symmpart](#), and the formal class (and subclasses) "[symmetricMatrix](#)".

**Examples**

```

isSymmetric(Diagonal(4)) # TRUE of course
M <- Matrix(c(1,2,2,1), 2,2)
isSymmetric(M) # TRUE (*and* of formal class "dsyMatrix")
isSymmetric(as(M, "dgeMatrix")) # still symmetric, even if not "formally"
isSymmetric(triu(M)) # FALSE

Look at implementations:
showMethods("isSymmetric", includeDefs=TRUE) # "ANY": base's S3 generic; 6 more

```

---

isTriangular

*isTriangular() and isDiagonal() Methods*

---

**Description**

isTriangular(M) returns a **logical** indicating if M is a triangular matrix. Analogously, isDiagonal(M) is true iff M is a diagonal matrix.

Contrary to [isSymmetric\(\)](#), these two functions are generically from package **Matrix**, and hence also define methods for traditional (**class** "matrix") matrices.

By our definition, triangular, diagonal and symmetric matrices are all *square*, i.e. have the same number of rows and columns.

**Usage**

```
isDiagonal(object)

isTriangular(object, upper = NA, ...)
```

**Arguments**

|                     |                                                                                                                                     |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code> | any R object, typically a matrix (traditional or Matrix package).                                                                   |
| <code>upper</code>  | logical, one of NA (default), FALSE, or TRUE where the last two cases require a lower or upper triangular object to result in TRUE. |
| <code>...</code>    | potentially further arguments for other methods.                                                                                    |

**Value**

a (“scalar”) logical, TRUE or FALSE, never NA. For `isTriangular()`, if the result is TRUE, it may contain an attribute (see [attributes](#) "kind", either "L" or "U" indicating if it is a lower or upper triangular matrix.

**See Also**

`isSymmetric`; formal class (and subclasses) `"triangularMatrix"` and `"diagonalMatrix"`.

**Examples**

```
isTriangular(Diagonal(4))
is TRUE: a diagonal matrix is also (both upper and lower) triangular
(M <- Matrix(c(1,2,0,1), 2,2))
isTriangular(M) # TRUE (*and* of formal class "dtrMatrix")
isTriangular(as(M, "dgeMatrix")) # still triangular, even if not "formally"
isTriangular(crossprod(M)) # FALSE

isDiagonal(matrix(c(2,0,0,1), 2,2)) # TRUE
```

---

KhatriRao

*Khatri-Rao Matrix Product*

---

**Description**

Computes Khatri-Rao products for any kind of matrices.

The Khatri-Rao product is a column-wise Kronecker product. Originally introduced by Khatri and Rao (1968), it has many different applications, see Liu and Trenkler (2008) for a survey. Notably, it is used in higher-dimensional tensor decompositions, see Bader and Kolda (2008).

**Usage**

```
KhatriRao(X, Y = X, FUN = "*", make.dimnames = FALSE)
```

## Arguments

|                            |                                                                                                                                                                       |
|----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>X, Y</code>          | matrices of with the same number of columns.                                                                                                                          |
| <code>FUN</code>           | the (name of the) <a href="#">function</a> to be used for the column-wise Kronecker products, see <a href="#">kronecker</a> , defaulting to the usual multiplication. |
| <code>make.dimnames</code> | logical indicating if the result should inherit <a href="#">dimnames</a> from <code>X</code> and <code>Y</code> in a simple way.                                      |

## Value

a "[CsparseMatrix](#)", say `R`, the Khatri-Rao product of `X` ( $n \times k$ ) and `Y` ( $m \times k$ ), is of dimension  $(n \cdot m) \times k$ , where the  $j$ -th column, `R[, j]` is the kronecker product [kronecker](#)(`X[, j]`, `Y[, j]`).

## Note

The current implementation is efficient for large sparse matrices.

## Author(s)

Original by Michael Cysouw, Univ. Marburg; minor tweaks, bug fixes etc, by Martin Maechler.

dimnames(m) <- list(LETTERS[1:3], letters[1:4])
KhatriRao(m, d, make.dimnames=TRUE)
KhatriRao(d, m, make.dimnames=TRUE)
dimnames(d) <- list(NULL, paste0("D", 1:4))
KhatriRao(m, d, make.dimnames=TRUE)
KhatriRao(d, m, make.dimnames=TRUE)
dimnames(d) <- list(paste0("d", 10*1:4), paste0("D", 1:4))
(Kmd <- KhatriRao(m, d, make.dimnames=TRUE))
(Kdm <- KhatriRao(d, m, make.dimnames=TRUE))
```

```

nm <- as(m, "nMatrix")
nd <- as(d, "nMatrix")
KhatRao(nm, nd, make.dimnames=TRUE)
KhatRao(nd, nm, make.dimnames=TRUE)

stopifnot(dim(KhatRao(m, d)) == c(nrow(m)*nrow(d), ncol(d)))
border cases / checks:
zm <- nm; zm[] <- 0 # all 0 matrix
stopifnot(all(K1 <- KhatRao(nd, zm) == 0), identical(dim(K1), c(12L, 4L)),
 all(K2 <- KhatRao(zm, nd) == 0), identical(dim(K2), c(12L, 4L)))

d0 <- d; d0[] <- 0; m0 <- Matrix(d0[-1,])
stopifnot(all(K3 <- KhatRao(d0, m) == 0), identical(dim(K3), dim(Kdm)),
 all(K4 <- KhatRao(m, d0) == 0), identical(dim(K4), dim(Kmd)),
 all(KhatRao(d0, d0) == 0), all(KhatRao(m0, d0) == 0),
 all(KhatRao(d0, m0) == 0), all(KhatRao(m0, m0) == 0),
 identical(dimnames(KhatRao(m, d0, make.dimnames=TRUE)), dimnames(Kmd)))

```

KNex

*Koenker-Ng Example Sparse Model Matrix and Response Vector*

## Description

A model matrix `mm` and corresponding response vector `y` used in an example by Koenker and Ng. The matrix `mm` is a sparse matrix with 1850 rows and 712 columns but only 8758 non-zero entries. It is a "dgCMatrix" object. The vector `y` is just `numeric` of length 1850.

## Usage

```
data(KNex)
```

## References

Roger Koenker and Pin Ng (2003). SparseM: A sparse matrix package for R; *J. of Statistical Software*, **8** (6), doi: [10.18637/jss.v008.i06](https://doi.org/10.18637/jss.v008.i06)

## Examples

```

data(KNex)
class(KNex$mm)
dim(KNex$mm)
image(KNex$mm)
str(KNex)

system.time(# a fraction of a second
 sparse.sol <- with(KNex, solve(crossprod(mm), crossprod(mm, y))))

head(round(sparse.sol, 3))

Compare with QR-based solution ("more accurate, but slightly slower"):
system.time(
 sp.sol2 <- with(KNex, qr.coef(qr(mm), y)))

all.equal(sparse.sol, sp.sol2, tolerance = 1e-13) # TRUE

```

---

kronecker-methods    *Methods for Function 'kronecker()' in Package 'Matrix'*

---

## Description

Computes Kronecker products for objects inheriting from "[Matrix](#)".

In order to preserve sparseness, we treat  $0 * NA$  as 0, not as [NA](#) as usually in R (and as used for the base function [kronecker](#)).

## Methods

```
kronecker signature(X = "Matrix", Y = "ANY")
kronecker signature(X = "ANY", Y = "Matrix")
kronecker signature(X = "diagonalMatrix", Y = "ANY")
kronecker signature(X = "sparseMatrix", Y = "ANY")
kronecker signature(X = "TsparseMatrix", Y = "TsparseMatrix")
kronecker signature(X = "dgTMatrix", Y = "dgTMatrix")
kronecker signature(X = "dtTMatrix", Y = "dtTMatrix")
kronecker signature(X = "indMatrix", Y = "indMatrix")
```

## Examples

```
(t1 <- spMatrix(5,4, x= c(3,2,-7,11), i= 1:4, j=4:1)) # 5 x 4
(t2 <- kronecker(Diagonal(3, 2:4), t1)) # 15 x 12

should also work with special-cased logical matrices
l3 <- upper.tri(matrix(,3,3))
M <- Matrix(l3)
(N <- as(M, "nsparseMatrix")) # "ntCMatrix" (upper triangular)
N2 <- as(N, "generalMatrix") # (lost "triangularity")
MM <- kronecker(M,M)
NN <- kronecker(N,N) # "dtTMatrix" i.e. did keep
NN2 <- kronecker(N2,N2)
stopifnot(identical(NN,MM),
 is(NN2, "sparseMatrix"), all(NN2 == NN),
 is(NN, "triangularMatrix"))
```

---

ldenseMatrix-class    *Virtual Class "ldenseMatrix" of Dense Logical Matrices*

---

## Description

[ldenseMatrix](#) is the virtual class of all dense logical (S4) matrices. It extends both [denseMatrix](#) and [lMatrix](#) directly.

## Slots

**x:** logical vector containing the entries of the matrix.

**Dim, Dimnames:** see [Matrix](#).

**Extends**

Class "lMatrix", directly. Class "denseMatrix", directly. Class "Matrix", by class "lMatrix". Class "Matrix", by class "denseMatrix".

**Methods**

**coerce** signature(from = "matrix", to = "ldenseMatrix"): ...  
**coerce** signature(from = "ldenseMatrix", to = "matrix"): ...  
**as.vector** signature(x = "ldenseMatrix", mode = "missing"): ...  
**which** signature(x = "ndenseMatrix"), semantically equivalent to **base** function `which(x, arr.ind)`; for details, see the [lMatrix](#) class documentation.

**See Also**

Class [lgeMatrix](#) and the other subclasses.

**Examples**

```
showClass("ldenseMatrix")

as(diag(3) > 0, "ldenseMatrix")
```

---

lDiMatrix-class

---

Class "lDiMatrix" of Diagonal Logical Matrices

---

**Description**

The class "lDiMatrix" of logical diagonal matrices.

**Objects from the Class**

Objects can be created by calls of the form `new("lDiMatrix", ...)` but typically rather via [Diagonal](#).

**Slots**

**x**: "logical" vector.  
**diag**: "character" string, either "U" or "N", see [ddiMatrix](#).  
**Dim,Dimnames**: matrix dimension and **dimnames**, see the [Matrix](#) class description.

**Extends**

Class "[diagonalMatrix](#)" and class "[lMatrix](#)", directly.  
Class "[sparseMatrix](#)", by class "diagonalMatrix".

**See Also**

Classes [ddiMatrix](#) and [diagonalMatrix](#); function [Diagonal](#).

**Examples**

```
(lM <- Diagonal(x = c(TRUE,FALSE,FALSE)))
str(lM) #> gory details (slots)

crossprod(lM) # numeric
(nM <- as(lM, "nMatrix")) # -> sparse (not formally ``diagonal'')
crossprod(nM) # logical sparse
```

---

lgeMatrix-class      *Class "lgeMatrix" of General Dense Logical Matrices*

---

**Description**

This is the class of general dense [logical](#) matrices.

**Slots**

**x:** Object of class "logical". The logical values that constitute the matrix, stored in column-major order.

**Dim,Dimnames:** The dimension (a length-2 "integer") and corresponding names (or NULL), see the [Matrix](#) class.

**factors:** Object of class "list". A named list of factorizations that have been computed for the matrix.

**Extends**

Class "ldenseMatrix", directly. Class "lMatrix", by class "ldenseMatrix". Class "denseMatrix", by class "ldenseMatrix". Class "Matrix", by class "ldenseMatrix". Class "Matrix", by class "ldenseMatrix".

**Methods**

Currently, mainly [t\(\)](#) and coercion methods (for [as\(.\)](#)); use, e.g., [showMethods](#)(class="lgeMatrix") for details.

**See Also**

Non-general logical dense matrix classes such as [ltrMatrix](#), or [lsyMatrix](#); *sparse* logical classes such as [lgCMatrix](#).

**Examples**

```
showClass("lgeMatrix")
str(new("lgeMatrix"))
set.seed(1)
(lM <- Matrix(matrix(rnorm(28), 4,7) > 0)) # a simple random lgeMatrix

lsparseMatrix-classes

*Sparse logical matrices*

---

## Description

The `lsparseMatrix` class is a virtual class of sparse matrices with TRUE/FALSE or NA entries. Only the positions of the elements that are TRUE are stored.

These can be stored in the “triplet” form (class `TsparseMatrix`, subclasses `lgTMatrix`, `lsTMatrix`, and `ltTMatrix`) or in compressed column-oriented form (class `CsparseMatrix`, subclasses `lgCMatrix`, `lsCMatrix`, and `ltCMatrix`) or—rarely—in compressed row-oriented form (class `RsparseMatrix`, subclasses `lgRMatrix`, `lsRMatrix`, and `ltRMatrix`). The second letter in the name of these non-virtual classes indicates general, symmetric, or triangular.

## Details

Note that triplet stored (`TsparseMatrix`) matrices such as `lgTMatrix` may contain duplicated pairs of indices  $(i, j)$  as for the corresponding numeric class `dgTMatrix` where for such pairs, the corresponding `x` slot entries are added. For logical matrices, the `x` entries corresponding to duplicated index pairs  $(i, j)$  are “added” as well if the addition is defined as logical *or*, i.e., “TRUE + TRUE  $\rightarrow$  TRUE” and “TRUE + FALSE  $\rightarrow$  TRUE”. Note the use of `uniqTsparse()` for getting an internally unique representation without duplicated  $(i, j)$  entries.

## Objects from the Class

Objects can be created by calls of the form `new("lgCMatrix", ...)` and so on. More frequently objects are created by coercion of a numeric sparse matrix to the logical form, e.g. in an expression `x != 0`.

The logical form is also used in the symbolic analysis phase of an algorithm involving sparse matrices. Such algorithms often involve two phases: a symbolic phase wherein the positions of the non-zeros in the result are determined and a numeric phase wherein the actual results are calculated. During the symbolic phase only the positions of the non-zero elements in any operands are of interest, hence any numeric sparse matrices can be treated as logical sparse matrices.

## Slots

- x:** Object of class "logical", i.e., either TRUE, NA, or FALSE.
- uplo:** Object of class "character". Must be either "U", for upper triangular, and "L", for lower triangular. Present in the triangular and symmetric classes but not in the general class.
- diag:** Object of class "character". Must be either "U", for unit triangular (diagonal is all ones), or "N" for non-unit. The implicit diagonal elements are not explicitly stored when `diag` is "U". Present in the triangular classes only.
- p:** Object of class "integer" of pointers, one for each column (row), to the initial (zero-based) index of elements in the column. Present in compressed column-oriented and compressed row-oriented forms only.
- i:** Object of class "integer" of length `nnzero` (number of non-zero elements). These are the row numbers for each TRUE element in the matrix. All other elements are FALSE. Present in triplet and compressed column-oriented forms only.

**j**: Object of class "integer" of length nnzero (number of non-zero elements). These are the column numbers for each TRUE element in the matrix. All other elements are FALSE. Present in triplet and compressed row-oriented forms only.

**Dim**: Object of class "integer" - the dimensions of the matrix.

## Methods

**coerce** signature (from = "dgCMatrix", to = "lgCMatrix")

**t** signature (x = "lgCMatrix"): returns the transpose of x

**which** signature (x = "lsparseMatrix"), semantically equivalent to **base** function `which(x, arr.ind)`; for details, see the `lMatrix` class documentation.

## See Also

the class `dgCMatrix` and `dgTMatrix`

## Examples

```
(m <- Matrix(c(0,0,2:0), 3,5, dimnames=list(LETTERS[1:3],NULL)))
(lm <- (m > 1)) # lgC
!lm # no longer sparse
stopifnot(is(lm,"lsparseMatrix"),
 identical(!lm, m <= 1))

data(KNex)
str(mmG.1 <- (KNex $ mm) > 0.1) # "lgC..."
table(mmG.1@x) # however with many ``non-structural zeros''
from logical to nz_pattern -- okay when there are no NA's :
nmG.1 <- as(mmG.1, "nMatrix") # <<< has "TRUE" also where mmG.1 had FALSE
from logical to "double"
dmG.1 <- as(mmG.1, "dMatrix") # has '0' and back:
lmG.1 <- as(dmG.1, "lMatrix") # has no extra FALSE, i.e. drop0() included
stopifnot(identical(nmG.1, as((KNex $ mm) != 0, "nMatrix")),
 validObject(lmG.1), all(lmG.1@x),
 # same "logical" but lmG.1 has no 'FALSE' in x slot:
 all(lmG.1 == mmG.1))

class(xnx <- crossprod(nmG.1)) # "nsC.."
class(xlx <- crossprod(mmG.1)) # "dsC.." : numeric
is0 <- (xlx == 0)
mean(as.vector(is0)) # 99.3% zeros: quite sparse, but
table(xlx@x == 0) # more than half of the entries are (non-structural!) 0
stopifnot(isSymmetric(xlx), isSymmetric(xnx),
 ## compare xnx and xlx : have the *same* non-structural 0s :
 sapply(slotNames(xnx),
 function(n) identical(slot(xnx, n), slot(xlx, n)))))
```

## Description

The "lsyMatrix" class is the class of symmetric, dense logical matrices in non-packed storage and "lspMatrix" is the class of these in packed storage. In the packed form, only the upper triangle or the lower triangle is stored.

## Objects from the Class

Objects can be created by calls of the form `new("lsyMatrix", ...)`.

## Slots

**uplo:** Object of class "character". Must be either "U", for upper triangular, and "L", for lower triangular.

**x:** Object of class "logical". The logical values that constitute the matrix, stored in column-major order.

**Dim,Dimnames:** The dimension (a length-2 "integer") and corresponding names (or NULL), see the [Matrix](#) class.

**factors:** Object of class "list". A named list of factorizations that have been computed for the matrix.

## Extends

Both extend classes "[ldenseMatrix](#)" and "[symmetricMatrix](#)", directly; further, class "[Matrix](#)" and others, indirectly. Use `showClass("lsyMatrix")`, e.g., for details.

## Methods

Currently, mainly `t()` and coercion methods (for `as(.)`; use, e.g., `showMethods(class="dsyMatrix")` for details.

## See Also

[lgeMatrix](#), [Matrix](#), [t](#)

## Examples

```
(M2 <- Matrix(c(TRUE, NA,FALSE,FALSE), 2,2)) # logical dense (ltr)
str(M2)
can
(sM <- M2 | t(M2)) # "lge"
as(sM, "lsyMatrix")
str(sM <- as(sM, "lspMatrix")) # packed symmetric
```

---

ltrMatrix-class      *Triangular Dense Logical Matrices*

---

**Description**

The "ltrMatrix" class is the class of triangular, dense, logical matrices in nonpacked storage. The "ltpMatrix" class is the same except in packed storage.

**Slots**

**x:** Object of class "logical". The logical values that constitute the matrix, stored in column-major order.

**uplo:** Object of class "character". Must be either "U", for upper triangular, and "L", for lower triangular.

**diag:** Object of class "character". Must be either "U", for unit triangular (diagonal is all ones), or "N"; see [triangularMatrix](#).

**Dim,Dimnames:** The dimension (a length-2 "integer") and corresponding names (or NULL), see the [Matrix](#) class.

**factors:** Object of class "list". A named list of factorizations that have been computed for the matrix.

**Extends**

Both extend classes "[ldenseMatrix](#)" and "[triangularMatrix](#)", directly; further, class "[Matrix](#)", "[lMatrix](#)" and others, indirectly. Use [showClass](#)("ltrMatrix"), e.g., for details.

**Methods**

Currently, mainly [t\(\)](#) and coercion methods (for [as\(.\)](#); use, e.g., [showMethods](#)(class="ltpMatrix") for details.

**See Also**

Classes [lgeMatrix](#), [Matrix](#); function [t](#)

**Examples**

```
showClass("ltrMatrix")

str(new("ltpMatrix"))
(lutr <- as(upper.tri(matrix(,4,4)), "ltrMatrix"))
str(lutp <- as(lutr, "ltpMatrix"))# packed matrix: only 10 = (4+1)*4/2 entries
!lutp ## the logical negation (is *not* logical triangular !)
but this one is:
stopifnot(all.equal(lutp, as(!lutp, "ltpMatrix")))
```

---

lu *(Generalized) Triangular Decomposition of a Matrix*

---

**Description**

Computes (generalized) triangular decompositions of square (sparse or dense) and non-square dense matrices.

**Usage**

```
lu(x, ...)
S4 method for signature 'matrix'
lu(x, warnSing = TRUE, ...)
S4 method for signature 'dgeMatrix'
lu(x, warnSing = TRUE, ...)
S4 method for signature 'dgCMatrix'
lu(x, errSing = TRUE, order = TRUE, tol = 1,
 keep.dimnames = TRUE, ...)
```

**Arguments**

|               |                                                                                                                                                                                                                                                                                                                                         |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x             | a dense or sparse matrix, in the latter case of square dimension. No missing values or IEEE special values are allowed.                                                                                                                                                                                                                 |
| warnSing      | (when x is a " <a href="#">denseMatrix</a> ") logical specifying if a <a href="#">warning</a> should be signalled when x is singular.                                                                                                                                                                                                   |
| errSing       | (when x is a " <a href="#">sparseMatrix</a> ") logical specifying if an error (see <a href="#">stop</a> ) should be signalled when x is singular. When x is singular, <code>lu(x, errSing=FALSE)</code> returns <a href="#">NA</a> instead of an LU decomposition. No warning is signalled and the user should be careful in that case. |
| order         | logical or integer, used to choose which fill-reducing permutation technique will be used internally. Do not change unless you know what you are doing.                                                                                                                                                                                 |
| tol           | positive number indicating the pivoting tolerance used in <code>cs_lu</code> . Do only change with much care.                                                                                                                                                                                                                           |
| keep.dimnames | logical indicating that <a href="#">dimnames</a> should be propagated to the result, i.e., “kept”. This was hardcoded to <code>FALSE</code> in upto <b>Matrix</b> version 1.2-0. Setting to <code>FALSE</code> may gain some performance.                                                                                               |
| ...           | further arguments passed to or from other methods.                                                                                                                                                                                                                                                                                      |

**Details**

`lu()` is a generic function with special methods for different types of matrices. Use [showMethods](#)("lu") to list all the methods for the `lu` generic.

The method for class [dgeMatrix](#) (and all dense matrices) is based on LAPACK's "dgetrf" subroutine. It returns a decomposition also for singular and non-square matrices.

The method for class [dgCMatrix](#) (and all sparse matrices) is based on functions from the `CSparse` library. It signals an error (or returns `NA`, when `errSing = FALSE`, see above) when the decomposition algorithm fails, as when x is (too close to) singular.

**Value**

An object of class "LU", i.e., "[denseLU](#)" (see its separate help page), or "[sparseLU](#)", see [sparseLU](#); this is a representation of a triangular decomposition of  $x$ .

**Note**

Because the underlying algorithm differ entirely, in the *dense* case (class [denseLU](#)), the decomposition is

$$A = PLU,$$

where as in the *sparse* case (class [sparseLU](#)), it is

$$A = P'LUQ.$$

**Examples**

```
##--- Dense -----
x <- Matrix(rnorm(9), 3, 3)
lu(x)
dim(x2 <- round(10 * x[, -3])) # non-square
expand(lu2 <- lu(x2))

##--- Sparse (see more in ?"sparseLU-class")----- % ./sparseLU-class.Rd

pm <- as(readMM(system.file("external/pores_1.mtx",
 package = "Matrix")),
 "CsparseMatrix")
str(pmLU <- lu(pm)) # p is a 0-based permutation of the rows
 # q is a 0-based permutation of the columns
permute rows and columns of original matrix
ppm <- pm[pmLU@p + 1L, pmLU@q + 1L]
pLU <- drop0(pmLU@L %*% pmLU@U) # L %*% U -- dropping extra zeros
equal up to "rounding"
ppm[1:14, 1:5]
pLU[1:14, 1:5]
```

LU-class

*LU (dense) Matrix Decompositions***Description**

The "LU" class is the *virtual* class of LU decompositions of real matrices. "denseLU" the class of LU decompositions of dense real matrices.

**Details**

The decomposition is of the form

$$A = PLU$$

where typically all matrices are of size  $n \times n$ , and the matrix  $P$  is a permutation matrix,  $L$  is lower triangular and  $U$  is upper triangular (both of class [dtrMatrix](#)).

Note that the *dense* decomposition is also implemented for a  $m \times n$  matrix  $A$ , when  $m \neq n$ .

If  $m < n$  ("wide case"),  $U$  is  $m \times n$ , and hence not triangular.

If  $m > n$  ("long case"),  $L$  is  $m \times n$ , and hence not triangular.

**Objects from the Class**

Objects can be created by calls of the form `new("denseLU", ...)`. More commonly the objects are created explicitly from calls of the form `lu(mm)` where `mm` is an object that inherits from the "dgeMatrix" class or as a side-effect of other functions applied to "dgeMatrix" objects.

**Extends**

"LU" directly extends the virtual class "MatrixFactorization".

"denseLU" directly extends "LU".

**Slots**

**x:** object of class "numeric". The "L" (unit lower triangular) and "U" (upper triangular) factors of the original matrix. These are stored in a packed format described in the Lapack manual, and can be retrieved by the `expand()` method, see below.

**perm:** Object of class "integer" - a vector of length `min(Dim)` that describes the permutation applied to the rows of the original matrix. The contents of this vector are described in the Lapack manual.

**Dim:** the dimension of the original matrix; inherited from class [MatrixFactorization](#).

**Methods**

**expand** signature(`x = "denseLU"`): Produce the "L" and "U" (and "P") factors as a named list of matrices, see also the example below.

**solve** signature(`a = "denseLU"`, `b = "missing"`): Compute the inverse of  $A$ ,  $A^{-1}$ , `solve(A)` using the LU decomposition, see also [solve-methods](#).

**See Also**

class [sparseLU](#) for LU decompositions of *sparse* matrices; further, class [dgeMatrix](#) and functions [lu](#), [expand](#).

## Examples

```
set.seed(1)
mm <- Matrix(round(rnorm(9),2), nrow = 3)
mm
str(lum <- lu(mm))
elu <- expand(lum)
elu # three components: "L", "U", and "P", the permutation
elu$L %*% elu$U
(m2 <- with(elu, P %*% L %*% U)) # the same as 'mm'
stopifnot(all.equal(as(mm, "matrix"),
 as(m2, "matrix")))
```

---

mat2triplet

---

*Map Matrix to its Triplet Representation*

---

## Description

From an R object coercible to `"TsparseMatrix"`, typically a (sparse) matrix, produce its triplet representation which may collapse to a “Duplet” in the case of binary aka pattern, such as `"nMatrix"` objects.

## Usage

```
mat2triplet(x, uniqT = FALSE)
```

## Arguments

|                    |                                                                                                                                                 |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>     | any R object for which <code>as(x, "TsparseMatrix")</code> works; typically a <code>matrix</code> of one of the <b>Matrix</b> package matrices. |
| <code>uniqT</code> | <code>logical</code> indicating if the triplet representation should be ‘unique’ in the sense of <code>uniqTsparse()</code> .                   |

## Value

A `list`, typically with three components,

|                |                                                                                                                                                               |
|----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>i</code> | vector of row indices for all non-zero entries of <code>x</code>                                                                                              |
| <code>j</code> | vector of columns indices for all non-zero entries of <code>x</code>                                                                                          |
| <code>x</code> | vector of all non-zero entries of <code>x</code> ; exists <b>only</b> when <code>as(x, "TsparseMatrix")</code> is <b>not</b> a <code>"nsparseMatrix"</code> . |

Note that the `order` of the entries is determined by the coercion to `"TsparseMatrix"` and hence typically with increasing `j` (and increasing `i` within ties of `j`).

## Note

The `mat2triplet()` utility was created to be a more efficient and more predictable substitute for `summary(<sparseMatrix>)`. UseRs have wrongly expected the latter to return a data frame with columns `i` and `j` which however is wrong for a `"diagonalMatrix"`.

See Also

The `summary()` method for "sparseMatrix", [summary, sparseMatrix-method](#).  
`mat2triplet()` is conceptually the *inverse* function of [spMatrix](#) and (one case of) [sparseMatrix](#).

Examples

```
if(FALSE) ## The function is defined (don't redefine here!), simply as
mat2triplet <- function(x, uniqT = FALSE) {
 T <- as(x, "TsparseMatrix")
 if(uniqT && anyDuplicatedT(T)) T <- .uniqTsparse(T)
 if(is(T, "nsparseMatrix"))
 list(i = T@i + 1L, j = T@j + 1L)
 else list(i = T@i + 1L, j = T@j + 1L, x = T@x)
}

i <- c(1,3:8); j <- c(2,9,6:10); x <- 7 * (1:7)
(Ax <- sparseMatrix(i, j, x = x)) ## 8 x 10 "dgCMatrix"
str(trA <- mat2triplet(Ax))
stopifnot(i == sort(trA$i), sort(j) == trA$j, x == sort(trA$x))

D <- Diagonal(x=4:2)
summary(D)
str(mat2triplet(D))
```

---

|        |                                   |
|--------|-----------------------------------|
| Matrix | <i>Construct a Classed Matrix</i> |
|--------|-----------------------------------|

---

Description

Construct a Matrix of a class that inherits from `Matrix`.

Usage

```
Matrix(data=NA, nrow=1, ncol=1, byrow=FALSE, dimnames=NULL,
 sparse = NULL, doDiag = TRUE, forceCheck = FALSE)
```

Arguments

|                       |                                                                                                                                                          |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>data</code>     | an optional numeric data vector or matrix.                                                                                                               |
| <code>nrow</code>     | when data is not a matrix, the desired number of rows                                                                                                    |
| <code>ncol</code>     | when data is not a matrix, the desired number of columns                                                                                                 |
| <code>byrow</code>    | logical. If <code>FALSE</code> (the default) the matrix is filled by columns, otherwise the matrix is filled by rows.                                    |
| <code>dimnames</code> | a <a href="#">dimnames</a> attribute for the matrix: a list of two character components. They are set if not <code>NULL</code> (as per default).         |
| <code>sparse</code>   | logical or <code>NULL</code> , specifying if the result should be sparse or not. By default, it is made sparse when more than half of the entries are 0. |

|                         |                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>doDiag</code>     | logical indicating if a <code>diagonalMatrix</code> object should be returned when the resulting matrix is diagonal ( <i>mathematically</i> ). As class <code>diagonalMatrix</code> extends <code>sparseMatrix</code> , this is a natural default for all values of <code>sparse</code> . Otherwise, if <code>doDiag</code> is false, a dense or sparse (depending on <code>sparse</code> ) <i>symmetric</i> matrix will be returned. |
| <code>forceCheck</code> | logical indicating if the checks for structure should even happen when data is already a "Matrix" object.                                                                                                                                                                                                                                                                                                                             |

### Details

If either of `nrow` or `ncol` is not given, an attempt is made to infer it from the length of `data` and the other parameter. Further, `Matrix()` makes efforts to keep `logical` matrices logical, i.e., inheriting from class `lMatrix`, and to determine specially structured matrices such as symmetric, triangular or diagonal ones. Note that a *symmetric* matrix also needs symmetric `dimnames`, e.g., by specifying `dimnames = list(NULL, NULL)`, see the examples.

Most of the time, the function works via a traditional (*full*) `matrix`. However, `Matrix(0, nrow, ncol)` directly constructs an “empty” `sparseMatrix`, as does `Matrix(FALSE, *)`.

Although it is sometime possible to mix unclassed matrices (created with `matrix`) with ones of class "Matrix", it is much safer to always use carefully constructed ones of class "Matrix".

### Value

Returns matrix of a class that inherits from "Matrix". Only if `data` is not a `matrix` and does not already inherit from class `Matrix` are the arguments `nrow`, `ncol` and `byrow` made use of.

### See Also

The classes `Matrix`, `symmetricMatrix`, `triangularMatrix`, and `diagonalMatrix`; further, `matrix`.

Special matrices can be constructed, e.g., via `sparseMatrix` (`sparse`), `bdiag` (block-diagonal), `bandSparse` (banded sparse), or `Diagonal`.

### Examples

```
Matrix(0, 3, 2) # 3 by 2 matrix of zeros -> sparse
Matrix(0, 3, 2, sparse=FALSE) # -> 'dense'

4 cases - 3 different results :
Matrix(0, 2, 2) # diagonal !
Matrix(0, 2, 2, sparse=FALSE) # (ditto)
Matrix(0, 2, 2, doDiag=FALSE) # -> sparse symm. "dsCMatrix"
Matrix(0, 2, 2, sparse=FALSE, doDiag=FALSE) # -> dense symm. "dsyMatrix"

Matrix(1:6, 3, 2) # a 3 by 2 matrix (+ integer warning)
Matrix(1:6 + 1, nrow=3)

logical ones:
Matrix(diag(4) > 0) # -> "ldiMatrix" with diag = "U"
Matrix(diag(4) > 0, sparse=TRUE) # (ditto)
Matrix(diag(4) >= 0) # -> "lsyMatrix" (of all 'TRUE')
triangular
l3 <- upper.tri(matrix(,3,3))
(M <- Matrix(l3)) # -> "ltCMatrix"
```

```

Matrix(! 13) # -> "ltrMatrix"
as(13, "CsparseMatrix")# "lgCMatrix"

Matrix(1:9, nrow=3,
 dimnames = list(c("a", "b", "c"), c("A", "B", "C")))
(I3 <- Matrix(diag(3)))# identity, i.e., unit "diagonalMatrix"
str(I3) # note 'diag = "U"' and the empty 'x' slot

(A <- cbind(a=c(2,1), b=1:2))# symmetric *apart* from dimnames
Matrix(A) # hence 'dgeMatrix'
(As <- Matrix(A, dimnames = list(NULL,NULL)))# -> symmetric
forceSymmetric(A) # also symmetric, w/ symm. dimnames
stopifnot(is(As, "symmetricMatrix"),
 is(Matrix(0, 3,3), "sparseMatrix"),
 is(Matrix(FALSE, 1,1), "sparseMatrix"))

```

Matrix-class

Virtual Class "Matrix" Class of Matrices

## Description

The `Matrix` class is a class contained by all actual classes in the **Matrix** package. It is a “virtual” class.

## Slots

Common to *all* matrix objects in the package:

**Dim:** Object of class "integer" - the dimensions of the matrix - must be an integer vector with exactly two non-negative values.

**Dimnames:** list of length two; each component containing NULL or a [character](#) vector length equal the corresponding `Dim` element.

## Methods

**determinant** signature(x = "Matrix", logarithm = "missing"): and

**determinant** signature(x = "Matrix", logarithm = "logical"): compute the (log) determinant of x. The method chosen depends on the actual `Matrix` class of x. Note that [det](#) also works for all our matrices, calling the appropriate `determinant()` method. The `Matrix::det` is an exact copy of `base::det`, but in the correct namespace, and hence calling the S4-aware version of `determinant()`.

**diff** signature(x = "Matrix"): As [diff\(\)](#) for traditional matrices, i.e., applying `diff()` to each column.

**dim** signature(x = "Matrix"): extract matrix dimensions [dim](#).

**dim<-** signature(x = "Matrix", value = "ANY"): where value is integer of length 2. Allows to *reshape* `Matrix` objects, but only when `prod(value) == prod(dim(x))`.

**dimnames** signature(x = "Matrix"): extract [dimnames](#).

**dimnames<-** signature(x = "Matrix", value = "list"): set the dimnames to a [list](#) of length 2, see [dimnames<-](#).

**length** signature(x = "Matrix"): simply defined as `prod(dim(x))` (and hence of mode "double").

**show** signature(object = "Matrix"): [show](#) method for [printing](#). For printing *sparse* matrices, see [printSpMatrix](#).

**image** signature(object = "Matrix"): draws an [image](#) of the matrix entries, using [levelplot\(\)](#) from package [lattice](#).

**head** signature(object = "Matrix"): return only the “*head*”, i.e., the first few rows.

**tail** signature(object = "Matrix"): return only the “*tail*”, i.e., the last few rows of the respective matrix.

**as.matrix, as.array** signature(x = "Matrix"): the same as `as(x, "matrix")`; see also the note below.

**as.vector** signature(x = "Matrix", mode = "missing"): `as.vector(m)` should be identical to `as.vector(as(m, "matrix"))`, implemented more efficiently for some subclasses.

**as(x, "vector"), as(x, "numeric")** etc, similarly.

**coerce** signature(from = "ANY", to = "Matrix"): This relies on a correct [as.matrix\(\)](#) method for from.

There are many more methods that (conceptually should) work for all "Matrix" objects, e.g., [colSums](#), [rowMeans](#). Even **base** functions may work automatically (if they first call [as.matrix\(\)](#) on their principal argument), e.g., [apply](#), [eigen](#), [svd](#) or [kappa](#) all do work via coercion to a “traditional” (dense) [matrix](#).

## Note

Loading the *Matrix* namespace “overloads” [as.matrix](#) and [as.array](#) in the **base** namespace by the equivalent of `function(x) as(x, "matrix")`. Consequently, `as.matrix(m)` or `as.array(m)` will properly work when `m` inherits from the "Matrix" class — *also* for functions in package **base** and other packages. E.g., [apply](#) or [outer](#) can therefore be applied to "Matrix" matrices.

## Author(s)

Douglas Bates <bates@stat.wisc.edu> and Martin Maechler

## See Also

the classes [dgeMatrix](#), [dgCMatrix](#), and function [Matrix](#) for construction (and examples).  
Methods, e.g., for [kronecker](#).

## Examples

```
slotNames("Matrix")

cl <- getClass("Matrix")
names(cl@subclasses) # more than 40 ..

showClass("Matrix")#> output with slots and all subclasses

(M <- Matrix(c(0,1,0,0), 6, 4))
dim(M)
diag(M)
cm <- M[1:4,] + 10*Diagonal(4)
diff(M)
```

```
can reshape it even :
dim(M) <- c(2, 12)
M
stopifnot(identical(M, Matrix(c(0,1,0,0), 2,12)),
 all.equal(det(cm),
 determinant(as(cm,"matrix"), log=FALSE)$modulus,
 check.attributes=FALSE))
```

|                 |                                               |
|-----------------|-----------------------------------------------|
| matrix-products | <i>Matrix (Cross) Products (of Transpose)</i> |
|-----------------|-----------------------------------------------|

---

## Description

The basic matrix product, `%%` is implemented for all our [Matrix](#) and also for [sparseVector](#) classes, fully analogously to R's base `matrix` and vector objects.

The functions `crossprod` and `tcrossprod` are matrix products or “cross products”, ideally implemented efficiently without computing `t(.)`'s unnecessarily. They also return [symmetricMatrix](#) classed matrices when easily detectable, e.g., in `crossprod(m)`, the one argument case.

`tcrossprod()` takes the cross-product of the transpose of a matrix. `tcrossprod(x)` is formally equivalent to, but faster than, the call `x %*% t(x)`, and so is `tcrossprod(x, y)` instead of `x %*% t(y)`.

*Boolean* matrix products are computed via either `%&%` or `boolArith = TRUE`.

## Usage

```
S4 method for signature 'CsparseMatrix,diagonalMatrix'
x %*% y

S4 method for signature 'dgeMatrix,missing'
crossprod(x, y = NULL, boolArith = NA, ...)
S4 method for signature 'CsparseMatrix,diagonalMatrix'
crossprod(x, y = NULL, boolArith = NA, ...)
.... and for many more signatures

S4 method for signature 'CsparseMatrix,ddenseMatrix'
tcrossprod(x, y = NULL, boolArith = NA, ...)
S4 method for signature 'TsparseMatrix,missing'
tcrossprod(x, y = NULL, boolArith = NA, ...)
.... and for many more signatures
```

## Arguments

|                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>         | a matrix-like object                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <code>y</code>         | a matrix-like object, or for <code>[t]crossprod()</code> <code>NULL</code> (by default); the latter case is formally equivalent to <code>y = x</code> .                                                                                                                                                                                                                                                                                                                                               |
| <code>boolArith</code> | <a href="#">logical</a> , i.e., <code>NA</code> , <code>TRUE</code> , or <code>FALSE</code> . If true the result is (coerced to) a pattern matrix, i.e., <code>"nMatrix"</code> , unless there are <code>NA</code> entries and the result will be a <code>"lMatrix"</code> . If false the result is (coerced to) numeric. When <code>NA</code> , currently the default, the result is a pattern matrix when <code>x</code> and <code>y</code> are <code>"nsparseMatrix"</code> and numeric otherwise. |
| <code>...</code>       | potentially more arguments passed to and from methods.                                                                                                                                                                                                                                                                                                                                                                                                                                                |

## Details

For some classes in the `Matrix` package, such as `dgCMatrix`, it is much faster to calculate the cross-product of the transpose directly instead of calculating the transpose first and then its cross-product.

`boolArith = TRUE` for regular (“non cross”) matrix products, `%%` cannot be specified. Instead, we provide the `%&%` operator for *boolean* matrix products.

## Value

A `Matrix` object, in the one argument case of an appropriate *symmetric* matrix class, i.e., inheriting from `symmetricMatrix`.

## Methods

`%%` signature (`x = "dgeMatrix"`, `y = "dgeMatrix"`): `Matrix` multiplication; ditto for several other signature combinations, see `showMethods("%%", class = "dgeMatrix")`.

`%%` signature (`x = "dtrMatrix"`, `y = "matrix"`) and other signatures (use `showMethods("%%", class = "dtrMatrix")`): matrix multiplication. Multiplication of (matching) triangular matrices now should remain triangular (in the sense of class `triangularMatrix`).

**crossprod** signature (`x = "dgeMatrix"`, `y = "dgeMatrix"`): ditto for several other signatures, use `showMethods("crossprod", class = "dgeMatrix")`, matrix crossproduct, an efficient version of `t(x) %*% y`.

**crossprod** signature (`x = "CsparseMatrix"`, `y = "missing"`) returns `t(x) %*% x` as an `dsCMatrix` object.

**crossprod** signature (`x = "TsparseMatrix"`, `y = "missing"`) returns `t(x) %*% x` as an `dsCMatrix` object.

**crossprod, tcrossprod** signature (`x = "dtrMatrix"`, `y = "matrix"`) and other signatures, see `"%%"` above.

## Note

`boolArith = TRUE`, `FALSE` or `NA` has been newly introduced for **Matrix** 1.2.0 (March 2015). Its implementation may be incomplete and partly missing. Please report such omissions if detected!

Currently, `boolArith = TRUE` is implemented via `CsparseMatrix` coercions which may be quite inefficient for dense matrices. Contributions for efficiency improvements are welcome.

## See Also

`tcrossprod` in R's base, `crossprod` and `%%`.

## Examples

```
A random sparse "incidence" matrix :
m <- matrix(0, 400, 500)
set.seed(12)
m[runif(314, 0, length(m))] <- 1
mm <- as(m, "dgCMatrix")
object.size(m) / object.size(mm) # smaller by a factor of > 200
```

```
tcrossprod() is very fast:
system.time(tCmm <- tcrossprod(mm)) # 0 (PIII, 933 MHz)
system.time(cm <- crossprod(t(m))) # 0.16
system.time(cm. <- tcrossprod(m)) # 0.02

stopifnot(cm == as(tCmm, "matrix"))

show sparse sub matrix
tCmm[1:16, 1:30]
```

MatrixClass

*The Matrix (Super-) Class of a Class*

## Description

Return the (maybe super-)class of class `cl` from package **Matrix**, returning `character(0)` if there is none.

## Usage

```
MatrixClass(cl, cld = getClassDef(cl), ...Matrix = TRUE,
 dropVirtual = TRUE, ...)
```

## Arguments

|                          |                                                                                                                                               |
|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------|
| <code>cl</code>          | string, class name                                                                                                                            |
| <code>cld</code>         | its class definition                                                                                                                          |
| <code>...Matrix</code>   | <code>logical</code> indicating if the result must be of pattern "[dlniz]..Matrix" where the first letter "[dlniz]" denotes the content kind. |
| <code>dropVirtual</code> | <code>logical</code> indicating if virtual classes are included or not.                                                                       |
| <code>...</code>         | further arguments are passed to <code>.selectSuperClasses()</code> .                                                                          |

## Value

a `character` string

## Author(s)

Martin Maechler, 24 Mar 2009

## See Also

[Matrix](#), the mother of all **Matrix** classes.

```
mkA <- setClass("A", contains="dgCMatrix")
(A <- mkA())
stopifnot(identical(
 MatrixClass("A"),
 "dgCMatrix"))
```

---

MatrixFactorization-class

*Class "MatrixFactorization" of Matrix Factorizations*

---

## Description

The class "MatrixFactorization" is the virtual (super) class of (potentially) all matrix factorizations of matrices from package **Matrix**.

The class "CholeskyFactorization" is the virtual class of all Cholesky decompositions from **Matrix** (and trivial sub class of "MatrixFactorization").

## Objects from the Class

A virtual Class: No objects may be created from it.

## Slots

**Dim:** Object of class "integer" - the dimensions of the original matrix - must be an integer vector with exactly two non-negative values.

## Methods

**dim** (x) simply returns x@Dim, see above.

**expand** signature (x = "MatrixFactorization"): this has not been implemented yet for all matrix factorizations. It should return a list whose components are matrices which when multiplied return the original [Matrix](#) object.

**show** signature (object = "MatrixFactorization"): simple printing, see [show](#).

**solve** signature (a = "MatrixFactorization", b = .): solve  $Ax = b$  for  $x$ ; see [solve-methods](#).

## See Also

classes inheriting from "MatrixFactorization", such as [LU](#), [Cholesky](#), [CHMfactor](#), and [sparseQR](#).

## Examples

```
showClass("MatrixFactorization")
getClass("CholeskyFactorization")
```

---

ndenseMatrix-class *Virtual Class "ndenseMatrix" of Dense Logical Matrices*

---

## Description

`ndenseMatrix` is the virtual class of all dense logical (S4) matrices. It extends both `denseMatrix` and `lMatrix` directly.

## Slots

**x:** logical vector containing the entries of the matrix.

**Dim, Dimnames:** see `Matrix`.

## Extends

Class "`nMatrix`", directly. Class "`denseMatrix`", directly. Class "`Matrix`", by class "`nMatrix`". Class "`Matrix`", by class "`denseMatrix`".

## Methods

**%%** signature(x = "`nsparseMatrix`", y = "`ndenseMatrix`"): ...

**%%** signature(x = "`ndenseMatrix`", y = "`nsparseMatrix`"): ...

**coerce** signature(from = "`matrix`", to = "`ndenseMatrix`"): ...

**coerce** signature(from = "`ndenseMatrix`", to = "`matrix`"): ...

**crossprod** signature(x = "`nsparseMatrix`", y = "`ndenseMatrix`"): ...

**crossprod** signature(x = "`ndenseMatrix`", y = "`nsparseMatrix`"): ...

**as.vector** signature(x = "`ndenseMatrix`", mode = "missing"): ...

**diag** signature(x = "`ndenseMatrix`"): extracts the diagonal as for all matrices, see the generic `diag()`.

**which** signature(x = "`ndenseMatrix`"), semantically equivalent to **base** function `which(x, arr.ind)`; for details, see the `lMatrix` class documentation.

## See Also

Class `ngeMatrix` and the other subclasses.

## Examples

```
showClass("ndenseMatrix")
```

```
as(diag(3) > 0, "ndenseMatrix")# -> "nge"
```

nearPD

*Nearest Positive Definite Matrix***Description**

Compute the nearest positive definite matrix to an approximate one, typically a correlation or variance-covariance matrix.

**Usage**

```
nearPD(x, corr = FALSE, keepDiag = FALSE, base.matrix = FALSE,
 do2eigen = TRUE, doSym = FALSE,
 doDykstra = TRUE, only.values = FALSE,
 ensureSymmetry = !isSymmetric(x),
 eig.tol = 1e-06, conv.tol = 1e-07, posd.tol = 1e-08,
 maxit = 100, conv.norm.type = "I", trace = FALSE)
```

**Arguments**

|                             |                                                                                                                                                                                                                                                                                                  |
|-----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>              | numeric $n \times n$ approximately positive definite matrix, typically an approximation to a correlation or covariance matrix. If <code>x</code> is not symmetric (and <code>ensureSymmetry</code> is not false), <code>symmpart(x)</code> is used.                                              |
| <code>corr</code>           | logical indicating if the matrix should be a <i>correlation</i> matrix.                                                                                                                                                                                                                          |
| <code>keepDiag</code>       | logical, generalizing <code>corr</code> : if TRUE, the resulting matrix should have the same diagonal ( <code>diag(x)</code> ) as the input matrix.                                                                                                                                              |
| <code>base.matrix</code>    | logical indicating if the resulting <code>mat</code> component should be a <b>base matrix</b> or (by default) a <b>Matrix</b> of class <code>dpoMatrix</code> .                                                                                                                                  |
| <code>do2eigen</code>       | logical indicating if a <code>posdefify()</code> eigen step should be applied to the result of the Higham algorithm.                                                                                                                                                                             |
| <code>doSym</code>          | logical indicating if <code>X &lt;- (X + t(X))/2</code> should be done, after <code>X &lt;- tcrossprod(Qd, Q)</code> ; some doubt if this is necessary.                                                                                                                                          |
| <code>doDykstra</code>      | logical indicating if Dykstra's correction should be used; true by default. If false, the algorithm is basically the direct fixpoint iteration $Y_k = P_U(P_S(Y_{k-1}))$ .                                                                                                                       |
| <code>only.values</code>    | logical; if TRUE, the result is just the vector of eigenvalues of the approximating matrix.                                                                                                                                                                                                      |
| <code>ensureSymmetry</code> | logical; by default, <code>symmpart(x)</code> is used whenever <code>isSymmetric(x)</code> is not true. The user can explicitly set this to TRUE or FALSE, saving the symmetry test. <i>Beware</i> however that setting it FALSE for an asymmetric input <code>x</code> , is typically nonsense! |
| <code>eig.tol</code>        | defines relative positiveness of eigenvalues compared to largest one, $\lambda_1$ . Eigenvalues $\lambda_k$ are treated as if zero when $\lambda_k/\lambda_1 \leq \text{eig.tol}$ .                                                                                                              |
| <code>conv.tol</code>       | convergence tolerance for Higham algorithm.                                                                                                                                                                                                                                                      |
| <code>posd.tol</code>       | tolerance for enforcing positive definiteness (in the final <code>posdefify</code> step when <code>do2eigen</code> is TRUE).                                                                                                                                                                     |
| <code>maxit</code>          | maximum number of iterations allowed.                                                                                                                                                                                                                                                            |

|                             |                                                                                                                                                                                                                 |
|-----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>conv.norm.type</code> | convergence norm type ( <code>norm(*, type)</code> ) used for Higham algorithm. The default is "I" (infinity), for reasons of speed (and back compatibility); using "F" is more in line with Higham's proposal. |
| <code>trace</code>          | logical or integer specifying if convergence monitoring should be traced.                                                                                                                                       |

### Details

This implements the algorithm of Higham (2002), and then (if `do2eigen` is true) forces positive definiteness using code from `posdefify`. The algorithm of Knol and ten Berge (1989) (not implemented here) is more general in that it allows constraints to (1) fix some rows (and columns) of the matrix and (2) force the smallest eigenvalue to have a certain value.

Note that setting `corr = TRUE` just sets `diag(.) <- 1` within the algorithm.

Higham (2002) uses Dykstra's correction, but the version by Jens Oehlschlaegel did not use it (accidentally), and still gave reasonable results; this simplification, now only used if `doDykstra = FALSE`, was active in `nearPD()` up to Matrix version 0.999375-40.

### Value

If `only.values = TRUE`, a numeric vector of eigenvalues of the approximating matrix; Otherwise, as by default, an S3 object of class "nearPD", basically a list with components

|                          |                                                                                                                     |
|--------------------------|---------------------------------------------------------------------------------------------------------------------|
| <code>mat</code>         | a matrix of class <code>dpoMatrix</code> , the computed positive-definite matrix.                                   |
| <code>eigenvalues</code> | numeric vector of eigenvalues of <code>mat</code> .                                                                 |
| <code>corr</code>        | logical, just the argument <code>corr</code> .                                                                      |
| <code>normF</code>       | the Frobenius norm ( <code>norm(x-X, "F")</code> ) of the difference between the original and the resulting matrix. |
| <code>iterations</code>  | number of iterations needed.                                                                                        |
| <code>converged</code>   | logical indicating if iterations converged.                                                                         |

### Author(s)

Jens Oehlschlaegel donated a first version. Subsequent changes by the Matrix package authors.

### See Also

A first version of this (with non-optional `corr=TRUE`) has been available as `nearcor()`; and more simple versions with a similar purpose `posdefify()`, both from package `sfsmisc`.

**Examples**

```
Higham(2002), p.334f - simple example
A <- matrix(1, 3,3); A[1,3] <- A[3,1] <- 0
n.A <- nearPD(A, corr=TRUE, do2eigen=FALSE)
n.A[c("mat", "normF")]
n.A.m <- nearPD(A, corr=TRUE, do2eigen=FALSE, base.matrix=TRUE)$mat
stopifnot(exprs = { #-----
 all.equal(n.A$mat[1,2], 0.760689917)
 all.equal(n.A$normF, 0.52779033, tolerance=1e-9)
 all.equal(n.A.m, unname(as.matrix(n.A$mat)), tolerance = 1e-15) # seen rel.d.= 1.46e-16
})
set.seed(27)
m <- matrix(round(rnorm(25),2), 5, 5)
m <- m + t(m)
diag(m) <- pmax(0, diag(m)) + 1
(m <- round(cov2cor(m), 2))

str(near.m <- nearPD(m, trace = TRUE))
round(near.m$mat, 2)
norm(m - near.m$mat) # 1.102 / 1.08

if(require("sfsmisc")) {
 m2 <- posdefify(m) # a simpler approach
 norm(m - m2) # 1.185, i.e., slightly "less near"
}

round(nearPD(m, only.values=TRUE), 9)

A longer example, extended from Jens' original,
showing the effects of some of the options:

pr <- Matrix(c(1, 0.477, 0.644, 0.478, 0.651, 0.826,
 0.477, 1, 0.516, 0.233, 0.682, 0.75,
 0.644, 0.516, 1, 0.599, 0.581, 0.742,
 0.478, 0.233, 0.599, 1, 0.741, 0.8,
 0.651, 0.682, 0.581, 0.741, 1, 0.798,
 0.826, 0.75, 0.742, 0.8, 0.798, 1),
 nrow = 6, ncol = 6)

nc. <- nearPD(pr, conv.tol = 1e-7) # default
nc.$iterations # 2
nc.l <- nearPD(pr, conv.tol = 1e-7, corr = TRUE)
nc.l$iterations # 11 / 12 (!)
ncr <- nearPD(pr, conv.tol = 1e-15)
str(ncr) # still 2 iterations
ncr.l <- nearPD(pr, conv.tol = 1e-15, corr = TRUE)
ncr.l $ iterations # 27 / 30 !

ncF <- nearPD(pr, conv.tol = 1e-15, conv.norm = "F")
stopifnot(all.equal(ncr, ncF)) # norm type does not matter at all in this example

But indeed, the 'corr = TRUE' constraint did ensure a better solution;
cov2cor() does not just fix it up equivalently :
norm(pr - cov2cor(ncr$mat)) # = 0.09994
norm(pr - ncr.l$mat) # = 0.08746 / 0.08805
```

```

3) a real data example from a 'systemfit' model (3 eq.):
(load(system.file("external", "symW.rda", package="Matrix"))) # "symW"
dim(symW) # 24 x 24
class(symW) # "dsCMatrix": sparse symmetric
if(dev.interactive()) image(symW)
EV <- eigen(symW, only=TRUE)$values
summary(EV) ## looking more closely {EV sorted decreasingly}:
tail(EV) # all 6 are negative
EV2 <- eigen(sWpos <- nearPD(symW)$mat, only=TRUE)$values
stopifnot(EV2 > 0)
if(require("sfsmisc")) {
 plot(pmax(1e-3, EV), EV2, type="o", log="xy", xaxt="n", yaxt="n")
 eaxis(1); eaxis(2)
} else plot(pmax(1e-3, EV), EV2, type="o", log="xy")
abline(0, 1, col="red3", lty=2)

```

---

ngeMatrix-class      *Class "ngeMatrix" of General Dense Nonzero-pattern Matrices*

---

## Description

This is the class of general dense nonzero-pattern matrices, see [nMatrix](#).

## Slots

**x:** Object of class "logical". The logical values that constitute the matrix, stored in column-major order.

**Dim, Dimnames:** The dimension (a length-2 "integer") and corresponding names (or NULL), see the [Matrix](#) class.

**factors:** Object of class "list". A named list of factorizations that have been computed for the matrix.

## Extends

Class "ndenseMatrix", directly. Class "lMatrix", by class "ndenseMatrix". Class "denseMatrix", by class "ndenseMatrix". Class "Matrix", by class "ndenseMatrix". Class "Matrix", by class "ndenseMatrix".

## Methods

Currently, mainly `t()` and coercion methods (for `as(.)`); use, e.g., `showMethods(class="ngeMatrix")` for details.

## See Also

Non-general logical dense matrix classes such as [ntrMatrix](#), or [nsyMatrix](#); *sparse* logical classes such as [ngCMatrix](#).

## Examples

```

showClass("ngeMatrix")
"lgeMatrix" is really more relevant

```

---

nMatrix-class

Class "nMatrix" of Non-zero Pattern Matrices

---

## Description

The `nMatrix` class is the virtual “mother” class of all *non-zero pattern* (or simply *pattern*) matrices in the **Matrix** package.

## Slots

Common to *all* matrix object in the package:

**Dim:** Object of class "integer" - the dimensions of the matrix - must be an integer vector with exactly two non-negative values.

**Dimnames:** list of length two; each component containing NULL or a `character` vector length equal the corresponding **Dim** element.

## Methods

There is a bunch of coercion methods (for `as(.)`), e.g.,

**coerce** signature(from = "matrix", to = "nMatrix"): Note that these coercions (must) coerce `NA`s to non-zero, hence conceptually TRUE. This is particularly important when `sparseMatrix` objects are coerced to "nMatrix" and hence to `nsparseMatrix`.

**coerce** signature(from = "dMatrix", to = "nMatrix"), and

**coerce** signature(from = "lMatrix", to = "nMatrix"): For dense matrices with `NA`s, these coercions are valid since **Matrix** version 1.2.0 (still with a `warning` or a `message` if "Matrix.warn", or "Matrix.verbose" `options` are set.)

**coerce** signature(from = "nMatrix", to = "matrix"): ...

**coerce** signature(from = "nMatrix", to = "dMatrix"): ...

**coerce** signature(from = "nMatrix", to = "lMatrix"): ...

— — —

Additional methods contain group methods, such as

**Ops** signature(e1 = "nMatrix", e2 = "...."), ...

**Arith** signature(e1 = "nMatrix", e2 = "...."), ...

**Compare** signature(e1 = "nMatrix", e2 = "...."), ...

**Logic** signature(e1 = "nMatrix", e2 = "...."), ...

**Summary** signature(x = "nMatrix", "...."), ...

## See Also

The classes `lMatrix`, `nsparseMatrix`, and the mother class, `Matrix`.

## Examples

```
getClass("nMatrix")

L3 <- Matrix(upper.tri(diag(3)))
L3 # an "ltCMatrix"
as(L3, "nMatrix") # -> ntC*

similar, not using Matrix()
as(upper.tri(diag(3)), "nMatrix") # currently "ngTMatrix"
```

nnzero

*The Number of Non-Zero Values of a Matrix*

## Description

Returns the number of non-zero values of a numeric-like R object, and in particular an object `x` inheriting from class `Matrix`.

## Usage

```
nnzero(x, na.counted = NA)
```

## Arguments

`x` an R object, typically inheriting from class `Matrix` or `numeric`.

`na.counted` a `logical` describing how `NA`s should be counted. There are three possible settings for `na.counted`:

- TRUE** `NA`s are counted as non-zero (since “they are not zero”).
- NA** (default) the result will be `NA` if there are `NA`’s in `x` (since “`NA`’s are not known, i.e., *may be* zero”).
- FALSE** `NA`s are *omitted* from `x` before the non-zero entries are counted.

For sparse matrices, you may often want to use `na.counted = TRUE`.

## Value

the number of non zero entries in `x` (typically `integer`).

Note that for a *symmetric* sparse matrix `S` (i.e., inheriting from class `symmetricMatrix`), `nnzero(S)` is typically *twice* the `length(S@x)`.

## Methods

`signature(x = "ANY")` the default method for non-`Matrix` class objects, simply counts the number 0s in `x`, counting `NA`’s depending on the `na.counted` argument, see above.

`signature(x = "denseMatrix")` conceptually the same as for traditional `matrix` objects, care has to be taken for `"symmetricMatrix"` objects.

`signature(x = "diagonalMatrix")`, **and** `signature(x = "indMatrix")` fast simple methods for these special `"sparseMatrix"` classes.

`signature(x = "sparseMatrix")` typically, the most interesting method, also carefully taking `"symmetricMatrix"` objects into account.

See Also

The `Matrix` class also has a `length` method; typically, `length(M)` is much larger than `nnzero(M)` for a sparse matrix `M`, and the latter is a better indication of the *size* of `M`.  
`drop0`, `zapsmall`.

Examples

```
m <- Matrix(0+1:28, nrow = 4)
m[-3,c(2,4:5,7)] <- m[3, 1:4] <- m[1:3, 6] <- 0
(mT <- as(m, "dgTMatrix"))
nnzero(mT)
(S <- crossprod(mT))
nnzero(S)
str(S) # slots are smaller than nnzero()
stopifnot(nnzero(S) == sum(as.matrix(S) != 0)) # failed earlier

data(KNex)
M <- KNex$mm
class(M)
dim(M)
length(M); stopifnot(length(M) == prod(dim(M)))
nnzero(M) # more relevant than length
the above are also visible from
str(M)
```

---

|      |                     |
|------|---------------------|
| norm | <i>Matrix Norms</i> |
|------|---------------------|

---

Description

Computes a matrix norm of `x`, using Lapack for dense matrices. The norm can be the one ("O", or "1") norm, the infinity ("I") norm, the Frobenius ("F") norm, the maximum modulus ("M") among elements of a matrix, or the spectral norm or 2-norm ("2"), as determined by the value of `type`.

Usage

```
norm(x, type, ...)
```

Arguments

|                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>    | a real or complex matrix.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>type</code> | A character indicating the type of norm desired.<br>"O", "o" or "1" specifies the one norm, (maximum absolute column sum);<br>"I" or "i" specifies the infinity norm (maximum absolute row sum);<br>"F" or "f" specifies the Frobenius norm (the Euclidean norm of <code>x</code> treated as if it were a vector);<br>"M" or "m" specifies the maximum modulus of all the elements in <code>x</code> ; and<br>"2" specifies the “spectral norm” or 2-norm, which is the largest singular value ( <a href="#">svd</a> ) of <code>x</code> .<br>The default is "O". Only the first character of <code>type[1]</code> is used. |
| <code>...</code>  | further arguments passed to or from other methods.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

## Details

For dense matrices, the methods eventually call the Lapack functions `dlange`, `dlansy`, `dlantr`, `zlange`, `zlansy`, and `zlantr`.

## Value

A numeric value of class `"norm"`, representing the quantity chosen according to `type`.

## References

Anderson, E., et al. (1994). *LAPACK User's Guide*, 2nd edition, SIAM, Philadelphia.

The `norm()` function from R's **base** package.

## Examples

```
x <- Hilbert(9)
norm(x) # = "O" = "1"
stopifnot(identical(norm(x), norm(x, "1")))
norm(x, "I") # the same, because 'x' is symmetric

allnorms <- function(d) vapply(c("1", "I", "F", "M", "2"),
 norm, x = d, double(1))

allnorms(x)
allnorms(Hilbert(10))

i <- c(1,3:8); j <- c(2,9,6:10); x <- 7 * (1:7)
A <- sparseMatrix(i, j, x = x) ## 8 x 10 "dgCMatrix"
(sA <- sparseMatrix(i, j, x = x, symmetric = TRUE)) ## 10 x 10 "dsCMatrix"
(tA <- sparseMatrix(i, j, x = x, triangular = TRUE)) ## 10 x 10 "dtCMatrix"
(allnorms(A) -> nA)
allnorms(sA)
allnorms(tA)
stopifnot(all.equal(nA, allnorms(as(A, "matrix"))),
 all.equal(nA, allnorms(tA))) # because tA == rbind(A, 0, 0)
A. <- A; A.[1,3] <- NA
stopifnot(is.na(allnorms(A.))) # gave error
```

---

nsparseMatrix-classes

*Sparse "pattern" Matrices*

---

## Description

The `nsparseMatrix` class is a virtual class of sparse “*pattern*” matrices, i.e., binary matrices conceptually with TRUE/FALSE entries. Only the positions of the elements that are TRUE are stored.

These can be stored in the “triplet” form ([TsparseMatrix](#), subclasses `ngTMatrix`, `nsTMatrix`, and `ntTMatrix` which really contain pairs, not triplets) or in compressed column-oriented form (class [CsparseMatrix](#), subclasses `ngCMatrix`, `nsCMatrix`, and `ntCMatrix`) or—rarely—in compressed row-oriented form (class [RsparseMatrix](#), subclasses `ngRMatrix`, `nsRMatrix`, and `ntRMatrix`). The second letter in the name of these non-virtual classes indicates general, symmetric, or triangular.

### Objects from the Class

Objects can be created by calls of the form `new("ngCMatrix", ...)` and so on. More frequently objects are created by coercion of a numeric sparse matrix to the pattern form for use in the symbolic analysis phase of an algorithm involving sparse matrices. Such algorithms often involve two phases: a symbolic phase wherein the positions of the non-zeros in the result are determined and a numeric phase wherein the actual results are calculated. During the symbolic phase only the positions of the non-zero elements in any operands are of interest, hence numeric sparse matrices can be treated as sparse pattern matrices.

### Slots

- uplo:** Object of class "character". Must be either "U", for upper triangular, and "L", for lower triangular. Present in the triangular and symmetric classes but not in the general class.
- diag:** Object of class "character". Must be either "U", for unit triangular (diagonal is all ones), or "N" for non-unit. The implicit diagonal elements are not explicitly stored when `diag` is "U". Present in the triangular classes only.
- p:** Object of class "integer" of pointers, one for each column (row), to the initial (zero-based) index of elements in the column. Present in compressed column-oriented and compressed row-oriented forms only.
- i:** Object of class "integer" of length `nnzero` (number of non-zero elements). These are the row numbers for each TRUE element in the matrix. All other elements are FALSE. Present in triplet and compressed column-oriented forms only.
- j:** Object of class "integer" of length `nnzero` (number of non-zero elements). These are the column numbers for each TRUE element in the matrix. All other elements are FALSE. Present in triplet and compressed column-oriented forms only.
- Dim:** Object of class "integer" - the dimensions of the matrix.

### Methods

**coerce** signature (`from = "dgCMatrix"`, `to = "ngCMatrix"`), and many similar ones; typically you should coerce to "nsparseMatrix" (or "nMatrix"). Note that coercion to a sparse pattern matrix records all the potential non-zero entries, i.e., explicit (“non-structural”) zeroes are coerced to TRUE, not FALSE, see the example.

**t** signature (`x = "ngCMatrix"`): returns the transpose of `x`

**which** signature (`x = "lsparseMatrix"`), semantically equivalent to **base** function `which(x, arr.ind)`; for details, see the [lMatrix](#) class documentation.

### See Also

the class [dgCMatrix](#)

## Examples

```
(m <- Matrix(c(0,0,2:0), 3,5, dimnames=list(LETTERS[1:3],NULL)))
``extract the nonzero-pattern of (m) into an nMatrix'':
nm <- as(m, "nsparseMatrix") ## -> will be a "ngCMatrix"
str(nm) # no 'x' slot
nnm <- !nm # no longer sparse
(nnm <- as(nnm, "sparseMatrix"))# "lgCMatrix"
consistency check:
stopifnot(xor(as(nm, "matrix"),
 as(nnm, "matrix"))

low-level way of adding "non-structural zeros" :
nnm@x[2:4] <- c(FALSE,NA,NA)
nnm
as(nnm, "nMatrix") # NAs *and* non-structural 0 |---> 'TRUE'

data(KNex)
nmm <- as(KNex $ mm, "ngCMatrix")
str(xlx <- crossprod(nmm))# "nsCMatrix"
stopifnot(isSymmetric(xlx))
image(xlx, main=paste("crossprod(nmm) : Sparse", class(xlx)))
```

---

nsyMatrix-class

*Symmetric Dense Nonzero-Pattern Matrices*

---

## Description

The "nsyMatrix" class is the class of symmetric, dense nonzero-pattern matrices in non-packed storage and "nspMatrix" is the class of these in packed storage. Only the upper triangle or the lower triangle is stored.

## Objects from the Class

Objects can be created by calls of the form `new("nsyMatrix", ...)`.

## Slots

**uplo:** Object of class "character". Must be either "U", for upper triangular, and "L", for lower triangular.

**x:** Object of class "logical". The logical values that constitute the matrix, stored in column-major order.

**Dim,Dimnames:** The dimension (a length-2 "integer") and corresponding names (or NULL), see the [Matrix](#) class.

**factors:** Object of class "list". A named list of factorizations that have been computed for the matrix.

## Extends

"nsyMatrix" extends class "ngeMatrix", directly, whereas

"nspMatrix" extends class "ndenseMatrix", directly.

Both extend class "symmetricMatrix", directly, and class "Matrix" and others, *indirectly*, use `showClass("nsyMatrix")`, e.g., for details.

## Methods

Currently, mainly `t()` and coercion methods (for `as(.)`; use, e.g., `showMethods(class="dsyMatrix")` for details.

## See Also

`ngeMatrix`, `Matrix`, `t`

## Examples

```
(s0 <- new("nsyMatrix"))

(M2 <- Matrix(c(TRUE, NA,FALSE,FALSE), 2,2)) # logical dense (ltr)
(sM <- M2 & t(M2)) # "lge"
class(sM <- as(sM, "nMatrix")) # -> "nge"
(sM <- as(sM, "nsyMatrix")) # -> "nsy"
str (sM <- as(sM, "nspMatrix")) # -> "nsp": packed symmetric
```

---

|                 |                                          |
|-----------------|------------------------------------------|
| ntrMatrix-class | <i>Triangular Dense Logical Matrices</i> |
|-----------------|------------------------------------------|

---

## Description

The "ntrMatrix" class is the class of triangular, dense, logical matrices in nonpacked storage. The "ntpMatrix" class is the same except in packed storage.

## Slots

**x:** Object of class "logical". The logical values that constitute the matrix, stored in column-major order.

**uplo:** Object of class "character". Must be either "U", for upper triangular, and "L", for lower triangular.

**diag:** Object of class "character". Must be either "U", for unit triangular (diagonal is all ones), or "N"; see `triangularMatrix`.

**Dim,Dimnames:** The dimension (a length-2 "integer") and corresponding names (or NULL), see the `Matrix` class.

**factors:** Object of class "list". A named list of factorizations that have been computed for the matrix.

## Extends

"ntrMatrix" extends class "ngeMatrix", directly, whereas  
 "ntpMatrix" extends class "ndenseMatrix", directly.

Both extend Class "triangularMatrix", directly, and class "denseMatrix", "lMatrix" and others, *indirectly*, use `showClass("nsyMatrix")`, e.g., for details.

## Methods

Currently, mainly `t()` and coercion methods (for `as(.)`; use, e.g., `showMethods(class="nsyMatrix")` for details.

**See Also**

Classes [ngeMatrix](#), [Matrix](#); function [t](#)

**Examples**

```
showClass("ntrMatrix")

str(new("ntpMatrix"))
(nutr <- as(upper.tri(matrix(,4,4)), "ntrMatrix"))
str(nutp <- as(nutr, "ntpMatrix"))# packed matrix: only 10 = (4+1)*4/2 entries
!nutp ## the logical negation (is *not* logical triangular !)
but this one is:
stopifnot(all.equal(nutp, as(!!nutp, "ntpMatrix")))
```

---

number-class

*Class "number" of Possibly Complex Numbers*

---

**Description**

The class "number" is a virtual class, currently used for vectors of eigen values which can be "numeric" or "complex".

It is a simple class union ([setClassUnion](#)) of "numeric" and "complex".

**Objects from the Class**

Since it is a virtual Class, no objects may be created from it.

**Examples**

```
showClass("number")
stopifnot(is(1i, "number"), is(pi, "number"), is(1:3, "number"))
```

---

pMatrix-class

*Permutation matrices*

---

**Description**

The "pMatrix" class is the class of permutation matrices, stored as 1-based integer permutation vectors.

Matrix (vector) multiplication with permutation matrices is equivalent to row or column permutation, and is implemented that way in the **Matrix** package, see the 'Details' below.

## Details

Matrix multiplication with permutation matrices is equivalent to row or column permutation. Here are the four different cases for an arbitrary matrix  $M$  and a permutation matrix  $P$  (where we assume matching dimensions):

$$\begin{aligned}
 MP &= M \%*\% P &&= M[, i(p)] \\
 PM &= P \%*\% M &&= M[p, ] \\
 P'M &= \text{crossprod}(P, M) (\approx t(P) \%*\% M) &&= M[i(p), ] \\
 MP' &= \text{tcrossprod}(M, P) (\approx M \%*\% t(P)) &&= M[, p]
 \end{aligned}$$

where  $p$  is the “permutation vector” corresponding to the permutation matrix  $P$  (see first note), and  $i(p)$  is short for `invPerm(p)`.

Also one could argue that these are really only two cases if you take into account that inversion (`solve`) and transposition (`t`) are the same for permutation matrices  $P$ .

## Objects from the Class

Objects can be created by calls of the form `new("pMatrix", ...)` or by coercion from an integer permutation vector, see below.

## Slots

**perm:** An integer, 1-based permutation vector, i.e. an integer vector of length `Dim[1]` whose elements form a permutation of `1:Dim[1]`.

**Dim:** Object of class "integer". The dimensions of the matrix which must be a two-element vector of equal, non-negative integers.

**Dimnames:** list of length two; each component containing NULL or a `character` vector length equal the corresponding `Dim` element.

## Extends

Class "`indMatrix`", directly.

## Methods

`%*%` signature(`x` = "matrix", `y` = "pMatrix") and other signatures (use `showMethods("%*%", class="pMatrix")`): ...

**coerce** signature(`from` = "integer", `to` = "pMatrix"): This enables typical "pMatrix" construction, given a permutation vector of `1:n`, see the first example.

**coerce** signature(`from` = "numeric", `to` = "pMatrix"): a user convenience, to allow `as(perm, "pMatrix")` for numeric `perm` with integer values.

**coerce** signature(`from` = "pMatrix", `to` = "matrix"): coercion to a traditional FALSE/TRUE `matrix` of `mode` logical. (in earlier version of **Matrix**, it resulted in a 0/1-integer matrix; logical makes slightly more sense, corresponding better to the “natural” `sparseMatrix` counterpart, "`ngTMatrix`".)

**coerce** signature(`from` = "pMatrix", `to` = "ngTMatrix"): coercion to sparse logical matrix of class `ngTMatrix`.

**determinant** signature(`x` = "pMatrix", `logarithm` = "logical"): Since permutation matrices are orthogonal, the determinant must be +1 or -1. In fact, it is exactly the *sign of the permutation*.

**solve** signature (a = "pMatrix", b = "missing"): return the inverse permutation matrix; note that solve(P) is identical to t(P) for permutation matrices. See [solve-methods](#) for other methods.

**t** signature (x = "pMatrix"): return the transpose of the permutation matrix (which is also the inverse of the permutation matrix).

### Note

For every permutation matrix  $P$ , there is a corresponding permutation vector  $p$  (of indices, 1:n), and these are related by

```
P <- as(p, "pMatrix")
p <- P@perm
```

see also the ‘Examples’.

“Row-indexing” a permutation matrix typically returns an "indMatrix". See ["indMatrix"](#) for all other subsetting/indexing and subassignment ( $A[. .] <- v$ ) operations.

### See Also

[invPerm](#)(p) computes the inverse permutation of an integer (index) vector p.

### Examples

```
(pml <- as(as.integer(c(2,3,1)), "pMatrix"))
t(pml) # is the same as
solve(pml)
pml %*% t(pml) # check that the transpose is the inverse
stopifnot(all(diag(3) == as(pml %*% t(pml), "matrix")),
 is.logical(as(pml, "matrix")))

set.seed(11)
random permutation matrix :
(p10 <- as(sample(10), "pMatrix"))

Permute rows / columns of a numeric matrix :
(mm <- round(array(rnorm(3 * 3), c(3, 3)), 2))
mm %*% pml
pml %*% mm
try(as(as.integer(c(3,3,1)), "pMatrix")) # Error: not a permutation

as(pml, "ngTMatrix")
p10[1:7, 1:4] # gives an "ngTMatrix" (most economic!)

row-indexing of a <pMatrix> keeps it as an <indMatrix>:
p10[1:3,]
```

---

|               |                                                  |
|---------------|--------------------------------------------------|
| printSpMatrix | <i>Format and Print Sparse Matrices Flexibly</i> |
|---------------|--------------------------------------------------|

---

## Description

Format and print sparse matrices flexibly. These are the “workhorses” used by the `format`, `show` and `print` methods for sparse matrices. If `x` is large, `printSpMatrix2(x)` calls `printSpMatrix()` twice, namely, for the first and the last few rows, suppressing those in between, and also suppresses columns when `x` is too wide.

`printSpMatrix()` basically prints the result of `formatSpMatrix()`.

## Usage

```
formatSpMatrix(x, digits = NULL, maxp = 1e9,
 cld = getClassDef(class(x)), zero.print = ".",
 col.names, note.dropping.colnames = TRUE, uniDiag = TRUE,
 align = c("fancy", "right"))

printSpMatrix(x, digits = NULL, maxp = max(100L, getOption("max.print")),
 cld = getClassDef(class(x)),
 zero.print = ".", col.names, note.dropping.colnames = TRUE,
 uniDiag = TRUE, col.trailer = "",
 align = c("fancy", "right"))

printSpMatrix2(x, digits = NULL, maxp = max(100L, getOption("max.print")),
 zero.print = ".", col.names, note.dropping.colnames = TRUE,
 uniDiag = TRUE, suppRows = NULL, suppCols = NULL,
 col.trailer = if(suppCols) "....." else "",
 align = c("fancy", "right"),
 width = getOption("width"), fitWidth = TRUE)
```

## Arguments

|                         |                                                                                                                                                                                                                                                                                                                                  |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>          | an R object inheriting from class <code>sparseMatrix</code> .                                                                                                                                                                                                                                                                    |
| <code>digits</code>     | significant digits to use for printing, see <code>print.default</code> , the default, <code>NULL</code> , corresponds to using <code>getOption("digits")</code> .                                                                                                                                                                |
| <code>maxp</code>       | integer, default from <code>options(max.print)</code> , influences how many entries of large matrices are printed at all. Typically should not be smaller than around 1000; values smaller than 100 are silently “rounded up” to 100.                                                                                            |
| <code>cld</code>        | the class definition of <code>x</code> ; must be equivalent to <code>getClassDef(class(x))</code> and exists mainly for possible speedup.                                                                                                                                                                                        |
| <code>zero.print</code> | character which should be printed for <i>structural</i> zeroes. The default <code>"."</code> may occasionally be replaced by <code>" "</code> (blank); using <code>"0"</code> would look almost like <code>print()</code> ing of non-sparse matrices.                                                                            |
| <code>col.names</code>  | logical or string specifying if and how column names of <code>x</code> should be printed, possibly abbreviated. The default is taken from <code>options("sparse.colnames")</code> if that is set, otherwise <code>FALSE</code> unless there are less than ten columns. When <code>TRUE</code> the full column names are printed. |

|                                     |                                                                                                                                                                                                                                                                                                                                                                                                   |
|-------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                     | When <code>col.names</code> is a string beginning with "abb" or "sub" and ending with an integer <code>n</code> (i.e., of the form "abb...<n>"), the column names are <code>abbreviate()</code> d or <code>substring()</code> ed to (target) length <code>n</code> , see the examples.                                                                                                            |
| <code>note.dropping.colnames</code> | logical specifying, when <code>col.names</code> is FALSE if the dropping of the column names should be noted, TRUE by default.                                                                                                                                                                                                                                                                    |
| <code>uniDiag</code>                | logical indicating if the diagonal entries of a sparse unit triangular or unit-diagonal matrix should be formatted as "I" instead of "1" (to emphasize that the 1's are "structural").                                                                                                                                                                                                            |
| <code>col.trailer</code>            | a string to be appended to the right of each column; this is typically made use of by <code>show(&lt;sparseMatrix&gt;)</code> only, when suppressing columns.                                                                                                                                                                                                                                     |
| <code>suppRows, suppCols</code>     | logicals or NULL, for <code>printSpMatrix2()</code> specifying if rows or columns should be suppressed in printing. If NULL, sensible defaults are determined from <code>dim(x)</code> and <code>options(c("width", "max.print"))</code> . Setting both to FALSE may be a very bad idea.                                                                                                          |
| <code>align</code>                  | a string specifying how the <code>zero.print</code> codes should be aligned, i.e., padded as strings. The default, "fancy", takes some effort to align the typical <code>zero.print = "."</code> with the position of 0, i.e., the first decimal (one left of decimal point) of the numbers printed, whereas <code>align = "right"</code> just makes use of <code>print(*, right = TRUE)</code> . |
| <code>width</code>                  | number, a positive integer, indicating the approximately desired (line) width of the output, see also <code>fitWidth</code> .                                                                                                                                                                                                                                                                     |
| <code>fitWidth</code>               | logical indicating if some effort should be made to match the desired <code>width</code> or temporarily enlarge that if deemed necessary.                                                                                                                                                                                                                                                         |

## Details

**formatSpMatrix:** If `x` is large, only the first rows making up the approximately first `maxp` entries is used, otherwise all of `x`. `.formatSparseSimple()` is applied to (a dense version of) the matrix. Then, `formatSparseM` is used, unless in trivial cases or for sparse matrices without `x` slot.

## Value

`formatSpMatrix()`  
returns a character matrix with possibly empty column names, depending on `col.names` etc, see above.

`printSpMatrix*()`  
return `x` *invisibly*, see `invisible`.

## Author(s)

Martin Maechler

## See Also

the virtual class `sparseMatrix` and the classes extending it; maybe `sparseMatrix` or `spMatrix` as simple constructors of such matrices.

The underlying utilities `formatSparseM` and `.formatSparseSimple()` (on the same page).

## Examples

```
f1 <- gl(5, 3, labels = LETTERS[1:5])
X <- as(f1, "sparseMatrix")
X ## <==> show(X) <==> print(X)
t(X) ## shows column names, since only 5 columns

X2 <- as(gl(12, 3, labels = paste(LETTERS[1:12], "c", sep=".")),
 "sparseMatrix")
X2
less nice, but possible:
print(X2, col.names = TRUE) # use [,1] [,2] .. => does not fit

Possibilities with column names printing:
t(X2) # suppressing column names
print(t(X2), col.names=TRUE)
print(t(X2), zero.print = "", col.names="abbr. 1")
print(t(X2), zero.print = "-", col.names="substring 2")
```

qr-methods

---

*QR Decomposition – S4 Methods and Generic*

---

## Description

The **Matrix** package provides methods for the QR decomposition of special classes of matrices. There is a generic function which uses `qr` as default, but methods defined in this package can take extra arguments. In particular there is an option for determining a fill-reducing permutation of the columns of a sparse, rectangular matrix.

## Usage

```
qr(x, ...)
qrR(qr, complete=FALSE, backPermute=TRUE, row.names = TRUE)
```

## Arguments

|                          |                                                                                                                                                                                         |
|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>           | a numeric or complex matrix whose QR decomposition is to be computed. Logical matrices are coerced to numeric.                                                                          |
| <code>qr</code>          | a QR decomposition of the type computed by <code>qr</code> .                                                                                                                            |
| <code>complete</code>    | logical indicating whether the <b>R</b> matrix is to be completed by binding zero-value rows beneath the square upper triangle.                                                         |
| <code>backPermute</code> | logical indicating if the rows of the <b>R</b> matrix should be back permuted such that <code>qrR()</code> 's result can be used directly to reconstruct the original matrix <b>X</b> . |
| <code>row.names</code>   | logical indicating if <code>rownames</code> should be propagated to the result.                                                                                                         |
| <code>...</code>         | further arguments passed to or from other methods                                                                                                                                       |

## Methods

**x = "dgCMatrix"** QR decomposition of a general sparse double-precision matrix with `nrow(x) >= ncol(x)`. Returns an object of class `"sparseQR"`.

**x = "sparseMatrix"** works via `"dgCMatrix"`.

## See Also

`qr`; then, the class documentations, mainly `sparseQR`, and also `dgCMatrix`.

## Examples

```
##----- example of pivoting -- from base' qraux.Rd -----
X <- cbind(int = 1,
 b1=rep(1:0, each=3), b2=rep(0:1, each=3),
 c1=rep(c(1,0,0), 2), c2=rep(c(0,1,0), 2), c3=rep(c(0,0,1),2))
rownames(X) <- paste0("r", seq_len(nrow(X)))
dnX <- dimnames(X)
bX <- X # [b]ase version of X
X <- as(bX, "sparseMatrix")
X # is singular, columns "b2" and "c3" are "extra"
stopifnot(identical(dimnames(X), dnX)) # some versions changed X's dimnames!
c(rankMatrix(X)) # = 4 (not 6)
m <- function(.) as(., "matrix")

##----- regular case -----
Xr <- X[, -c(3,6)] # the "regular" (non-singular) version of X
stopifnot(rankMatrix(Xr) == ncol(Xr))
Y <- cbind(y <- setNames(1:6, paste0("y", 1:6)))
regular case:
qXr <- qr(Xr)
qxr <- qr(m(Xr))
qxrLA <- qr(m(Xr), LAPACK=TRUE) # => qr.fitted(), qr.resid() not supported
qcfXy <- qr.coef(qXr, y) # vector
qcfXY <- qr.coef(qXr, Y) # 4x1 dgeMatrix
cf <- c(int=6, b1=-3, c1=-2, c2=-1)
doExtras <- interactive() || nzchar(Sys.getenv("R_MATRIX_CHECK_EXTRA")) ||
 identical("true", unname(Sys.getenv("R_PKG_CHECKING_doExtras")))
tolE <- if(doExtras) 1e-15 else 1e-13
stopifnot(
 all.equal(qr.coef(qxr, y), cf, tol=tolE)
 , getRversion() <= "3.4.1" ||
 all.equal(qr.coef(qxrLA, y), cf, tol=tolE)
 , all.equal(qr.coef(qxr, Y), m(cf), tol=tolE)
 , all.equal(qcfXy, cf, tol=tolE)
 , all.equal(m(qcfXY), m(cf), tol=tolE)
 , all.equal(y, qr.fitted(qxr, y), tol=2*tolE)
 , all.equal(y, qr.fitted(qXr, y), tol=2*tolE)
 , all.equal(m(qr.fitted(qXr, Y)), qr.fitted(qxr, Y), tol=tolE)
 , all.equal(qr.resid(qXr, y), qr.resid(qxr, y), tol=tolE)
 , all.equal(m(qr.resid(qXr, Y)), qr.resid(qxr, Y), tol=tolE)
)

##----- rank-deficient ("singular") case -----

(qX <- qr(X)) # both @p and @q are non-trivial permutations
qx <- qr(m(X)) ; str(qx) # $pivot is non-trivial, too

drop0(R. <- qr.R(qX), tol=tolE) # columns *permuted*: c3 b1 ..
Q. <- qr.Q(qX)
qI <- sort.list(qX@q) # the inverse 'q' permutation
(X. <- drop0(Q. %*% R., qI, tol=tolE)) ## just = X, incl. correct colnames
stopifnot(all(X - X.) < 8*.Machine$double.eps,
```

```

qrR(.) returns R already "back permuted" (as with qI):
identical(R[, qI], qrR(qX)))

##
In this sense, classical qr.coef() is fine:
cfqx <- qr.coef(qx, y) # quite different from
nna <- !is.na(cfqx)
stopifnot(all.equal(unname(qr.fitted(qx,y)),
 as.numeric(X[,nna] %*% cfqx[nna])))
FIXME: do these make *any* sense? --- should give warnings !
qr.coef(qX, y)
qr.coef(qX, Y)
rm(m)

```

rankMatrix

*Rank of a Matrix*

## Description

Compute ‘the’ matrix rank, a well-defined functional in theory(\*), somewhat ambiguous in practice. We provide several methods, the default corresponding to Matlab’s definition.

(\*) The rank of a  $n \times m$  matrix  $A$ ,  $rk(A)$ , is the maximal number of linearly independent columns (or rows); hence  $rk(A) \leq \min(n, m)$ .

## Usage

```

rankMatrix(x, tol = NULL,
 method = c("tolNorm2", "qr.R", "qrLINPACK", "qr",
 "useGrad", "maybeGrad"),
 sval = svd(x, 0, 0)$d, warn.t = TRUE, warn.qr = TRUE)

qr2rankMatrix(qr, tol = NULL, isBqr = is.qr(qr), do.warn = TRUE)

```

## Arguments

|        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x      | numeric matrix, of dimension $n \times m$ , say.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| tol    | nonnegative number specifying a (relative, “scalefree”) tolerance for testing of “practically zero” with specific meaning depending on method; by default, $\max(\dim(x)) * .Machine\$double.eps$ is according to Matlab’s default (for its only method which is our <code>method="tolNorm2"</code> ).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| method | <p>a character string specifying the computational method for the rank, can be abbreviated:</p> <p><b>"tolNorm2"</b>: the number of singular values <math>\geq \text{tol} * \max(\text{sval})</math>;</p> <p><b>"qrLINPACK"</b>: for a dense matrix, this is the rank of <code>qr(x, tol, LAPACK=FALSE)</code> (which is <code>qr(...)\$rank</code>); This ("qr*", dense) version used to be <i>the</i> recommended way to compute a matrix rank for a while in the past. For sparse x, this is equivalent to <code>"qr.R"</code>.</p> <p><b>"qr.R"</b>: this is the rank of triangular matrix <math>R</math>, where <code>qr()</code> uses LAPACK or a "sparseQR" method (see <a href="#">qr-methods</a>) to compute the decomposition <math>QR</math>. The rank of <math>R</math> is then defined as the number of “non-zero” diagonal entries <math>d_i</math> of <math>R</math>, and “non-zero”s fulfill <math> d_i  \geq \text{tol} \cdot \max( d_i )</math>.</p> |

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                      | <p>"qr": is for back compatibility; for dense <math>x</math>, it corresponds to "qrLAPACK", whereas for sparse <math>x</math>, it uses "qr.R".</p> <p>For all the "qr*" methods, singular values <code>sval</code> are not used, which may be crucially important for a large sparse matrix <math>x</math>, as in that case, when <code>sval</code> is not specified, the default, computing <code>svd()</code> currently coerces <math>x</math> to a dense matrix.</p> <p>"useGrad": considering the "gradient" of the (decreasing) singular values, the index of the <i>smallest</i> gap.</p> <p>"maybeGrad": choosing method "useGrad" only when that seems <i>reasonable</i>; otherwise using "tolNorm2".</p> |
| <code>sval</code>    | numeric vector of non-increasing singular values of $x$ ; typically unspecified and computed from $x$ when needed, i.e., unless <code>method = "qr"</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>warn.t</code>  | logical indicating if <code>rankMatrix()</code> should warn when it needs <code>t(x)</code> instead of $x$ . Currently, for <code>method = "qr"</code> only, gives a warning by default because the caller often could have passed <code>t(x)</code> directly, more efficiently.                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <code>warn.qr</code> | in the $QR$ cases (i.e., if <code>method</code> starts with "qr"), <code>rankMatrix()</code> calls <code>qr2rankMatrix(..., do.warn = warn.qr)</code> , see below.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>qr</code>      | an R object resulting from <code>qr(x, ...)</code> , i.e., typically inheriting from class "qr" or "sparseQR".                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>isBqr</code>   | logical indicating if <code>qr</code> is resulting from <code>base qr()</code> . (Otherwise, it is typically from <b>Matrix</b> package <code>sparse qr</code> .)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <code>do.warn</code> | logical; if true, warn about non-finite (or in the <code>sparseQR</code> case negative) diagonal entries in the $R$ matrix of the $QR$ decomposition. Do not change lightly!                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

## Details

`qr2rankMatrix()` is typically called from `rankMatrix()` for the "qr"\* methods, but can be used directly - much more efficiently in case the  $qr$ -decomposition is available anyway.

## Value

If  $x$  is a matrix of all 0 (or of zero dimension), the rank is zero; otherwise, typically a positive integer in `1:min(dim(x))` with attributes detailing the method used.

There are rare cases where the sparse  $QR$  decomposition "fails" in so far as the diagonal entries of  $R$ , the  $d_i$  (see above), end with non-finite, typically NaN entries. Then, a warning is signalled (unless `warn.qr / do.warn` is not true) and NA (specifically, `NA_integer_`) is returned.

## Note

For large sparse matrices  $x$ , unless you can specify `sval` yourself, currently `method = "qr"` may be the only feasible one, as the others need `sval` and call `svd()` which currently coerces  $x$  to a `denseMatrix` which may be very slow or impossible, depending on the matrix dimensions.

Note that in the case of sparse  $x$ , `method = "qr"`, all non-strictly zero diagonal entries  $d_i$  where counted, up to including **Matrix** version 1.1-0, i.e., that method implicitly used `tol = 0`, see also the `set.seed(42)` example below.

## Author(s)

Martin Maechler; for the "\*Grad" methods building on suggestions by Ravi Varadhan.

**Examples**

```
rankMatrix(cbind(1, 0, 1:3)) # 2

(meths <- eval(formals(rankMatrix)$method))

a "border" case:
H12 <- Hilbert(12)
rankMatrix(H12, tol = 1e-20) # 12; but 11 with default method & tol.
sapply(meths, function(.m.) rankMatrix(H12, method = .m.))
tolNorm2 qr.R qrLINPACK qr useGrad maybeGrad
11 11 12 12 11 11
The meaning of 'tol' for method="qrLINPACK" and *dense* x is not entirely "scale free"
rMQL <- function(ex, M) rankMatrix(M, method="qrLINPACK", tol = 10^-ex)
rMQR <- function(ex, M) rankMatrix(M, method="qr.R", tol = 10^-ex)
sapply(5:15, rMQL, M = H12) # result is platform dependent
7 7 8 10 10 11 11 11 12 12 12 {x86_64}
sapply(5:15, rMQL, M = 1000 * H12) # not identical unfortunately
7 7 8 10 11 11 12 12 12 12 12
sapply(5:15, rMQR, M = H12)
5 6 7 8 8 9 9 10 10 11 11
sapply(5:15, rMQR, M = 1000 * H12) # the *same*

"sparse" case:
M15 <- kronecker(diag(x=c(100,1,10)), Hilbert(5))
sapply(meths, function(.m.) rankMatrix(M15, method = .m.))
#--> all 15, but 'useGrad' has 14.
sapply(meths, function(.m.) rankMatrix(M15, method = .m., tol = 1e-7)) # all 14

"large" sparse
n <- 250000; p <- 33; nnz <- 10000
L <- sparseMatrix(i = sample.int(n, nnz, replace=TRUE),
 j = sample.int(p, nnz, replace=TRUE), x = rnorm(nnz))
(st1 <- system.time(r1 <- rankMatrix(L))) # warning+ ~1.5 sec (2013)
(st2 <- system.time(r2 <- rankMatrix(L, method = "qr"))) # considerably faster!
r1[[1]] == print(r2[[1]]) ## --> (33 TRUE)

another sparse-"qr" one, which ``failed'' till 2013-11-23:
set.seed(42)
f1 <- factor(sample(50, 1000, replace=TRUE))
f2 <- factor(sample(50, 1000, replace=TRUE))
f3 <- factor(sample(50, 1000, replace=TRUE))
rbind. <- if(getRversion() < "3.2.0") rBind else rbind
D <- t(do.call(rbind., lapply(list(f1,f2,f3), as, 'sparseMatrix'))))
dim(D); nnzero(D) ## 1000 x 150 // 3000 non-zeros (= 2%)
stopifnot(rankMatrix(D, method='qr') == 148,
 rankMatrix(crossprod(D),method='qr') == 148)

zero matrix has rank 0 :
stopifnot(sapply(meths, function(.m.)
 rankMatrix(matrix(0, 2, 2), method = .m.)) == 0)
```

rcond

*Estimate the Reciprocal Condition Number***Description**

Estimate the reciprocal of the condition number of a matrix.

This is a generic function with several methods, as seen by [showMethods\(rcond\)](#).

**Usage**

```
rcond(x, norm, ...)
```

```
S4 method for signature 'sparseMatrix,character'
rcond(x, norm, useInv=FALSE, ...)
```

**Arguments**

|        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x      | an R object that inherits from the <code>Matrix</code> class.                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| norm   | character string indicating the type of norm to be used in the estimate. The default is "O" for the 1-norm ("O" is equivalent to "1"). For sparse matrices, when <code>useInv=TRUE</code> , <code>norm</code> can be any of the kinds allowed for <a href="#">norm</a> ; otherwise, the other possible value is "I" for the infinity norm, see also <a href="#">norm</a> .                                                                                                                                                                |
| useInv | logical (or "Matrix" containing <a href="#">solve(x)</a> ). If not false, compute the reciprocal condition number as $1/(\ x\  \cdot \ x^{-1}\ )$ , where $x^{-1}$ is the inverse of $x$ , <a href="#">solve(x)</a> .<br>This may be an efficient alternative (only) in situations where <a href="#">solve(x)</a> is fast (or known), e.g., for (very) sparse or triangular matrices.<br>Note that the <i>result</i> may differ depending on <code>useInv</code> , as per default, when it is false, an <i>approximation</i> is computed. |
| ...    | further arguments passed to or from other methods.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

**Value**

An estimate of the reciprocal condition number of `x`.

**BACKGROUND**

The condition number of a regular (square) matrix is the product of the [norm](#) of the matrix and the norm of its inverse (or pseudo-inverse).

More generally, the condition number is defined (also for non-square matrices  $A$ ) as

$$\kappa(A) = \frac{\max_{\|v\|=1} \|Av\|}{\min_{\|v\|=1} \|Av\|}.$$

Whenever `x` is *not* a square matrix, in our method definitions, this is typically computed via `rcond(qr.R(qr(X)), ...)` where  $X$  is `x` or `t(x)`.

The condition number takes on values between 1 and infinity, inclusive, and can be viewed as a factor by which errors in solving linear systems with this matrix as coefficient matrix could be magnified.

`rcond()` computes the *reciprocal* condition number  $1/\kappa$  with values in  $[0, 1]$  and can be viewed as a scaled measure of how close a matrix is to being rank deficient (aka “singular”).

Condition numbers are usually estimated, since exact computation is costly in terms of floating-point operations. An (over) estimate of reciprocal condition number is given, since by doing so overflow is avoided. Matrices are well-conditioned if the reciprocal condition number is near 1 and ill-conditioned if it is near zero.

## References

Golub, G., and Van Loan, C. F. (1989). *Matrix Computations*, 2nd edition, Johns Hopkins, Baltimore.

## See Also

`norm`, `kappa()` from package **base** computes an *approximate* condition number of a “traditional” matrix, even non-square ones, with respect to the  $p = 2$  (Euclidean) `norm`. `solve`.

`condest`, a newer *approximate* estimate of the (1-norm) condition number, particularly efficient for large sparse matrices.

## Examples

```
x <- Matrix(rnorm(9), 3, 3)
rcond(x)
typically "the same" (with more computational effort):
1 / (norm(x) * norm(solve(x)))
rcond(Hilbert(9)) # should be about 9.1e-13

For non-square matrices:
rcond(x1 <- cbind(1,1:10))# 0.05278
rcond(x2 <- cbind(x1, 2:11))# practically 0, since x2 does not have full rank

sparse
(S1 <- Matrix(rbind(0:1,0, diag(3:-2))))
rcond(S1)
m1 <- as(S1, "denseMatrix")
all.equal(rcond(S1), rcond(m1))

wide and sparse
rcond(Matrix(cbind(0, diag(2:-1))))

Large sparse example -----
m <- Matrix(c(3,0:2), 2,2)
M <- bdiag(kronecker(Diagonal(2), m), kronecker(m,m))
36*(iM <- solve(M)) # still sparse
MM <- kronecker(Diagonal(10), kronecker(Diagonal(5),kronecker(m,M)))
dim(M3 <- kronecker(bdiag(M,M),MM)) # 12'800 ^ 2
if(interactive()) ## takes about 2 seconds if you have >= 8 GB RAM
 system.time(r <- rcond(M3))
whereas this is *fast* even though it computes solve(M3)
system.time(r. <- rcond(M3, useInv=TRUE))
if(interactive()) ## the values are not the same
 c(r, r.) # 0.05555 0.013888
for all 4 norms available for sparseMatrix :
cbind(rr <- sapply(c("1","I","F","M"),
 function(N) rcond(M3, norm=N, useInv=TRUE)))
```

|         |                                                |
|---------|------------------------------------------------|
| rep2abI | <i>Replicate Vectors into 'abIndex' Result</i> |
|---------|------------------------------------------------|

---

**Description**

rep2abI(x,times) conceptually computes `rep.int(x,times)` but with an `abIndex` class result.

**Usage**

```
rep2abI(x, times)
```

**Arguments**

|       |                                                    |
|-------|----------------------------------------------------|
| x     | numeric vector                                     |
| times | integer (valued) scalar: the number of repetitions |

**Value**

a vector of `class abIndex`

**See Also**

`rep.int()`, the base function; `abIseq`, `abIndex`.

**Examples**

```
(ab <- rep2abI(2:7, 4))
stopifnot(identical(as(ab, "numeric"),
 rep(2:7, 4)))
```

---

|                 |                                                                          |
|-----------------|--------------------------------------------------------------------------|
| replValue-class | <i>Virtual Class "replValue" - Simple Class for subassignment Values</i> |
|-----------------|--------------------------------------------------------------------------|

---

**Description**

The class "replValue" is a virtual class used for values in signatures for sub-assignment of **Matrix** matrices.

In fact, it is a simple class union (`setClassUnion`) of "numeric" and "logical" (and maybe "complex" in the future).

**Objects from the Class**

Since it is a virtual Class, no objects may be created from it.

**See Also**

`Subassign-methods`, also for examples.

**Examples**

```
showClass("replValue")
```

---

|               |                                                |
|---------------|------------------------------------------------|
| rleDiff-class | Class "rleDiff" of rle(diff(.)) Stored Vectors |
|---------------|------------------------------------------------|

---

## Description

Class "rleDiff" is for compactly storing long vectors which mainly consist of *linear* stretches. For such a vector `x`, `diff(x)` consists of *constant* stretches and is hence well compressable via `rle()`.

## Objects from the Class

Objects can be created by calls of the form `new("rleDiff", ...)`.

Currently experimental, see below.

## Slots

**first:** A single number (of class "numLike", a class union of "numeric" and "logical").

**rle:** Object of class "rle", basically a `list` with components "lengths" and "values", see `rle()`. As this is used to encode potentially huge index vectors, lengths may be of type `double` here.

## Methods

There is a simple `show` method only.

## Note

This is currently an *experimental* auxiliary class for the class `abIndex`, see there.

## See Also

`rle`, `abIndex`.

## Examples

```
showClass("rleDiff")

ab <- c(abIseq(2, 100), abIseq(20, -2))
ab@rleD # is "rleDiff"
```

---

rsparsematrix      *Random Sparse Matrix*

---

## Description

Generate a random sparse matrix efficiently. The default has rounded gaussian non-zero entries, and `rand.x = NULL` generates random pattern matrices, i.e. inheriting from `nsparseMatrix`.

## Usage

```
rsparsematrix(nrow, ncol, density, nnz = round(density * maxE),
 symmetric = FALSE,
 rand.x = function(n) signif(rnorm(n), 2), ...)
```

## Arguments

|                         |                                                                                                                                                                                                                                                                                                                               |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>nrow, ncol</code> | number of rows and columns, i.e., the matrix dimension ( <code>dim</code> ).                                                                                                                                                                                                                                                  |
| <code>density</code>    | optional number in $[0, 1]$ , the density is the proportion of non-zero entries among all matrix entries. If specified it determines the default for <code>nnz</code> , otherwise <code>nnz</code> needs to be specified.                                                                                                     |
| <code>nnz</code>        | number of non-zero entries, for a sparse matrix typically considerably smaller than <code>nrow*ncol</code> . Must be specified if <code>density</code> is not.                                                                                                                                                                |
| <code>symmetric</code>  | logical indicating if result should be a matrix of class <code>symmetricMatrix</code> . Note that in the symmetric case, <code>nnz</code> denotes the number of non zero entries of the upper (or lower) part of the matrix, including the diagonal.                                                                          |
| <code>rand.x</code>     | <code>NULL</code> or the random number generator for the <code>x</code> slot, a <code>function</code> such that <code>rand.x(n)</code> generates a numeric vector of length <code>n</code> . Typical examples are <code>rand.x = rnorm</code> , or <code>rand.x = runif</code> ; the default is nice for didactical purposes. |
| <code>...</code>        | optionally further arguments passed to <code>sparseMatrix()</code> , notably <code>repr</code> .                                                                                                                                                                                                                              |

## Details

The algorithm first samples “encoded”  $(i, j)$ s without replacement, via one dimensional indices, if not symmetric `sample.int(nrow*ncol, nnz)`, then—if `rand.x` is not `NULL`—gets `x <- rand.x(nnz)` and calls `sparseMatrix(i=i, j=j, x=x, ...)`. When `rand.x=NULL`, `sparseMatrix(i=i, j=j, ...)` will return a pattern matrix (i.e., inheriting from `nsparseMatrix`).

## Value

a `sparseMatrix`, say `M` of dimension  $(nrow, ncol)$ , i.e., with `dim(M) == c(nrow, ncol)`, if `symmetric` is not true, with `nzM <- nnzero(M)` fulfilling `nzM <= nnz` and typically, `nzM == nnz`.

## Author(s)

Martin Maechler

**Examples**

```

set.seed(17) # to be reproducible
M <- rsparsematrix(8, 12, nnz = 30) # small example, not very sparse
M
M1 <- rsparsematrix(1000, 20, nnz = 123, rand.x = runif)
summary(M1)

a random *symmetric* Matrix
(S9 <- rsparsematrix(9, 9, nnz = 10, symmetric=TRUE)) # dsCMatrix
nnzero(S9) # ~ 20: as 'nnz' only counts one "triangle"

a random patter*n* aka boolean Matrix (no 'x' slot):
(n7 <- rsparsematrix(5, 12, nnz = 10, rand.x = NULL))

a [T]riplet representation sparseMatrix:
T2 <- rsparsematrix(40, 12, nnz = 99, repr = "T")
head(T2)

```

---

RsparseMatrix-class

*Class "RsparseMatrix" of Sparse Matrices in Column-compressed Form*

---

**Description**

The "RsparseMatrix" class is the virtual class of all sparse matrices coded in sorted compressed row-oriented form. Since it is a virtual class, no objects may be created from it. See `showClass("RsparseMatrix")` for its subclasses.

**Slots**

**j**: Object of class "integer" of length `nnzero` (number of non-zero elements). These are the row numbers for each non-zero element in the matrix.

**p**: Object of class "integer" of pointers, one for each row, to the initial (zero-based) index of elements in the row.

**Dim, Dimnames**: inherited from the superclass, see [sparseMatrix](#).

**Extends**

Class "sparseMatrix", directly. Class "Matrix", by class "sparseMatrix".

**Methods**

Only **few** methods are defined currently on purpose, since we rather use the [CsparseMatrix](#) in **Matrix**. Recently, more methods were added but *beware* that these typically do *not* return "RsparseMatrix" results, but rather *Csparse\** or *Tsparse\** ones.

```

t signature(x = "RsparseMatrix"): ...
coerce signature(from = "RsparseMatrix", to = "CsparseMatrix"): ...
coerce signature(from = "RsparseMatrix", to = "TsparseMatrix"): ...

```

**See Also**

its superclass, [sparseMatrix](#), and, e.g., class [dgRMatrix](#) for the links to other classes.

**Examples**

```
showClass("RsparseMatrix")
```

---

 Schur

---

*Schur Decomposition of a Matrix*

---

**Description**

Computes the Schur decomposition and eigenvalues of a square matrix; see the BACKGROUND information below.

**Usage**

```
Schur(x, vectors, ...)
```

**Arguments**

|                      |                                                                                                                                                                   |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>       | numeric square Matrix (inheriting from class "Matrix") or traditional <a href="#">matrix</a> . Missing values (NAs) are not allowed.                              |
| <code>vectors</code> | logical. When TRUE (the default), the Schur vectors are computed, and the result is a proper <a href="#">MatrixFactorization</a> of class <a href="#">Schur</a> . |
| <code>...</code>     | further arguments passed to or from other methods.                                                                                                                |

**Details**

Based on the Lapack subroutine dgees.

**Value**

If `vectors` are TRUE, as per default: If `x` is a [Matrix](#) an object of class [Schur](#), otherwise, for a traditional [matrix](#) `x`, a [list](#) with components `T`, `Q`, and `EValues`.

If `vectors` are FALSE, a list with components

|                      |                                                                                               |
|----------------------|-----------------------------------------------------------------------------------------------|
| <code>T</code>       | the upper quasi-triangular (square) matrix of the Schur decomposition.                        |
| <code>EValues</code> | the vector of <a href="#">numeric</a> or <a href="#">complex</a> eigen values of $T$ or $A$ . |

**BACKGROUND**

If  $A$  is a square matrix, then  $A = Q T^t (Q)$ , where  $Q$  is orthogonal, and  $T$  is upper block-triangular (nearly triangular with either 1 by 1 or 2 by 2 blocks on the diagonal) where the 2 by 2 blocks correspond to (non-real) complex eigenvalues. The eigenvalues of  $A$  are the same as those of  $T$ , which are easy to compute. The Schur form is used most often for computing non-symmetric eigenvalue decompositions, and for computing functions of matrices such as matrix exponentials.

**References**

Anderson, E., et al. (1994). *LAPACK User's Guide*, 2nd edition, SIAM, Philadelphia.

## Examples

```
Schur(Hilbert(9)) # Schur factorization (real eigenvalues)

(A <- Matrix(round(rnorm(5*5, sd = 100)), nrow = 5))
(Sch.A <- Schur(A))

eTA <- eigen(Sch.A@T)
str(SchA <- Schur(A, vectors=FALSE)) # no 'T' ==> simple list
stopifnot(all.equal(eTA$values, eigen(A)$values, tolerance = 1e-13),
 all.equal(eTA$values,
 local({z <- Sch.A@EValues
 z[order(Mod(z), decreasing=TRUE)]}), tolerance = 1e-13),
 identical(SchA$T, Sch.A@T),
 identical(SchA$EValues, Sch.A@EValues))

For the faint of heart, we provide Schur() also for traditional matrices:

a.m <- function(M) unname(as(M, "matrix"))
a <- a.m(A)
Sch.a <- Schur(a)
stopifnot(identical(Sch.a, list(Q = a.m(Sch.A @ Q),
T = a.m(Sch.A @ T),
EValues = Sch.A@EValues)),
 all.equal(a, with(Sch.a, Q %*% T %*% t(Q))))
)
```

---

Schur-class

*Class "Schur" of Schur Matrix Factorizations*

---

## Description

Class "Schur" is the class of Schur matrix factorizations. These are a generalization of eigen value (or "spectral") decompositions for general (possibly asymmetric) square matrices, see the [Schur\(\)](#) function.

## Objects from the Class

Objects of class "Schur" are typically created by [Schur\(\)](#).

## Slots

"Schur" has slots

**T:** Upper Block-triangular [Matrix](#) object.

**Q:** Square *orthogonal* "Matrix".

**EValues:** numeric or complex vector of eigenvalues of T.

**Dim:** the matrix dimension: equal to `c(n,n)` of class "integer".

## Extends

Class "[MatrixFactorization](#)", directly.

**See Also**

`Schur()` for object creation; [MatrixFactorization](#).

**Examples**

```
showClass("Schur")
Schur(M <- Matrix(c(1:7, 10:2), 4,4))
Trivial, of course:
str(Schur(Diagonal(5)))

for more examples, see Schur()
```

---

solve-methods

*Methods in Package Matrix for Function solve()*

---

**Description**

Methods for function `solve` to solve a linear system of equations, or equivalently, solve for  $X$  in

$$AX = B$$

where  $A$  is a square matrix, and  $X$ ,  $B$  are matrices or vectors (which are treated as 1-column matrices), and the R syntax is

```
X <- solve(A,B)
```

In `solve(a,b)` in the **Matrix** package,  $a$  may also be a [MatrixFactorization](#) instead of directly a matrix.

**Usage**

```
S4 method for signature 'CHMfactor,ddenseMatrix'
solve(a, b,
 system = c("A", "LDLt", "LD", "DLt", "L", "Lt", "D", "P", "Pt"), ...)

S4 method for signature 'dgCMatrix,matrix'
solve(a, b, sparse = FALSE, tol = .Machine$double.eps, ...)

 solve(a, b, ...) ## *the* two-argument version, almost always preferred to
solve(a) ## the *rarely* needed one-argument version
```

**Arguments**

|                     |                                                                                                                                                                                                                     |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>a</code>      | a square numeric matrix, $A$ , typically of one of the classes in <b>Matrix</b> . Logical matrices are coerced to corresponding numeric ones.                                                                       |
| <code>b</code>      | numeric vector or matrix (dense or sparse) as RHS of the linear system $Ax = b$ .                                                                                                                                   |
| <code>system</code> | only if $a$ is a <a href="#">CHMfactor</a> : character string indicating the kind of linear system to be solved, see below. Note that the default, "A", does <i>not</i> solve the triangular system (but "L" does). |

|        |                                                                                                                                                                |
|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| sparse | only when a is a <code>sparseMatrix</code> , i.e., typically a <code>dgCMatrix</code> : logical specifying if the result should be a (formally) sparse matrix. |
| tol    | only used when a is sparse, in the <code>isSymmetric(a, tol=*)</code> test, where that applies.                                                                |
| ...    | potentially further arguments to the methods.                                                                                                                  |

## Methods

`signature(a = "ANY", b = "ANY")` is simply the **base** package's S3 generic `solve`.

`signature(a = "CHMfactor", b = "...")`, `system=*` The `solve` methods for a `"CHMfactor"` object take an optional third argument `system` whose value can be one of the character strings `"A"`, `"LDLt"`, `"LD"`, `"DLt"`, `"L"`, `"Lt"`, `"D"`, `"P"` or `"Pt"`. This argument describes the system to be solved. The default, `"A"`, is to solve  $Ax = b$  for  $x$  where  $A$  is sparse, positive-definite matrix that was factored to produce  $a$ . Analogously, `system = "L"` returns the solution  $x$ , of  $Lx = b$ ; similarly, for all system codes **but** `"P"` and `"Pt"` where, e.g., `x <- solve(a, b, system="P")` is equivalent to `x <- P %*% b`.

If  $b$  is a `sparseMatrix`, `system` is used as above the corresponding sparse CHOLMOD algorithm is called.

`signature(a = "ddenseMatrix", b = "...")` (for all  $b$ ) work via `as(a, "dgeMatrix")`, using the its methods, see below.

`signature(a = "denseLU", b = "missing")` basically computes uses triangular forward- and back-solve.

`signature(a = "dgCMatrix", b = "matrix")` , and

`signature(a = "dgCMatrix", b = "ddenseMatrix")` with extra argument list (`sparse=FALSE, tol=.Machine$double.eps`) : Uses the sparse `lu(a)` decomposition (which is cached in  $a$ 's `factor` slot). By default, `sparse=FALSE`, returns a `denseMatrix`, since  $U^{-1}L^{-1}B$  may not be sparse at all, even when  $L$  and  $U$  are.

If `sparse=TRUE`, returns a `sparseMatrix` (which may not be very sparse at all, even if  $a$  was sparse).

`signature(a = "dgCMatrix", b = "dsparseMatrix")` , and

`signature(a = "dgCMatrix", b = "missing")` with extra argument list (`sparse=FALSE, tol=.Machine$double.eps`) : Checks if  $a$  is symmetric, and in that case, coerces it to `"symmetricMatrix"`, and then computes a *sparse* solution via sparse Cholesky factorization, independently of the `sparse` argument. If  $a$  is not symmetric, the sparse `lu` decomposition is used and the result will be sparse or dense, depending on the `sparse` argument, exactly as for the above ( $b = "ddenseMatrix"$ ) case.

`signature(a = "dgeMatrix", b = ".....")` solve the system via internal LU, calling LAPACK routines `dgetri` or `dgetrs`.

`signature(a = "diagonalMatrix", b = "matrix")` and other  $b$ s: Of course this is trivially implemented, as  $D^{-1}$  is diagonal with entries  $1/D[i, i]$ .

`signature(a = "dpoMatrix", b = "....Matrix")` , and

`signature(a = "dppMatrix", b = "....Matrix")` The Cholesky decomposition of  $a$  is calculated (if needed) while solving the system.

`signature(a = "dsCMatrix", b = ".....")` All these methods first try Cholmod's Cholesky factorization; if that works, i.e., typically if  $a$  is positive semi-definite, it is made use of. Otherwise, the sparse LU decomposition is used as for the "general" matrices of class `"dgCMatrix"`.

```
signature(a = "dspMatrix", b = "....") , and
signature(a = "dsyMatrix", b = "....") all end up calling LAPACK routines
 dsptri, dspttrs, dsytrs and dsytri.
signature(a = "dtCMatrix", b = "CsparseMatrix") ,
signature(a = "dtCMatrix", b = "dgeMatrix") , etc sparse triangular solve, in tra-
ditional S/R also known as backsolve, or forwardsolve. solve(a,b) is a
sparseMatrix if b is, and hence a denseMatrix otherwise.
signature(a = "dtrMatrix", b = "ddenseMatrix") , and
signature(a = "dtpMatrix", b = "matrix") , and similar b, including "missing",
 and "diagonalMatrix":
 all use LAPACK based versions of efficient triangular backsolve, or forwardsolve.
signature(a = "Matrix", b = "diagonalMatrix") works via
 as(b, "CsparseMatrix").
signature(a = "sparseQR", b = "ANY") simply uses qr.coef(a,b).
signature(a = "pMatrix", b = ".....") these methods typically use
 crossprod(a,b), as the inverse of a permutation matrix is the same as its transpose.
signature(a = "TsparseMatrix", b = "ANY") all work via
 as(a, "CsparseMatrix").
```

### Examples

```
A close to symmetric example with "quite sparse" inverse:
n1 <- 7; n2 <- 3
dd <- data.frame(a = gl(n1,n2), b = gl(n2,1,n1*n2))# balanced 2-way
X <- sparse.model.matrix(~ -1+ a + b, dd)# no intercept --> even sparser
XXt <- tcrossprod(X)
diag(XXt) <- rep(c(0,0,1,0), length.out = nrow(XXt))

n <- nrow(ZZ <- kronecker(XXt, Diagonal(x=c(4,1))))
image(a <- 2*Diagonal(n) + ZZ %*% Diagonal(x=c(10, rep(1, n-1))))
isSymmetric(a) # FALSE
image(drop0(skewpart(a)))
image(ia0 <- solve(a)) # checker board, dense [but really, a is singular!]
try(solve(a, sparse=TRUE))##-> error [TODO: assertError]
ia. <- solve(a, sparse=TRUE, tol = 1e-19)##-> *no* error
if(R.version$sarch == "x86_64")
 ## Fails on 32-bit [Fedora 19, R 3.0.2] from Matrix 1.1-0 on [FIXME ??] only
 stopifnot(all.equal(as.matrix(ia.), as.matrix(ia0)))
a <- a + Diagonal(n)
iad <- solve(a)
ias <- solve(a, sparse=TRUE)
stopifnot(all.equal(as(ias, "denseMatrix"), iad, tolerance=1e-14))
I. <- iad %*% a ; image(I.)
I0 <- drop0(zapsmall(I.)); image(I0)
.I <- a %*% iad
.I0 <- drop0(zapsmall(.I))
stopifnot(all.equal(as(I0, "diagonalMatrix"), Diagonal(n)),
```

```
all.equal(as(.I0,"diagonalMatrix"), Diagonal(n)))
```

---

```
sparse.model.matrix
```

*Construct Sparse Design / Model Matrices*

---

## Description

Construct a sparse model or “design” matrix, from a formula and data frame (sparse.model.matrix) or a single factor (fac2sparse).

The fac2[Ss]parse() functions are utilities, also used internally in the principal user level function sparse.model.matrix().

## Usage

```
sparse.model.matrix(object, data = environment(object),
 contrasts.arg = NULL, xlev = NULL, transpose = FALSE,
 drop.unused.levels = FALSE, row.names = TRUE,
 sep = "", verbose = FALSE, ...)

fac2sparse(from, to = c("d", "i", "l", "n", "z"),
 drop.unused.levels = TRUE, repr = c("C", "T", "R"), giveCsparse)
fac2Sparse(from, to = c("d", "i", "l", "n", "z"),
 drop.unused.levels = TRUE, repr = c("C", "T", "R"), giveCsparse,
 factorPatt12, contrasts.arg = NULL)
```

## Arguments

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object             | an object of an appropriate class. For the default method, a model formula or terms object.                                                                                                                                                                                                                                                                                                                                         |
| data               | a data frame created with <code>model.frame</code> . If another sort of object, <code>model.frame</code> is called first.                                                                                                                                                                                                                                                                                                           |
| contrasts.arg      | <p><b>for</b> <code>sparse.model.matrix()</code>: A list, whose entries are contrasts suitable for input to the <code>contrasts</code> replacement function and whose names are the names of columns of data containing <code>factors</code>.</p> <p><b>for</b> <code>fac2Sparse()</code>: character string or NULL or (coercable to) <code>"sparseMatrix"</code>, specifying the contrasts to be applied to the factor levels.</p> |
| xlev               | to be used as argument of <code>model.frame</code> if data has no "terms" attribute.                                                                                                                                                                                                                                                                                                                                                |
| transpose          | logical indicating if the <i>transpose</i> should be returned; if the transposed is used anyway, setting <code>transpose = TRUE</code> is more efficient.                                                                                                                                                                                                                                                                           |
| drop.unused.levels | should factors have unused levels dropped? The default for <code>sparse.model.matrix</code> has been changed to FALSE, 2010-07, for compatibility with R's standard (dense) <code>model.matrix()</code> .                                                                                                                                                                                                                           |
| row.names          | logical indicating if row names should be used.                                                                                                                                                                                                                                                                                                                                                                                     |

|              |                                                                                                                                                                                                                                       |
|--------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| sep          | character string passed to <code>paste()</code> when constructing column names from the variable name and its levels.                                                                                                                 |
| verbose      | logical or integer indicating if (and how much) progress output should be printed.                                                                                                                                                    |
| ...          | further arguments passed to or from other methods.                                                                                                                                                                                    |
| from         | (for <code>fac2sparse()</code> ) a <code>factor</code> .                                                                                                                                                                              |
| to           | a character indicating the “kind” of sparse matrix to be returned. The default, “d” is for <code>double</code> .                                                                                                                      |
| giveCsparse  | <b>deprecated</b> , replaced with <code>repr</code> ; logical indicating if the result must be a <code>CsparseMatrix</code> .                                                                                                         |
| repr         | character string, one of “C”, “T”, or “R”, specifying the sparse representation to be used for the result, i.e., one from the super classes <code>CsparseMatrix</code> , <code>TsparseMatrix</code> , or <code>RsparseMatrix</code> . |
| factorPatt12 | logical vector, say <code>fp</code> , of length two; when <code>fp[1]</code> is true, return “contrasted” $t(X)$ ; when <code>fp[2]</code> is true, the original (“dummy”) $t(X)$ , i.e., the result of <code>fac2sparse()</code> .   |

### Value

a sparse matrix, extending `CsparseMatrix` (for `fac2sparse()` if `repr = "C"` as per default; a `TsparseMatrix` or `RsparseMatrix`, otherwise).

For `fac2Sparse()`, a `list` of length two, both components with the corresponding transposed model matrix, where the corresponding `factorPatt12` is true.

Note that `model.Matrix(*, sparse=TRUE)` from package **MatrixModels** may be often be preferable to `sparse.model.matrix()` nowadays, as `model.Matrix()` returns `modelMatrix` objects with additional slots `assign` and `contrasts` which relate back to the variables used.

`fac2sparse()`, the basic workhorse of `sparse.model.matrix()`, returns the *transpose* (`t`) of the model matrix.

### Author(s)

Doug Bates and Martin Maechler, with initial suggestions from Tim Hesterberg.

### See Also

`model.matrix` in standard R’s package **stats**.

`model.Matrix` which calls `sparse.model.matrix` or `model.matrix` depending on its `sparse` argument may be preferred to `sparse.model.matrix`.

`as(f, "sparseMatrix")` (see `coerce(from = "factor", ...)` in the class doc `sparseMatrix`) produces the *transposed* sparse model matrix for a single factor `f` (and *no* contrasts).

### Examples

```
dd <- data.frame(a = gl(3,4), b = gl(4,1,12)) # balanced 2-way
options("contrasts") # the default: "contr.treatment"
sparse.model.matrix(~ a + b, dd)
sparse.model.matrix(~ -1+ a + b, dd) # no intercept --> even sparser
sparse.model.matrix(~ a + b, dd, contrasts = list(a="contr.sum"))
sparse.model.matrix(~ a + b, dd, contrasts = list(b="contr.SAS"))
```

```
Sparse method is equivalent to the traditional one :
stopifnot(all(sparse.model.matrix(~ a + b, dd) ==
 Matrix(model.matrix(~ a + b, dd), sparse=TRUE)),
 all(sparse.model.matrix(~ 0+ a + b, dd) ==
 Matrix(model.matrix(~ 0+ a + b, dd), sparse=TRUE)))

(ff <- gl(3,4,, c("X","Y", "Z")))
fac2sparse(ff) # 3 x 12 sparse Matrix of class "dgCMatrix"
##
X 1 1 1 1
Y 1 1 1 1
Z 1 1 1 1

can also be computed via sparse.model.matrix():
f30 <- gl(3,0)
f12 <- gl(3,0, 12)
stopifnot(
 all.equal(t(fac2sparse(ff)),
 sparse.model.matrix(~ 0+ff),
 tolerance = 0, check.attributes=FALSE),
 is(M <- fac2sparse(f30, drop= TRUE), "CsparseMatrix"), dim(M) == c(0, 0),
 is(M <- fac2sparse(f30, drop=FALSE), "CsparseMatrix"), dim(M) == c(3, 0),
 is(M <- fac2sparse(f12, drop= TRUE), "CsparseMatrix"), dim(M) == c(0,12),
 is(M <- fac2sparse(f12, drop=FALSE), "CsparseMatrix"), dim(M) == c(3,12)
)
```

---

sparseLU-class

*Sparse LU decomposition of a square sparse matrix*

---

## Description

Objects of this class contain the components of the LU decomposition of a sparse square matrix.

## Objects from the Class

Objects can be created by calls of the form `new("sparseLU", ...)` but are more commonly created by function `lu()` applied to a sparse matrix, such as a matrix of class `dgCMatrix`.

## Slots

**L:** Object of class "`dtCMatrix`", the lower triangular factor from the left.  
**U:** Object of class "`dtCMatrix`", the upper triangular factor from the right.  
**p:** Object of class "`integer`", permutation applied from the left.  
**q:** Object of class "`integer`", permutation applied from the right.  
**Dim:** the dimension of the original matrix; inherited from class `MatrixFactorization`.

## Extends

Class "`LU`", directly. Class "`MatrixFactorization`", by class "`LU`".

**Methods**

**expand** signature(x = "sparseLU") Returns a list with components P, L, U, and Q, where *P* and *Q* represent fill-reducing permutations, and *L*, and *U* the lower and upper triangular matrices of the decomposition. The original matrix corresponds to the product  $P'LUQ$ .

**Note**

The decomposition is of the form

$$A = P'LUQ,$$

or equivalently  $PAQ' = LU$ , where all matrices are sparse and of size  $n \times n$ . The matrices *P* and *Q*, and their transposes *P'* and *Q'* are permutation matrices, *L* is lower triangular and *U* is upper triangular.

**See Also**

[lu](#), [solve](#), [dgCMatrix](#)

**Examples**

```
Extending the one in examples(lu), calling the matrix A,
and confirming the factorization identities :
A <- as(readMM(system.file("external/pores_1.mtx",
 package = "Matrix")),
 "CsparseMatrix")
with dimnames(.) - to see that they propagate to L, U :
dimnames(A) <- dnA <- list(paste0("r", seq_len(nrow(A))),
 paste0("C", seq_len(ncol(A))))
str(luA <- lu(A)) # p is a 0-based permutation of the rows
 # q is a 0-based permutation of the columns
xA <- expand(luA)
which is simply doing
stopifnot(identical(xA$L, luA@L),
 identical(xA$U, luA@U),
 identical(xA$P, as(luA@p + 1L, "pMatrix")),
 identical(xA$Q, as(luA@q + 1L, "pMatrix")))

P.LUQ <- with(xA, t(P) %*% L %*% U %*% Q)
stopifnot(all.equal(A, P.LUQ, tolerance = 1e-12),
 identical(dimnames(P.LUQ), dnA))
permute rows and columns of original matrix
pA <- A[luA@p + 1L, luA@q + 1L]
stopifnot(identical(pA, with(xA, P %*% A %*% t(Q))))

pLU <- drop0(luA@L %*% luA@U) # L %*% U -- dropping extra zeros
stopifnot(all.equal(pA, pLU, tolerance = 1e-12))
```

## Description

Methods for coercion from and to sparse matrices from package **SparseM** are provided here, for ease of porting functionality to the **Matrix** package, and comparing functionality of the two packages. All these work via the usual `as(., "<class>")` coercion,

```
as(from, Class)
```

## Methods

```
from = "matrix.csr", to = "dgRMatrix" ...
from = "matrix.csc", to = "dgCMatrix" ...
from = "matrix.coo", to = "dgTMatrix" ...
from = "dgRMatrix", to = "matrix.csr" ...
from = "dgCMatrix", to = "matrix.csc" ...
from = "dgTMatrix", to = "matrix.coo" ...
from = "sparseMatrix", to = "matrix.csr" ...
from = "matrix.csr", to = "dgCMatrix" ...
from = "matrix.coo", to = "dgCMatrix" ...
from = "matrix.csr", to = "Matrix" ...
from = "matrix.csc", to = "Matrix" ...
from = "matrix.coo", to = "Matrix" ...
```

## See Also

sparseMatrix

*General Sparse Matrix Construction from Nonzero Entries*

---

## Description

User friendly construction of a compressed, column-oriented, sparse matrix, inheriting from `class CsparseMatrix` (or `TsparseMatrix` if `giveCsparse` is false), from locations (and values) of its non-zero entries.

This is the recommended user interface rather than direct `new("***Matrix", ...)` calls.

## Usage

```
sparseMatrix(i = ep, j = ep, p, x, dims, dimnames,
 symmetric = FALSE, triangular = FALSE, index1 = TRUE,
 repr = "C", giveCsparse = (repr == "C"),
 check = TRUE, use.last.ij = FALSE)
```

**Arguments**

|                          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>i, j</code>        | integer vectors of the same length specifying the locations (row and column indices) of the non-zero (or non-TRUE) entries of the matrix. Note that for <i>repeated</i> pairs $(i_k, j_k)$ , when <code>x</code> is not missing, the corresponding $x_k$ are <i>added</i> , in consistency with the definition of the " <a href="#">TsparseMatrix</a> " class, unless <code>use.last.ij</code> is true, in which case only the <i>last</i> of the corresponding $(i_k, j_k, x_k)$ triplet is used. |
| <code>p</code>           | numeric (integer valued) vector of pointers, one for each column (or row), to the initial (zero-based) index of elements in the column (or row). Exactly one of <code>i</code> , <code>j</code> or <code>p</code> must be missing.                                                                                                                                                                                                                                                                 |
| <code>x</code>           | optional values of the matrix entries. If specified, must be of the same length as <code>i</code> / <code>j</code> , or of length one where it will be recycled to full length. If missing, the resulting matrix will be a 0/1 pattern matrix, i.e., extending class <a href="#">nsparseMatrix</a> .                                                                                                                                                                                               |
| <code>dims</code>        | optional, non-negative, integer, dimensions vector of length 2. Defaults to <code>c(max(i), max(j))</code> .                                                                                                                                                                                                                                                                                                                                                                                       |
| <code>dimnames</code>    | optional list of <a href="#">dimnames</a> ; if not specified, none, i.e., <code>NULL</code> ones, are used.                                                                                                                                                                                                                                                                                                                                                                                        |
| <code>symmetric</code>   | logical indicating if the resulting matrix should be symmetric. In that case, only the lower or upper triangle needs to be specified via $(i/j/p)$ .                                                                                                                                                                                                                                                                                                                                               |
| <code>triangular</code>  | logical indicating if the resulting matrix should be triangular. In that case, the lower or upper triangle needs to be specified via $(i/j/p)$ .                                                                                                                                                                                                                                                                                                                                                   |
| <code>index1</code>      | logical scalar. If TRUE, the default, the index vectors <code>i</code> and/or <code>j</code> are 1-based, as is the convention in R. That is, counting of rows and columns starts at 1. If FALSE the index vectors are 0-based so counting of rows and columns starts at 0; this corresponds to the internal representation.                                                                                                                                                                       |
| <code>repr</code>        | <a href="#">character</a> string, one of "C", "T", or "R", specifying the sparse representation to be used for the result, i.e., one from the super classes <a href="#">CsparseMatrix</a> , <a href="#">TsparseMatrix</a> , or <a href="#">RsparseMatrix</a> .                                                                                                                                                                                                                                     |
| <code>giveCsparse</code> | <b>(deprecated, replaced with <code>repr</code>):</b> logical indicating if the result should be a <a href="#">CsparseMatrix</a> or a <a href="#">TsparseMatrix</a> , where the default was TRUE, and now is determined from <code>repr</code> ; very often Csparse matrices are more efficient subsequently, but not always.                                                                                                                                                                      |
| <code>check</code>       | logical indicating if a validity check is performed; do not set to FALSE unless you know what you're doing!                                                                                                                                                                                                                                                                                                                                                                                        |
| <code>use.last.ij</code> | logical indicating if in the case of repeated, i.e., duplicated pairs $(i_k, j_k)$ only the last one should be used. The default, FALSE, corresponds to the " <a href="#">TsparseMatrix</a> " definition.                                                                                                                                                                                                                                                                                          |

**Details**

Exactly one of the arguments `i`, `j` and `p` must be missing.

In typical usage, `p` is missing, `i` and `j` are vectors of positive integers and `x` is a numeric vector. These three vectors, which must have the same length, form the triplet representation of the sparse matrix.

If `i` or `j` is missing then `p` must be a non-decreasing integer vector whose first element is zero. It provides the compressed, or "pointer" representation of the row or column indices, whichever is missing. The expanded form of `p`, `rep(seq_along(dp), dp)` where `dp <- diff(p)`, is used as the (1-based) row or column indices.

You cannot set both `singular` and `triangular` to `true`; rather use `Diagonal()` (or its alternatives, see there).

The values of `i`, `j`, `p` and `index1` are used to create 1-based index vectors `i` and `j` from which a `TsparseMatrix` is constructed, with numerical values given by `x`, if non-missing. Note that in that case, when some pairs  $(i_k, j_k)$  are repeated (aka “duplicated”), the corresponding  $x_k$  are *added*, in consistency with the definition of the “`TsparseMatrix`” class, unless use `.last.ij` is set to `true`.

By default, when `repr = "C"`, the `CsparseMatrix` derived from this triplet form is returned, where `repr = "R"` now allows to directly get an `RsparseMatrix` and `repr = "T"` leaves the result as `TsparseMatrix`.

The reason for returning a `CsparseMatrix` object instead of the triplet format by default is that the compressed column form is easier to work with when performing matrix operations. In particular, if there are no zeros in `x` then a `CsparseMatrix` is a unique representation of the sparse matrix.

### Value

A sparse matrix, by default (from `repr = "C"`) in compressed, column-oriented form, as an R object inheriting from both `CsparseMatrix` and `generalMatrix`.

### Note

You *do* need to use `index1 = FALSE` (or add + 1 to `i` and `j`) if you want use the 0-based `i` (and `j`) slots from existing sparse matrices.

### See Also

`Matrix(*, sparse=TRUE)` for the constructor of such matrices from a *dense* matrix. That is easier in small sample, but much less efficient (or impossible) for large matrices, where something like `sparseMatrix()` is needed. Further `bdiag` and `Diagonal` for (block-)diagonal and `bandSparse` for banded sparse matrix constructors.

Random sparse matrices via `rsparsematrix()`.

The standard R `xtabs(*, sparse=TRUE)`, for sparse tables and `sparse.model.matrix()` for building sparse model matrices.

Consider `CsparseMatrix` and similar class definition help files.

### Examples

```
simple example
i <- c(1,3:8); j <- c(2,9,6:10); x <- 7 * (1:7)
(A <- sparseMatrix(i, j, x = x)) ## 8 x 10 "dgCMatrix"
summary(A)
str(A) # note that *internally* 0-based row indices are used

(sA <- sparseMatrix(i, j, x = x, symmetric = TRUE)) ## 10 x 10 "dsCMatrix"
(tA <- sparseMatrix(i, j, x = x, triangular= TRUE)) ## 10 x 10 "dtCMatrix"
stopifnot(all(sA == tA + t(tA)) ,
 identical(sA, as(tA + t(tA), "symmetricMatrix")))

dims can be larger than the maximum row or column indices
(AA <- sparseMatrix(c(1,3:8), c(2,9,6:10), x = 7 * (1:7), dims = c(10,20)))
summary(AA)
```

```

i, j and x can be in an arbitrary order, as long as they are consistent
set.seed(1); (perm <- sample(1:7))
(A1 <- sparseMatrix(i[perm], j[perm], x = x[perm]))
stopifnot(identical(A, A1))

The slots are 0-index based, so
try(sparseMatrix(i=A@i, p=A@p, x= seq_along(A@x)))
fails and you should say so: 1-indexing is FALSE:
 sparseMatrix(i=A@i, p=A@p, x= seq_along(A@x), index1 = FALSE)

the (i,j) pairs can be repeated, in which case the x's are summed
(args <- data.frame(i = c(i, 1), j = c(j, 2), x = c(x, 2)))
(Aa <- do.call(sparseMatrix, args))
explicitly ask for elimination of such duplicates, so
that the last one is used:
(A. <- do.call(sparseMatrix, c(args, list(use.last.ij = TRUE))))
stopifnot(Aa[1,2] == 9, # 2+7 == 9
 A.[1,2] == 2) # 2 was *after* 7

for a pattern matrix, of course there is no "summing":
(nA <- do.call(sparseMatrix, args[c("i","j")]))

dn <- list(LETTERS[1:3], letters[1:5])
pointer vectors can be used, and the (i,x) slots are sorted if necessary:
m <- sparseMatrix(i = c(3,1, 3:2, 2:1), p= c(0:2, 4,4,6), x = 1:6, dimnames = dn)
m
str(m)
stopifnot(identical(dimnames(m), dn))

sparseMatrix(x = 2.72, i=1:3, j=2:4) # recycling x
sparseMatrix(x = TRUE, i=1:3, j=2:4) # recycling x, |--> "lgCMatrix"

no 'x' --> patter*n* matrix:
(n <- sparseMatrix(i=1:6, j=rev(2:7)))# -> ngCMatrix

an empty sparse matrix:
(e <- sparseMatrix(dims = c(4,6), i={}, j={}))

a symmetric one:
(sy <- sparseMatrix(i= c(2,4,3:5), j= c(4,7:5,5), x = 1:5,
 dims = c(7,7), symmetric=TRUE))
stopifnot(isSymmetric(sy),
 identical(sy, ## switch i <-> j {and transpose }
 t(sparseMatrix(j= c(2,4,3:5), i= c(4,7:5,5), x = 1:5,
 dims = c(7,7), symmetric=TRUE))))

rsparsematrix() calls sparseMatrix() :
M1 <- rsparsematrix(1000, 20, nnz = 200)
summary(M1)

pointers example in converting from other sparse matrix representations.
if(require(SparseM) && packageVersion("SparseM") >= 0.87 &&
 nzchar(dfil <- system.file("extdata", "rua_32_ax.rua", package = "SparseM"))) {
 X <- model.matrix(read.matrix.hb(dfil))
 XX <- sparseMatrix(j = X@ja, p = X@ia - 1L, x = X@ra, dims = X@dimension)
 validObject(XX)
}

```

```
Alternatively, and even more user friendly :
X. <- as(X, "Matrix") # or also
X2 <- as(X, "sparseMatrix")
stopifnot(identical(XX, X.), identical(X., X2))
}
```

---

sparseMatrix-class *Virtual Class "sparseMatrix" — Mother of Sparse Matrices*

---

## Description

Virtual Mother Class of All Sparse Matrices

## Slots

**Dim:** Object of class "integer" - the dimensions of the matrix - must be an integer vector with exactly two non-negative values.

**Dimnames:** a list of length two - inherited from class `Matrix`, see [Matrix](#).

## Extends

Class "Matrix", directly.

## Methods

**show** (object = "sparseMatrix"): The [show](#) method for sparse matrices prints “*structural*” zeroes as "." using [printSpMatrix\(\)](#) which allows further customization.

**print** signature(x = "sparseMatrix"), ...

The [print](#) method for sparse matrices by default is the same as [show\(\)](#) but can be called with extra optional arguments, see [printSpMatrix\(\)](#).

**format** signature(x = "sparseMatrix"), ...

The [format](#) method for sparse matrices, see [formatSpMatrix\(\)](#) for details such as the extra optional arguments.

**summary** (object = "sparseMatrix", uniqT=FALSE): Returns an object of S3 class "sparseSummary" which is basically a [data.frame](#) with columns (i, j, x) (or just (i, j) for [nsparseMatrix](#) class objects) with the stored (typically non-zero) entries. The [print](#) method resembles Matlab's way of printing sparse matrices, and also the `MatrixMarket` format, see [writeMM](#).

**cbind2** (x = \*, y = \*): several methods for binding matrices together, column-wise, see the basic [cbind](#) and [rbind](#) functions.

Note that the result will typically be sparse, even when one argument is dense and larger than the sparse one.

**rbind2** (x = \*, y = \*): binding matrices together row-wise, see [cbind2](#) above.

**determinant** (x = "sparseMatrix", logarithm=TRUE): [determinant\(\)](#) methods for sparse matrices typically work via [Cholesky](#) or [lu](#) decompositions.

**diag** (x = "sparseMatrix"): extracts the diagonal of a sparse matrix.

**dim<-** signature(x = "sparseMatrix", value = "ANY"): allows to *reshape* a sparse matrix to a sparse matrix with the same entries but different dimensions. `value` must be of length two and fulfill `prod(value) == prod(dim(x))`.

**coerce** signature (from = "factor", to = "sparseMatrix"): Coercion of a factor to "sparseMatrix" produces the matrix of indicator **rows** stored as an object of class "dgCMatrix". To obtain columns representing the interaction of the factor and a numeric covariate, replace the "x" slot of the result by the numeric covariate then take the transpose. Missing values (NA) from the factor are translated to columns of all 0s.

See also [colSums](#), [norm](#), ... for methods with separate help pages.

### Note

In method selection for multiplication operations (i.e. `%%` and the two-argument form of [crossprod](#)) the `sparseMatrix` class takes precedence in the sense that if one operand is a sparse matrix and the other is any type of dense matrix then the dense matrix is coerced to a `dgeMatrix` and the appropriate sparse matrix method is used.

### See Also

[sparseMatrix](#), and its references, such as [xtabs](#)(\*, sparse=TRUE), or [sparse.model.matrix](#)(), for constructing sparse matrices.

[T2graph](#) for conversion of "graph" objects (package **graph**) to and from sparse matrices.

### Examples

```
showClass("sparseMatrix") ## and look at the help() of its subclasses
M <- Matrix(0, 10000, 100)
M[1,1] <- M[2,3] <- 3.14
M ## show(.) method suppresses printing of the majority of rows

data(CAex); dim(CAex) # 72 x 72 matrix
determinant(CAex) # works via sparse lu(.)

factor -> t(<sparse design matrix>) :
(fact <- gl(5, 3, 30, labels = LETTERS[1:5]))
(Xt <- as(fact, "sparseMatrix")) # indicator rows

missing values --> all-0 columns:
f.mis <- fact
i.mis <- c(3:5, 17)
is.na(f.mis) <- i.mis
Xt != (X. <- as(f.mis, "sparseMatrix")) # differ only in columns 3:5,17
stopifnot(all(X.[,i.mis] == 0), all(Xt[,-i.mis] == X.[,-i.mis]))
```

### Description

Objects class "sparseQR" represent a QR decomposition of a sparse  $m \times n$  ("long":  $m \geq n$ ) rectangular matrix  $A$ , typically resulting from [qr](#) (), see 'Details' notably about row and column permutations for pivoting.

## Details

For a sparse  $m \times n$  ("long":  $m \geq n$ ) rectangular matrix  $A$ , the sparse QR decomposition is either of the form  $PA = QR$  with a (row) permutation matrix  $P$ , (encoded in the `p` slot of the result) if the `q` slot is of length 0,

or of the form  $PAP^* = QR$  with an extra (column) permutation matrix  $P^*$  (encoded in the `q` slot). Note that the row permutation  $PA$  in R is simply  $A[p+1, ]$  where `p` is the `p`-slot, a 0-based permutation of  $1:m$  applied to the rows of the original matrix.

If the `q` slot has length `n` it is a 0-based permutation of  $1:n$  applied to the columns of the original matrix to reduce the amount of "fill-in" in the matrix  $R$ , and  $AP^*$  in R is simply  $A[, q+1]$ .

$R$  is an  $m \times n$  matrix that is zero below the main diagonal, i.e., upper triangular ( $m \times m$ ) with  $m - n$  extra zero rows.

The matrix  $Q$  is a "virtual matrix". It is the product of  $n$  Householder transformations. The information to generate these Householder transformations is stored in the `V` and `beta` slots.

Note however that `qr.Q()` returns the row permuted matrix  $Q^* := P^{-1}Q = P'Q$  as permutation matrices are orthogonal; and  $Q^*$  is orthogonal itself because  $Q$  and  $P$  are. This is useful because then, as in the dense matrix and **base** R matrix `qr` case, we have the mathematical identity

$$PA = Q^* R,$$

in R as

```
A[p+1,] == qr.Q(*) %*% R .
```

The "sparseQR" methods for the `qr.*` functions return objects of class "dgcMatrix" (see `dgcMatrix`). Results from `qr.coef`, `qr.resid` and `qr.fitted` (when `k == ncol(R)`) are well-defined and should match those from the corresponding dense matrix calculations. However, because the matrix  $Q$  is not uniquely defined, the results of `qr.qy` and `qr.qty` do not necessarily match those from the corresponding dense matrix calculations.

Also, the results of `qr.qy` and `qr.qty` apply to the permuted column order when the `q` slot has length `n`.

## Objects from the Class

Objects can be created by calls of the form `new("sparseQR", ...)` but are more commonly created by function `qr` applied to a sparse matrix such as a matrix of class `dgCMatrix`.

## Slots

**V:** Object of class "dgCMatrix". The columns of `V` are the vectors that generate the Householder transformations of which the matrix  $Q$  is composed.

**beta:** Object of class "numeric", the normalizing factors for the Householder transformations.

**p:** Object of class "integer": Permutation (of  $0:(n-1)$ ) applied to the rows of the original matrix.

**R:** Object of class "dgCMatrix": An upper triangular matrix of the same dimension as  $X$ .

**q:** Object of class "integer": Permutation applied from the right, i.e., to the *columns* of the original matrix. Can be of length 0 which implies no permutation.

## Methods

**qr.R** signature(`qr = "sparseQR"`): compute the upper triangular  $R$  matrix of the QR decomposition. Note that this currently warns because of possible permutation mismatch with the classical `qr.R()` result, *and* you can suppress these warnings by setting `options()` either `"Matrix.quiet.qr.R"` or (the more general) either `"Matrix.quiet"` to `TRUE`.

**qr.Q** signature(`qr = "sparseQR"`): compute the orthogonal  $Q$  matrix of the QR decomposition.

**qr.coef** signature(`qr = "sparseQR"`, `y = "ddenseMatrix"`): ...

**qr.coef** signature(`qr = "sparseQR"`, `y = "matrix"`): ...

**qr.coef** signature(`qr = "sparseQR"`, `y = "numeric"`): ...

**qr.fitted** signature(`qr = "sparseQR"`, `y = "ddenseMatrix"`): ...

**qr.fitted** signature(`qr = "sparseQR"`, `y = "matrix"`): ...

**qr.fitted** signature(`qr = "sparseQR"`, `y = "numeric"`): ...

**qr.qty** signature(`qr = "sparseQR"`, `y = "ddenseMatrix"`): ...

**qr.qty** signature(`qr = "sparseQR"`, `y = "matrix"`): ...

**qr.qty** signature(`qr = "sparseQR"`, `y = "numeric"`): ...

**qr.qy** signature(`qr = "sparseQR"`, `y = "ddenseMatrix"`): ...

**qr.qy** signature(`qr = "sparseQR"`, `y = "matrix"`): ...

**qr.qy** signature(`qr = "sparseQR"`, `y = "numeric"`): ...

**qr.resid** signature(`qr = "sparseQR"`, `y = "ddenseMatrix"`): ...

**qr.resid** signature(`qr = "sparseQR"`, `y = "matrix"`): ...

**qr.resid** signature(`qr = "sparseQR"`, `y = "numeric"`): ...

**solve** signature(`a = "sparseQR"`, `b = "ANY"`): For `solve(a,b)`, simply uses `qr.coef(a,b)`.

## See Also

`qr`, `qr.Q`, `qr.R`, `qr.fitted`, `qr.resid`, `qr.coef`, `qr.qty`, `qr.qy`,  
 Permutation matrices in the **Matrix** package: `pMatrix`; `dgCMatrix`, `dgeMatrix`.

## Examples

```
data(KNex)
mm <- KNex $ mm
y <- KNex $ y
y. <- as(as.matrix(y), "dgCMatrix")
str(qrm <- qr(mm))
qc <- qr.coef (qrm, y); qc. <- qr.coef (qrm, y.) # 2nd failed in Matrix <= 1.1-0
qf <- qr.fitted(qrm, y); qf. <- qr.fitted(qrm, y.)
qs <- qr.resid (qrm, y); qs. <- qr.resid (qrm, y.)
stopifnot(all.equal(qc, as.numeric(qc.), tolerance=1e-12),
 all.equal(qf, as.numeric(qf.), tolerance=1e-12),
 all.equal(qs, as.numeric(qs.), tolerance=1e-12),
 all.equal(qf+qs, y, tolerance=1e-12))
```

## sparseVector

*Sparse Vector Construction from Nonzero Entries***Description**

User friendly construction of sparse vectors, i.e., objects inheriting from `class sparseVector`, from indices and values of its non-zero entries.

**Usage**

```
sparseVector(x, i, length)
```

**Arguments**

|                     |                                                                                                                                           |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>      | vector of the non zero entries; may be missing in which case a "nsparseVector" will be returned.                                          |
| <code>i</code>      | integer vector (of the same length as <code>x</code> ) specifying the indices of the non-zero (or non-TRUE) entries of the sparse vector. |
| <code>length</code> | length of the sparse vector.                                                                                                              |

**Details**

zero entries in `x` are dropped automatically, analogously as `drop0()` acts on sparse matrices.

**Value**

a sparse vector, i.e., inheriting from `class sparseVector`.

**Author(s)**

Martin Maechler

**See Also**

`sparseMatrix()` constructor for sparse matrices; the class `sparseVector`.

**Examples**

```
str(sv <- sparseVector(x = 1:10, i = sample(999, 10), length=1000))

sx <- c(0,0,3, 3.2, 0,0,0,-3:1,0,0,2,0,0,5,0,0)
ss <- as(sx, "sparseVector")
stopifnot(identical(ss,
 sparseVector(x = c(2, -1, -2, 3, 1, -3, 5, 3.2),
 i = c(15L, 10:9, 3L,12L,8L,18L, 4L), length = 20L)))

(ns <- sparseVector(i= c(7, 3, 2), length = 10))
stopifnot(identical(ns,
 new("nsparseVector", length = 10, i = c(2, 3, 7))))
```

---

sparseVector-class *Sparse Vector Classes*

---

**Description**

**Sparse Vector Classes:** The virtual mother class "sparseVector" has the five actual daughter classes "dsparseVector", "isparseVector", "lsparseVector", "nsparseVector", and "zsparseVector", where we've mainly implemented methods for the d\*, l\* and n\* ones.

**Slots**

- length:** class "numeric" - the `length` of the sparse vector. Note that "numeric" can be considerably larger than the maximal "integer", `.Machine$integer.max`, on purpose.
- i:** class "numeric" - the (1-based) indices of the non-zero entries. Must *not* be NA and strictly sorted increasingly.  
Note that "integer" is "part of" "numeric", and can (and often will) be used for non-huge sparseVectors.
- x:** (for all but "nsparseVector"): the non-zero entries. This is of class "numeric" for class "dsparseVector", "logical" for class "lsparseVector", etc.  
Note that "nsparseVector"s have no x slot. Further, mainly for ease of method definitions, we've defined the class union (see `setClassUnion`) of all sparse vector classes which *have* an x slot, as class "xsparseVector".

**Methods**

- length** signature (x = "sparseVector"): simply extracts the length slot.
- show** signature (object = "sparseVector"): The `show` method for sparse vectors prints "structural" zeroes as "." using the non-exported `prSpVector` function which allows further customization such as replacing "." by " " (blank).  
Note that `options(max.print)` will influence how many entries of large sparse vectors are printed at all.
- as.vector** signature (x = "sparseVector", mode = "character") coerces sparse vectors to "regular", i.e., atomic vectors. This is the same as `as(x, "vector")`.
- as** `..`: see `coerce` below
- coerce** signature (from = "sparseVector", to = "sparseMatrix"), and  
**coerce** signature (from = "sparseMatrix", to = "sparseVector"), etc: coercions to and from sparse matrices (`sparseMatrix`) are provided and work analogously as in standard R, i.e., a vector is coerced to a 1-column matrix.
- dim<-** signature (x = "sparseVector", value = "integer") coerces a sparse vector to a sparse Matrix, i.e., an object inheriting from `sparseMatrix`, of the appropriate dimension.
- head** signature (x = "sparseVector"): as with R's (package `util`) `head`, `head(x, n)` (for  $n \geq 1$ ) is equivalent to `x[1:n]`, but here can be much more efficient, see the example.
- tail** signature (x = "sparseVector"): analogous to `head`, see above.

**toeplitz** signature(x = "sparseVector"): as `toeplitz(x)`, produce the  $n \times n$  Toeplitz matrix from x, where  $n = \text{length}(x)$ .

**rep** signature(x = "sparseVector") repeat x, with the same argument list (x, times, length.out, each, ...) as the default method for rep().

**which** signature(x = "nsparseVector") and

**which** signature(x = "lsparseVector") return the indices of the non-zero entries (which is trivial for sparse vectors).

**Ops** signature(e1 = "sparseVector", e2 = "\*"): define arithmetic, compare and logic operations, (see [Ops](#)).

**Summary** signature(x = "sparseVector"): define all the [Summary](#) methods.

[ signature(x = "atomicVector", i = ...): not only can you subset (aka "index into") sparseVectors x[i] using sparseVectors i, but we also support efficient subsetting of traditional vectors x by logical sparse vectors (i.e., i of class "nsparseVector" or "lsparseVector").

**is.na, is.finite, is.infinite** (x = "sparseVector"), and

**is.na, is.finite, is.infinite** (x = "nsparseVector"): return `logical` or "nsparseVector" of the same length as x, indicating if/where x is NA (or NaN), finite or infinite, entirely analogously to the corresponding base R functions.

`c.sparseVector()` is an S3 method for all "sparseVector"s, but automatic dispatch only happens for the first argument, so it is useful also as regular R function, see the examples.

## See Also

`sparseVector()` for friendly construction of sparse vectors (apart from `as(*, "sparseVector")`).

## Examples

```
getClass("sparseVector")
getClass("dsparseVector")
getClass("xsparseVector") # those with an 'x' slot

sx <- c(0,0,3, 3.2, 0,0,0,-3:1,0,0,2,0,0,5,0,0)
(ss <- as(sx, "sparseVector"))

ix <- as.integer(round(sx))
(is <- as(ix, "sparseVector")) ## an "isparseVector" (!)
(ns <- sparseVector(i= c(7, 3, 2), length = 10)) # "nsparseVector"
rep() works too:
(ri <- rep(is, length.out= 25))

Using `dim<-` as in base R :
r <- ss
dim(r) <- c(4,5) # becomes a sparse Matrix:
r
or coercion (as as.matrix() in base R):
as(ss, "Matrix")
stopifnot(all(ss == print(as(ss, "CsparseMatrix"))))

currently has "non-structural" FALSE -- printing as ":"
(lis <- is & FALSE)
(nn <- is[is == 0]) # all "structural" FALSE
```

```

NA-case
sN <- sx; sN[4] <- NA
(svN <- as(sN, "sparseVector"))

v <- as(c(0,0,3, 3.2, rep(0,9),-3,0,-1, rep(0,20),5,0),
 "sparseVector")
v <- rep(rep(v, 50), 5000)
set.seed(1); v[sample(v@i, 1e6)] <- 0
str(v)

system.time(for(i in 1:4) hv <- head(v, 1e6))
user system elapsed
0.033 0.000 0.032
system.time(for(i in 1:4) h2 <- v[1:1e6])
user system elapsed
1.317 0.000 1.319

stopifnot(identical(hv, h2),
 identical(is | FALSE, is != 0),
 validObject(svN), validObject(lis), as.logical(is.na(svN[4])),
 identical(is^2 > 0, is & TRUE),
 all(!lis), !any(lis), length(nn@i) == 0, !any(nn), all(!nn),
 sum(lis) == 0, !prod(lis), range(lis) == c(0,0))

create and use the t(.) method:
t(x20 <- sparseVector(c(9,3:1), i=c(1:2,4,7), length=20))
(T20 <- toeplitz(x20))
stopifnot(is(T20, "symmetricMatrix"), is(T20, "sparseMatrix"),
 identical(unname(as.matrix(T20)),
 toeplitz(as.vector(x20))))

c() method for "sparseVector" - also available as regular function
(c1 <- c(x20, 0,0,0, -10*x20))
(c2 <- c(ns, is, FALSE))
(c3 <- c(ns, !ns, TRUE, NA, FALSE))
(c4 <- c(ns, rev(ns)))
here, c() would produce a list {not dispatching to c.sparseVector()}
(c5 <- c.sparseVector(0,0, x20))

checking (consistency)
.v <- as.vector
.s <- function(v) as(v, "sparseVector")
stopifnot(
 all.equal(c1, .s(c(.v(x20), 0,0,0, -10*.v(x20))), tol=0),
 all.equal(c2, .s(c(.v(ns), .v(is), FALSE)), tol=0),
 all.equal(c3, .s(c(.v(ns), !.v(ns), TRUE, NA, FALSE)), tol=0),
 all.equal(c4, .s(c(.v(ns), rev(.v(ns)))), tol=0),
 all.equal(c5, .s(c(0,0, .v(x20))), tol=0)
)

```

## Description

User friendly construction of a sparse matrix (inheriting from class `TsparseMatrix`) from the triplet representation.

This is much less flexible than `sparseMatrix()` and hence somewhat *deprecated*.

## Usage

```
spMatrix(nrow, ncol, i = integer(), j = integer(), x = numeric())
```

## Arguments

|                         |                                                                                                                        |
|-------------------------|------------------------------------------------------------------------------------------------------------------------|
| <code>nrow, ncol</code> | integers specifying the desired number of rows and columns.                                                            |
| <code>i, j</code>       | integer vectors of the same length specifying the locations of the non-zero (or non-TRUE) entries of the matrix.       |
| <code>x</code>          | atomic vector of the same length as <code>i</code> and <code>j</code> , specifying the values of the non-zero entries. |

## Value

A sparse matrix in triplet form, as an R object inheriting from both `TsparseMatrix` and `generalMatrix`.

The matrix  $M$  will have  $M[i[k], j[k]] == x[k]$ , for  $k = 1, 2, \dots, n$ , where  $n = \text{length}(i)$  and  $M[i', j'] == 0$  for all other pairs  $(i', j')$ .

## See Also

`Matrix(*, sparse=TRUE)` for the more usual constructor of such matrices. Then, `sparseMatrix` is more general and flexible than `spMatrix()` and by default returns a `CsparseMatrix` which is often slightly more desirable. Further, `bdiag` and `Diagonal` for (block-)diagonal matrix constructors.

Consider `TsparseMatrix` and similar class definition help files.

## Examples

```
simple example
A <- spMatrix(10,20, i = c(1,3:8),
 j = c(2,9,6:10),
 x = 7 * (1:7))

A # a "dgTMatrix"
summary(A)
str(A) # note that *internally* 0-based indices (i,j) are used

L <- spMatrix(9, 30, i = rep(1:9, 3), 1:27,
 (1:27) %% 4 != 1)
L # an "lgTMatrix"

A simplified predecessor of Matrix' rsparsematrix() function :

rSpMatrix <- function(nrow, ncol, nnz,
 rand.x = function(n) round(rnorm(nnz), 2))
{
 ## Purpose: random sparse matrix
```

```

Arguments: (nrow,ncol): dimension
nnz : number of non-zero entries
rand.x: random number generator for 'x' slot

Author: Martin Maechler, Date: 14.-16. May 2007
stopifnot((nnz <- as.integer(nnz)) >= 0,
 nrow >= 0, ncol >= 0, nnz <= nrow * ncol)
spMatrix(nrow, ncol,
 i = sample(nrow, nnz, replace = TRUE),
 j = sample(ncol, nnz, replace = TRUE),
 x = rand.x(nnz))
}

M1 <- rSpMatrix(100000, 20, nnz = 200)
summary(M1)
```

---

symmetricMatrix-class

*Virtual Class of Symmetric Matrices in Package Matrix*

---

## Description

The virtual class of symmetric matrices, "symmetricMatrix", from the package **Matrix** contains numeric and logical, dense and sparse matrices, e.g., see the examples with the “actual” sub-classes.

The main use is in methods (and C functions) that can deal with all symmetric matrices, and in `as(*, "symmetricMatrix")`.

## Slots

**uplo**: Object of class "character". Must be either "U", for upper triangular, and "L", for lower triangular.

**Dim, Dimnames**: The dimension (a length-2 "integer") and corresponding names (or NULL), inherited from the [Matrix](#), see there. See below, about storing only one of the two Dimnames components.

**factors**: a list of matrix factorizations, also from the `Matrix` class.

## Extends

Class "Matrix", directly.

## Methods

**coerce** signature (from = "ddiMatrix", to = "symmetricMatrix"): and many other coercion methods, some of which are particularly optimized.

**dimnames** signature (object = "symmetricMatrix"): returns *symmetric* [dimnames](#), even when the Dimnames slot only has row or column names. This allows to save storage for large (typically sparse) symmetric matrices.

**isSymmetric** signature (object = "symmetricMatrix"): returns TRUE trivially.

There's a C function `symmetricMatrix_validate()` called by the internal validity checking functions, and also from [getValidity](#) (`getClass("symmetricMatrix")`).

### Validity and `dimnames`

The validity checks do not require a symmetric `Dimnames` slot, so it can be `list(NULL, <character>)`, e.g., for efficiency. However, `dimnames()` and other functions and methods should behave as if the `dimnames` were symmetric, i.e., with both list components identical.

### See Also

`isSymmetric` which has efficient methods ([isSymmetric-methods](#)) for the **Matrix** classes. Classes `triangularMatrix`, and, e.g., `dsyMatrix` for numeric *dense* matrices, or `lsCMatrix` for a logical *sparse* matrix class.

### Examples

```
An example about the symmetric Dimnames:
sy <- sparseMatrix(i= c(2,4,3:5), j= c(4,7:5,5), x = 1:5, dims = c(7,7),
 symmetric=TRUE, dimnames = list(NULL, letters[1:7]))
sy # shows symmetrical dimnames
sy@Dimnames # internally only one part is stored
dimnames(sy) # both parts - as sy *is* symmetrical

showClass("symmetricMatrix")

The names of direct subclasses:
scl <- getClass("symmetricMatrix")@subclasses
directly <- sapply(lapply(scl, slot, "by"), length) == 0
names(scl)[directly]

Methods -- applicable to all subclasses above:
showMethods(classes = "symmetricMatrix")
```

---

symmpart

*Symmetric Part and Skew(symmetric) Part of a Matrix*

---

### Description

`symmpart(x)` computes the symmetric part  $(x + t(x))/2$  and `skewpart(x)` the skew symmetric part  $(x - t(x))/2$  of a square matrix `x`, more efficiently for specific **Matrix** classes.

Note that `x == symmpart(x) + skewpart(x)` for all square matrices – apart from extraneous [NA](#) values in the RHS.

### Usage

```
symmpart(x)
skewpart(x)
```

### Arguments

`x` a *square* matrix; either “traditional” of class `"matrix"`, or typically, inheriting from the [Matrix](#) class.

## Details

These are generic functions with several methods for different matrix classes, use e.g., `showMethods(sympart)` to see them.

If the row and column names differ, the result will use the column names unless they are (partly) NULL where the row names are non-NULL (see also the examples).

## Value

`sympart()` returns a symmetric matrix, inheriting from `symmetricMatrix` iff `x` inherited from `Matrix`.

`skewpart()` returns a skew-symmetric matrix, typically of the same class as `x` (or the closest “general” one, see `generalMatrix`).

## See Also

`isSymmetric`.

## Examples

```
m <- Matrix(1:4, 2, 2)
sympart(m)
skewpart(m)

stopifnot(all(m == sympart(m) + skewpart(m)))

dn <- dimnames(m) <- list(row = c("r1", "r2"), col = c("var.1", "var.2"))
stopifnot(all(m == sympart(m) + skewpart(m)))
colnames(m) <- NULL
stopifnot(all(m == sympart(m) + skewpart(m)))
dimnames(m) <- unname(dn)
stopifnot(all(m == sympart(m) + skewpart(m)))

investigate the current methods:
showMethods(skewpart, include = TRUE)
```

---

triangularMatrix-class

*Virtual Class of Triangular Matrices in Package Matrix*

---

## Description

The virtual class of triangular matrices, "triangularMatrix", the package **Matrix** contains *square* (`nrow == ncol`) numeric and logical, dense and sparse matrices, e.g., see the examples. A main use of the virtual class is in methods (and C functions) that can deal with all triangular matrices.

**Slots**

**uplo:** String (of class "character"). Must be either "U", for upper triangular, and "L", for lower triangular.

**diag:** String (of class "character"). Must be either "U", for unit triangular (diagonal is all ones), or "N" for non-unit. The diagonal elements are not accessed internally when `diag` is "U". For `denseMatrix` classes, they need to be allocated though, i.e., the length of the `x` slot does not depend on `diag`.

**Dim, Dimnames:** The dimension (a length-2 "integer") and corresponding names (or NULL), inherited from the `Matrix`, see there.

**Extends**

Class "Matrix", directly.

**Methods**

There's a C function `triangularMatrix_validity()` called by the internal validity checking functions.

Currently, `Schur`, `isSymmetric` and `as()` (i.e. `coerce`) have methods with `triangularMatrix` in their signature.

**See Also**

`isTriangular()` for testing any matrix for triangularity; classes `symmetricMatrix`, and, e.g., `dtrMatrix` for numeric *dense* matrices, or `ltcMatrix` for a logical *sparse* matrix subclass of "triangularMatrix".

**Examples**

```
showClass("triangularMatrix")

The names of direct subclasses:
scl <- getClass("triangularMatrix")@subclasses
directly <- sapply(lapply(scl, slot, "by"), length) == 0
names(scl)[directly]

(m <- matrix(c(5,1,0,3), 2))
as(m, "triangularMatrix")
```

---

TsparseMatrix-class

*Class "TsparseMatrix" of Sparse Matrices in Triplet Form*

---

**Description**

The "TsparseMatrix" class is the virtual class of all sparse matrices coded in triplet form. Since it is a virtual class, no objects may be created from it. See `showClass("TsparseMatrix")` for its subclasses.

**Slots**

Dim, Dimnames: from the "Matrix" class,

i: Object of class "integer" - the row indices of non-zero entries *in 0-base*, i.e., must be in  $0:(\text{nrow}(.)-1)$ .

j: Object of class "integer" - the column indices of non-zero entries. Must be the same length as slot i and *0-based* as well, i.e., in  $0:(\text{ncol}(.)-1)$ . For numeric Tsparse matrices, (i, j) pairs can occur more than once, see [dgTMatrix](#).

**Extends**

Class "sparseMatrix", directly. Class "Matrix", by class "sparseMatrix".

**Methods**

Extraction ("[" ) methods, see [\[-methods](#).

**Note**

Most operations with sparse matrices are performed using the compressed, column-oriented or [CsparseMatrix](#) representation. The triplet representation is convenient for creating a sparse matrix or for reading and writing such matrices. Once it is created, however, the matrix is generally coerced to a [CsparseMatrix](#) for further operations.

Note that all `new()`, [spMatrix](#) and [sparseMatrix](#)(\*, repr="T") constructors for "TsparseMatrix" classes implicitly add (i.e., "sum up")  $x_k$ 's that belong to identical  $(i_k, j_k)$  pairs, see, the example below, or also [dgTMatrix](#).

For convenience, methods for some operations such as `%%` and `crossprod` are defined for [TsparseMatrix](#) objects. These methods simply coerce the [TsparseMatrix](#) object to a [CsparseMatrix](#) object then perform the operation.

**See Also**

its superclass, [sparseMatrix](#), and the [dgTMatrix](#) class, for the links to other classes.

**Examples**

```
showClass("TsparseMatrix")
or just the subclasses' names
names(getClass("TsparseMatrix")@subclasses)

T3 <- spMatrix(3,4, i=c(1,3:1), j=c(2,4:2), x=1:4)
T3 # only 3 non-zero entries, 5 = 1+4 !
```

uniqTsparse

*Unique (Sorted) TsparseMatrix Representations***Description**

Detect or “unify” (or “standardize”) non-unique `TsparseMatrix` matrices, producing unique  $(i, j, x)$  triplets which are *sorted*, first in  $j$ , then in  $i$  (in the sense of `order(j, i)`).

Note that `new()`, `spMatrix` or `sparseMatrix` constructors for “`dgTMatrix`” (and other “`TsparseMatrix`” classes) implicitly add  $x_k$ ’s that belong to identical  $(i_k, j_k)$  pairs.

`anyDuplicatedT()` reports the index of the first duplicated pair, or 0 if there is none.

`uniqTsparse(x)` replaces duplicated index pairs  $(i, j)$  and their corresponding  $x$  slot entries by the triple  $(i, j, sx)$  where  $sx = \sum(x[\text{<all pairs matching } (i, j)>])$ , and for logical  $x$ , addition is replaced by logical *or*.

**Usage**

```
uniqTsparse(x, class.x = c(class(x)))
anyDuplicatedT(x, di = dim(x))
```

**Arguments**

`x` a sparse matrix stored in triplet form, i.e., inheriting from class `TsparseMatrix`.

`class.x` optional character string specifying `class(x)`.

`di` the matrix dimension of  $x$ , `dim(x)`.

**Value**

`uniqTsparse(x)` returns a `TsparseMatrix` “like  $x$ ”, of the same class and with the same elements, just internally possibly changed to “unique”  $(i, j, x)$  triplets in *sorted* order.

`anyDuplicatedT(x)` returns an *integer* as `anyDuplicated`, the *index* of the first duplicated entry (from the  $(i, j)$  pairs) if there is one, and 0 otherwise.

**See Also**

`TsparseMatrix`, for uniqueness, notably `dgTMatrix`.

**Examples**

```
example("dgTMatrix-class", echo=FALSE)
-> 'T2' with (i,j,x) slots of length 5 each
T2u <- uniqTsparse(T2)
stopifnot(## They "are" the same (and print the same):
 all.equal(T2, T2u, tol=0),
 ## but not internally:
 anyDuplicatedT(T2) == 2,
 anyDuplicatedT(T2u) == 0,
 length(T2 @x) == 5,
 length(T2u @x) == 3)

is 'x' a "uniq Tsparse" Matrix ? [requires x to be TsparseMatrix!]
```

```

non_uniqT <- function(x, di = dim(x))
 is.unsorted(x@j) || anyDuplicatedT(x, di)
non_uniqT(T2) # TRUE
non_uniqT(T2u) # FALSE

T3 <- T2u
T3[1, c(1,3)] <- 10; T3[2, c(1,5)] <- 20
T3u <- uniqTsparse(T3)
str(T3u) # sorted in 'j', and within j, sorted in i
stopifnot(!non_uniqT(T3u))

Logical l.TMatrix and n.TMatrix :
(L2 <- T2 > 0)
validObject(L2u <- uniqTsparse(L2))
(N2 <- as(L2, "nMatrix"))
validObject(N2u <- uniqTsparse(N2))
stopifnot(N2u@i == L2u@i, L2u@i == T2u@i, N2@i == L2@i, L2@i == T2@i,
 N2u@j == L2u@j, L2u@j == T2u@j, N2@j == L2@j, L2@j == T2@j)
now with a nasty NA [partly failed in Matrix 1.1-5]:
L2.N <- L2; L2.N@x[2] <- NA; L2.N
validObject(L2.N)
(m2N <- as.matrix(L2.N)) # looks "ok"
iL <- as.integer(m2N)
stopifnot(identical(10L, which(is.na(match(iL, 0:1)))))
symnum(m2N)

```

unpack

*Representation of Packed and Unpacked (Dense) Matrices*

## Description

“Packed” matrix storage here applies to dense matrices ([denseMatrix](#)) only, and there is available only for symmetric ([symmetricMatrix](#)) or triangular ([triangularMatrix](#)) matrices, where only one triangle of the matrix needs to be stored.

`unpack()` unpacks “packed” matrices, where  
`pack()` produces “packed” matrices.

## Usage

```

pack(x, ...)
S4 method for signature 'matrix'
pack(x, symmetric = NA, upperTri = NA, ...)

unpack(x, ...)

```

## Arguments

|                        |                                                                                                                                                                                                                                                                                                        |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>         | <b>for</b> <code>unpack()</code> : a matrix stored in packed form, e.g., of class <code>"d?pMatrix"</code> where <code>"?"</code> is <code>"t"</code> for triangular or <code>"s"</code> for symmetric.<br><b>for</b> <code>pack()</code> : a (symmetric or triangular) matrix stored in full storage. |
| <code>symmetric</code> | logical (including NA) for optionally specifying if <code>x</code> is symmetric (or rather triangular).                                                                                                                                                                                                |

`upperTri` (for the triangular case only) logical (incl. NA) indicating if `x` is upper (or lower) triangular.

`...` further arguments passed to or from other methods.

### Details

These are generic functions with special methods for different types of packed (or non-packed) symmetric or triangular dense matrices. Use `showMethods("unpack")` to list the methods for `unpack()`, and similarly for `pack()`.

### Value

**for** `unpack()`: A `Matrix` object containing the full-storage representation of `x`.

**for** `pack()`: A packed `Matrix` (i.e. of class `"..pMatrix"`) representation of `x`.

### Examples

```
showMethods("unpack")
(cp4 <- chol(Hilbert(4))) # is triangular
tp4 <- as(cp4,"dtpMatrix")# [t]riangular [p]acked
str(tp4)
(unpack(tp4))
stopifnot(identical(tp4, pack(unpack(tp4))))

(s <- crossprod(matrix(sample(15), 5,3))) # traditional symmetric matrix
(sp <- pack(s))
mt <- as.matrix(tt <- tril(s))
(pt <- pack(mt))
stopifnot(identical(pt, pack(tt)),
 dim(s) == dim(sp), all(s == sp),
 dim(mt) == dim(pt), all(mt == pt), all(mt == tt))
showMethods("pack")
```

### Description

`iMatrix` is the virtual class of all integer (S4) matrices. It extends the `Matrix` class directly.

`zMatrix` is the virtual class of all `complex` (S4) matrices. It extends the `Matrix` class directly.

### Examples

```
showClass("iMatrix")
showClass("zMatrix")
```

updown

*Up- and Down-Dating a Cholesky Decomposition***Description**

Compute the up- or down-dated Cholesky decomposition

**Usage**

```
updown(update, C, L)
```

**Arguments**

|        |                                                                                                  |
|--------|--------------------------------------------------------------------------------------------------|
| update | logical (TRUE or FALSE) or "+" or "-" indicating if an up- or a down-date is to be computed.     |
| C      | any R object, coercable to a sparse matrix (i.e., of subclass of <a href="#">sparseMatrix</a> ). |
| L      | a Cholesky factor, specifically, of class " <a href="#">CHMfactor</a> ".                         |

**Value**

an updated Cholesky factor, of the same dimension as L. Typically of class "[dCHMsimpl](#)" (a subclass of "[CHMfactor](#)").

**Methods**

```
signature(update = "character", C = "mMatrix", L = "CHMfactor") ..
signature(update = "logical", C = "mMatrix", L = "CHMfactor") ..
```

**Author(s)**

Contributed by Nicholas Nagle, University of Tennessee, Knoxville, USA

**References**

CHOLMOD manual, currently beginning of chapter~18. ...

**See Also**

[Cholesky](#),

**Examples**

```
dn <- list(LETTERS[1:3], letters[1:5])
pointer vectors can be used, and the (i,x) slots are sorted if necessary:
m <- sparseMatrix(i = c(3,1, 3:2, 2:1), p = c(0:2, 4,4,6), x = 1:6, dimnames = dn)
cA <- Cholesky(A <- crossprod(m) + Diagonal(5))
166 * as(cA,"Matrix") ^ 2
uc1 <- updown("+", Diagonal(5), cA)
Hmm: this loses positive definiteness:
uc2 <- updown("-", 2*Diagonal(5), cA)
image(show(as(cA, "Matrix")))
```

```
image(show(c2 <- as(uc2, "Matrix")))# severely negative entries
##--> Warning
```

---

USCounties

*USCounties Contiguity Matrix*

---

## Description

This matrix represents the contiguities of 3111 US counties using the Queen criterion of at least a single shared boundary point. The representation is as a row standardised spatial weights matrix transformed to a symmetric matrix (see Ord (1975), p. 125).

## Usage

```
data(USCounties)
```

## Format

A  $3111^2$  symmetric sparse matrix of class `dsCMatrix` with 9101 non-zero entries.

## Details

The data were read into R using `read.gal`, and row-standardised and transformed to symmetry using `nb2listw` and `similar.listw`. This spatial weights object was converted to class `dsCMatrix` using `as_dsTMatrix_listw` and coercion.

## Source

The data were retrieved from <http://sal.uiuc.edu/weights/zips/usc.zip>, files “usc.txt” and “usc\\_q.GAL”, with permission for use and distribution from Luc Anselin (in early 2008).

## References

Ord, J. K. (1975) Estimation methods for models of spatial interaction; *Journal of the American Statistical Association* **70**, 120–126.

## Examples

```
data(USCounties)
(n <- ncol(USCounties))
IM <- .symDiagonal(n)
nn <- 50
set.seed(1)
rho <- runif(nn, 0, 1)
system.time(MJ <- sapply(rho, function(x)
 determinant(IM - x * USCounties, logarithm = TRUE)$modulus))

can be done faster, by update()ing the Cholesky factor:
nWC <- -USCounties
C1 <- Cholesky(nWC, Imult = 2)
system.time(MJ1 <- n * log(rho) +
 sapply(rho, function(x)
```

```

 2 * c(determinant(update(C1, nWC, 1/x))$modulus)))
all.equal(MJ, MJ1)

C2 <- Cholesky(nWC, super = TRUE, Imult = 2)
system.time(MJ2 <- n * log(rho) +
 sapply(rho, function(x)
 2 * c(determinant(update(C2, nWC, 1/x))$modulus)))
all.equal(MJ, MJ2)
system.time(MJ3 <- n * log(rho) + Matrix::ldetL2up(C1, nWC, 1/rho))
stopifnot(all.equal(MJ, MJ3))
system.time(MJ4 <- n * log(rho) + Matrix::ldetL2up(C2, nWC, 1/rho))
stopifnot(all.equal(MJ, MJ4))

```

wrlld\_1deg

*World 1-degree grid contiguity matrix***Description**

This matrix represents the distance-based contiguities of 15260 one-degree grid cells of land areas. The representation is as a row standardised spatial weights matrix transformed to a symmetric matrix (see Ord (1975), p. 125).

**Usage**

```
data(wrlld_1deg)
```

**Format**

A  $15260^2$  symmetric sparse matrix of class `dsCMatrix` with 55973 non-zero entries.

**Details**

The data were created into R using the coordinates of a ‘SpatialPixels’ object containing approximately one-degree grid cells for land areas only (world excluding Antarctica), using package **spdep**’s `dnearneigh` with a cutoff distance of `sqrt(2)`, and row-standardised and transformed to symmetry using `nb2listw` and `similar.listw`. This spatial weights object was converted to a `dsTMatrix` using `as_dsTMatrix_listw` and then coerced (column-compressed).

**Source**

The shoreline data was read into R using `Rgshhs` from the GSHHS coarse shoreline database distributed with the **maptools** package, omitting Antarctica. A matching approximately one-degree grid was generated using `Sobj_SpatialGrid`, and the grids on land were found using the appropriate `over` method for the ‘SpatialPolygons’ and ‘SpatialGrid’ objects, yielding a ‘SpatialPixels’ one containing only the grid cells with centres on land.

**References**

Ord, J. K. (1975) Estimation methods for models of spatial interaction; *Journal of the American Statistical Association* **70**, 120–126.

## Examples

```
data(wrld_1deg)
(n <- ncol(wrld_1deg))
IM <- .symDiagonal(n)
doExtras <- interactive() || nzchar(Sys.getenv("R_MATRIX_CHECK_EXTRA")) ||
 identical("true", unname(Sys.getenv("R_PKG_CHECKING_doExtras")))
nn <- if(doExtras) 20 else 3
set.seed(1)
rho <- runif(nn, 0, 1)
system.time(MJ <- sapply(rho,
 function(x) determinant(IM - x * wrld_1deg,
 logarithm = TRUE)$modulus))

nWC <- -wrld_1deg
C1 <- Cholesky(nWC, Imult = 2)
Note that det(<CHMfactor>) = det(L) = sqrt(det(A))
=====> log det(A) = log(det(L)^2) = 2 * log det(L) :
system.time(MJ1 <- n * log(rho) +
 sapply(rho, function(x) c(2* determinant(update(C1, nWC, 1/x))$modulus))
)
stopifnot(all.equal(MJ, MJ1))
C2 <- Cholesky(nWC, super = TRUE, Imult = 2)
system.time(MJ2 <- n * log(rho) +
 sapply(rho, function(x) c(2* determinant(update(C2, nWC, 1/x))$modulus))
)
system.time(MJ3 <- n * log(rho) + Matrix::ldetL2up(C1, nWC, 1/rho))
system.time(MJ4 <- n * log(rho) + Matrix::ldetL2up(C2, nWC, 1/rho))
stopifnot(all.equal(MJ, MJ2),
 all.equal(MJ, MJ3),
 all.equal(MJ, MJ4))
```

---

[-methods

Methods for "[": Extraction or Subsetting in Package 'Matrix'

---

## Description

Methods for "[", i.e., extraction or subsetting mostly of matrices, in package **Matrix**.

## Methods

There are more than these:

```
x = "Matrix", i = "missing", j = "missing", drop= "ANY" ...
x = "Matrix", i = "numeric", j = "missing", drop= "missing" ...
x = "Matrix", i = "missing", j = "numeric", drop= "missing" ...
x = "dsparseMatrix", i = "missing", j = "numeric", drop= "logical" ...
x = "dsparseMatrix", i = "numeric", j = "missing", drop= "logical" ...
x = "dsparseMatrix", i = "numeric", j = "numeric", drop= "logical" ...
```

## See Also

[\[<--methods](#) for subassignment to "Matrix" objects. [Extract](#) about the standard extraction.

### Examples

```
str(m <- Matrix(round(rnorm(7*4),2), nrow = 7))
stopifnot(identical(m, m[]))
m[2, 3] # simple number
m[2, 3:4] # simple numeric of length 2
m[2, 3:4, drop=FALSE] # sub matrix of class 'dgeMatrix'
rows or columns only:
m[1,] # first row, as simple numeric vector
m[,1:2] # sub matrix of first two columns

showMethods("[", inherited = FALSE)
```

[&lt;-methods

Methods for "[&lt;-" - Assigning to Subsets for 'Matrix'

### Description

Methods for "[<-", i.e., extraction or subsetting mostly of matrices, in package **Matrix**.

**Note:** Contrary to standard `matrix` assignment in base R, in `x[...]` <- val it is typically an **error** (see [stop](#)) when the [type](#) or [class](#) of val would require the class of x to be changed, e.g., when x is logical, say "lsparseMatrix", and val is numeric. In other cases, e.g., when x is a "nsparseMatrix" and val is not TRUE or FALSE, a warning is signalled, and val is “interpreted” as [logical](#), and (logical) [NA](#) is interpreted as TRUE.

### Methods

There are *many many* more than these:

`x = "Matrix", i = "missing", j = "missing", value = "ANY"` is currently a simple fallback method implementation which ensures “readable” error messages.

`x = "Matrix", i = "ANY", j = "ANY", value = "ANY"` currently gives an error

`x = "denseMatrix", i = "index", j = "missing", value = "numeric" ...`

`x = "denseMatrix", i = "index", j = "index", value = "numeric" ...`

`x = "denseMatrix", i = "missing", j = "index", value = "numeric" ...`

### See Also

[\[-methods](#) for subsetting "Matrix" objects; the [index](#) class; [Extract](#) about the standard subset assignment (and extraction).

### Examples

```
set.seed(101)
(a <- m <- Matrix(round(rnorm(7*4),2), nrow = 7))

a[] <- 2.2 # <<- replaces every entry
a
as do these:
a[,] <- 3 ; a[TRUE,] <- 4

m[2, 3] <- 3.14 # simple number
```

```

m[3, 3:4] <- 3:4 # simple numeric of length 2

sub matrix assignment:
m[-(4:7), 3:4] <- cbind(1,2:4) #-> upper right corner of 'm'
m[3:5, 2:3] <- 0
m[6:7, 1:2] <- Diagonal(2)
m

rows or columns only:
m[1,] <- 10
m[,2] <- 1:7
m[-(1:6),] <- 3:0 # not the first 6 rows, i.e. only the 7th
as(m, "sparseMatrix")

```

---

%&%-methods*Boolean Arithmetic Matrix Products: %&% and Methods*

---

## Description

For boolean or “pattern” matrices, i.e., R objects of class `nMatrix`, it is natural to allow matrix products using boolean instead of numerical arithmetic.

In package **Matrix**, we use the binary operator `%&%` (aka “infix”) function) for this and provide methods for all our matrices and the traditional R matrices (see `matrix`).

## Value

a pattern matrix, i.e., inheriting from `"nMatrix"`, or an `"ldiMatrix"` in case of a diagonal matrix.

## Methods

We provide methods for both the “traditional” (R base) matrices and numeric vectors and conceptually all matrices and `sparseVectors` in package **Matrix**.

```

signature(x = "ANY", y = "ANY")
signature(x = "ANY", y = "Matrix")
signature(x = "Matrix", y = "ANY")
signature(x = "mMatrix", y = "mMatrix")
signature(x = "nMatrix", y = "nMatrix")
signature(x = "nMatrix", y = "nsparseMatrix")
signature(x = "nsparseMatrix", y = "nMatrix")
signature(x = "nsparseMatrix", y = "nsparseMatrix")
signature(x = "sparseVector", y = "mMatrix")
signature(x = "mMatrix", y = "sparseVector")
signature(x = "sparseVector", y = "sparseVector")

```

## Note

The current implementation ends up coercing both `x` and `y` to (virtual) class `nsparseMatrix` which may be quite inefficient. A future implementation may well return a matrix with **different** class, but the “same” content, i.e., the same matrix entries  $m_{ij}$ .

**Examples**

```

set.seed(7)
L <- Matrix(rnorm(20) > 1, 4,5)
(N <- as(L, "nMatrix"))
D <- Matrix(round(rnorm(30)), 5,6) # -> values in -1:1 (for this seed)
L %&% D
stopifnot(identical(L %&% D, N %&% D),
 all(L %&% D == as((L %*% abs(D)) > 0, "sparseMatrix")))

cross products , possibly with boolArith = TRUE :
crossprod(N) # -> sparse patter'n' (TRUE/FALSE : boolean arithmetic)
crossprod(N +0) # -> numeric Matrix (with same "pattern")
stopifnot(all(crossprod(N) == t(N) %&% N),
 identical(crossprod(N), crossprod(N +0, boolArith=TRUE)),
 identical(crossprod(L), crossprod(N , boolArith=FALSE)))
crossprod(D, boolArith = TRUE) # pattern: "nsCMatrix"
crossprod(L, boolArith = TRUE) # ditto
crossprod(L, boolArith = FALSE) # numeric: "dsCMatrix"

```

## Chapter 18

# The boot package

---

`abc.ci`

*Nonparametric ABC Confidence Intervals*

---

### Description

Calculate equi-tailed two-sided nonparametric approximate bootstrap confidence intervals for a parameter, given a set of data and an estimator of the parameter, using numerical differentiation.

### Usage

```
abc.ci(data, statistic, index=1, strata=rep(1, n), conf=0.95,
 eps=0.001/n, ...)
```

### Arguments

|                        |                                                                                                                                                                                                                                                                                                                                                                                     |
|------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>data</code>      | A data set expressed as a vector, matrix or data frame.                                                                                                                                                                                                                                                                                                                             |
| <code>statistic</code> | A function which returns the statistic of interest. The function must take at least 2 arguments; the first argument should be the data and the second a vector of weights. The weights passed to <code>statistic</code> will be normalized to sum to 1 within each stratum. Any other arguments should be passed to <code>abc.ci</code> as part of the <code>...{}</code> argument. |
| <code>index</code>     | If <code>statistic</code> returns a vector of length greater than 1, then this indicates the position of the variable of interest within that vector.                                                                                                                                                                                                                               |
| <code>strata</code>    | A factor or numerical vector indicating to which sample each observation belongs in multiple sample problems. The default is the one-sample case.                                                                                                                                                                                                                                   |
| <code>conf</code>      | A scalar or vector containing the confidence level(s) of the required interval(s).                                                                                                                                                                                                                                                                                                  |
| <code>eps</code>       | The value of epsilon to be used for the numerical differentiation.                                                                                                                                                                                                                                                                                                                  |
| <code>...</code>       | Any other arguments for <code>statistic</code> . These will be passed unchanged to <code>statistic</code> each time it is called within <code>abc.ci</code> .                                                                                                                                                                                                                       |

## Details

This function is based on the function `abcnon` written by R. Tibshirani. A listing of the original function is available in DiCiccio and Efron (1996). The function uses numerical differentiation for the first and second derivatives of the statistic and then uses these values to approximate the bootstrap BCa intervals. The total number of evaluations of the statistic is  $2 \cdot n + 2 + 2 \cdot \text{length}(\text{conf})$  where  $n$  is the number of data points (plus calculation of the original value of the statistic). The function works for the multiple sample case without the need to rewrite the statistic in an artificial form since the stratified normalization is done internally by the function.

## Value

A `length(conf)` by 3 matrix where each row contains the confidence level followed by the lower and upper end-points of the ABC interval at that level.

acme*Monthly Excess Returns*

---

**Description**

The `acme` data frame has 60 rows and 3 columns.

The excess return for the Acme Cleveland Corporation are recorded along with those for all stocks listed on the New York and American Stock Exchanges were recorded over a five year period. These excess returns are relative to the return on a risk-less investment such a U.S. Treasury bills.

**Usage**

`acme`

**Format**

This data frame contains the following columns:

`month` A character string representing the month of the observation.

`market` The excess return of the market as a whole.

`acme` The excess return for the Acme Cleveland Corporation.

**Source**

The data were obtained from

Simonoff, J.S. and Tsai, C.-L. (1994) Use of modified profile likelihood for improved tests of constancy of variance in regression. *Applied Statistics*, **43**, 353–370.

aids*Delay in AIDS Reporting in England and Wales*

---

**Description**

The `aids` data frame has 570 rows and 6 columns.

Although all cases of AIDS in England and Wales must be reported to the Communicable Disease Surveillance Centre, there is often a considerable delay between the time of diagnosis and the time that it is reported. In estimating the prevalence of AIDS, account must be taken of the unknown number of cases which have been diagnosed but not reported. The data set here records the reported cases of AIDS diagnosed from July 1983 and until the end of 1992. The data are cross-classified by the date of diagnosis and the time delay in the reporting of the cases.

**Usage**

`aids`

**Format**

This data frame contains the following columns:

`year` The year of the diagnosis.

`quarter` The quarter of the year in which diagnosis was made.

`delay` The time delay (in months) between diagnosis and reporting. 0 means that the case was reported within one month. Longer delays are grouped in 3 month intervals and the value of `delay` is the midpoint of the interval (therefore a value of 2 indicates that reporting was delayed for between 1 and 3 months).

`dud` An indicator of censoring. These are categories for which full information is not yet available and the number recorded is a lower bound only.

`time` The time interval of the diagnosis. That is the number of quarters from July 1983 until the end of the quarter in which these cases were diagnosed.

`y` The number of AIDS cases reported.

**Source**

The data were obtained from

De Angelis, D. and Gilks, W.R. (1994) Estimating acquired immune deficiency syndrome accounting for reporting delay. *Journal of the Royal Statistical Society, A*, **157**, 31–40.

aircondit

*Failures of Air-conditioning Equipment*

---

**Description**

Proschan (1963) reported on the times between failures of the air-conditioning equipment in 10 Boeing 720 aircraft. The `aircondit` data frame contains the intervals for the ninth aircraft while `aircondit7` contains those for the seventh aircraft.

Both data frames have just one column. Note that the data have been sorted into increasing order.

**Usage**

`aircondit`

**Format**

The data frames contain the following column:

`hours` The time interval in hours between successive failures of the air-conditioning equipment

**Source**

The data were taken from

Cox, D.R. and Snell, E.J. (1981) *Applied Statistics: Principles and Examples*. Chapman and Hall.

## References

---

amis

*Car Speeding and Warning Signs*

---

## Description

The `amis` data frame has 8437 rows and 4 columns.

In a study into the effect that warning signs have on speeding patterns, Cambridgeshire County Council considered 14 pairs of locations. The locations were paired to account for factors such as traffic volume and type of road. One site in each pair had a sign erected warning of the dangers of speeding and asking drivers to slow down. No action was taken at the second site. Three sets of measurements were taken at each site. Each set of measurements was nominally of the speeds of 100 cars but not all sites have exactly 100 measurements. These speed measurements were taken before the erection of the sign, shortly after the erection of the sign, and again after the sign had been in place for some time.

## Usage

`amis`

## Format

This data frame contains the following columns:

`speed` Speeds of cars (in miles per hour).

`period` A numeric column indicating the time that the reading was taken. A value of 1 indicates a reading taken before the sign was erected, a 2 indicates a reading taken shortly after erection of the sign and a 3 indicates a reading taken after the sign had been in place for some time.

`warning` A numeric column indicating whether the location of the reading was chosen to have a warning sign erected. A value of 1 indicates presence of a sign and a value of 2 indicates that no sign was erected.

`pair` A numeric column giving the pair number at which the reading was taken. Pairs were numbered from 1 to 14.

## Source

The data were kindly made available by Mr. Graham Amis, Cambridgeshire County Council, U.K.

aml

*Remission Times for Acute Myelogenous Leukaemia***Description**

The `aml` data frame has 23 rows and 3 columns.

A clinical trial to evaluate the efficacy of maintenance chemotherapy for acute myelogenous leukaemia was conducted by Embury et al. (1977) at Stanford University. After reaching a stage of remission through treatment by chemotherapy, patients were randomized into two groups. The first group received maintenance chemotherapy and the second group did not. The aim of the study was to see if maintenance chemotherapy increased the length of the remission. The data here formed a preliminary analysis which was conducted in October 1974.

**Usage**

```
aml
```

**Format**

This data frame contains the following columns:

`time` The length of the complete remission (in weeks).

`cens` An indicator of right censoring. 1 indicates that the patient had a relapse and so `time` is the length of the remission. 0 indicates that the patient had left the study or was still in remission in October 1974, that is the length of remission is right-censored.

`group` The group into which the patient was randomized. Group 1 received maintenance chemotherapy, group 2 did not.

**Note**

Package **survival** also has a dataset `aml`. It is the same data with different names and with `group` replaced by a factor `x`.

**Source**

The data were obtained from

Miller, R.G. (1981) *Survival Analysis*. John Wiley.

**References**

---

`beaver`*Beaver Body Temperature Data*

---

## Description

The `beaver` data frame has 100 rows and 4 columns. It is a multivariate time series of class `"ts"` and also inherits from class `"data.frame"`.

This data set is part of a long study into body temperature regulation in beavers. Four adult female beavers were live-trapped and had a temperature-sensitive radio transmitter surgically implanted. Readings were taken every 10 minutes. The location of the beaver was also recorded and her activity level was dichotomized by whether she was in the retreat or outside of it since high-intensity activities only occur outside of the retreat.

The data in this data frame are those readings for one of the beavers on a day in autumn.

## Usage

```
beaver
```

## Format

This data frame contains the following columns:

`day` The day number. The data includes only data from day 307 and early 308.

`time` The time of day formatted as hour-minute.

`temp` The body temperature in degrees Celsius.

`activ` The dichotomized activity indicator. 1 indicates that the beaver is outside of the retreat and therefore engaged in high-intensity activity.

## Source

The data were obtained from

Reynolds, P.S. (1994) Time-series analyses of beaver body temperatures. In *Case Studies in Biometry*. N. Lange, L. Ryan, L. Billard, D. Brillinger, L. Conquest and J. Greenhouse (editors), 211–228. John Wiley.

|---------|----------------------------------|
| bigcity | <i>Population of U.S. Cities</i> |
|---------|----------------------------------|

---

### Description

The `bigcity` data frame has 49 rows and 2 columns.

The `city` data frame has 10 rows and 2 columns.

The measurements are the population (in 1000's) of 49 U.S. cities in 1920 and 1930. The 49 cities are a random sample taken from the 196 largest cities in 1920. The `city` data frame consists of the first 10 observations in `bigcity`.

### Usage

```
bigcity
```

### Format

This data frame contains the following columns:

- u The 1920 population.
- x The 1930 population.

### Source

The data were obtained from

Cochran, W.G. (1977) *Sampling Techniques*. Third edition. John Wiley

---

|      |                             |
|------|-----------------------------|
| boot | <i>Bootstrap Resampling</i> |
|------|-----------------------------|

---

### Description

Generate R bootstrap replicates of a statistic applied to data. Both parametric and nonparametric resampling are possible. For the nonparametric bootstrap, possible resampling methods are the ordinary bootstrap, the balanced bootstrap, antithetic resampling, and permutation. For nonparametric multi-sample problems stratified resampling is used: this is specified by including a vector of strata in the call to `boot`. Importance resampling weights may be specified.

### Usage

```
boot(data, statistic, R, sim = "ordinary", stype = c("i", "f", "w"),
 strata = rep(1,n), L = NULL, m = 0, weights = NULL,
 ran.gen = function(d, p) d, mle = NULL, simple = FALSE, ...,
 parallel = c("no", "multicore", "snow"),
 ncpus = getOption("boot.ncpus", 1L), cl = NULL)
```

**Arguments**

|                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>data</code>      | The data as a vector, matrix or data frame. If it is a matrix or data frame then each row is considered as one multivariate observation.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <code>statistic</code> | A function which when applied to data returns a vector containing the statistic(s) of interest. When <code>sim = "parametric"</code> , the first argument to <code>statistic</code> must be the data. For each replicate a simulated dataset returned by <code>ran.gen</code> will be passed. In all other cases <code>statistic</code> must take at least two arguments. The first argument passed will always be the original data. The second will be a vector of indices, frequencies or weights which define the bootstrap sample. Further, if predictions are required, then a third argument is required which would be a vector of the random indices used to generate the bootstrap predictions. Any further arguments can be passed to <code>statistic</code> through the <code>...</code> argument. |
| <code>R</code>         | The number of bootstrap replicates. Usually this will be a single positive integer. For importance resampling, some resamples may use one set of weights and others use a different set of weights. In this case <code>R</code> would be a vector of integers where each component gives the number of resamples from each of the rows of weights.                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>sim</code>       | A character string indicating the type of simulation required. Possible values are "ordinary" (the default), "parametric", "balanced", "permutation", or "antithetic". Importance resampling is specified by including importance weights; the type of importance resampling must still be specified but may only be "ordinary" or "balanced" in this case.                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>stype</code>     | A character string indicating what the second argument of <code>statistic</code> represents. Possible values of <code>stype</code> are "i" (indices - the default), "f" (frequencies), or "w" (weights). Not used for <code>sim = "parametric"</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <code>strata</code>    | An integer vector or factor specifying the strata for multi-sample problems. This may be specified for any simulation, but is ignored when <code>sim = "parametric"</code> . When <code>strata</code> is supplied for a nonparametric bootstrap, the simulations are done within the specified strata.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>L</code>         | Vector of influence values evaluated at the observations. This is used only when <code>sim</code> is "antithetic". If not supplied, they are calculated through a call to <code>empinf</code> . This will use the infinitesimal jackknife provided that <code>stype</code> is "w", otherwise the usual jackknife is used.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>m</code>         | The number of predictions which are to be made at each bootstrap replicate. This is most useful for (generalized) linear models. This can only be used when <code>sim</code> is "ordinary". <code>m</code> will usually be a single integer but, if there are strata, it may be a vector with length equal to the number of strata, specifying how many of the errors for prediction should come from each strata. The actual predictions should be returned as the final part of the output of <code>statistic</code> , which should also take an argument giving the vector of indices of the errors to be used for the predictions.                                                                                                                                                                         |
| <code>weights</code>   | Vector or matrix of importance weights. If a vector then it should have as many elements as there are observations in <code>data</code> . When simulation from more than one set of weights is required, <code>weights</code> should be a matrix where each row of the matrix is one set of importance weights. If <code>weights</code> is a matrix then <code>R</code> must be a vector of length <code>nrow(weights)</code> . This parameter is ignored if <code>sim</code> is not "ordinary" or "balanced".                                                                                                                                                                                                                                                                                                 |
| <code>ran.gen</code>   | This function is used only when <code>sim = "parametric"</code> when it describes how random values are to be generated. It should be a function of two arguments.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

|                       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                       | The first argument should be the observed data and the second argument consists of any other information needed (e.g. parameter estimates). The second argument may be a list, allowing any number of items to be passed to <code>ran.gen</code> . The returned value should be a simulated data set of the same form as the observed data which will be passed to <code>statistic</code> to get a bootstrap replicate. It is important that the returned value be of the same shape and type as the original dataset. If <code>ran.gen</code> is not specified, the default is a function which returns the original data in which case all simulation should be included as part of <code>statistic</code> . Use of <code>sim = "parametric"</code> with a suitable <code>ran.gen</code> allows the user to implement any types of nonparametric resampling which are not supported directly. |
| <code>mle</code>      | The second argument to be passed to <code>ran.gen</code> . Typically these will be maximum likelihood estimates of the parameters. For efficiency <code>mle</code> is often a list containing all of the objects needed by <code>ran.gen</code> which can be calculated using the original data set only.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <code>simple</code>   | logical, only allowed to be <code>TRUE</code> for <code>sim = "ordinary"</code> , <code>stype = "i"</code> , <code>n = 0</code> (otherwise ignored with a warning). By default a <code>n</code> by <code>R</code> index array is created: this can be large and if <code>simple = TRUE</code> this is avoided by sampling separately for each replication, which is slower but uses less memory.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>...</code>      | Other named arguments for <code>statistic</code> which are passed unchanged each time it is called. Any such arguments to <code>statistic</code> should follow the arguments which <code>statistic</code> is required to have for the simulation. Beware of partial matching to arguments of <code>boot</code> listed above, and that arguments named <code>X</code> and <code>FUN</code> cause conflicts in some versions of <b>boot</b> (but not this one).                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>parallel</code> | The type of parallel operation to be used (if any). If missing, the default is taken from the option <code>"boot.parallel"</code> (and if that is not set, <code>"no"</code> ).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <code>ncpus</code>    | integer: number of processes to be used in parallel operation: typically one would chose this to the number of available CPUs.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <code>cl</code>       | An optional <b>parallel</b> or <b>snow</b> cluster for use if <code>parallel = "snow"</code> . If not supplied, a cluster on the local machine is created for the duration of the <code>boot</code> call.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

## Details

The statistic to be bootstrapped can be as simple or complicated as desired as long as its arguments correspond to the dataset and (for a nonparametric bootstrap) a vector of indices, frequencies or weights. `statistic` is treated as a black box by the `boot` function and is not checked to ensure that these conditions are met.

The first order balanced bootstrap is described in Davison, Hinkley and Schechtman (1986). The antithetic bootstrap is described by Hall (1989) and is experimental, particularly when used with `strata`. The other non-parametric simulation types are the ordinary bootstrap (possibly with unequal probabilities), and permutation which returns random permutations of cases. All of these methods work independently within `strata` if that argument is supplied.

For the parametric bootstrap it is necessary for the user to specify how the resampling is to be conducted. The best way of accomplishing this is to specify the function `ran.gen` which will return a simulated data set from the observed data set and a set of parameter estimates specified in `mle`.

## Value

The returned value is an object of class `"boot"`, containing the following components:

|                        |                                                                                                                                                                                                                                                                                                                                            |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>t0</code>        | The observed value of <code>statistic</code> applied to data.                                                                                                                                                                                                                                                                              |
| <code>t</code>         | A matrix with <code>sum(R)</code> rows each of which is a bootstrap replicate of the result of calling <code>statistic</code> .                                                                                                                                                                                                            |
| <code>R</code>         | The value of <code>R</code> as passed to <code>boot</code> .                                                                                                                                                                                                                                                                               |
| <code>data</code>      | The data as passed to <code>boot</code> .                                                                                                                                                                                                                                                                                                  |
| <code>seed</code>      | The value of <code>.Random.seed</code> when <code>boot</code> started work.                                                                                                                                                                                                                                                                |
| <code>statistic</code> | The function <code>statistic</code> as passed to <code>boot</code> .                                                                                                                                                                                                                                                                       |
| <code>sim</code>       | Simulation type used.                                                                                                                                                                                                                                                                                                                      |
| <code>stype</code>     | Statistic type as passed to <code>boot</code> .                                                                                                                                                                                                                                                                                            |
| <code>call</code>      | The original call to <code>boot</code> .                                                                                                                                                                                                                                                                                                   |
| <code>strata</code>    | The strata used. This is the vector passed to <code>boot</code> , if it was supplied or a vector of ones if there were no strata. It is not returned if <code>sim</code> is "parametric".                                                                                                                                                  |
| <code>weights</code>   | The importance sampling weights as passed to <code>boot</code> or the empirical distribution function weights if no importance sampling weights were specified. It is omitted if <code>sim</code> is not one of "ordinary" or "balanced".                                                                                                  |
| <code>pred.i</code>    | If predictions are required ( <code>m &gt; 0</code> ) this is the matrix of indices at which predictions were calculated as they were passed to <code>statistic</code> . Omitted if <code>m</code> is 0 or <code>sim</code> is not "ordinary".                                                                                             |
| <code>L</code>         | The influence values used when <code>sim</code> is "antithetic". If no such values were specified and <code>stype</code> is not "w" then <code>L</code> is returned as consecutive integers corresponding to the assumption that data is ordered by influence values. This component is omitted when <code>sim</code> is not "antithetic". |
| <code>ran.gen</code>   | The random generator function used if <code>sim</code> is "parametric". This component is omitted for any other value of <code>sim</code> .                                                                                                                                                                                                |
| <code>mle</code>       | The parameter estimates passed to <code>boot</code> when <code>sim</code> is "parametric". It is omitted for all other values of <code>sim</code> .                                                                                                                                                                                        |

There are `c`, `plot` and `print` methods for this class.

### Parallel operation

When `parallel = "multicore"` is used (not available on Windows), each worker process inherits the environment of the current session, including the workspace and the loaded namespaces and attached packages (but not the random number seed: see below).

More work is needed when `parallel = "snow"` is used: the worker processes are newly created R processes, and `statistic` needs to arrange to set up the environment it needs: often a good way to do that is to make use of lexical scoping since when `statistic` is sent to the worker processes its enclosing environment is also sent. (E.g. see the example for `jack.after.boot` where ancillary functions are nested inside the `statistic` function.) `parallel = "snow"` is primarily intended to be used on multi-core Windows machine where `parallel = "multicore"` is not available.

For most of the `boot` methods the resampling is done in the master process, but not if `simple = TRUE` nor `sim = "parametric"`. In those cases (or where `statistic` itself uses random numbers), more care is needed if the results need to be reproducible. Resampling is done in the worker processes by `censboot` (`sim = "wierd"`) and by most of the schemes in `tsboot` (the exceptions being `sim == "fixed"` and `sim == "geom"` with the default `ran.gen`).

Where random-number generation is done in the worker processes, the default behaviour is that each worker chooses a separate seed, non-reproducibly. However, with `parallel =`

"multicore" or `parallel = "snow"` using the default cluster, a second approach is used if `RNGkind("L'Ecuyer-CMRG")` has been selected. In that approach each worker gets a different subsequence of the RNG stream based on the seed at the time the worker is spawned and so the results will be reproducible if `ncpus` is unchanged, and for `parallel = "multicore"` if `parallel::mc.reset.stream()` is called: see the examples for `mclapply`.

Note that loading the **parallel** namespace may change the random seed, so for maximum reproducibility this should be done before calling this function.

## References

There are many references explaining the bootstrap and its variations. Among them are :

## Examples

```
Usual bootstrap of the ratio of means using the city data
ratio <- function(d, w) sum(d$x * w)/sum(d$u * w)
boot(city, ratio, R = 999, stype = "w")

Stratified resampling for the difference of means. In this
example we will look at the difference of means between the final
two series in the gravity data.
diff.means <- function(d, f)
{
 n <- nrow(d)
 gp1 <- 1:table(as.numeric(d$series))[1]
 m1 <- sum(d[gp1,1] * f[gp1])/sum(f[gp1])
 m2 <- sum(d[-gp1,1] * f[-gp1])/sum(f[-gp1])
 ss1 <- sum(d[gp1,1]^2 * f[gp1]) - (m1 * m1 * sum(f[gp1]))
 ss2 <- sum(d[-gp1,1]^2 * f[-gp1]) - (m2 * m2 * sum(f[-gp1]))
}
```

```

 c(m1 - m2, (ss1 + ss2)/(sum(f) - 2))
 }
 grav1 <- gravity[as.numeric(gravity[,2]) >= 7,]
 boot(grav1, diff.means, R = 999, stype = "f", strata = grav1[,2])

In this example we show the use of boot in a prediction from
regression based on the nuclear data. This example is taken
from Example 6.8 of Davison and Hinkley (1997). Notice also
that two extra arguments to 'statistic' are passed through boot.
nuke <- nuclear[, c(1, 2, 5, 7, 8, 10, 11)]
nuke.lm <- glm(log(cost) ~ date+log(cap)+ne+ct+log(cum.n)+pt, data = nuke)
nuke.diag <- glm.diag(nuke.lm)
nuke.res <- nuke.diag$res * nuke.diag$sd
nuke.res <- nuke.res - mean(nuke.res)

We set up a new data frame with the data, the standardized
residuals and the fitted values for use in the bootstrap.
nuke.data <- data.frame(nuke, resid = nuke.res, fit = fitted(nuke.lm))

Now we want a prediction of plant number 32 but at date 73.00
new.data <- data.frame(cost = 1, date = 73.00, cap = 886, ne = 0,
 ct = 0, cum.n = 11, pt = 1)
new.fit <- predict(nuke.lm, new.data)

nuke.fun <- function(dat, inds, i.pred, fit.pred, x.pred)
{
 lm.b <- glm(fit+resid[inds] ~ date+log(cap)+ne+ct+log(cum.n)+pt,
 data = dat)
 pred.b <- predict(lm.b, x.pred)
 c(coef(lm.b), pred.b - (fit.pred + dat$resid[i.pred]))
}

nuke.boot <- boot(nuke.data, nuke.fun, R = 999, m = 1,
 fit.pred = new.fit, x.pred = new.data)
The bootstrap prediction squared error would then be found by
mean(nuke.boot$t[, 8]^2)
Basic bootstrap prediction limits would be
new.fit - sort(nuke.boot$t[, 8])[c(975, 25)]

Finally a parametric bootstrap. For this example we shall look
at the air-conditioning data. In this example our aim is to test
the hypothesis that the true value of the index is 1 (i.e. that
the data come from an exponential distribution) against the
alternative that the data come from a gamma distribution with
index not equal to 1.
air.fun <- function(data) {
 ybar <- mean(data$hours)
 para <- c(log(ybar), mean(log(data$hours)))
 ll <- function(k) {
 if (k <= 0) 1e200 else lgamma(k)-k*(log(k)-1-para[1]+para[2])
 }
 khat <- nlm(ll, ybar^2/var(data$hours))$estimate
 c(ybar, khat)
}

air.rg <- function(data, mle) {

```

```

Function to generate random exponential variates.
mle will contain the mean of the original data
out <- data
out$hours <- rexp(nrow(out), 1/mle)
out
}

air.boot <- boot(aircondit, air.fun, R = 999, sim = "parametric",
 ran.gen = air.rg, mle = mean(aircondit$hours))

The bootstrap p-value can then be approximated by
sum(abs(air.boot$t[,2]-1) > abs(air.boot$t0[2]-1))/(1+air.boot$R)

```

boot.array

*Bootstrap Resampling Arrays*

### Description

This function takes a bootstrap object calculated by one of the functions `boot`, `censboot`, or `tilt.boot` and returns the frequency (or index) array for the bootstrap resamples.

### Usage

```
boot.array(boot.out, indices)
```

### Arguments

|                       |                                                                                                                                                                                                                                                                     |
|-----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>boot.out</code> | An object of class "boot" returned by one of the generation functions for such an object.                                                                                                                                                                           |
| <code>indices</code>  | A logical argument which specifies whether to return the frequency array or the raw index array. The default is <code>indices=FALSE</code> unless <code>boot.out</code> was created by <code>tsboot</code> in which case the default is <code>indices=TRUE</code> . |

### Details

The process by which the original index array was generated is repeated with the same value of `.Random.seed`. If the frequency array is required then `freq.array` is called to convert the index array to a frequency array.

A resampling array can only be returned when such a concept makes sense. In particular it cannot be found for any parametric or model-based resampling schemes. Hence for objects generated by `censboot` the only resampling scheme for which such an array can be found is ordinary case resampling. Similarly if `boot.out$sim` is "parametric" in the case of `boot` or "model" in the case of `tsboot` the array cannot be found. Note also that for post-blackened bootstraps from `tsboot` the indices found will relate to those prior to any post-blackening and so will not be useful.

Frequency arrays are used in many post-bootstrap calculations such as the jackknife-after-bootstrap and finding importance sampling weights. They are also used to find empirical influence values through the regression method.

**Value**

A matrix with `boot.out$R` rows and `n` columns where `n` is the number of observations in `boot.out$data`. If `indices` is `FALSE` then this will give the frequency of each of the original observations in each bootstrap resample. If `indices` is `TRUE` it will give the indices of the bootstrap resamples in the order in which they would have been passed to the statistic.

**Side Effects**

This function temporarily resets `.Random.seed` to the value in `boot.out$seed` and then returns it to its original value at the end of the function.

**See Also**

`boot`, `censboot`, `freq.array`, `tilt.boot`, `tsboot`

**Examples**

```
A frequency array for a nonparametric bootstrap
city.boot <- boot(city, corr, R = 40, stype = "w")
boot.array(city.boot)

perm.cor <- function(d,i) cor(dx,du[i])
city.perm <- boot(city, perm.cor, R = 40, sim = "permutation")
boot.array(city.perm, indices = TRUE)
```

---

boot.ci

*Nonparametric Bootstrap Confidence Intervals*

---

**Description**

This function generates 5 different types of equi-tailed two-sided nonparametric confidence intervals. These are the first order normal approximation, the basic bootstrap interval, the studentized bootstrap interval, the bootstrap percentile interval, and the adjusted bootstrap percentile (BCa) interval. All or a subset of these intervals can be generated.

**Usage**

```
boot.ci(boot.out, conf = 0.95, type = "all",
 index = 1:min(2,length(boot.out$t0)), var.t0 = NULL,
 var.t = NULL, t0 = NULL, t = NULL, L = NULL,
 h = function(t) t, hdot = function(t) rep(1,length(t)),
 hinv = function(t) t, ...)
```

**Arguments**

|                       |                                                                                                                                                                                                                                                |
|-----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>boot.out</code> | An object of class "boot" containing the output of a bootstrap calculation.                                                                                                                                                                    |
| <code>conf</code>     | A scalar or vector containing the confidence level(s) of the required interval(s).                                                                                                                                                             |
| <code>type</code>     | A vector of character strings representing the type of intervals required. The value should be any subset of the values <code>c("norm", "basic", "stud", "perc", "bca")</code> or simply "all" which will compute all five types of intervals. |

|                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|---------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>index</code>  | This should be a vector of length 1 or 2. The first element of <code>index</code> indicates the position of the variable of interest in <code>boot.out\$t0</code> and the relevant column in <code>boot.out\$t</code> . The second element indicates the position of the variance of the variable of interest. If both <code>var.t0</code> and <code>var.t</code> are supplied then the second element of <code>index</code> (if present) is ignored. The default is that the variable of interest is in position 1 and its variance is in position 2 (as long as there are 2 positions in <code>boot.out\$t0</code> ).                          |
| <code>var.t0</code> | If supplied, a value to be used as an estimate of the variance of the statistic for the normal approximation and studentized intervals. If it is not supplied and <code>length(index)</code> is 2 then <code>var.t0</code> defaults to <code>boot.out\$t0[index[2]]</code> otherwise <code>var.t0</code> is undefined. For studentized intervals <code>var.t0</code> must be defined. For the normal approximation, if <code>var.t0</code> is undefined it defaults to <code>var(t)</code> . If a transformation is supplied through the argument <code>h</code> then <code>var.t0</code> should be the variance of the untransformed statistic. |
| <code>var.t</code>  | This is a vector (of length <code>boot.out\$R</code> ) of variances of the bootstrap replicates of the variable of interest. It is used only for studentized intervals. If it is not supplied and <code>length(index)</code> is 2 then <code>var.t</code> defaults to <code>boot.out\$t[,index[2]]</code> , otherwise its value is undefined which will cause an error for studentized intervals. If a transformation is supplied through the argument <code>h</code> then <code>var.t</code> should be the variance of the untransformed bootstrap statistics.                                                                                  |
| <code>t0</code>     | The observed value of the statistic of interest. The default value is <code>boot.out\$t0[index[1]]</code> . Specification of <code>t0</code> and <code>t</code> allows the user to get intervals for a transformed statistic which may not be in the bootstrap output object. See the second example below. An alternative way of achieving this would be to supply the functions <code>h</code> , <code>hdot</code> , and <code>hinv</code> below.                                                                                                                                                                                              |
| <code>t</code>      | The bootstrap replicates of the statistic of interest. It must be a vector of length <code>boot.out\$R</code> . It is an error to supply one of <code>t0</code> or <code>t</code> but not the other. Also if studentized intervals are required and <code>t0</code> and <code>t</code> are supplied then so should be <code>var.t0</code> and <code>var.t</code> . The default value is <code>boot.out\$t[,index]</code> .                                                                                                                                                                                                                       |
| <code>L</code>      | The empirical influence values of the statistic of interest for the observed data. These are used only for BCa intervals. If a transformation is supplied through the parameter <code>h</code> then <code>L</code> should be the influence values for <code>t</code> ; the values for <code>h(t)</code> are derived from these and <code>hdot</code> within the function. If <code>L</code> is not supplied then the values are calculated using <code>empinf</code> if they are needed.                                                                                                                                                         |
| <code>h</code>      | A function defining a transformation. The intervals are calculated on the scale of <code>h(t)</code> and the inverse function <code>hinv</code> applied to the resulting intervals. It must be a function of one variable only and for a vector argument, it must return a vector of the same length, i.e. <code>h(c(t1,t2,t3))</code> should return <code>c(h(t1),h(t2),h(t3))</code> . The default is the identity function.                                                                                                                                                                                                                   |
| <code>hdot</code>   | A function of one argument returning the derivative of <code>h</code> . It is a required argument if <code>h</code> is supplied and normal, studentized or BCa intervals are required. The function is used for approximating the variances of <code>h(t0)</code> and <code>h(t)</code> using the delta method, and also for finding the empirical influence values for BCa intervals. Like <code>h</code> it should be able to take a vector argument and return a vector of the same length. The default is the constant function 1.                                                                                                           |
| <code>hinv</code>   | A function, like <code>h</code> , which returns the inverse of <code>h</code> . It is used to transform the intervals calculated on the scale of <code>h(t)</code> back to the original scale. The default is the identity function. If <code>h</code> is supplied but <code>hinv</code> is not, then the intervals returned will be on the transformed scale.                                                                                                                                                                                                                                                                                   |

... Any extra arguments that `boot.out$statistic` is expecting. These arguments are needed only if BCa intervals are required and `L` is not supplied since in that case `L` is calculated through a call to `empinf` which calls `boot.out$statistic`.

## Details

The formulae on which the calculations are based can be found in Chapter 5 of Davison and Hinkley (1997). Function `boot` must be run prior to running this function to create the object to be passed as `boot.out`.

Variance estimates are required for studentized intervals. The variance of the observed statistic is optional for normal theory intervals. If it is not supplied then the bootstrap estimate of variance is used. The normal intervals also use the bootstrap bias correction.

Interpolation on the normal quantile scale is used when a non-integer order statistic is required. If the order statistic used is the smallest or largest of the `R` values in `boot.out` a warning is generated and such intervals should not be considered reliable.

## Value

An object of type `"bootci"` which contains the intervals. It has components

|                      |                                                                                                                                                                                                                                                                                                                                    |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>R</code>       | The number of bootstrap replicates on which the intervals were based.                                                                                                                                                                                                                                                              |
| <code>t0</code>      | The observed value of the statistic on the same scale as the intervals.                                                                                                                                                                                                                                                            |
| <code>call</code>    | The call to <code>boot.ci</code> which generated the object.<br>It will also contain one or more of the following components depending on the value of <code>type</code> used in the call to <code>bootci</code> .                                                                                                                 |
| <code>normal</code>  | A matrix of intervals calculated using the normal approximation. It will have 3 columns, the first being the level and the other two being the upper and lower endpoints of the intervals.                                                                                                                                         |
| <code>basic</code>   | The intervals calculated using the basic bootstrap method.                                                                                                                                                                                                                                                                         |
| <code>student</code> | The intervals calculated using the studentized bootstrap method.                                                                                                                                                                                                                                                                   |
| <code>percent</code> | The intervals calculated using the bootstrap percentile method.                                                                                                                                                                                                                                                                    |
| <code>bca</code>     | The intervals calculated using the adjusted bootstrap percentile (BCa) method.<br>These latter four components will be matrices with 5 columns, the first column containing the level, the next two containing the indices of the order statistics used in the calculations and the final two the calculated endpoints themselves. |

**Examples**

```

confidence intervals for the city data
ratio <- function(d, w) sum(d$x * w)/sum(d$u * w)
city.boot <- boot(city, ratio, R = 999, stype = "w", sim = "ordinary")
boot.ci(city.boot, conf = c(0.90, 0.95),
 type = c("norm", "basic", "perc", "bca"))

studentized confidence interval for the two sample
difference of means problem using the final two series
of the gravity data.
diff.means <- function(d, f)
{
 n <- nrow(d)
 gp1 <- 1:table(as.numeric(d$series))[1]
 m1 <- sum(d[gp1,1] * f[gp1])/sum(f[gp1])
 m2 <- sum(d[-gp1,1] * f[-gp1])/sum(f[-gp1])
 ss1 <- sum(d[gp1,1]^2 * f[gp1]) - (m1 * m1 * sum(f[gp1]))
 ss2 <- sum(d[-gp1,1]^2 * f[-gp1]) - (m2 * m2 * sum(f[-gp1]))
 c(m1 - m2, (ss1 + ss2)/(sum(f) - 2))
}
grav1 <- gravity[as.numeric(gravity[,2]) >= 7,]
grav1.boot <- boot(grav1, diff.means, R = 999, stype = "f",
 strata = grav1[,2])
boot.ci(grav1.boot, type = c("stud", "norm"))

Nonparametric confidence intervals for mean failure time
of the air-conditioning data as in Example 5.4 of Davison
and Hinkley (1997)
mean.fun <- function(d, i)
{
 m <- mean(d$hours[i])
 n <- length(i)
 v <- (n-1)*var(d$hours[i])/n^2
 c(m, v)
}
air.boot <- boot(aircondit, mean.fun, R = 999)
boot.ci(air.boot, type = c("norm", "basic", "perc", "stud"))

Now using the log transformation
There are two ways of doing this and they both give the
same intervals.

Method 1
boot.ci(air.boot, type = c("norm", "basic", "perc", "stud"),
 h = log, hdot = function(x) 1/x)

Method 2
vt0 <- air.boot$t0[2]/air.boot$t0[1]^2
vt <- air.boot$t[, 2]/air.boot$t[, 1]^2
boot.ci(air.boot, type = c("norm", "basic", "perc", "stud"),
 t0 = log(air.boot$t0[1]), t = log(air.boot$t[,1]),
 var.t0 = vt0, var.t = vt)

```

**Description**

The `brambles` data frame has 823 rows and 3 columns.

The location of living bramble canes in a 9m square plot was recorded. We take 9m to be the unit of distance so that the plot can be thought of as a unit square. The bramble canes were also classified by their age.

**Usage**

```
brambles
```

**Format**

This data frame contains the following columns:

`x` The x coordinate of the position of the cane in the plot.

`y` The y coordinate of the position of the cane in the plot.

`age` The age classification of the canes; 0 indicates a newly emerged cane, 1 indicates a one year old cane and 2 indicates a two year old cane.

**Source**

The data were obtained from

`breslow`*Smoking Deaths Among Doctors*

---

**Description**

The `breslow` data frame has 10 rows and 5 columns.

In 1961 Doll and Hill sent out a questionnaire to all men on the British Medical Register enquiring about their smoking habits. Almost 70% of such men replied. Death certificates were obtained for medical practitioners and causes of death were assigned on the basis of these certificates. The `breslow` data set contains the person-years of observations and deaths from coronary artery disease accumulated during the first ten years of the study.

**Usage**

```
breslow
```

**Format**

This data frame contains the following columns:

- age The mid-point of the 10 year age-group for the doctors.
- smoke An indicator of whether the doctors smoked (1) or not (0).
- n The number of person-years in the category.
- y The number of deaths attributed to coronary artery disease.
- ns The number of smoker years in the category (`smoke*n`).

**Source**

The data were obtained from

Breslow, N.E. (1985) Cohort Analysis in Epidemiology. In *A Celebration of Statistics* A.C. Atkinson and S.E. Fienberg (editors), 109–143. Springer-Verlag.

calcium

*Calcium Uptake Data*

---

**Description**

The `calcium` data frame has 27 rows and 2 columns.

Howard Grimes from the Botany Department, North Carolina State University, conducted an experiment for biochemical analysis of intracellular storage and transport of calcium across plasma membrane. Cells were suspended in a solution of radioactive calcium for a certain length of time and then the amount of radioactive calcium that was absorbed by the cells was measured. The experiment was repeated independently with 9 different times of suspension each replicated 3 times.

**Usage**

`calcium`

**Format**

This data frame contains the following columns:

- time The time (in minutes) that the cells were suspended in the solution.
- cal The amount of calcium uptake (nmoles/mg).

**Source**

The data were obtained from

Rawlings, J.O. (1988) *Applied Regression Analysis*. Wadsworth and Brooks/Cole Statistics/Probability Series.

cane

*Sugar-cane Disease Data*

---

## Description

The `cane` data frame has 180 rows and 5 columns. The data frame represents a randomized block design with 45 varieties of sugar-cane and 4 blocks.

## Usage

`cane`

## Format

This data frame contains the following columns:

- `n` The total number of shoots in each plot.
- `r` The number of diseased shoots.
- `x` The number of pieces of the stems, out of 50, planted in each plot.
- `var` A factor indicating the variety of sugar-cane in each plot.
- `block` A factor for the blocks.

## Details

The aim of the experiment was to classify the varieties into resistant, intermediate and susceptible to a disease called "coal of sugar-cane" (carvão da cana-de-açúcar). This is a disease that is common in sugar-cane plantations in certain areas of Brazil.

For each plot, fifty pieces of sugar-cane stem were put in a solution containing the disease agent and then some were planted in the plot. After a fixed period of time, the total number of shoots and the number of diseased shoots were recorded.

## Source

The data were kindly supplied by Dr. C.G.B. Demetrio of Escola Superior de Agricultura, Universidade de São Paulo, Brazil.

|------------|---------------------------------------------|
| capability | <i>Simulated Manufacturing Process Data</i> |
|------------|---------------------------------------------|

---

**Description**

The `capability` data frame has 75 rows and 1 columns.

The data are simulated successive observations from a process in equilibrium. The process is assumed to have specification limits (5.49, 5.79).

**Usage**

```
capability
```

**Format**

This data frame contains the following column:

`y` The simulated measurements.

**Source**

The data were obtained from

Bissell, A.F. (1990) How reliable is your capability index? *Applied Statistics*, **39**, 331–340.

|-------|--------------------------------------|
| catsM | <i>Weight Data for Domestic Cats</i> |
|-------|--------------------------------------|

---

**Description**

The `catsM` data frame has 97 rows and 3 columns.

144 adult (over 2kg in weight) cats used for experiments with the drug digitalis had their heart and body weight recorded. 47 of the cats were female and 97 were male. The `catsM` data frame consists of the data for the male cats. The full data are in dataset `cats` in package `MASS`.

**Usage**

```
catsM
```

### Format

This data frame contains the following columns:

`Sex` A factor for the sex of the cat (levels are F and M: all cases are M in this subset).

`Bwt` Body weight in kg.

`Hwt` Heart weight in g.

cav

*Position of Muscle Caveolae*

---

### Description

The `cav` data frame has 138 rows and 2 columns.

The data gives the positions of the individual caveolae in a square region with sides of length 500 units. This grid was originally on a 2.65µm square of muscle fibre. The data are those points falling in the lower left hand quarter of the region used for the dataset `caveolae.dat` in the **spatial** package by B.D. Ripley (1994).

### Usage

`cav`

### Format

This data frame contains the following columns:

`x` The x coordinate of the caveola's position in the region.

`y` The y coordinate of the caveola's position in the region.

cd4

*CD4 Counts for HIV-Positive Patients***Description**

The `cd4` data frame has 20 rows and 2 columns.

CD4 cells are carried in the blood as part of the human immune system. One of the effects of the HIV virus is that these cells die. The count of CD4 cells is used in determining the onset of full-blown AIDS in a patient. In this study of the effectiveness of a new anti-viral drug on HIV, 20 HIV-positive patients had their CD4 counts recorded and then were put on a course of treatment with this drug. After using the drug for one year, their CD4 counts were again recorded. The aim of the experiment was to show that patients taking the drug had increased CD4 counts which is not generally seen in HIV-positive patients.

**Usage**

cd4

**Format**

This data frame contains the following columns:

`baseline` The CD4 counts (in 100's) on admission to the trial.

`oneyear` The CD4 counts (in 100's) after one year of treatment with the new drug.

**Source**

The data were obtained from

DiCiccio, T.J. and Efron B. (1996) Bootstrap confidence intervals (with Discussion). *Statistical Science*, **11**, 189–228.

**References**

cd4.nested

*Nested Bootstrap of cd4 data***Description**

This is an example of a nested bootstrap for the correlation coefficient of the `cd4` data frame. It is used in a practical in Chapter 5 of Davison and Hinkley (1997).

**References**

Davison, A.C. and Hinkley, D.V. (1997) *Bootstrap Methods and Their Application*. Cambridge University Press.

**See Also**

[cd4](#)

**Description**

This function applies types of bootstrap resampling which have been suggested to deal with right-censored data. It can also do model-based resampling using a Cox regression model.

**Usage**

```
censboot(data, statistic, R, F.surv, G.surv, strata = matrix(1,n,2),
 sim = "ordinary", cox = NULL, index = c(1, 2), ...,
 parallel = c("no", "multicore", "snow"),
 ncpus = getOption("boot.ncpus", 1L), cl = NULL)
```

**Arguments**

|                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>data</code>      | The data frame or matrix containing the data. It must have at least two columns, one of which contains the times and the other the censoring indicators. It is allowed to have as many other columns as desired (although efficiency is reduced for large numbers of columns) except for <code>sim = "weird"</code> when it should only have two columns - the times and censoring indicators. The columns of <code>data</code> referenced by the components of <code>index</code> are taken to be the times and censoring indicators.                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>statistic</code> | A function which operates on the data frame and returns the required statistic. Its first argument must be the data. Any other arguments that it requires can be passed using the <code>...</code> argument. In the case of <code>sim = "weird"</code> , the data passed to <code>statistic</code> only contains the times and censoring indicator regardless of the actual number of columns in <code>data</code> . In all other cases the data passed to <code>statistic</code> will be of the same form as the original data. When <code>sim = "weird"</code> , the actual number of observations in the resampled data sets may not be the same as the number in <code>data</code> . For this reason, if <code>sim = "weird"</code> and <code>strata</code> is supplied, <code>statistic</code> should also take a numeric vector indicating the strata. This allows the statistic to depend on the strata if required. |
| <code>R</code>         | The number of bootstrap replicates.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>F.surv</code>    | An object returned from a call to <code>survfit</code> giving the survivor function for the data. This is a required argument unless <code>sim = "ordinary"</code> or <code>sim = "model"</code> and <code>cox</code> is missing.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>G.surv</code>    | Another object returned from a call to <code>survfit</code> but with the censoring indicators reversed to give the product-limit estimate of the censoring distribution. Note that for consistency the uncensored times should be reduced by a small amount in the call to <code>survfit</code> . This is a required argument whenever <code>sim = "cond"</code> or when <code>sim = "model"</code> and <code>cox</code> is supplied.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <code>strata</code>    | The strata used in the calls to <code>survfit</code> . It can be a vector or a matrix with 2 columns. If it is a vector then it is assumed to be the strata for the survival distribution, and the censoring distribution is assumed to be the same for all observations. If it is a matrix then the first column is the strata for the survival distribution and the second is the strata for the censoring distribution. When <code>sim = "weird"</code> only the strata for the survival distribution are used since the                                                                                                                                                                                                                                                                                                                                                                                                 |

censoring times are considered fixed. When `sim = "ordinary"`, only one set of strata is used to stratify the observations, this is taken to be the first column of `strata` when it is a matrix.

`sim` The simulation type. Possible types are "ordinary" (case resampling), "model" (equivalent to "ordinary" if `cox` is missing, otherwise it is model-based resampling), "weird" (the weird bootstrap - this cannot be used if `cox` is supplied), and "cond" (the conditional bootstrap, in which censoring times are resampled from the conditional censoring distribution).

`cox` An object returned from `coxph`. If it is supplied, then `F.surv` should have been generated by a call of the form `survfit(cox)`.

`index` A vector of length two giving the positions of the columns in `data` which correspond to the times and censoring indicators respectively.

`...` Other named arguments which are passed unchanged to `statistic` each time it is called. Any such arguments to `statistic` must follow the arguments which `statistic` is required to have for the simulation. Beware of partial matching to arguments of `censboot` listed above, and that arguments named `X` and `FUN` cause conflicts in some versions of **boot** (but not this one).

`parallel, ncpus, cl`  
See the help for `boot`.

## Details

The various types of resampling are described in Davison and Hinkley (1997) in sections 3.5 and 7.3. The simplest is case resampling which simply resamples with replacement from the observations.

The conditional bootstrap simulates failure times from the estimate of the survival distribution. Then, for each observation its simulated censoring time is equal to the observed censoring time if the observation was censored and generated from the estimated censoring distribution conditional on being greater than the observed failure time if the observation was uncensored. If the largest value is censored then it is given a nominal failure time of `Inf` and conversely if it is uncensored it is given a nominal censoring time of `Inf`. This is necessary to allow the largest observation to be in the resamples.

If a Cox regression model is fitted to the data and supplied, then the failure times are generated from the survival distribution using that model. In this case the censoring times can either be simulated from the estimated censoring distribution (`sim = "model"`) or from the conditional censoring distribution as in the previous paragraph (`sim = "cond"`).

The weird bootstrap holds the censored observations as fixed and also the observed failure times. It then generates the number of events at each failure time using a binomial distribution with mean 1 and denominator the number of failures that could have occurred at that time in the original data set. In our implementation we insist that there is a least one simulated event in each stratum for every bootstrap dataset.

When there are strata involved and `sim` is either "model" or "cond" the situation becomes more difficult. Since the strata for the survival and censoring distributions are not the same it is possible that for some observations both the simulated failure time and the simulated censoring time are infinite. To see this consider an observation in stratum 1F for the survival distribution and stratum 1G for the censoring distribution. Now if the largest value in stratum 1F is censored it is given a nominal failure time of `Inf`, also if the largest value in stratum 1G is uncensored it is given a nominal censoring time of `Inf` and so both the simulated failure and censoring times could be infinite. When this happens the simulated value is considered to be a failure at the time of the largest observed failure time in the stratum for the survival distribution.

When `parallel = "snow"` and `cl` is not supplied, `library(survival)` is run in each of the worker processes.

## Value

An object of class `"boot"` containing the following components:

|                        |                                                                                                                                                                                                                                                                                                                                         |
|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>t0</code>        | The value of <code>statistic</code> when applied to the original data.                                                                                                                                                                                                                                                                  |
| <code>t</code>         | A matrix of bootstrap replicates of the values of <code>statistic</code> .                                                                                                                                                                                                                                                              |
| <code>R</code>         | The number of bootstrap replicates performed.                                                                                                                                                                                                                                                                                           |
| <code>sim</code>       | The simulation type used. This will usually be the input value of <code>sim</code> unless that was <code>"model"</code> but <code>cox</code> was not supplied, in which case it will be <code>"ordinary"</code> .                                                                                                                       |
| <code>data</code>      | The data used for the bootstrap. This will generally be the input value of <code>data</code> unless <code>sim = "weird"</code> , in which case it will just be the columns containing the times and the censoring indicators.                                                                                                           |
| <code>seed</code>      | The value of <code>.Random.seed</code> when <code>censboot</code> started work.                                                                                                                                                                                                                                                         |
| <code>statistic</code> | The input value of <code>statistic</code> .                                                                                                                                                                                                                                                                                             |
| <code>strata</code>    | The strata used in the resampling. When <code>sim = "ordinary"</code> this will be a vector which stratifies the observations, when <code>sim = "weird"</code> it is the strata for the survival distribution and in all other cases it is a matrix containing the strata for the survival distribution and the censoring distribution. |
| <code>call</code>      | The original call to <code>censboot</code> .                                                                                                                                                                                                                                                                                            |

**Examples**

```

library(survival)
Example 3.9 of Davison and Hinkley (1997) does a bootstrap on some
remission times for patients with a type of leukaemia. The patients
were divided into those who received maintenance chemotherapy and
those who did not. Here we are interested in the median remission
time for the two groups.
data(aml, package = "boot") # not the version in survival.
aml.fun <- function(data) {
 surv <- survfit(Surv(time, cens) ~ group, data = data)
 out <- NULL
 st <- 1
 for (s in 1:length(surv$strata)) {
 inds <- st:(st + surv$strata[s]-1)
 md <- min(surv$time[inds[1-surv$surv[inds] >= 0.5]])
 st <- st + surv$strata[s]
 out <- c(out, md)
 }
 out
}
aml.case <- censboot(aml, aml.fun, R = 499, strata = aml$group)

Now we will look at the same statistic using the conditional
bootstrap and the weird bootstrap. For the conditional bootstrap
the survival distribution is stratified but the censoring
distribution is not.

aml.s1 <- survfit(Surv(time, cens) ~ group, data = aml)
aml.s2 <- survfit(Surv(time-0.001*cens, 1-cens) ~ 1, data = aml)
aml.cond <- censboot(aml, aml.fun, R = 499, strata = aml$group,
 F.surv = aml.s1, G.surv = aml.s2, sim = "cond")

For the weird bootstrap we must redefine our function slightly since
the data will not contain the group number.
aml.fun1 <- function(data, str) {
 surv <- survfit(Surv(data[, 1], data[, 2]) ~ str)
 out <- NULL
 st <- 1
 for (s in 1:length(surv$strata)) {
 inds <- st:(st + surv$strata[s] - 1)
 md <- min(surv$time[inds[1-surv$surv[inds] >= 0.5]])
 st <- st + surv$strata[s]
 out <- c(out, md)
 }
 out
}
aml.wei <- censboot(cbind(aml$time, aml$cens), aml.fun1, R = 499,
 strata = aml$group, F.surv = aml.s1, sim = "weird")

Now for an example where a cox regression model has been fitted
the data we will look at the melanoma data of Example 7.6 from
Davison and Hinkley (1997). The fitted model assumes that there
is a different survival distribution for the ulcerated and
non-ulcerated groups but that the thickness of the tumour has a
common effect. We will also assume that the censoring distribution

```

```

is different in different age groups. The statistic of interest
is the linear predictor. This is returned as the values at a
number of equally spaced points in the range of interest.
data(melanoma, package = "boot")
library(splines) # for ns
mel.cox <- coxph(Surv(time, status == 1) ~ ns(thickness, df=4) + strata(ulcer),
 data = melanoma)
mel.surv <- survfit(mel.cox)
agec <- cut(melanoma$age, c(0, 39, 49, 59, 69, 100))
mel.cens <- survfit(Surv(time - 0.001*(status == 1), status != 1) ~
 strata(agec), data = melanoma)
mel.fun <- function(d) {
 t1 <- ns(d$thickness, df=4)
 cox <- coxph(Surv(d$time, d$status == 1) ~ t1+strata(d$ulcer))
 ind <- !duplicated(d$thickness)
 u <- d$thickness[!ind]
 eta <- cox$linear.predictors[!ind]
 sp <- smooth.spline(u, eta, df=20)
 th <- seq(from = 0.25, to = 10, by = 0.25)
 predict(sp, th)$y
}
mel.str <- cbind(melanoma$ulcer, agec)

this is slow!
mel.mod <- censboot(melanoma, mel.fun, R = 499, F.surv = mel.surv,
 G.surv = mel.cens, cox = mel.cox, strata = mel.str, sim = "model")
To plot the original predictor and a 95% pointwise envelope for it
mel.env <- envelope(mel.mod)$point
th <- seq(0.25, 10, by = 0.25)
plot(th, mel.env[1,], ylim = c(-2, 2),
 xlab = "thickness (mm)", ylab = "linear predictor", type = "n")
lines(th, mel.mod$t0, lty = 1)
matlines(th, t(mel.env), lty = 2)

```

channing

Channing House Data

---

## Description

The channing data frame has 462 rows and 5 columns.

Channing House is a retirement centre in Palo Alto, California. These data were collected between the opening of the house in 1964 until July 1, 1975. In that time 97 men and 365 women passed through the centre. For each of these, their age on entry and also on leaving or death was recorded. A large number of the observations were censored mainly due to the resident being alive on July 1, 1975 when the data was collected. Over the time of the study 130 women and 46 men died at Channing House. Differences between the survival of the sexes, taking age into account, was one of the primary concerns of this study.

## Usage

```
channing
```

**Format**

This data frame contains the following columns:

- `sex` A factor for the sex of each resident ("Male" or "Female").
- `entry` The residents age (in months) on entry to the centre
- `exit` The age (in months) of the resident on death, leaving the centre or July 1, 1975 whichever event occurred first.
- `time` The length of time (in months) that the resident spent at Channing House.  
(`time=exit-entry`)
- `cens` The indicator of right censoring. 1 indicates that the resident died at Channing House, 0 indicates that they left the house prior to July 1, 1975 or that they were still alive and living in the centre at that date.

claridge

*Genetic Links to Left-handedness*

---

**Description**

The `claridge` data frame has 37 rows and 2 columns.

The data are from an experiment which was designed to look for a relationship between a certain genetic characteristic and handedness. The 37 subjects were women who had a son with mental retardation due to inheriting a defective X-chromosome. For each such mother a genetic measurement of their DNA was made. Larger values of this measurement are known to be linked to the defective gene and it was hypothesized that larger values might also be linked to a progressive shift away from right-handedness. Each woman also filled in a questionnaire regarding which hand they used for various tasks. From these questionnaires a measure of hand preference was found for each mother. The scale of this measure goes from 1, indicating someone who always favours their right hand, to 8, indicating someone who always favours their left hand. Between these two extremes are people who favour one hand for some tasks and the other for other tasks.

**Usage**

```
claridge
```

**Format**

This data frame contains the following columns:

- `dnan` The genetic measurement on each woman's DNA.
- `hand` The measure of left-handedness on an integer scale from 1 to 8.

**Source**

The data were kindly made available by Dr. Gordon S. Claridge from the Department of Experimental Psychology, University of Oxford.

`co.transfer`
*Carbon Monoxide Transfer*

---

### Description

The `co.transfer` data frame has 7 rows and 2 columns. Seven smokers with chickenpox had their levels of carbon monoxide transfer measured on entry to hospital and then again after 1 week. The main question being whether one week of hospitalization has changed the carbon monoxide transfer factor.

### Usage

```
co.transfer
```

### Format

This data frame contains the following columns:

`entry` Carbon monoxide transfer factor on entry to hospital.

`week` Carbon monoxide transfer one week after admittance to hospital.

### Source

The data were obtained from

---

`coal`
*Dates of Coal Mining Disasters*

---

### Description

The `coal` data frame has 191 rows and 1 columns.

This data frame gives the dates of 191 explosions in coal mines which resulted in 10 or more fatalities. The time span of the data is from March 15, 1851 until March 22 1962.

### Usage

```
coal
```

## Format

This data frame contains the following column:

`date` The date of the disaster. The integer part of `date` gives the year. The day is represented as the fraction of the year that had elapsed on that day.

## Source

The data were obtained from

Hand, D.J., Daly, F., Lunn, A.D., McConway, K.J. and Ostrowski, E. (1994) *A Handbook of Small Data Sets*, Chapman and Hall.

|---------|-------------------------------------|
| control | <i>Control Variate Calculations</i> |
|---------|-------------------------------------|

---

## Description

This function will find control variate estimates from a bootstrap output object. It can either find the adjusted bias estimate using post-simulation balancing or it can estimate the bias, variance, third cumulant and quantiles, using the linear approximation as a control variate.

## Usage

```
control(boot.out, L = NULL, distn = NULL, index = 1, t0 = NULL,
 t = NULL, bias.adj = FALSE, alpha = NULL, ...)
```

## Arguments

|                       |                                                                                                                                                                                                                                                                                                                                                             |
|-----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>boot.out</code> | A bootstrap output object returned from <code>boot</code> . The bootstrap replicates must have been generated using the usual nonparametric bootstrap.                                                                                                                                                                                                      |
| <code>L</code>        | The empirical influence values for the statistic of interest. If <code>L</code> is not supplied then <code>empinf</code> is called to calculate them from <code>boot.out</code> .                                                                                                                                                                           |
| <code>distn</code>    | If present this must be the output from <code>smooth.spline</code> giving the distribution function of the linear approximation. This is used only if <code>bias.adj</code> is <code>FALSE</code> . Normally this would be found using a saddlepoint approximation. If it is not supplied in that case then it is calculated by <code>saddle.distn</code> . |
| <code>index</code>    | The index of the variable of interest in the output of <code>boot.out\$statistic</code> .                                                                                                                                                                                                                                                                   |
| <code>t0</code>       | The observed value of the statistic of interest on the original data set <code>boot.out\$data</code> . This argument is used only if <code>bias.adj</code> is <code>FALSE</code> . The input value is ignored if <code>t</code> is not also supplied. The default value is <code>boot.out\$t0[index]</code> .                                               |
| <code>t</code>        | The bootstrap replicate values of the statistic of interest. This argument is used only if <code>bias.adj</code> is <code>FALSE</code> . The input is ignored if <code>t0</code> is not supplied also. The default value is <code>boot.out\$t[, index]</code> .                                                                                             |

|                       |                                                                                                                                                                                                                                                                                                                                                                                      |
|-----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>bias.adj</code> | A logical variable which if <code>TRUE</code> specifies that the adjusted bias estimate using post-simulation balance is all that is required. If <code>bias.adj</code> is <code>FALSE</code> (default) then the linear approximation to the statistic is calculated and used as a control variate in estimates of the bias, variance and third cumulant as well as quantiles.       |
| <code>alpha</code>    | The alpha levels for the required quantiles if <code>bias.adj</code> is <code>FALSE</code> .                                                                                                                                                                                                                                                                                         |
| <code>...</code>      | Any additional arguments that <code>boot.out\$statistic</code> requires. These are passed unchanged every time <code>boot.out\$statistic</code> is called. <code>boot.out\$statistic</code> is called once if <code>bias.adj</code> is <code>TRUE</code> , otherwise it may be called by <code>empinf</code> for empirical influence calculations if <code>L</code> is not supplied. |

### Details

If `bias.adj` is `FALSE` then the linear approximation to the statistic is found and evaluated at each bootstrap replicate. Then using the equation  $T^* = Tl^* + (T^* - Tl^*)$ , moment estimates can be found. For quantile estimation the distribution of the linear approximation to  $t$  is approximated very accurately by saddlepoint methods, this is then combined with the bootstrap replicates to approximate the bootstrap distribution of  $t$  and hence to estimate the bootstrap quantiles of  $t$ .

### Value

If `bias.adj` is `TRUE` then the returned value is the adjusted bias estimate.

If `bias.adj` is `FALSE` then the returned value is a list with the following components

|                        |                                                                                                                                                                                                                                                                                                                 |
|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>L</code>         | The empirical influence values used. These are the input values if supplied, and otherwise they are the values calculated by <code>empinf</code> .                                                                                                                                                              |
| <code>tL</code>        | The linear approximations to the bootstrap replicates $t$ of the statistic of interest.                                                                                                                                                                                                                         |
| <code>bias</code>      | The control estimate of bias using the linear approximation to $t$ as a control variate.                                                                                                                                                                                                                        |
| <code>var</code>       | The control estimate of variance using the linear approximation to $t$ as a control variate.                                                                                                                                                                                                                    |
| <code>k3</code>        | The control estimate of the third cumulant using the linear approximation to $t$ as a control variate.                                                                                                                                                                                                          |
| <code>quantiles</code> | A matrix with two columns; the first column are the alpha levels used for the quantiles and the second column gives the corresponding control estimates of the quantiles using the linear approximation to $t$ as a control variate.                                                                            |
| <code>distn</code>     | An output object from <code>smooth.spline</code> describing the saddlepoint approximation to the bootstrap distribution of the linear approximation to $t$ . If <code>distn</code> was supplied on input then this is the same as the input otherwise it is calculated by a call to <code>saddle.distn</code> . |

**Examples**

```
Use of control variates for the variance of the air-conditioning data
mean.fun <- function(d, i)
{
 m <- mean(d$hours[i])
 n <- nrow(d)
 v <- (n-1)*var(d$hours[i])/n^2
 c(m, v)
}
air.boot <- boot(aircondit, mean.fun, R = 999)
control(air.boot, index = 2, bias.adj = TRUE)
air.cont <- control(air.boot, index = 2)
Now let us try the variance on the log scale.
air.cont1 <- control(air.boot, t0 = log(air.boot$t0[2]),
 t = log(air.boot$t[, 2]))
```

corr

*Correlation Coefficient***Description**

Calculates the weighted correlation given a data set and a set of weights.

**Usage**

```
corr(d, w = rep(1, nrow(d))/nrow(d))
```

**Arguments**

|   |                                                                                                                                                                                                    |
|---|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| d | A matrix with two columns corresponding to the two variables whose correlation we wish to calculate.                                                                                               |
| w | A vector of weights to be applied to each pair of observations. The default is equal weights for each pair. Normalization takes place within the function so <code>sum(w)</code> need not equal 1. |

**Details**

This function finds the correlation coefficient in weighted form. This is often useful in bootstrap methods since it allows for numerical differentiation to get the empirical influence values. It is also necessary to have the statistic in this form to find ABC intervals.

**Value**

The correlation coefficient between `d[, 1]` and `d[, 2]`.

**See Also**

[cor](#)

cum3

*Calculate Third Order Cumulants***Description**

Calculates an estimate of the third cumulant, or skewness, of a vector. Also, if more than one vector is specified, a product-moment of order 3 is estimated.

**Usage**

```
cum3(a, b = a, c = a, unbiased = TRUE)
```

**Arguments**

|          |                                                                                                                                |
|----------|--------------------------------------------------------------------------------------------------------------------------------|
| a        | A vector of observations.                                                                                                      |
| b        | Another vector of observations, if not supplied it is set to the value of a. If supplied then it must be the same length as a. |
| c        | Another vector of observations, if not supplied it is set to the value of a. If supplied then it must be the same length as a. |
| unbiased | A logical value indicating whether the unbiased estimator should be used.                                                      |

**Details**

The unbiased estimator uses a multiplier of  $n / ((n-1) * (n-2))$  where  $n$  is the sample size, if `unbiased` is `FALSE` then a multiplier of  $1/n$  is used. This is multiplied by `sum((a-mean(a)) * (b-mean(b)) * (c-mean(c)))` to give the required estimate.

**Value**

The required estimate.

cv.glm

*Cross-validation for Generalized Linear Models***Description**

This function calculates the estimated K-fold cross-validation prediction error for generalized linear models.

**Usage**

```
cv.glm(data, glmfit, cost, K)
```

## Arguments

|                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>data</code>   | A matrix or data frame containing the data. The rows should be cases and the columns correspond to variables, one of which is the response.                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>glmfit</code> | An object of class "glm" containing the results of a generalized linear model fitted to <code>data</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>cost</code>   | A function of two vector arguments specifying the cost function for the cross-validation. The first argument to <code>cost</code> should correspond to the observed responses and the second argument should correspond to the predicted or fitted responses from the generalized linear model. <code>cost</code> must return a non-negative scalar value. The default is the average squared error function.                                                                                                                                                   |
| <code>K</code>      | The number of groups into which the data should be split to estimate the cross-validation prediction error. The value of <code>K</code> must be such that all groups are of approximately equal size. If the supplied value of <code>K</code> does not satisfy this criterion then it will be set to the closest integer which does and a warning is generated specifying the value of <code>K</code> used. The default is to set <code>K</code> equal to the number of observations in <code>data</code> which gives the usual leave-one-out cross-validation. |

## Details

The data is divided randomly into `K` groups. For each group the generalized linear model is fit to `data` omitting that group, then the function `cost` is applied to the observed responses in the group that was omitted from the fit and the prediction made by the fitted models for those observations.

When `K` is the number of observations leave-one-out cross-validation is used and all the possible splits of the data are used. When `K` is less than the number of observations the `K` splits to be used are found by randomly partitioning the data into `K` groups of approximately equal size. In this latter case a certain amount of bias is introduced. This can be reduced by using a simple adjustment (see equation 6.48 in Davison and Hinkley, 1997). The second value returned in `delta` is the estimate adjusted by this method.

## Value

The returned value is a list with the following components.

|                    |                                                                                                                                                                                                                                                                                     |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>call</code>  | The original call to <code>cv.glm</code> .                                                                                                                                                                                                                                          |
| <code>K</code>     | The value of <code>K</code> used for the <code>K</code> -fold cross validation.                                                                                                                                                                                                     |
| <code>delta</code> | A vector of length two. The first component is the raw cross-validation estimate of prediction error. The second component is the adjusted cross-validation estimate. The adjustment is designed to compensate for the bias introduced by not using leave-one-out cross-validation. |
| <code>seed</code>  | The value of <code>.Random.seed</code> when <code>cv.glm</code> was called.                                                                                                                                                                                                         |

## Side Effects

The value of `.Random.seed` is updated.

### Examples

```
leave-one-out and 6-fold cross-validation prediction error for
the mammals data set.
data(mammals, package="MASS")
mammals.glm <- glm(log(brain) ~ log(body), data = mammals)
(cv.err <- cv.glm(mammals, mammals.glm)$delta)
(cv.err.6 <- cv.glm(mammals, mammals.glm, K = 6)$delta)

As this is a linear model we could calculate the leave-one-out
cross-validation estimate without any extra model-fitting.
muhat <- fitted(mammals.glm)
mammals.diag <- glm.diag(mammals.glm)
(cv.err <- mean((mammals.glm$y - muhat)^2 / (1 - mammals.diag$h)^2))

leave-one-out and 11-fold cross-validation prediction error for
the nodal data set. Since the response is a binary variable an
appropriate cost function is
cost <- function(r, pi = 0) mean(abs(r-pi) > 0.5)

nodal.glm <- glm(r ~ stage+xray+acid, binomial, data = nodal)
(cv.err <- cv.glm(nodal, nodal.glm, cost, K = nrow(nodal))$delta)
(cv.11.err <- cv.glm(nodal, nodal.glm, cost, K = 11)$delta)
```

`darwin`

*Darwin's Plant Height Differences*

---

### Description

The `darwin` data frame has 15 rows and 1 columns.

Charles Darwin conducted an experiment to examine the superiority of cross-fertilized plants over self-fertilized plants. 15 pairs of plants were used. Each pair consisted of one cross-fertilized plant and one self-fertilized plant which germinated at the same time and grew in the same pot. The plants were measured at a fixed time after planting and the difference in heights between the cross- and self-fertilized plants are recorded in eighths of an inch.

### Usage

`darwin`

**Format**

This data frame contains the following column:

**y** The difference in heights for the pairs of plants (in units of 0.125 inches).

**Source**

The data were obtained from

Fisher, R.A. (1935) *Design of Experiments*. Oliver and Boyd.

**References**

Darwin, C. (1876) *The Effects of Cross- and Self-fertilisation in the Vegetable Kingdom*. John Murray.

---

dogs

*Cardiac Data for Domestic Dogs*

---

**Description**

The dogs data frame has 7 rows and 2 columns.

Data on the cardiac oxygen consumption and left ventricular pressure were gathered on 7 domestic dogs.

**Usage**

dogs

**Format**

This data frame contains the following columns:

**mvo** Cardiac Oxygen Consumption

**lvp** Left Ventricular Pressure

**References**

downs.bc

---

*Incidence of Down's Syndrome in British Columbia*

---

## Description

The `downs.bc` data frame has 30 rows and 3 columns.

Down's syndrome is a genetic disorder caused by an extra chromosome 21 or a part of chromosome 21 being translocated to another chromosome. The incidence of Down's syndrome is highly dependent on the mother's age and rises sharply after age 30. In the 1960's a large scale study of the effect of maternal age on the incidence of Down's syndrome was conducted at the British Columbia Health Surveillance Registry. These are the data which was collected in that study.

Mothers were classified by age. Most groups correspond to the age in years but the first group comprises all mothers with ages in the range 15-17 and the last is those with ages 46-49. No data for mothers over 50 or below 15 were collected.

## Usage

`downs.bc`

## Format

This data frame contains the following columns:

`age` The average age of all mothers in the age category.

`m` The total number of live births to mothers in the age category.

`r` The number of cases of Down's syndrome.

## Source

The data were obtained from

Geyer, C.J. (1991) Constrained maximum likelihood exemplified by isotonic convex logistic regression. *Journal of the American Statistical Association*, **86**, 717–724.

ducks*Behavioral and Plumage Characteristics of Hybrid Ducks*

---

**Description**

The `ducks` data frame has 11 rows and 2 columns.

Each row of the data frame represents a male duck who is a second generation cross of mallard and pintail ducks. For 11 such ducks a behavioural and plumage index were calculated. These were measured on scales devised for this experiment which was to examine whether there was any link between which species the ducks resembled physically and which they resembled in behaviour. The scale for the physical appearance ranged from 0 (identical in appearance to a mallard) to 20 (identical to a pintail). The behavioural traits of the ducks were on a scale from 0 to 15 with lower numbers indicating closer to mallard-like in behaviour.

**Usage**

`ducks`

**Format**

This data frame contains the following columns:

`plumage` The index of physical appearance based on the plumage of individual ducks.

`behaviour` The index of behavioural characteristics of the ducks.

**Source**

The data were obtained from

Larsen, R.J. and Marx, M.L. (1986) *An Introduction to Mathematical Statistics and its Applications* (Second Edition). Prentice-Hall.

---

`EEF.profile`*Empirical Likelihoods*

---

**Description**

Construct the empirical log likelihood or empirical exponential family log likelihood for a mean.

**Usage**

```
EEF.profile(y, tmin = min(y) + 0.1, tmax = max(y) - 0.1, n.t = 25,
 u = function(y, t) y - t)
EL.profile(y, tmin = min(y) + 0.1, tmax = max(y) - 0.1, n.t = 25,
 u = function(y, t) y - t)
```

**Arguments**

|                   |                                                                                                                                   |
|-------------------|-----------------------------------------------------------------------------------------------------------------------------------|
| <code>y</code>    | A vector or matrix of data                                                                                                        |
| <code>tmin</code> | The minimum value of the range over which the likelihood should be computed. This must be larger than <code>min(y)</code> .       |
| <code>tmax</code> | The maximum value of the range over which the likelihood should be computed. This must be smaller than <code>max(y)</code> .      |
| <code>n.t</code>  | The number of points between <code>tmin</code> and <code>tmax</code> at which the value of the log-likelihood should be computed. |
| <code>u</code>    | A function of the data and the parameter.                                                                                         |

**Details**

These functions calculate the log likelihood for a mean using either an empirical likelihood or an empirical exponential family likelihood. They are supplied as part of the package `boot` for demonstration purposes with the practicals in chapter 10 of Davison and Hinkley (1997). The functions are not intended for general use and are not supported as part of the `boot` package. For more general and more robust code to calculate empirical likelihoods see Professor A. B. Owen's empirical likelihood home page at the URL <https://statweb.stanford.edu/~owen/empirical/>.

**Value**

A matrix with `n.t` rows. The first column contains the values of the parameter used. The second column of the output of `EL.profile` contains the values of the empirical log likelihood. The second and third columns of the output of `EEF.profile` contain two versions of the empirical exponential family log-likelihood. The final column of the output matrix contains the values of the Lagrange multiplier used in the optimization procedure.

empinf

*Empirical Influence Values***Description**

This function calculates the empirical influence values for a statistic applied to a data set. It allows four types of calculation, namely the infinitesimal jackknife (using numerical differentiation), the usual jackknife estimates, the ‘positive’ jackknife estimates and a method which estimates the empirical influence values using regression of bootstrap replicates of the statistic. All methods can be used with one or more samples.

**Usage**

```
empinf(boot.out = NULL, data = NULL, statistic = NULL,
 type = NULL, stype = NULL, index = 1, t = NULL,
 strata = rep(1, n), eps = 0.001, ...)
```

**Arguments**

|                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>boot.out</code>  | A bootstrap object created by the function <code>boot</code> . If <code>type</code> is "reg" then this argument is required. For any of the other types it is an optional argument. If it is included when optional then the values of <code>data</code> , <code>statistic</code> , <code>stype</code> , and <code>strata</code> are taken from the components of <code>boot.out</code> and any values passed to <code>empinf</code> directly are ignored.                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <code>data</code>      | A vector, matrix or data frame containing the data for which empirical influence values are required. It is a required argument if <code>boot.out</code> is not supplied. If <code>boot.out</code> is supplied then <code>data</code> is set to <code>boot.out\$data</code> and any value supplied is ignored.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>statistic</code> | The statistic for which empirical influence values are required. It must be a function of at least two arguments, the data set and a vector of weights, frequencies or indices. The nature of the second argument is given by the value of <code>stype</code> . Any other arguments that it takes must be supplied to <code>empinf</code> and will be passed to <code>statistic</code> unchanged. This is a required argument if <code>boot.out</code> is not supplied, otherwise its value is taken from <code>boot.out</code> and any value supplied here will be ignored.                                                                                                                                                                                                                                                                                               |
| <code>type</code>      | The calculation type to be used for the empirical influence values. Possible values of <code>type</code> are "inf" (infinitesimal jackknife), "jack" (usual jackknife), "pos" (positive jackknife), and "reg" (regression estimation). The default value depends on the other arguments. If <code>t</code> is supplied then the default value of <code>type</code> is "reg" and <code>boot.out</code> should be present so that its frequency array can be found. If <code>t</code> is not supplied then if <code>stype</code> is "w", the default value of <code>type</code> is "inf"; otherwise, if <code>boot.out</code> is present the default is "reg". If none of these conditions apply then the default is "jack". Note that it is an error for <code>type</code> to be "reg" if <code>boot.out</code> is missing or to be "inf" if <code>stype</code> is not "w". |
| <code>stype</code>     | A character variable giving the nature of the second argument to <code>statistic</code> . It can take on three values: "w" (weights), "f" (frequencies), or "i" (indices). If <code>boot.out</code> is supplied the value of <code>stype</code> is set to <code>boot.out\$stype</code> and any value supplied here is ignored. Otherwise it is an optional argument which defaults to "w". If <code>type</code> is "inf" then <code>stype</code> MUST be "w".                                                                                                                                                                                                                                                                                                                                                                                                              |

|                     |                                                                                                                                                                                                                                                                                                     |
|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>index</code>  | An integer giving the position of the variable of interest in the output of <code>statistic</code> .                                                                                                                                                                                                |
| <code>t</code>      | A vector of length <code>boot.out\$R</code> which gives the bootstrap replicates of the statistic of interest. <code>t</code> is used only when <code>type</code> is <code>reg</code> and it defaults to <code>boot.out\$t[, index]</code> .                                                        |
| <code>strata</code> | An integer vector or a factor specifying the strata for multi-sample problems. If <code>boot.out</code> is supplied the value of <code>strata</code> is set to <code>boot.out\$strata</code> . Otherwise it is an optional argument which has default corresponding to the single sample situation. |
| <code>eps</code>    | This argument is used only if <code>type</code> is <code>"inf"</code> . In that case the value of epsilon to be used for numerical differentiation will be <code>eps</code> divided by the number of observations in <code>data</code> .                                                            |
| <code>...</code>    | Any other arguments that <code>statistic</code> takes. They will be passed unchanged to <code>statistic</code> every time that it is called.                                                                                                                                                        |

### Details

If `type` is `"inf"` then numerical differentiation is used to approximate the empirical influence values. This makes sense only for statistics which are written in weighted form (i.e. `stype` is `"w"`). If `type` is `"jack"` then the usual leave-one-out jackknife estimates of the empirical influence are returned. If `type` is `"pos"` then the positive (include-one-twice) jackknife values are used. If `type` is `"reg"` then a bootstrap object must be supplied. The regression method then works by regressing the bootstrap replicates of `statistic` on the frequency array from which they were derived. The bootstrap frequency array is obtained through a call to `boot.array`. Further details of the methods are given in Section 2.7 of Davison and Hinkley (1997).

Empirical influence values are often used frequently in nonparametric bootstrap applications. For this reason many other functions call `empinf` when they are required. Some examples of their use are for nonparametric delta estimates of variance, BCa intervals and finding linear approximations to statistics for use as control variates. They are also used for antithetic bootstrap resampling.

### Value

A vector of the empirical influence values of `statistic` applied to `data`. The values will be in the same order as the observations in `data`.

### Warning

All arguments to `empinf` must be passed using the `name = value` convention. If this is not followed then unpredictable errors can occur.

**Examples**

```
The empirical influence values for the ratio of means in
the city data.
ratio <- function(d, w) sum(d$x *w)/sum(d$u*w)
empinf(data = city, statistic = ratio)
city.boot <- boot(city, ratio, 499, stype="w")
empinf(boot.out = city.boot, type = "reg")

A statistic that may be of interest in the difference of means
problem is the t-statistic for testing equality of means. In
the bootstrap we get replicates of the difference of means and
the variance of that statistic and then want to use this output
to get the empirical influence values of the t-statistic.
grav1 <- gravity[as.numeric(gravity[,2]) >= 7,]
grav.fun <- function(dat, w) {
 strata <- tapply(dat[, 2], as.numeric(dat[, 2]))
 d <- dat[, 1]
 ns <- tabulate(strata)
 w <- w/tapply(w, strata, sum)[strata]
 mns <- as.vector(tapply(d * w, strata, sum)) # drop names
 mn2 <- tapply(d * d * w, strata, sum)
 s2hat <- sum((mn2 - mns^2)/ns)
 c(mns[2] - mns[1], s2hat)
}

grav.boot <- boot(grav1, grav.fun, R = 499, stype = "w",
 strata = grav1[, 2])

Since the statistic of interest is a function of the bootstrap
statistics, we must calculate the bootstrap replicates and pass
them to empinf using the t argument.
grav.z <- (grav.boot$t[,1]-grav.boot$t0[1])/sqrt(grav.boot$t[,2])
empinf(boot.out = grav.boot, t = grav.z)
```

**Description**

This function calculates overall and pointwise confidence envelopes for a curve based on bootstrap replicates of the curve evaluated at a number of fixed points.

**Usage**

```
envelope(boot.out = NULL, mat = NULL, level = 0.95, index = 1:ncol(mat))
```

## Arguments

|                       |                                                                                                                                                                                                                                                                                                                                                                                   |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>boot.out</code> | An object of class "boot" for which <code>boot.out\$t</code> contains the replicates of the curve at a number of fixed points.                                                                                                                                                                                                                                                    |
| <code>mat</code>      | A matrix of bootstrap replicates of the values of the curve at a number of fixed points. This is a required argument if <code>boot.out</code> is not supplied and is set to <code>boot.out\$t</code> otherwise.                                                                                                                                                                   |
| <code>level</code>    | The confidence level of the envelopes required. The default is to find 95% confidence envelopes. It can be a scalar or a vector of length 2. If it is scalar then both the pointwise and the overall envelopes are found at that level. If is a vector then the first element gives the level for the pointwise envelope and the second gives the level for the overall envelope. |
| <code>index</code>    | The numbers of the columns of <code>mat</code> which contain the bootstrap replicates. This can be used to ensure that other statistics which may have been calculated in the bootstrap are not considered as values of the function.                                                                                                                                             |

## Details

The pointwise envelope is found by simply looking at the quantiles of the replicates at each point. The overall error for that envelope is then calculated using equation (4.17) of Davison and Hinkley (1997). A sequence of pointwise envelopes is then found until one of them has overall error approximately equal to the level required. If no such envelope can be found then the envelope returned will just contain the extreme values of each column of `mat`.

## Value

A list with the following components :

|                      |                                                                                                                                                                         |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>point</code>   | A matrix with two rows corresponding to the values of the upper and lower pointwise confidence envelope at the same points as the bootstrap replicates were calculated. |
| <code>overall</code> | A matrix similar to <code>point</code> but containing the envelope which controls the overall error.                                                                    |
| <code>k.pt</code>    | The quantiles used for the pointwise envelope.                                                                                                                          |
| <code>err.pt</code>  | A vector with two components, the first gives the pointwise error rate for the pointwise envelope, and the second the overall error rate for that envelope.             |
| <code>k.ov</code>    | The quantiles used for the overall envelope.                                                                                                                            |
| <code>err.ov</code>  | A vector with two components, the first gives the pointwise error rate for the overall envelope, and the second the overall error rate for that envelope.               |
| <code>err.nom</code> | A vector of length 2 giving the nominal error rates for the pointwise and the overall envelopes.                                                                        |

lines(grav.qq$x, grav.env$overall[1,], lty = 1)
lines(grav.qq$x, grav.env$overall[2,], lty = 1)
```

---

exp.tilt

*Exponential Tilting*

---

## Description

This function calculates exponentially tilted multinomial distributions such that the resampling distributions of the linear approximation to a statistic have the required means.

## Usage

```
exp.tilt(L, theta = NULL, t0 = 0, lambda = NULL,
 strata = rep(1, length(L)))
```

## Arguments

|                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>L</code>      | The empirical influence values for the statistic of interest based on the observed data. The length of <code>L</code> should be the same as the size of the original data set. Typically <code>L</code> will be calculated by a call to <code>empinf</code> .                                                                                                                                                                                                                                |
| <code>theta</code>  | The value at which the tilted distribution is to be centred. This is not required if <code>lambda</code> is supplied but is needed otherwise.                                                                                                                                                                                                                                                                                                                                                |
| <code>t0</code>     | The current value of the statistic. The default is that the statistic equals 0.                                                                                                                                                                                                                                                                                                                                                                                                              |
| <code>lambda</code> | The Lagrange multiplier(s). For each value of <code>lambda</code> a multinomial distribution is found with probabilities proportional to $\exp(\text{lambda} * L)$ . In general <code>lambda</code> is not known and so <code>theta</code> would be supplied, and the corresponding value of <code>lambda</code> found. If both <code>lambda</code> and <code>theta</code> are supplied then <code>lambda</code> is ignored and the multipliers for tilting to <code>theta</code> are found. |
| <code>strata</code> | A vector or factor of the same length as <code>L</code> giving the strata for the observed data and the empirical influence values <code>L</code> .                                                                                                                                                                                                                                                                                                                                          |

## Details

Exponential tilting involves finding a set of weights for a data set to ensure that the bootstrap distribution of the linear approximation to a statistic of interest has mean `theta`. The weights chosen to achieve this are given by `p[j]` proportional to  $\exp(\lambda L[j]/n)$ , where `n` is the number of data points. `lambda` is then chosen to make the mean of the bootstrap distribution, of the linear approximation to the statistic of interest, equal to the required value `theta`. Thus `lambda` is defined as the solution of a nonlinear equation. The equation is solved by minimizing the Euclidean distance between the left and right hand sides of the equation using the function `nlmin`. If this minimum is not equal to zero then the method fails.

Typically exponential tilting is used to find suitable weights for importance resampling. If a small tail probability or quantile of the distribution of the statistic of interest is required then a more efficient simulation is to centre the resampling distribution close to the point of interest and then use the functions `imp.prob` or `imp.quantile` to estimate the required quantity.

Another method of achieving a similar shifting of the distribution is through the use of `smooth.f`. The function `tilt.boot` uses `exp.tilt` or `smooth.f` to find the weights for a tilted bootstrap.

## Value

A list with the following components :

|                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>p</code>      | The tilted probabilities. There will be <code>m</code> distributions where <code>m</code> is the length of <code>theta</code> (or <code>lambda</code> if supplied). If <code>m</code> is 1 then <code>p</code> is a vector of length <code>(L)</code> probabilities. If <code>m</code> is greater than 1 then <code>p</code> is a matrix with <code>m</code> rows, each of which contain length <code>(L)</code> probabilities. In this case the vector <code>p[i, ]</code> is the distribution tilted to <code>theta[i]</code> . <code>p</code> is in the form required by the argument <code>weights</code> of the function <code>boot</code> for importance resampling. |
| <code>lambda</code> | The Lagrange multiplier used in the equation to determine the tilted probabilities. <code>lambda</code> is a vector of the same length as <code>theta</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>theta</code>  | The values of <code>theta</code> to which the distributions have been tilted. In general this will be the input value of <code>theta</code> but if <code>lambda</code> was supplied then this is the vector of the corresponding <code>theta</code> values.                                                                                                                                                                                                                                                                                                                                                                                                                |

## Examples

```
Example 9.8 of Davison and Hinkley (1997) requires tilting the resampling
distribution of the studentized statistic to be centred at the observed
value of the test statistic 1.84. This can be achieved as follows.
grav1 <- gravity[as.numeric(gravity[,2]) >= 7 ,]
grav.fun <- function(dat, w, orig) {
 strata <- tapply(dat[, 2], as.numeric(dat[, 2]))
 d <- dat[, 1]
```

```

ns <- tabulate(strata)
w <- w/tapply(w, strata, sum)[strata]
mns <- as.vector(tapply(d * w, strata, sum)) # drop names
mn2 <- tapply(d * d * w, strata, sum)
s2hat <- sum(mn2 - mns^2)/ns
c(mns[2]-mns[1], s2hat, (mns[2]-mns[1]-orig)/sqrt(s2hat))
}
grav.z0 <- grav.fun(grav1, rep(1, 26), 0)
grav.L <- empinf(data = grav1, statistic = grav.fun, stype = "w",
 strata = grav1[,2], index = 3, orig = grav.z0[1])
grav.tilt <- exp.tilt(grav.L, grav.z0[3], strata = grav1[,2])
boot(grav1, grav.fun, R = 499, stype = "w", weights = grav.tilt$p,
 strata = grav1[,2], orig = grav.z0[1])

```

fir

*Counts of Balsam-fir Seedlings*

## Description

The `fir` data frame has 50 rows and 3 columns.

The number of balsam-fir seedlings in each quadrant of a grid of 50 five foot square quadrants were counted. The grid consisted of 5 rows of 10 quadrants in each row.

## Usage

```
fir
```

## Format

This data frame contains the following columns:

`count` The number of seedlings in the quadrant.

`row` The row number of the quadrant.

`col` The quadrant number within the row.

---

freq.array

*Bootstrap Frequency Arrays*

---

### Description

Take a matrix of indices for nonparametric bootstrap resamples and return the frequencies of the original observations in each resample.

### Usage

```
freq.array(i.array)
```

### Arguments

`i.array` This will be an matrix of integers between 1 and `n`, where `n` is the number of observations in a data set. The matrix will have `n` columns and `R` rows where `R` is the number of bootstrap resamples. Such matrices are found by `boot` when doing nonparametric bootstraps. They can also be found after a bootstrap has been run through the function `boot.array`.

### Value

A matrix of the same dimensions as the input matrix. Each row of the matrix corresponds to a single bootstrap resample. Each column of the matrix corresponds to one of the original observations and specifies its frequency in each bootstrap resample. Thus the first column tells us how often the first observation appeared in each bootstrap resample. Such frequency arrays are often useful for diagnostic purposes such as the jackknife-after-bootstrap plot. They are also necessary for the regression estimates of empirical influence values and for finding importance sampling weights.

frets

*Head Dimensions in Brothers*

---

### Description

The `frets` data frame has 25 rows and 4 columns.

The data consist of measurements of the length and breadth of the heads of pairs of adult brothers in 25 randomly sampled families. All measurements are expressed in millimetres.

### Usage

```
frets
```

**Format**

This data frame contains the following columns:

- l1 The head length of the eldest son.
- b1 The head breadth of the eldest son.
- l2 The head length of the second son.
- b2 The head breadth of the second son.

**Source**

The data were obtained from

Frets, G.P. (1921) Heredity of head form in man. *Genetica*, **3**, 193.

---

glm.diag

---

Generalized Linear Model Diagnostics

---

**Description**

Calculates jackknife deviance residuals, standardized deviance residuals, standardized Pearson residuals, approximate Cook statistic, leverage and estimated dispersion.

**Usage**

```
glm.diag(glmfit)
```

**Arguments**

glmfit            glmfit is a glm.object - the result of a call to glm()

**Value**

Returns a list with the following components

- |      |                                                                                                                                                                                                                                  |
|------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| res  | The vector of jackknife deviance residuals.                                                                                                                                                                                      |
| rd   | The vector of standardized deviance residuals.                                                                                                                                                                                   |
| rp   | The vector of standardized Pearson residuals.                                                                                                                                                                                    |
| cook | The vector of approximate Cook statistics.                                                                                                                                                                                       |
| h    | The vector of leverages of the observations.                                                                                                                                                                                     |
| sd   | The value used to standardize the residuals. This is the estimate of residual standard deviation in the Gaussian family and is the square root of the estimated shape parameter in the Gamma family. In all other cases it is 1. |

**Note**

See the help for `glm.diag.plots` for an example of the use of `glm.diag`.

| <code>glm.diag.plots</code> | <i>Diagnostics plots for generalized linear models</i> |
|-----------------------------|--------------------------------------------------------|

---

**Description**

Makes plot of jackknife deviance residuals against linear predictor, normal scores plots of standardized deviance residuals, plot of approximate Cook statistics against leverage/(1-leverage), and case plot of Cook statistic.

**Usage**

```
glm.diag.plots(glmfit, glmdiag = glm.diag(glmfit), subset = NULL,
 iden = FALSE, labels = NULL, ret = FALSE)
```

**Arguments**

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>glmfit</code>  | <code>glm.object</code> : the result of a call to <code>glm()</code>                                                                                                                                                                                                                                                                                                                                                                                            |
| <code>glmdiag</code> | Diagnostics of <code>glmfit</code> obtained from a call to <code>glm.diag</code> . If it is not supplied then it is calculated.                                                                                                                                                                                                                                                                                                                                 |
| <code>subset</code>  | Subset of data for which <code>glm</code> fitting performed: should be the same as the <code>subset</code> option used in the call to <code>glm()</code> which generated <code>glmfit</code> . Needed only if the <code>subset=</code> option was used in the call to <code>glm</code> .                                                                                                                                                                        |
| <code>iden</code>    | A logical argument. If <code>TRUE</code> then, after the plots are drawn, the user will be prompted for an integer between 0 and 4. A positive integer will select a plot and invoke <code>identify()</code> on that plot. After exiting <code>identify()</code> , the user is again prompted, this loop continuing until the user responds to the prompt with 0. If <code>iden</code> is <code>FALSE</code> (default) the user cannot interact with the plots. |
| <code>labels</code>  | A vector of labels for use with <code>identify()</code> if <code>iden</code> is <code>TRUE</code> . If it is not supplied then the labels are derived from <code>glmfit</code> .                                                                                                                                                                                                                                                                                |
| <code>ret</code>     | A logical argument indicating if <code>glmdiag</code> should be returned. The default is <code>FALSE</code> .                                                                                                                                                                                                                                                                                                                                                   |

## Details

The diagnostics required for the plots are calculated by `glm.diag`. These are then used to produce the four plots on the current graphics device.

The plot on the top left is a plot of the jackknife deviance residuals against the fitted values.

The plot on the top right is a normal QQ plot of the standardized deviance residuals. The dotted line is the expected line if the standardized residuals are normally distributed, i.e. it is the line with intercept 0 and slope 1.

The bottom two panels are plots of the Cook statistics. On the left is a plot of the Cook statistics against the standardized leverages. In general there will be two dotted lines on this plot. The horizontal line is at  $8/(n-2p)$  where  $n$  is the number of observations and  $p$  is the number of parameters estimated. Points above this line may be points with high influence on the model. The vertical line is at  $2p/(n-2p)$  and points to the right of this line have high leverage compared to the variance of the raw residual at that point. If all points are below the horizontal line or to the left of the vertical line then the line is not shown.

The final plot again shows the Cook statistic this time plotted against case number enabling us to find which observations are influential.

Use of `iden=T` is encouraged for proper exploration of these four plots as a guide to how well the model fits the data and whether certain observations have an unduly large effect on parameter estimates.

## Value

If `ret` is TRUE then the value of `glm.diag` is returned otherwise there is no returned value.

## Side Effects

The current device is cleared and four plots are plotted by use of `split.screen(c(2,2))`. If `iden` is TRUE, interactive identification of points is enabled. All screens are closed, but not cleared, on termination of the function.

gravity

---

*Acceleration Due to Gravity***Description**

The `gravity` data frame has 81 rows and 2 columns.

The `grav` data set has 26 rows and 2 columns.

Between May 1934 and July 1935, the National Bureau of Standards in Washington D.C. conducted a series of experiments to estimate the acceleration due to gravity,  $g$ , at Washington. Each experiment produced a number of replicate estimates of  $g$  using the same methodology. Although the basic method remained the same for all experiments, that of the reversible pendulum, there were changes in configuration.

The `gravity` data frame contains the data from all eight experiments. The `grav` data frame contains the data from the experiments 7 and 8. The data are expressed as deviations from 980.000 in centimetres per second squared.

**Usage**

```
gravity
```

**Format**

This data frame contains the following columns:

`g` The deviation of the estimate from 980.000 centimetres per second squared.

`series` A factor describing from which experiment the estimate was derived.

**Source**

The data were obtained from

Cressie, N. (1982) Playing safe with misweighted means. *Journal of the American Statistical Association*, **77**, 754–759.

hirose

---

*Failure Time of PET Film***Description**

The `hirose` data frame has 44 rows and 3 columns.

PET film is used in electrical insulation. In this accelerated life test the failure times for 44 samples in gas insulated transformers. 4 different voltage levels were used.

**Usage**

```
hirose
```

**Format**

This data frame contains the following columns:

`volt` The voltage (in kV).

`time` The failure or censoring time in hours.

`cens` The censoring indicator; 1 means right-censored data.

**Source**

The data were obtained from

Hirose, H. (1993) Estimation of threshold stress in accelerated life-testing. *IEEE Transactions on Reliability*, **42**, 650–657.

**References**

Davison, A.C. and Hinkley, D.V. (1997) *Bootstrap Methods and Their Application*. Cambridge University Press.

Imp.Estimates

---

Importance Sampling Estimates

---

**Description**

Central moment, tail probability, and quantile estimates for a statistic under importance resampling.

**Usage**

```
imp.moments(boot.out = NULL, index = 1, t = boot.out$t[, index],
 w = NULL, def = TRUE, q = NULL)
imp.prob(boot.out = NULL, index = 1, t0 = boot.out$t0[index],
 t = boot.out$t[, index], w = NULL, def = TRUE, q = NULL)
imp.quantile(boot.out = NULL, alpha = NULL, index = 1,
 t = boot.out$t[, index], w = NULL, def = TRUE, q = NULL)
```

**Arguments**

|                       |                                                                                                                                                                                                                                                                                                                                                                                    |
|-----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>boot.out</code> | A object of class "boot" generated by a call to <code>boot</code> or <code>tilt.boot</code> . Use of these functions makes sense only when the bootstrap resampling used unequal weights for the observations. If the importance weights <code>w</code> are not supplied then <code>boot.out</code> is a required argument. It is also required if <code>t</code> is not supplied. |
| <code>alpha</code>    | The alpha levels for the required quantiles. The default is to calculate the 1%, 2.5%, 5%, 10%, 90%, 95%, 97.5% and 99% quantiles.                                                                                                                                                                                                                                                 |
| <code>index</code>    | The index of the variable of interest in the output of <code>boot.out\$statistic</code> . This is not used if the argument <code>t</code> is supplied.                                                                                                                                                                                                                             |

|                  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>t0</code>  | The values at which tail probability estimates are required. For each value <code>t0[i]</code> the function will estimate the bootstrap cdf evaluated at <code>t0[i]</code> . If <code>imp.prob</code> is called without the argument <code>t0</code> then the bootstrap cdf evaluated at the observed value of the statistic is found.                                                                                                                                                                                                                   |
| <code>t</code>   | The bootstrap replicates of a statistic. By default these are taken from the bootstrap output object <code>boot.out</code> but they can be supplied separately if required (e.g. when the statistic of interest is a function of the calculated values in <code>boot.out</code> ). Either <code>boot.out</code> or <code>t</code> must be supplied.                                                                                                                                                                                                       |
| <code>w</code>   | The importance resampling weights for the bootstrap replicates. If they are not supplied then <code>boot.out</code> must be supplied, in which case the importance weights are calculated by a call to <code>imp.weights</code> .                                                                                                                                                                                                                                                                                                                         |
| <code>def</code> | A logical value indicating whether a defensive mixture is to be used for weight calculation. This is used only if <code>w</code> is missing and it is passed unchanged to <code>imp.weights</code> to calculate <code>w</code> .                                                                                                                                                                                                                                                                                                                          |
| <code>q</code>   | A vector of probabilities specifying the resampling distribution from which any estimates should be found. In general this would correspond to the usual bootstrap resampling distribution which gives equal weight to each of the original observations. The estimates depend on this distribution only through the importance weights <code>w</code> so this argument is ignored if <code>w</code> is supplied. If <code>w</code> is missing then <code>q</code> is passed as an argument to <code>imp.weights</code> and used to find <code>w</code> . |

### Value

A list with the following components :

|                    |                                                                                                                                                                                                                                                                                                                                                                             |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>alpha</code> | The alpha levels used for the quantiles, if <code>imp.quantile</code> is used.                                                                                                                                                                                                                                                                                              |
| <code>t0</code>    | The values at which the tail probabilities are estimated, if <code>imp.prob</code> is used.                                                                                                                                                                                                                                                                                 |
| <code>raw</code>   | The raw importance resampling estimates. For <code>imp.moments</code> this has length 2, the first component being the estimate of the mean and the second being the variance estimate. For <code>imp.prob</code> , <code>raw</code> is of the same length as <code>t0</code> , and for <code>imp.quantile</code> it is of the same length as <code>alpha</code> .          |
| <code>rat</code>   | The ratio importance resampling estimates. In this method the weights <code>w</code> are rescaled to have average value one before they are used. The format of this vector is the same as <code>raw</code> .                                                                                                                                                               |
| <code>reg</code>   | The regression importance resampling estimates. In this method the weights which are used are derived from a regression of $t \cdot w$ on <code>w</code> . This choice of weights can be shown to minimize the variance of the weights and also the Euclidean distance of the weights from the uniform weights. The format of this vector is the same as <code>raw</code> . |

 alpha = c(0.9, 0.95, 0.975, 0.99))
as.data.frame(grav.q)
```

---

imp.weights

---

*Importance Sampling Weights*

---

**Description**

This function calculates the importance sampling weight required to correct for simulation from a distribution with probabilities  $p$  when estimates are required assuming that simulation was from an alternative distribution with probabilities  $q$ .

**Usage**

```
imp.weights(boot.out, def = TRUE, q = NULL)
```

## Arguments

|                       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>boot.out</code> | A object of class "boot" generated by <code>boot</code> or <code>tilt.boot</code> . Typically the bootstrap simulations would have been done using importance resampling and we wish to do our calculations under the assumption of sampling with equal probabilities.                                                                                                                                                                                                                                                |
| <code>def</code>      | A logical variable indicating whether the defensive mixture distribution weights should be calculated. This makes sense only in the case where the replicates in <code>boot.out</code> were simulated under a number of different distributions. If this is the case then the defensive mixture weights use a mixture of the distributions used in the bootstrap. The alternative is to calculate the weights for each replicate using knowledge of the distribution from which the bootstrap resample was generated. |
| <code>q</code>        | A vector of probabilities specifying the resampling distribution from which we require inferences to be made. In general this would correspond to the usual bootstrap resampling distribution which gives equal weight to each of the original observations and this is the default. <code>q</code> must have length equal to the number of observations in the <code>boot.out\$data</code> and all elements of <code>q</code> must be positive.                                                                      |

## Details

The importance sampling weight for a bootstrap replicate with frequency vector  $\mathbf{f}$  is given by  $\text{prod}((q/p)^{\mathbf{f}})$ . This reweights the replicates so that estimates can be found as if the bootstrap resamples were generated according to the probabilities  $q$  even though, in fact, they came from the distribution  $p$ .

## Value

A vector of importance weights of the same length as `boot.out$t`. These weights can then be used to reweight `boot.out$t` so that estimates can be found as if the simulations were from a distribution with probabilities  $q$ .

## Note

See the example in the help for `imp.moments` for an example of using `imp.weights`.

---

inv.logit

*Inverse Logit Function*

---

**Description**

Given a numeric object return the inverse logit of the values.

**Usage**

```
inv.logit(x)
```

**Arguments**

`x` A numeric object. Missing values (NAs) are allowed.

**Details**

The inverse logit is defined by  $\exp(x) / (1 + \exp(x))$ . Values in `x` of `-Inf` or `Inf` return logits of 0 or 1 respectively. Any NAs in the input will also be NAs in the output.

**Value**

An object of the same type as `x` containing the inverse logits of the input values.

**See Also**

[logit](#), [plogis](#) for which this is a wrapper.

---

islay

*Jura Quartzite Azimuths on Islay*

---

**Description**

The `islay` data frame has 18 rows and 1 columns.

Measurements were taken of paleocurrent azimuths from the Jura Quartzite on the Scottish island of Islay.

**Usage**

```
islay
```

**Format**

This data frame contains the following column:

`theta` The angle of the azimuth in degrees East of North.

## Source

| jack.after.boot | <i>Jackknife-after-Bootstrap Plots</i> |
|-----------------|----------------------------------------|

---

## Description

This function calculates the jackknife influence values from a bootstrap output object and plots the corresponding jackknife-after-bootstrap plot.

## Usage

```
jack.after.boot (boot.out, index = 1, t = NULL, L = NULL,
 useJ = TRUE, stinf = TRUE, alpha = NULL,
 main = "", ylab = NULL, ...)
```

## Arguments

|          |                                                                                                                                                                                                                                                                                                                                   |
|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| boot.out | An object of class "boot" which would normally be created by a call to <a href="#">boot</a> . It should represent a nonparametric bootstrap. For reliable results <code>boot.out\$R</code> should be reasonably large.                                                                                                            |
| index    | The index of the statistic of interest in the output of <code>boot.out\$statistic</code> .                                                                                                                                                                                                                                        |
| t        | A vector of length <code>boot.out\$R</code> giving the bootstrap replicates of the statistic of interest. This is useful if the statistic of interest is a function of the calculated bootstrap output. If it is not supplied then the default is <code>boot.out\$t[, index]</code> .                                             |
| L        | The empirical influence values for the statistic of interest. These are used only if <code>useJ</code> is <code>FALSE</code> . If they are not supplied and are needed, they are calculated by a call to <code>empinf</code> . If <code>L</code> is supplied then it is assumed that they are the infinitesimal jackknife values. |
| useJ     | A logical variable indicating if the jackknife influence values calculated from the bootstrap replicates should be used. If <code>FALSE</code> the empirical influence values are used. The default is <code>TRUE</code> .                                                                                                        |
| stinf    | A logical variable indicating whether to standardize the jackknife values before plotting them. If <code>TRUE</code> then the jackknife values used are divided by their standard error.                                                                                                                                          |
| alpha    | The quantiles at which the plots are required. The default is <code>c(0.05, 0.1, 0.16, 0.5, 0.84, 0.9, 0.95)</code> .                                                                                                                                                                                                             |
| main     | A character string giving the main title for the plot.                                                                                                                                                                                                                                                                            |

|      |                                                                                                                                                                                                                                                                                          |
|------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ylab | The label for the Y axis. If the default values of <code>alpha</code> are used and <code>ylab</code> is not supplied then a label indicating which percentiles are plotted is used. If <code>alpha</code> is supplied then the default label will not say which percentiles were used.   |
| ...  | Any extra arguments required by <code>boot.out\$statistic</code> . These are required only if <code>useJ</code> is <code>FALSE</code> and <code>L</code> is not supplied, in which case they are passed to <code>empinf</code> for use in calculation of the empirical influence values. |

## Details

The centred jackknife quantiles for each observation are estimated from those bootstrap samples in which the particular observation did not appear. These are then plotted against the influence values. If `useJ` is `TRUE` then the influence values are found in the same way as the difference between the mean of the statistic in the samples excluding the observations and the mean in all samples. If `useJ` is `FALSE` then empirical influence values are calculated by calling `empinf`.

The resulting plots are useful diagnostic tools for looking at the way individual observations affect the bootstrap output.

The plot will consist of a number of horizontal dotted lines which correspond to the quantiles of the centred bootstrap distribution. For each data point the quantiles of the bootstrap distribution calculated by omitting that point are plotted against the (possibly standardized) jackknife values. The observation number is printed below the plots. To make it easier to see the effect of omitting points on quantiles, the plotted quantiles are joined by line segments. These plots provide a useful diagnostic tool in establishing the effect of individual observations on the bootstrap distribution. See the references below for some guidelines on the interpretation of the plots.

## Value

There is no returned value but a plot is generated on the current graphics display.

## Side Effects

A plot is created on the current graphics device.

## See Also

`boot`, `empinf`

## Examples

```
To draw the jackknife-after-bootstrap plot for the head size data as in
Example 3.24 of Davison and Hinkley (1997)
frets.fun <- function(data, i) {
 pcorr <- function(x) {
 # Function to find the correlations and partial correlations between
 # the four measurements.
 v <- cor(x)
```

```

v.d <- diag(var(x))
iv <- solve(v)
iv.d <- sqrt(diag(iv))
iv <- - diag(1/iv.d) %*% iv %*% diag(1/iv.d)
q <- NULL
n <- nrow(v)
for (i in 1:(n-1))
 q <- rbind(q, c(v[i, 1:i], iv[i, (i+1):n]))
q <- rbind(q, v[n,])
diag(q) <- round(diag(q))
q
}
d <- data[i,]
v <- pcorr(d)
c(v[1,], v[2,], v[3,], v[4,])
}
frets.boot <- boot(log(as.matrix(frets)), frets.fun, R = 999)
we will concentrate on the partial correlation between head breadth
for the first son and head length for the second. This is the 7th
element in the output of frets.fun so we set index = 7
jack.after.boot(frets.boot, useJ = FALSE, stinf = FALSE, index = 7)

```

k3.linear

*Linear Skewness Estimate***Description**

Estimates the skewness of a statistic from its empirical influence values.

**Usage**

```
k3.linear(L, strata = NULL)
```

**Arguments**

|                     |                                                                                                                                  |
|---------------------|----------------------------------------------------------------------------------------------------------------------------------|
| <code>L</code>      | Vector of the empirical influence values of a statistic. These will usually be calculated by a call to <code>empinf</code> .     |
| <code>strata</code> | A numeric vector or factor specifying which observations (and hence which components of <code>L</code> ) come from which strata. |

**Value**

The skewness estimate calculated from `L`.

**References**

## Examples

```
To estimate the skewness of the ratio of means for the city data.
ratio <- function(d, w) sum(d$x * w) / sum(d$u * w)
k3.linear(empinf(data = city, statistic = ratio))
```

linear.approx

*Linear Approximation of Bootstrap Replicates*

## Description

This function takes a bootstrap object and for each bootstrap replicate it calculates the linear approximation to the statistic of interest for that bootstrap sample.

## Usage

```
linear.approx(boot.out, L = NULL, index = 1, type = NULL,
 t0 = NULL, t = NULL, ...)
```

## Arguments

|                       |                                                                                                                                                                                                                                                                                                                                                                                          |
|-----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>boot.out</code> | An object of class "boot" representing a nonparametric bootstrap. It will usually be created by the function <code>boot</code> .                                                                                                                                                                                                                                                         |
| <code>L</code>        | A vector containing the empirical influence values for the statistic of interest. If it is not supplied then <code>L</code> is calculated through a call to <code>empinf</code> .                                                                                                                                                                                                        |
| <code>index</code>    | The index of the variable of interest within the output of <code>boot.out\$statistic</code> .                                                                                                                                                                                                                                                                                            |
| <code>type</code>     | This gives the type of empirical influence values to be calculated. It is not used if <code>L</code> is supplied. The possible types of empirical influence values are described in the help for <a href="#">empinf</a> .                                                                                                                                                                |
| <code>t0</code>       | The observed value of the statistic of interest. The input value is used only if one of <code>t</code> or <code>L</code> is also supplied. The default value is <code>boot.out\$t0[index]</code> . If <code>t0</code> is supplied but neither <code>t</code> nor <code>L</code> are supplied then <code>t0</code> is set to <code>boot.out\$t0[index]</code> and a warning is generated. |
| <code>t</code>        | A vector of bootstrap replicates of the statistic of interest. If <code>t0</code> is missing then <code>t</code> is not used, otherwise it is used to calculate the empirical influence values (if they are not supplied in <code>L</code> ).                                                                                                                                            |
| <code>...</code>      | Any extra arguments required by <code>boot.out\$statistic</code> . These are needed if <code>L</code> is not supplied as they are used by <code>empinf</code> to calculate empirical influence values.                                                                                                                                                                                   |

## Details

The linear approximation to a bootstrap replicate with frequency vector `f` is given by  $t_0 + \text{sum}(L * f) / n$  in the one sample with an easy extension to the stratified case. The frequencies are found by calling `boot.array`.

## Value

A vector of length `boot.out$R` with the linear approximations to the statistic of interest for each of the bootstrap samples.

## References

Davison, A.C. and Hinkley, D.V. (1997) *Bootstrap Methods and Their Application*. Cambridge University Press.

## Examples

```
Using the city data let us look at the linear approximation to the
ratio statistic and its logarithm. We compare these with the
corresponding plots for the bigcity data

ratio <- function(d, w) sum(d$x * w)/sum(d$u * w)
city.boot <- boot(city, ratio, R = 499, stype = "w")
bigcity.boot <- boot(bigcity, ratio, R = 499, stype = "w")
op <- par(pty = "s", mfrow = c(2, 2))

The first plot is for the city data ratio statistic.
city.lin1 <- linear.approx(city.boot)
lim <- range(c(city.boot$t, city.lin1))
plot(city.boot$t, city.lin1, xlim = lim, ylim = lim,
 main = "Ratio; n=10", xlab = "t*", ylab = "tL*")
abline(0, 1)

Now for the log of the ratio statistic for the city data.
city.lin2 <- linear.approx(city.boot, t0 = log(city.boot$t0),
 t = log(city.boot$t))
lim <- range(c(log(city.boot$t), city.lin2))
plot(log(city.boot$t), city.lin2, xlim = lim, ylim = lim,
 main = "Log(Ratio); n=10", xlab = "t*", ylab = "tL*")
abline(0, 1)

The ratio statistic for the bigcity data.
bigcity.lin1 <- linear.approx(bigcity.boot)
lim <- range(c(bigcity.boot$t, bigcity.lin1))
plot(bigcity.lin1, bigcity.boot$t, xlim = lim, ylim = lim,
 main = "Ratio; n=49", xlab = "t*", ylab = "tL*")
abline(0, 1)

Finally the log of the ratio statistic for the bigcity data.
bigcity.lin2 <- linear.approx(bigcity.boot, t0 = log(bigcity.boot$t0),
 t = log(bigcity.boot$t))
lim <- range(c(log(bigcity.boot$t), bigcity.lin2))
plot(bigcity.lin2, log(bigcity.boot$t), xlim = lim, ylim = lim,
 main = "Log(Ratio); n=49", xlab = "t*", ylab = "tL*")
abline(0, 1)

par(op)
```

---

lines.saddle.distn *Add a Saddlepoint Approximation to a Plot*

---

## Description

This function adds a line corresponding to a saddlepoint density or distribution function approximation to the current plot.

## Usage

```
S3 method for class 'saddle.distn'
lines(x, dens = TRUE, h = function(u) u, J = function(u) 1,
 npts = 50, lty = 1, ...)
```

## Arguments

|      |                                                                                                                                                                                                                                                                                                                 |
|------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x    | An object of class "saddle.distn" (see <a href="#">saddle.distn.object</a> representing a saddlepoint approximation to a distribution.                                                                                                                                                                          |
| dens | A logical variable indicating whether the saddlepoint density (TRUE; the default) or the saddlepoint distribution function (FALSE) should be plotted.                                                                                                                                                           |
| h    | Any transformation of the variable that is required. Its first argument must be the value at which the approximation is being performed and the function must be vectorized.                                                                                                                                    |
| J    | When dens=TRUE this function specifies the Jacobian for any transformation that may be necessary. The first argument of J must the value at which the approximation is being performed and the function must be vectorized. If h is supplied J must also be supplied and both must have the same argument list. |
| npts | The number of points to be used for the plot. These points will be evenly spaced over the range of points used in finding the saddlepoint approximation.                                                                                                                                                        |
| lty  | The line type to be used.                                                                                                                                                                                                                                                                                       |
| ...  | Any additional arguments to h and J.                                                                                                                                                                                                                                                                            |

## Details

The function uses `smooth.spline` to produce the saddlepoint curve. When `dens=TRUE` the spline is on the log scale and when `dens=FALSE` it is on the probit scale.

## Value

`sad.d` is returned invisibly.

## Side Effects

A line is added to the current plot.

## References

[saddle.distn](#)

**Examples**

```
In this example we show how a plot such as that in Figure 9.9 of
Davison and Hinkley (1997) may be produced. Note the large number of
bootstrap replicates required in this example.
expdata <- rexp(12)
vfun <- function(d, i) {
 n <- length(d)
 (n-1)/n*var(d[i])
}
exp.boot <- boot(expdata,vfun, R = 9999)
exp.L <- (expdata - mean(expdata))^2 - exp.boot$t0
exp.tL <- linear.approx(exp.boot, L = exp.L)
hist(exp.tL, nclass = 50, probability = TRUE)
exp.t0 <- c(0, sqrt(var(exp.boot$t)))
exp.sp <- saddle.distn(A = exp.L/12,wdist = "m", t0 = exp.t0)

The saddlepoint approximation in this case is to the density of
t-t0 and so t0 must be added for the plot.
lines(exp.sp, h = function(u, t0) u+t0, J = function(u, t0) 1,
 t0 = exp.boot$t0)
```

logit

*Logit of Proportions*

---

**Description**

This function calculates the logit of proportions.

**Usage**

```
logit(p)
```

**Arguments**

|   |                                                                                                       |
|---|-------------------------------------------------------------------------------------------------------|
| p | A numeric Splus object, all of whose values are in the range [0,1]. Missing values (NAs) are allowed. |
|---|-------------------------------------------------------------------------------------------------------|

**Details**

If any elements of p are outside the unit interval then an error message is generated. Values of p equal to 0 or 1 (to within machine precision) will return `-Inf` or `Inf` respectively. Any NAs in the input will also be NAs in the output.

**Value**

A numeric object of the same type as p containing the logits of the input values.

**See Also**

[inv.logit](#), [qlogis](#) for which this is a wrapper.

manaus

*Average Heights of the Rio Negro river at Manaus*

## Description

The manaus time series is of class "ts" and has 1080 observations on one variable.

The data values are monthly averages of the daily stages (heights) of the Rio Negro at Manaus. Manaus is 18km upstream from the confluence of the Rio Negro with the Amazon but because of the tiny slope of the water surface and the lower courses of its flatland affluents, they may be regarded as a good approximation of the water level in the Amazon at the confluence. The data here cover 90 years from January 1903 until December 1992.

The Manaus gauge is tied in with an arbitrary bench mark of 100m set in the steps of the Municipal Prefecture; gauge readings are usually referred to sea level, on the basis of a mark on the steps leading to the Parish Church (Matriz), which is assumed to lie at an altitude of 35.874 m according to observations made many years ago under the direction of Samuel Pereira, an engineer in charge of the Manaus Sanitation Committee Whereas such an altitude cannot, by any means, be considered to be a precise datum point, observations have been provisionally referred to it. The measurements are in metres.

## Source

The data were kindly made available by Professors H. O'Reilly Sternberg and D. R. Brillinger of the University of California at Berkeley.

melanoma

*Survival from Malignant Melanoma*

## Description

The melanoma data frame has 205 rows and 7 columns.

The data consist of measurements made on patients with malignant melanoma. Each patient had their tumour removed by surgery at the Department of Plastic Surgery, University Hospital of Odense, Denmark during the period 1962 to 1977. The surgery consisted of complete removal of the tumour together with about 2.5cm of the surrounding skin. Among the measurements taken were the thickness of the tumour and whether it was ulcerated or not. These are thought to be important prognostic variables in that patients with a thick and/or ulcerated tumour have an increased chance of death from melanoma. Patients were followed until the end of 1977.

**Usage**

```
melanoma
```

**Format**

This data frame contains the following columns:

`time` Survival time in days since the operation, possibly censored.

`status` The patients status at the end of the study. 1 indicates that they had died from melanoma, 2 indicates that they were still alive and 3 indicates that they had died from causes unrelated to their melanoma.

`sex` The patients sex; 1=male, 0=female.

`age` Age in years at the time of the operation.

`year` Year of operation.

`thickness` Tumour thickness in mm.

`ulcer` Indicator of ulceration; 1=present, 0=absent.

**Note**

This dataset is not related to the dataset in the **lattice** package with the same name.

**Source**

The data were obtained from

---

```
motor
```

*Data from a Simulated Motorcycle Accident*

---

**Description**

The `motor` data frame has 94 rows and 4 columns. The rows are obtained by removing replicate values of `time` from the dataset `mcycle`. Two extra columns are added to allow for strata with a different residual variance in each stratum.

**Usage**

```
motor
```

**Format**

This data frame contains the following columns:

`times` The time in milliseconds since impact.

`accel` The recorded head acceleration (in g).

`strata` A numeric column indicating to which of the three strata (numbered 1, 2 and 3) the observations belong.

`v` An estimate of the residual variance for the observation. `v` is constant within the strata but a different estimate is used for each of the three strata.

**Source**

The data were obtained from

neuro

*Neurophysiological Point Process Data*

---

**Description**

`neuro` is a matrix containing times of observed firing of a neuron in windows of 250ms either side of the application of a stimulus to a human subject. Each row of the matrix is a replication of the experiment and there were a total of 469 replicates.

**Note**

There are a lot of missing values in the matrix as different numbers of firings were observed in different replicates. The number of firings observed varied from 2 to 6.

**Source**

The data were collected and kindly made available by Dr. S.J. Boniface of the Neurophysiology Unit at the Radcliffe Infirmary, Oxford.

nitrofen*Toxicity of Nitrofen in Aquatic Systems*

---

### Description

The `nitrofen` data frame has 50 rows and 5 columns.

Nitrofen is a herbicide that was used extensively for the control of broad-leaved and grass weeds in cereals and rice. Although it is relatively non-toxic to adult mammals, nitrofen is a significant tetragen and mutagen. It is also acutely toxic and reproductively toxic to cladoceran zooplankton. Nitrofen is no longer in commercial use in the U.S., having been the first pesticide to be withdrawn due to tetragenic effects.

The data here come from an experiment to measure the reproductive toxicity of nitrofen on a species of zooplankton (*Ceriodaphnia dubia*). 50 animals were randomized into batches of 10 and each batch was put in a solution with a measured concentration of nitrofen. Then the number of live offspring in each of the three broods to each animal was recorded.

### Usage

```
nitrofen
```

### Format

This data frame contains the following columns:

`conc` The nitrofen concentration in the solution (mug/litre).

`brood1` The number of live offspring in the first brood.

`brood2` The number of live offspring in the second brood.

`brood3` The number of live offspring in the third brood.

`total` The total number of live offspring in the first three broods.

### Source

The data were obtained from

Bailer, A.J. and Oris, J.T. (1994) Assessing toxicity of pollutants in aquatic systems. In *Case Studies in Biometry*. N. Lange, L. Ryan, L. Billard, D. Brillinger, L. Conquest and J. Greenhouse (editors), 25–40. John Wiley.

nodal

*Nodal Involvement in Prostate Cancer***Description**

The `nodal` data frame has 53 rows and 7 columns.

The treatment strategy for a patient diagnosed with cancer of the prostate depend highly on whether the cancer has spread to the surrounding lymph nodes. It is common to operate on the patient to get samples from the nodes which can then be analysed under a microscope but clearly it would be preferable if an accurate assessment of nodal involvement could be made without surgery.

For a sample of 53 prostate cancer patients, a number of possible predictor variables were measured before surgery. The patients then had surgery to determine nodal involvement. It was required to see if nodal involvement could be accurately predicted from the predictor variables and which ones were most important.

**Usage**

```
nodal
```

**Format**

This data frame contains the following columns:

`m` A column of ones.

`r` An indicator of nodal involvement.

`aged` The patients age dichotomized into less than 60 (0) and 60 or over 1.

`stage` A measurement of the size and position of the tumour observed by palpitation with the fingers via the rectum. A value of 1 indicates a more serious case of the cancer.

`grade` Another indicator of the seriousness of the cancer, this one is determined by a pathology reading of a biopsy taken by needle before surgery. A value of 1 indicates a more serious case of the cancer.

`xray` A third measure of the seriousness of the cancer taken from an X-ray reading. A value of 1 indicates a more serious case of the cancer.

`acid` The level of acid phosphatase in the blood serum.

**Source**

The data were obtained from

Brown, B.W. (1980) Prediction analysis for binary data. In *Biostatistics Casebook*. R.G. Miller, B. Efron, B.W. Brown and L.E. Moses (editors), 3–18. John Wiley.

norm.ci

*Normal Approximation Confidence Intervals***Description**

Using the normal approximation to a statistic, calculate equi-tailed two-sided confidence intervals.

**Usage**

```
norm.ci(boot.out = NULL, conf = 0.95, index = 1, var.t0 = NULL,
 t0 = NULL, t = NULL, L = NULL, h = function(t) t,
 hdot = function(t) 1, hinv = function(t) t)
```

**Arguments**

|                       |                                                                                                                                                                                                                                                                                                                                                                |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>boot.out</code> | A bootstrap output object returned from a call to <code>boot</code> . If <code>t0</code> is missing then <code>boot.out</code> is a required argument. It is also required if both <code>var.t0</code> and <code>t</code> are missing.                                                                                                                         |
| <code>conf</code>     | A scalar or vector containing the confidence level(s) of the required interval(s).                                                                                                                                                                                                                                                                             |
| <code>index</code>    | The index of the statistic of interest within the output of a call to <code>boot.out\$statistic</code> . It is not used if <code>boot.out</code> is missing, in which case <code>t0</code> must be supplied.                                                                                                                                                   |
| <code>var.t0</code>   | The variance of the statistic of interest. If it is not supplied then <code>var(t)</code> is used.                                                                                                                                                                                                                                                             |
| <code>t0</code>       | The observed value of the statistic of interest. If it is missing then it is taken from <code>boot.out</code> which is required in that case.                                                                                                                                                                                                                  |
| <code>t</code>        | Bootstrap replicates of the variable of interest. These are used to estimate the variance of the statistic of interest if <code>var.t0</code> is not supplied. The default value is <code>boot.out\$t[, index]</code> .                                                                                                                                        |
| <code>L</code>        | The empirical influence values for the statistic of interest. These are used to calculate <code>var.t0</code> if neither <code>var.t0</code> nor <code>boot.out</code> are supplied. If a transformation is supplied through <code>h</code> then the influence values must be for the untransformed statistic <code>t0</code> .                                |
| <code>h</code>        | A function defining a monotonic transformation, the intervals are calculated on the scale of <code>h(t)</code> and the inverse function <code>hinv</code> is applied to the resulting intervals. <code>h</code> must be a function of one variable only and must be vectorized. The default is the identity function.                                          |
| <code>hdot</code>     | A function of one argument returning the derivative of <code>h</code> . It is a required argument if <code>h</code> is supplied and is used for approximating the variance of <code>h(t0)</code> . The default is the constant function 1.                                                                                                                     |
| <code>hinv</code>     | A function, like <code>h</code> , which returns the inverse of <code>h</code> . It is used to transform the intervals calculated on the scale of <code>h(t)</code> back to the original scale. The default is the identity function. If <code>h</code> is supplied but <code>hinv</code> is not, then the intervals returned will be on the transformed scale. |

## Details

It is assumed that the statistic of interest has an approximately normal distribution with variance `var.t0` and so a confidence interval of length  $2 * \text{qnorm}((1 + \text{conf}) / 2) * \text{sqrt}(\text{var.t0})$  is found. If `boot.out` or `t` are supplied then the interval is bias-corrected using the bootstrap bias estimate, and so the interval would be centred at  $2 * t_0 - \text{mean}(t)$ . Otherwise the interval is centred at `t0`.

## Value

If `length(conf)` is 1 then a vector containing the confidence level and the endpoints of the interval is returned. Otherwise, the returned value is a matrix where each row corresponds to a different confidence level.

## Note

This function is primarily designed to be called by `boot.ci` to calculate the normal approximation after a bootstrap but it can also be used without doing any bootstrap calculations as long as `t0` and `var.t0` can be supplied. See the examples below.

[boot.ci](#)

## Examples

```
In Example 5.1 of Davison and Hinkley (1997), normal approximation
confidence intervals are found for the air-conditioning data.
air.mean <- mean(aircondit$hours)
air.n <- nrow(aircondit)
air.v <- air.mean^2/air.n
norm.ci(t0 = air.mean, var.t0 = air.v)
exp(norm.ci(t0 = log(air.mean), var.t0 = 1/air.n)[2:3])

Now a more complicated example - the ratio estimate for the city data.
ratio <- function(d, w)
 sum(d$x * w)/sum(d$u * w)
city.v <- var.linear(empinf(data = city, statistic = ratio))
norm.ci(t0 = ratio(city, rep(0.1,10)), var.t0 = city.v)
```

## Description

The `nuclear` data frame has 32 rows and 11 columns.

The data relate to the construction of 32 light water reactor (LWR) plants constructed in the U.S.A in the late 1960's and early 1970's. The data was collected with the aim of predicting the cost of construction of further LWR plants. 6 of the power plants had partial turnkey guarantees and it is possible that, for these plants, some manufacturers' subsidies may be hidden in the quoted capital costs.

## Usage

```
nuclear
```

## Format

This data frame contains the following columns:

`cost` The capital cost of construction in millions of dollars adjusted to 1976 base.

`date` The date on which the construction permit was issued. The data are measured in years since January 1 1990 to the nearest month.

`t1` The time between application for and issue of the construction permit.

`t2` The time between issue of operating license and construction permit.

`cap` The net capacity of the power plant (MWe).

`pr` A binary variable where 1 indicates the prior existence of a LWR plant at the same site.

`ne` A binary variable where 1 indicates that the plant was constructed in the north-east region of the U.S.A.

`ct` A binary variable where 1 indicates the use of a cooling tower in the plant.

`bw` A binary variable where 1 indicates that the nuclear steam supply system was manufactured by Babcock-Wilcox.

`cum.n` The cumulative number of power plants constructed by each architect-engineer.

`pt` A binary variable where 1 indicates those plants with partial turnkey guarantees.

paulsen

*Neurotransmission in Guinea Pig Brains***Description**

The paulsen data frame has 346 rows and 1 columns.

Sections were prepared from the brain of adult guinea pigs. Spontaneous currents that flowed into individual brain cells were then recorded and the peak amplitude of each current measured. The aim of the experiment was to see if the current flow was quantal in nature (i.e. that it is not a single burst but instead is built up of many smaller bursts of current). If the current was indeed quantal then it would be expected that the distribution of the current amplitude would be multimodal with modes at regular intervals. The modes would be expected to decrease in magnitude for higher current amplitudes.

**Usage**

```
paulsen
```

**Format**

This data frame contains the following column:

y The current flowing into individual brain cells. The currents are measured in pico-amperes.

**Source**

The data were kindly made available by Dr. O. Paulsen from the Department of Pharmacology at the University of Oxford.

Paulsen, O. and Heggelund, P. (1994) The quantal size at retinogeniculate synapses determined from spontaneous and evoked EPSCs in guinea-pig thalamic slices. *Journal of Physiology*, **480**, 505–511.

plot.boot

*Plots of the Output of a Bootstrap Simulation***Description**

This takes a bootstrap object and produces plots for the bootstrap replicates of the variable of interest.

**Usage**

```
S3 method for class 'boot'
plot(x, index = 1, t0 = NULL, t = NULL, jack = FALSE,
 qdist = "norm", nclass = NULL, df, ...)
```

**Arguments**

|                     |                                                                                                                                                                                                                                                         |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>      | An object of class "boot" returned from one of the bootstrap generation functions.                                                                                                                                                                      |
| <code>index</code>  | The index of the variable of interest within the output of <code>boot.out</code> . This is ignored if <code>t</code> and <code>t0</code> are supplied.                                                                                                  |
| <code>t0</code>     | The original value of the statistic. This defaults to <code>boot.out\$t0[index]</code> unless <code>t</code> is supplied when it defaults to <code>NULL</code> . In that case no vertical line is drawn on the histogram.                               |
| <code>t</code>      | The bootstrap replicates of the statistic. Usually this will take on its default value of <code>boot.out\$t[, index]</code> , however it may be useful sometimes to supply a different set of values which are a function of <code>boot.out\$t</code> . |
| <code>jack</code>   | A logical value indicating whether a jackknife-after-bootstrap plot is required. The default is not to produce such a plot.                                                                                                                             |
| <code>qdist</code>  | The distribution against which the Q-Q plot should be drawn. At present "norm" (normal distribution - the default) and "chisq" (chi-squared distribution) are the only possible values.                                                                 |
| <code>nclass</code> | An integer giving the number of classes to be used in the bootstrap histogram. The default is the integer between 10 and 100 closest to <code>ceiling(length(t)/25)</code> .                                                                            |
| <code>df</code>     | If <code>qdist</code> is "chisq" then this is the degrees of freedom for the chi-squared distribution to be used. It is a required argument in that case.                                                                                               |
| <code>...</code>    | When <code>jack</code> is TRUE additional parameters to <code>jack.after.boot</code> can be supplied. See the help file for <code>jack.after.boot</code> for details of the possible parameters.                                                        |

**Details**

This function will generally produce two side-by-side plots. The left plot will be a histogram of the bootstrap replicates. Usually the breaks of the histogram will be chosen so that `t0` is at a breakpoint and all intervals are of equal length. A vertical dotted line indicates the position of `t0`. This cannot be done if `t` is supplied but `t0` is not and so, in that case, the breakpoints are computed by `hist` using the `nclass` argument and no vertical line is drawn.

The second plot is a Q-Q plot of the bootstrap replicates. The order statistics of the replicates can be plotted against normal or chi-squared quantiles. In either case the expected line is also plotted. For the normal, this will have intercept `mean(t)` and slope `sqrt(var(t))` while for the chi-squared it has intercept 0 and slope 1.

If `jack` is TRUE a third plot is produced beneath these two. That plot is the jackknife-after-bootstrap plot. This plot may only be requested when nonparametric simulation has been used. See `jack.after.boot` for further details of this plot.

**Value**

`boot.out` is returned invisibly.

**Side Effects**

All screens are closed and cleared and a number of plots are produced on the current graphics device. Screens are closed but not cleared at termination of this function.

**Examples**

```
We fit an exponential model to the air-conditioning data and use
that for a parametric bootstrap. Then we look at plots of the
resampled means.
air.rg <- function(data, mle) rexp(length(data), 1/mle)

air.boot <- boot(aircondit$hours, mean, R = 999, sim = "parametric",
 ran.gen = air.rg, mle = mean(aircondit$hours))
plot(air.boot)

In the difference of means example for the last two series of the
gravity data
grav1 <- gravity[as.numeric(gravity[, 2]) >= 7,]
grav.fun <- function(dat, w) {
 strata <- tapply(dat[, 2], as.numeric(dat[, 2]))
 d <- dat[, 1]
 ns <- tabulate(strata)
 w <- w/tapply(w, strata, sum)[strata]
 mns <- as.vector(tapply(d * w, strata, sum)) # drop names
 mn2 <- tapply(d * d * w, strata, sum)
 s2hat <- sum((mn2 - mns^2)/ns)
 c(mns[2] - mns[1], s2hat)
}

grav.boot <- boot(grav1, grav.fun, R = 499, stype = "w", strata = grav1[, 2])
plot(grav.boot)
now suppose we want to look at the studentized differences.
grav.z <- (grav.boot$t[, 1]-grav.boot$t0[1])/sqrt(grav.boot$t[, 2])
plot(grav.boot, t = grav.z, t0 = 0)

In this example we look at the one of the partial correlations for the
head dimensions in the dataset frets.
frets.fun <- function(data, i) {
 pcorr <- function(x) {
 # Function to find the correlations and partial correlations between
 # the four measurements.
 v <- cor(x)
 v.d <- diag(var(x))
 iv <- solve(v)
 iv.d <- sqrt(diag(iv))
 iv <- - diag(1/iv.d) %*% iv %*% diag(1/iv.d)
 q <- NULL
 n <- nrow(v)
 for (i in 1:(n-1))
 q <- rbind(q, c(v[i, 1:i], iv[i, (i+1):n]))
 q <- rbind(q, v[n,])
 diag(q) <- round(diag(q))
 q
 }
 d <- data[i,]
 v <- pcorr(d)
 c(v[1,], v[2,], v[3,], v[4,])
}
```

```

}
frets.boot <- boot(log(as.matrix(frets)), frets.fun, R = 999)
plot(frets.boot, index = 7, jack = TRUE, stinf = FALSE, useJ = FALSE)

```

---

poisons

*Animal Survival Times*

---

### Description

The `poisons` data frame has 48 rows and 3 columns.

The data form a 3x4 factorial experiment, the factors being three poisons and four treatments. Each combination of the two factors was used for four animals, the allocation to animals having been completely randomized.

### Usage

```
poisons
```

### Format

This data frame contains the following columns:

`time` The survival time of the animal in units of 10 hours.

`poison` A factor with levels 1, 2 and 3 giving the type of poison used.

`treat` A factor with levels A, B, C and D giving the treatment.

### Source

The data were obtained from

Box, G.E.P. and Cox, D.R. (1964) An analysis of transformations (with Discussion). *Journal of the Royal Statistical Society, B*, **26**, 211–252.

### References

---

polar

*Pole Positions of New Caledonian Laterites*

---

### Description

The `polar` data frame has 50 rows and 2 columns.

The data are the pole positions from a paleomagnetic study of New Caledonian laterites.

### Usage

```
polar
```

### Format

This data frame contains the following columns:

- lat The latitude (in degrees) of the pole position. Note that all latitudes are negative as the axis is taken to be in the lower hemisphere.
- long The longitude (in degrees) of the pole position.

### Source

The data were obtained from

Fisher, N.I., Lewis, T. and Embleton, B.J.J. (1987) *Statistical Analysis of Spherical Data*. Cambridge University Press.

|                         |                                              |
|-------------------------|----------------------------------------------|
| <code>print.boot</code> | <i>Print a Summary of a Bootstrap Object</i> |
|-------------------------|----------------------------------------------|

---

### Description

This is a method for the function `print()` for objects of the class "boot" created by a call to `boot`, `censboot`, `tilt.boot` or `tsboot`.

### Usage

```
S3 method for class 'boot'
print(x, digits = getOption("digits"),
 index = 1:ncol(boot.out$t), ...)
```

### Arguments

- `x` A bootstrap output object of class "boot" generated by one of the bootstrap functions.
- `digits` The number of digits to be printed in the summary statistics.
- `index` Indices indicating for which elements of the bootstrap output summary statistics are required.
- `...` further arguments passed to or from other methods.

### Details

For each statistic calculated in the bootstrap the original value and the bootstrap estimates of its bias and standard error are printed. If `boot.out$t0` is missing (such as when it was created by a call to `tsboot` with `orig.t = FALSE`) the bootstrap mean and standard error are printed. If resampling was done using importance resampling weights, then the bootstrap estimates are reweighted as if uniform resampling had been done. The ratio importance sampling estimates are used and if there were a number of distributions then defensive mixture distributions are used. In this case an extra column with the mean of the observed bootstrap statistics is also printed.

**Value**

The bootstrap object is returned invisibly.

---

`print.bootci`

*Print Bootstrap Confidence Intervals*

---

**Description**

This is a method for the function `print()` to print objects of the class "bootci".

**Usage**

```
S3 method for class 'bootci'
print(x, hinv = NULL, ...)
```

**Arguments**

|                   |                                                                                 |
|-------------------|---------------------------------------------------------------------------------|
| <code>x</code>    | The output from a call to <code>boot.ci</code> .                                |
| <code>hinv</code> | A transformation to be made to the interval end-points before they are printed. |
| <code>...</code>  | further arguments passed to or from other methods.                              |

**Details**

This function prints out the results from `boot.ci` in a "nice" format. It also notes whether the scale of the intervals is the original scale of the input to `boot.ci` or a different scale and whether the calculations were done on a transformed scale. It also looks at the order statistics that were used in calculating the intervals. If the smallest or largest values were used then it prints a message

```
Warning : Intervals used Extreme Quantiles
```

Such intervals should be considered very unstable and not relied upon for inferences. Even if the extreme values are not used, it is possible that the intervals are unstable if they used quantiles close to the extreme values. The function alerts the user to intervals which use the upper or lower 10 order statistics with the message

```
Some intervals may be unstable
```

**Value**

The object `ci.out` is returned invisibly.

**See Also**

`boot.ci`

---

```
print.saddle.distn
```

*Print Quantiles of Saddlepoint Approximations*

---

**Description**

This is a method for the function `print()` to print objects of class `"saddle.distn"`.

**Usage**

```
S3 method for class 'saddle.distn'
print(x, ...)
```

**Arguments**

|                  |                                                                                                 |
|------------------|-------------------------------------------------------------------------------------------------|
| <code>x</code>   | An object of class <code>"saddle.distn"</code> created by a call to <code>saddle.distn</code> . |
| <code>...</code> | further arguments passed to or from other methods.                                              |

**Details**

The quantiles of the saddlepoint approximation to the distribution are printed along with the original call and some other useful information.

**Value**

The input is returned invisibly.

**See Also**

`lines.saddle.distn`, `saddle.distn`

---

```
print.simplex
```

*Print Solution to Linear Programming Problem*

---

**Description**

This is a method for the function `print()` to print objects of class `"simplex"`.

**Usage**

```
S3 method for class 'simplex'
print(x, ...)
```

**Arguments**

|                  |                                                                                                                                       |
|------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>   | An object of class <code>"simplex"</code> created by calling the function <code>simplex</code> to solve a linear programming problem. |
| <code>...</code> | further arguments passed to or from other methods.                                                                                    |

**Details**

The coefficients of the objective function are printed. If a solution to the linear programming problem was found then the solution and the optimal value of the objective function are printed. If a feasible solution was found but the maximum number of iterations was exceeded then the last feasible solution and the objective function value at that point are printed. If no feasible solution could be found then a message stating that is printed.

**Value**

`x` is returned silently.

|           |                                           |
|-----------|-------------------------------------------|
| remission | <i>Cancer Remission and Cell Activity</i> |
|-----------|-------------------------------------------|

---

**Description**

The `remission` data frame has 27 rows and 3 columns.

**Usage**

```
remission
```

**Format**

This data frame contains the following columns:

- `LI` A measure of cell activity.
- `m` The number of patients in each group (all values are actually 1 here).
- `r` The number of patients (out of `m`) who went into remission.

**Source**

The data were obtained from  
Freeman, D.H. (1987) *Applied Categorical Data Analysis*. Marcel Dekker.

**References**

Davison, A.C. and Hinkley, D.V. (1997) *Bootstrap Methods and Their Application*. Cambridge University Press.

**Description**

This function calculates a saddlepoint approximation to the distribution of a linear combination of  $\mathbf{W}$  at a particular point  $u$ , where  $\mathbf{W}$  is a vector of random variables. The distribution of  $\mathbf{W}$  may be multinomial (default), Poisson or binary. Other distributions are possible also if the adjusted cumulant generating function and its second derivative are given. Conditional saddlepoint approximations to the distribution of one linear combination given the values of other linear combinations of  $\mathbf{W}$  can be calculated for  $\mathbf{W}$  having binary or Poisson distributions.

**Usage**

```
saddle(A = NULL, u = NULL, wdist = "m", type = "simp", d = NULL,
 d1 = 1, init = rep(0.1, d), mu = rep(0.5, n), LR = FALSE,
 strata = NULL, K.adj = NULL, K2 = NULL)
```

**Arguments**

|                     |                                                                                                                                                                                                                                                                                                                                                                                                                            |
|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>A</code>      | A vector or matrix of known coefficients of the linear combinations of $\mathbf{W}$ . It is a required argument unless <code>K.adj</code> and <code>K2</code> are supplied, in which case it is ignored.                                                                                                                                                                                                                   |
| <code>u</code>      | The value at which it is desired to calculate the saddlepoint approximation to the distribution of the linear combination of $\mathbf{W}$ . It is a required argument unless <code>K.adj</code> and <code>K2</code> are supplied, in which case it is ignored.                                                                                                                                                             |
| <code>wdist</code>  | The distribution of $\mathbf{W}$ . This can be one of "m" (multinomial), "p" (Poisson), "b" (binary) or "o" (other). If <code>K.adj</code> and <code>K2</code> are given <code>wdist</code> is set to "o".                                                                                                                                                                                                                 |
| <code>type</code>   | The type of saddlepoint approximation. Possible types are "simp" for simple saddlepoint and "cond" for the conditional saddlepoint. When <code>wdist</code> is "o" or "m", <code>type</code> is automatically set to "simp", which is the only type of saddlepoint currently implemented for those distributions.                                                                                                          |
| <code>d</code>      | This specifies the dimension of the whole statistic. This argument is required only when <code>wdist</code> = "o" and defaults to 1 if not supplied in that case. For other distributions it is set to <code>ncol(A)</code> .                                                                                                                                                                                              |
| <code>d1</code>     | When <code>type</code> is "cond" this is the dimension of the statistic of interest which must be less than <code>length(u)</code> . Then the saddlepoint approximation to the conditional distribution of the first <code>d1</code> linear combinations given the values of the remaining combinations is found. Conditional distribution function approximations can only be found if the value of <code>d1</code> is 1. |
| <code>init</code>   | Used if <code>wdist</code> is either "m" or "o", this gives initial values to <code>nlmin</code> which is used to solve the saddlepoint equation.                                                                                                                                                                                                                                                                          |
| <code>mu</code>     | The values of the parameters of the distribution of $\mathbf{W}$ when <code>wdist</code> is "m", "p" or "b". <code>mu</code> must be of the same length as $\mathbf{W}$ (i.e. <code>nrow(A)</code> ). The default is that all values of <code>mu</code> are equal and so the elements of $\mathbf{W}$ are identically distributed.                                                                                         |
| <code>LR</code>     | If TRUE then the Lugananni-Rice approximation to the cdf is used, otherwise the approximation used is based on Barndorff-Nielsen's $r^*$ .                                                                                                                                                                                                                                                                                 |
| <code>strata</code> | The strata for stratified data.                                                                                                                                                                                                                                                                                                                                                                                            |

|                    |                                                                                                                                                                                                                                                                                                                                                                                                           |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>K.adj</code> | The adjusted cumulant generating function used when <code>wdist</code> is "o". This is a function of a single parameter, <code>zeta</code> , which calculates $K(zeta) - u * zeta$ , where $K(zeta)$ is the cumulant generating function of $W$ .                                                                                                                                                         |
| <code>K2</code>    | This is a function of a single parameter <code>zeta</code> which returns the matrix of second derivatives of $K(zeta)$ for use when <code>wdist</code> is "o". If <code>K.adj</code> is given then this must be given also. It is called only once with the calculated solution to the saddlepoint equation being passed as the argument. This argument is ignored if <code>K.adj</code> is not supplied. |

### Details

If `wdist` is "o" or "m", the saddlepoint equations are solved using `nlmin` to minimize `K.adj` with respect to its parameter `zeta`. For the Poisson and binary cases, a generalized linear model is fitted such that the parameter estimates solve the saddlepoint equations. The response variable 'y' for the `glm` must satisfy the equation  $t(A) \%*\%y = u(t())$  being the transpose function). Such a vector can be found as a feasible solution to a linear programming problem. This is done by a call to `simplex`. The covariate matrix for the `glm` is given by `A`.

### Value

A list consisting of the following components

|                        |                                                                                                                                                                                |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>spa</code>       | The saddlepoint approximations. The first value is the density approximation and the second value is the distribution function approximation.                                  |
| <code>zeta.hat</code>  | The solution to the saddlepoint equation. For the conditional saddlepoint this is the solution to the saddlepoint equation for the numerator.                                  |
| <code>zeta2.hat</code> | If <code>type</code> is "cond" this is the solution to the saddlepoint equation for the denominator. This component is not returned for any other value of <code>type</code> . |

### Examples

```
To evaluate the bootstrap distribution of the mean failure time of
air-conditioning equipment at 80 hours
saddle(A = aircondit$hours/12, u = 80)

Alternatively this can be done using a conditional poisson
saddle(A = cbind(aircondit$hours/12,1), u = c(80, 12),
```

```

wdist = "p", type = "cond")

To use the Lugananni-Rice approximation to this
saddle(A = cbind(aircondit$hours/12,1), u = c(80, 12),
 wdist = "p", type = "cond",
 LR = TRUE)

Example 9.16 of Davison and Hinkley (1997) calculates saddlepoint
approximations to the distribution of the ratio statistic for the
city data. Since the statistic is not in itself a linear combination
of random Variables, its distribution cannot be found directly.
Instead the statistic is expressed as the solution to a linear
estimating equation and hence its distribution can be found. We
get the saddlepoint approximation to the pdf and cdf evaluated at
t = 1.25 as follows.
jacobian <- function(dat,t,zeta)
{
 p <- exp(zeta*(dat$x-t*dat$u))
 abs(sum(dat$u*p)/sum(p))
}
city.sp1 <- saddle(A = city$x-1.25*city$u, u = 0)
city.sp1$spa[1] <- jacobian(city, 1.25, city.sp1$zeta.hat) * city.sp1$spa[1]
city.sp1

```

*Saddlepoint Distribution Approximations for Bootstrap Statistics*

## Description

Approximate an entire distribution using saddlepoint methods. This function can calculate simple and conditional saddlepoint distribution approximations for a univariate quantity of interest. For the simple saddlepoint the quantity of interest is a linear combination of  $\mathbf{W}$  where  $\mathbf{W}$  is a vector of random variables. For the conditional saddlepoint we require the distribution of one linear combination given the values of any number of other linear combinations. The distribution of  $\mathbf{W}$  must be one of multinomial, Poisson or binary. The primary use of this function is to calculate quantiles of bootstrap distributions using saddlepoint approximations. Such quantiles are required by the function `control` to approximate the distribution of the linear approximation to a statistic.

## Usage

```

saddle.distn(A, u = NULL, alpha = NULL, wdist = "m",
 type = "simp", npts = 20, t = NULL, t0 = NULL,
 init = rep(0.1, d), mu = rep(0.5, n), LR = FALSE,
 strata = NULL, ...)

```

## Arguments

**A** This is a matrix of known coefficients or a function which returns such a matrix. If a function then its first argument must be the point  $t$  at which a saddlepoint is required. The most common reason for  $A$  being a function would be if the statistic is not itself a linear combination of the  $\mathbf{W}$  but is the solution to a linear estimating equation.

|                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>u</code>      | If <code>A</code> is a function then <code>u</code> must also be a function returning a vector with length equal to the number of columns of the matrix returned by <code>A</code> . Usually all components other than the first will be constants as the other components are the values of the conditioning variables. If <code>A</code> is a matrix with more than one column (such as when <code>wdist = "cond"</code> ) then <code>u</code> should be a vector with length one less than <code>ncol(A)</code> . In this case <code>u</code> specifies the values of the conditioning variables. If <code>A</code> is a matrix with one column or a vector then <code>u</code> is not used.                                 |
| <code>alpha</code>  | The alpha levels for the quantiles of the distribution which should be returned. By default the 0.1, 0.5, 1, 2.5, 5, 10, 20, 50, 80, 90, 95, 97.5, 99, 99.5 and 99.9 percentiles are calculated.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>wdist</code>  | The distribution of <b>W</b> . Possible values are "m" (multinomial), "p" (Poisson), or "b" (binary).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>type</code>   | The type of saddlepoint to be used. Possible values are "simp" (simple saddlepoint) and "cond" (conditional). If <code>wdist</code> is "m", <code>type</code> is set to "simp".                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <code>npts</code>   | The number of points at which the saddlepoint approximation should be calculated and then used to fit the spline.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>t</code>      | A vector of points at which the saddlepoint approximations are calculated. These points should extend beyond the extreme quantiles required but still be in the possible range of the bootstrap distribution. The observed value of the statistic should not be included in <code>t</code> as the distribution function approximation breaks down at that point. The points should, however cover the entire effective range of the distribution including close to the centre. If <code>t</code> is supplied then <code>npts</code> is set to <code>length(t)</code> . When <code>t</code> is not supplied, the function attempts to find the effective range of the distribution and then selects points to cover this range. |
| <code>t0</code>     | If <code>t</code> is not supplied then a vector of length 2 should be passed as <code>t0</code> . The first component of <code>t0</code> should be the centre of the distribution and the second should be an estimate of spread (such as a standard error). These two are then used to find the effective range of the distribution. The range finding mechanism does rely on an accurate estimate of location in <code>t0[1]</code> .                                                                                                                                                                                                                                                                                         |
| <code>init</code>   | When <code>wdist</code> is "m", this vector should contain the initial values to be passed to <code>nlmin</code> when it is called to solve the saddlepoint equations.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <code>mu</code>     | The vector of parameter values for the distribution. The default is that the components of <b>W</b> are identically distributed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>LR</code>     | A logical flag. When <code>LR</code> is <code>TRUE</code> the Lugananni-Rice cdf approximations are calculated and used to fit the spline. Otherwise the cdf approximations used are based on Barndorff-Nielsen's $r^*$ .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <code>strata</code> | A vector giving the strata when the rows of <code>A</code> relate to stratified data. This is used only when <code>wdist</code> is "m".                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>...</code>    | When <code>A</code> and <code>u</code> are functions any additional arguments are passed unchanged each time one of them is called.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

## Details

The range at which the saddlepoint is used is such that the cdf approximation at the endpoints is more extreme than required by the extreme values of `alpha`. The lower endpoint is found by evaluating the saddlepoint at the points `t0[1]-2*t0[2]`, `t0[1]-4*t0[2]`, `t0[1]-8*t0[2]` etc. until a point is found with a cdf approximation less than `min(alpha)/10`, then a bisection method is used to find the endpoint which has cdf approximation in the range `(min(alpha)/1000, min(alpha)/10)`. Then a number of, equally spaced, points are chosen

between the lower endpoint and `t0[1]` until a total of `npts/2` approximations have been made. The remaining `npts/2` points are chosen to the right of `t0[1]` in a similar manner. Any points which are very close to the centre of the distribution are then omitted as the cdf approximations are not reliable at the centre. A smoothing spline is then fitted to the probit of the saddlepoint distribution function approximations at the remaining points and the required quantiles are predicted from the spline.

Sometimes the function will terminate with the message "Unable to find range". There are two main reasons why this may occur. One is that the distribution is too discrete and/or the required quantiles too extreme, this can cause the function to be unable to find a point within the allowable range which is beyond the extreme quantiles. Another possibility is that the value of `t0[2]` is too small and so too many steps are required to find the range. The first problem cannot be solved except by asking for less extreme quantiles, although for very discrete distributions the approximations may not be very good. In the second case using a larger value of `t0[2]` will usually solve the problem.

### Value

The returned value is an object of class "saddle.distn". See the help file for [saddle.distn.object](#) for a description of such an object.

### Examples

```
The bootstrap distribution of the mean of the air-conditioning
failure data: fails to find value on R (and probably on S too)
air.t0 <- c(mean(aircondit$hours), sqrt(var(aircondit$hours)/12))
Not run: saddle.distn(A = aircondit$hours/12, t0 = air.t0)

alternatively using the conditional poisson
saddle.distn(A = cbind(aircondit$hours/12, 1), u = 12, wdist = "p",
 type = "cond", t0 = air.t0)

Distribution of the ratio of a sample of size 10 from the bigcity
data, taken from Example 9.16 of Davison and Hinkley (1997).
ratio <- function(d, w) sum(d$x * w) / sum(d$u * w)
city.v <- var.linear(empinf(data = city, statistic = ratio))
bigcity.t0 <- c(mean(bigcity$x) / mean(bigcity$u), sqrt(city.v))
Afn <- function(t, data) cbind(data$x - t * data$u, 1)
ufn <- function(t, data) c(0, 10)
saddle.distn(A = Afn, u = ufn, wdist = "b", type = "cond",
 t0 = bigcity.t0, data = bigcity)
```

```
From Example 9.16 of Davison and Hinkley (1997) again, we find the
conditional distribution of the ratio given the sum of city$u.
Afn <- function(t, data) cbind(data$x-t*data$u, data$u, 1)
ufn <- function(t, data) c(0, sum(data$u), 10)
city.t0 <- c(mean(city$x)/mean(city$u), sqrt(city.v))
saddle.distn(A = Afn, u = ufn, wdist = "p", type = "cond", t0 = city.t0,
 data = city)
```

---

saddle.distn.object

*Saddlepoint Distribution Approximation Objects*

---

## Description

Class of objects that result from calculating saddlepoint distribution approximations by a call to `saddle.distn`.

## Generation

This class of objects is returned from calls to the function `saddle.distn`.

## Methods

The class "saddle.distn" has methods for the functions `lines` and `print`.

## Structure

Objects of class "saddle.distn" are implemented as a list with the following components.

**quantiles** A matrix with 2 columns. The first column contains the probabilities  $\alpha$  and the second column contains the estimated quantiles of the distribution at those probabilities derived from the spline.

**points** A matrix of evaluations of the saddlepoint approximation. The first column contains the values of  $t$  which were used, the second and third contain the density and cdf approximations at those points and the rest of the columns contain the solutions to the saddlepoint equations. When `type` is "simp", there is only one of those. When `type` is "cond" there are  $2*d-1$  where  $d$  is the number of columns in  $A$  or the output of  $A(t, \dots \{ \})$ . The first  $d$  of these correspond to the numerator and the remainder correspond to the denominator.

**distn** An object of class `smooth.spline`. This corresponds to the spline fitted to the saddlepoint cdf approximations in `points` in order to approximate the entire distribution. For the structure of the object see `smooth.spline`.

**call** The original call to `saddle.distn` which generated the object.

**LR** A logical variable indicating whether the Lugananni-Rice approximations were used.

salinity

*Water Salinity and River Discharge***Description**

The `salinity` data frame has 28 rows and 4 columns.

Biweekly averages of the water salinity and river discharge in Pamlico Sound, North Carolina were recorded between the years 1972 and 1977. The data in this set consists only of those measurements in March, April and May.

**Usage**

```
salinity
```

**Format**

This data frame contains the following columns:

`sal` The average salinity of the water over two weeks.

`lag` The average salinity of the water lagged two weeks. Since only spring is used, the value of `lag` is not always equal to the previous value of `sal`.

`trend` A factor indicating in which of the 6 biweekly periods between March and May, the observations were taken. The levels of the factor are from 0 to 5 with 0 being the first two weeks in March.

`dis` The amount of river discharge during the two weeks for which `sal` is the average salinity.

**Source**

The data were obtained from

Ruppert, D. and Carroll, R.J. (1980) Trimmed least squares estimation in the linear model. *Journal of the American Statistical Association*, **75**, 828–838.

simplex

*Simplex Method for Linear Programming Problems***Description**

This function will optimize the linear function  $a \% \% x$  subject to the constraints  $A1 \% \% x \leq b1$ ,  $A2 \% \% x \geq b2$ ,  $A3 \% \% x = b3$  and  $x \geq 0$ . Either maximization or minimization is possible but the default is minimization.

**Usage**

```
simplex(a, A1 = NULL, b1 = NULL, A2 = NULL, b2 = NULL, A3 = NULL,
 b3 = NULL, maxi = FALSE, n.iter = n + 2 * m, eps = 1e-10)
```

**Arguments**

|                     |                                                                                                                                                                                                                                                                                                                               |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>a</code>      | A vector of length <code>n</code> which gives the coefficients of the objective function.                                                                                                                                                                                                                                     |
| <code>A1</code>     | An <code>m1</code> by <code>n</code> matrix of coefficients for the $\leq$ type of constraints.                                                                                                                                                                                                                               |
| <code>b1</code>     | A vector of length <code>m1</code> giving the right hand side of the $\leq$ constraints. This argument is required if <code>A1</code> is given and ignored otherwise. All values in <code>b1</code> must be non-negative.                                                                                                     |
| <code>A2</code>     | An <code>m2</code> by <code>n</code> matrix of coefficients for the $\geq$ type of constraints.                                                                                                                                                                                                                               |
| <code>b2</code>     | A vector of length <code>m2</code> giving the right hand side of the $\geq$ constraints. This argument is required if <code>A2</code> is given and ignored otherwise. All values in <code>b2</code> must be non-negative. Note that the constraints $x \geq 0$ are included automatically and so should not be repeated here. |
| <code>A3</code>     | An <code>m3</code> by <code>n</code> matrix of coefficients for the equality constraints.                                                                                                                                                                                                                                     |
| <code>b3</code>     | A vector of length <code>m3</code> giving the right hand side of equality constraints. This argument is required if <code>A3</code> is given and ignored otherwise. All values in <code>b3</code> must be non-negative.                                                                                                       |
| <code>maxi</code>   | A logical flag which specifies minimization if <code>FALSE</code> (default) and maximization otherwise. If <code>maxi</code> is <code>TRUE</code> then the maximization problem is recast as a minimization problem by changing the objective function coefficients to their negatives.                                       |
| <code>n.iter</code> | The maximum number of iterations to be conducted in each phase of the simplex method. The default is <code>n+2*(m1+m2+m3)</code> .                                                                                                                                                                                            |
| <code>eps</code>    | The floating point tolerance to be used in tests of equality.                                                                                                                                                                                                                                                                 |

**Details**

The method employed by this function is the two phase tableau simplex method. If there are  $\geq$  or equality constraints an initial feasible solution is not easy to find. To find a feasible solution an artificial variable is introduced into each  $\geq$  or equality constraint and an auxiliary objective function is defined as the sum of these artificial variables. If a feasible solution to the set of constraints exists then the auxiliary objective will be minimized when all of the artificial variables are 0. These are then discarded and the original problem solved starting at the solution to the auxiliary problem. If the only constraints are of the  $\leq$  form, the origin is a feasible solution and so the first stage can be omitted.

**Value**

An object of class "simplex": see `simplex.object`.

**Note**

The method employed here is suitable only for relatively small systems. Also if possible the number of constraints should be reduced to a minimum in order to speed up the execution time which is approximately proportional to the cube of the number of constraints. In particular if there are any constraints of the form `x[i] >= b2[i]` they should be omitted by setting `x[i] = x[i] - b2[i]`, changing all the constraints and the objective function accordingly and then transforming back after the solution has been found.

simplex.object

*Linear Programming Solution Objects*

---

## Description

Class of objects that result from solving a linear programming problem using `simplex`.

## Generation

This class of objects is returned from calls to the function `simplex`.

## Methods

The class `"saddle.distn"` has a method for the function `print`.

## Structure

Objects of class `"simplex"` are implemented as a list with the following components.

**soln** The values of  $x$  which optimize the objective function under the specified constraints provided those constraints are jointly feasible.

**solved** This indicates whether the problem was solved. A value of  $-1$  indicates that no feasible solution could be found. A value of  $0$  that the maximum number of iterations was reached without termination of the second stage. This may indicate an unbounded function or simply that more iterations are needed. A value of  $1$  indicates that an optimal solution has been found.

**value** The value of the objective function at `soln`.

**val.aux** This is `NULL` if a feasible solution is found. Otherwise it is a positive value giving the value of the auxiliary objective function when it was minimized.

**obj** The original coefficients of the objective function.

**a** The objective function coefficients re-expressed such that the basic variables have coefficient zero.

**a.aux** This is `NULL` if a feasible solution is found. Otherwise it is the re-expressed auxiliary objective function at the termination of the first phase of the simplex method.

**A** The final constraint matrix which is expressed in terms of the non-basic variables. If a feasible solution is found then this will have dimensions  $m_1+m_2+m_3$  by  $n+m_1+m_2$ , where the final  $m_1+m_2$  columns correspond to slack and surplus variables. If no feasible solution is found there will be an additional  $m_1+m_2+m_3$  columns for the artificial variables introduced to solve the first phase of the problem.

**basic** The indices of the basic (non-zero) variables in the solution. Indices between  $n+1$  and  $n+m_1$  correspond to slack variables, those between  $n+m_1+1$  and  $n+m_2$  correspond to surplus variables and those greater than  $n+m_2$  are artificial variables. Indices greater than  $n+m_2$  should occur only if `solved` is `-1` as the artificial variables are discarded in the second stage of the simplex method.

**slack** The final values of the  $m_1$  slack variables which arise when the " $\leq$ " constraints are re-expressed as the equalities  $A1 \% \% x + \text{slack} = b1$ .

**surplus** The final values of the  $m_2$  surplus variables which arise when the " $\leq$ " constraints are re-expressed as the equalities  $A2 \% \% x - \text{surplus} = b2$ .

**artificial** This is `NULL` if a feasible solution can be found. If no solution can be found then this contains the values of the  $m_1+m_2+m_3$  artificial variables which minimize their sum subject to the original constraints. A feasible solution exists only if all of the artificial variables can be made 0 simultaneously.

---

smooth.f

*Smooth Distributions on Data Points*

---

### Description

This function uses the method of frequency smoothing to find a distribution on a data set which has a required value, `theta`, of the statistic of interest. The method results in distributions which vary smoothly with `theta`.

### Usage

```
smooth.f(theta, boot.out, index = 1, t = boot.out$t[, index],
 width = 0.5)
```

### Arguments

|                       |                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>theta</code>    | The required value for the statistic of interest. If <code>theta</code> is a vector, a separate distribution will be found for each element of <code>theta</code> .                                                                                                                                                                                                                                                 |
| <code>boot.out</code> | A bootstrap output object returned by a call to <code>boot</code> .                                                                                                                                                                                                                                                                                                                                                 |
| <code>index</code>    | The index of the variable of interest in the output of <code>boot.out\$statistic</code> . This argument is ignored if <code>t</code> is supplied. <code>index</code> must be a scalar.                                                                                                                                                                                                                              |
| <code>t</code>        | The bootstrap values of the statistic of interest. This must be a vector of length <code>boot.out\$R</code> and the values must be in the same order as the bootstrap replicates in <code>boot.out</code> .                                                                                                                                                                                                         |
| <code>width</code>    | The standardized width for the kernel smoothing. The smoothing uses a value of <code>width*s</code> for epsilon, where <code>s</code> is the bootstrap estimate of the standard error of the statistic of interest. <code>width</code> should take a value in the range (0.2, 1) to produce a reasonable smoothed distribution. If <code>width</code> is too large then the distribution becomes closer to uniform. |

## Details

The new distributional weights are found by applying a normal kernel smoother to the observed values of  $t$  weighted by the observed frequencies in the bootstrap simulation. The resulting distribution may not have parameter value exactly equal to the required value `theta` but it will typically have a value which is close to `theta`. The details of how this method works can be found in Davison, Hinkley and Worton (1995) and Section 3.9.2 of Davison and Hinkley (1997).

## Value

If `length(theta)` is 1 then a vector with the same length as the data set `boot.out$data` is returned. The value in position `i` is the probability to be given to the data point in position `i` so that the distribution has parameter value approximately equal to `theta`. If `length(theta)` is bigger than 1 then the returned value is a matrix with `length(theta)` rows each of which corresponds to a distribution with the parameter value approximately equal to the corresponding value of `theta`.

## Examples

```
Example 9.8 of Davison and Hinkley (1997) requires tilting the resampling
distribution of the studentized statistic to be centred at the observed
value of the test statistic 1.84. In the book exponential tilting was used
but it is also possible to use smooth.f.
grav1 <- gravity[as.numeric(gravity[, 2]) >= 7,]
grav.fun <- function(dat, w, orig) {
 strata <- tapply(dat[, 2], as.numeric(dat[, 2]))
 d <- dat[, 1]
 ns <- tabulate(strata)
 w <- w/tapply(w, strata, sum)[strata]
 mns <- as.vector(tapply(d * w, strata, sum)) # drop names
 mn2 <- tapply(d * d * w, strata, sum)
 s2hat <- sum((mn2 - mns^2)/ns)
 c(mns[2] - mns[1], s2hat, (mns[2]-mns[1]-orig)/sqrt(s2hat))
}
grav.z0 <- grav.fun(grav1, rep(1, 26), 0)
grav.boot <- boot(grav1, grav.fun, R = 499, stype = "w",
 strata = grav1[, 2], orig = grav.z0[1])
grav.sm <- smooth.f(grav.z0[3], grav.boot, index = 3)

Now we can run another bootstrap using these weights
grav.boot2 <- boot(grav1, grav.fun, R = 499, stype = "w",
 strata = grav1[, 2], orig = grav.z0[1],
 weights = grav.sm)

Estimated p-values can be found from these as follows
```

```

mean(grav.boot$t[, 3] >= grav.z0[3])
imp.prob(grav.boot2, t0 = -grav.z0[3], t = -grav.boot2$t[, 3])

Note that for the importance sampling probability we must
multiply everything by -1 to ensure that we find the correct
probability. Raw resampling is not reliable for probabilities
greater than 0.5. Thus
1 - imp.prob(grav.boot2, index = 3, t0 = grav.z0[3])$raw
can give very strange results (negative probabilities).

```

---

sunspot

*Annual Mean Sunspot Numbers*

---

### Description

sunspot is a time series and contains 289 observations.

The Zurich sunspot numbers have been analyzed in almost all books on time series analysis as well as numerous papers. The data set, usually attributed to Rudolf Wolf, consists of means of daily relative numbers of sunspot sightings. The relative number for a day is given by  $k(f+10g)$  where  $g$  is the number of sunspot groups observed,  $f$  is the total number of spots within the groups and  $k$  is a scaling factor relating the observer and telescope to a baseline. The relative numbers are then averaged to give an annual figure. See Inzenman (1983) for a discussion of the relative numbers. The figures are for the years 1700-1988.

### Source

The data were obtained from

survival

*Survival of Rats after Radiation Doses*

---

### Description

The survival data frame has 14 rows and 2 columns.

The data measured the survival percentages of batches of rats who were given varying doses of radiation. At each of 6 doses there were two or three replications of the experiment.

### Usage

```
survival
```

**Format**

This data frame contains the following columns:

`dose` The dose of radiation administered (rads).

`surv` The survival rate of the batches expressed as a percentage.

**Source**

The data were obtained from

Efron, B. (1988) Computer-intensive methods in statistical regression. *SIAM Review*, **30**, 421–449.

|     |                                 |
|-----|---------------------------------|
| tau | <i>Tau Particle Decay Modes</i> |
|-----|---------------------------------|

---

**Description**

The `tau` data frame has 60 rows and 2 columns.

The tau particle is a heavy electron-like particle discovered in the 1970's by Martin Perl at the Stanford Linear Accelerator Center. Soon after its production the tau particle decays into various collections of more stable particles. About 86% of the time the decay involves just one charged particle. This rate has been measured independently 13 times.

The one-charged-particle event is made up of four major modes of decay as well as a collection of other events. The four main types of decay are denoted rho, pi, e and mu. These rates have been measured independently 6, 7, 14 and 19 times respectively. Due to physical constraints each experiment can only estimate the composite one-charged-particle decay rate or the rate of one of the major modes of decay.

Each experiment consists of a major research project involving many years work. One of the goals of the experiments was to estimate the rate of decay due to events other than the four main modes of decay. These are uncertain events and so cannot themselves be observed directly.

**Usage**

`tau`

**Format**

This data frame contains the following columns:

`rate` The decay rate expressed as a percentage.

`decay` The type of decay measured in the experiment. It is a factor with levels 1, rho, pi, e and mu.

Source

The data were obtained from

---

|           |                                        |
|-----------|----------------------------------------|
| tilt.boot | <i>Non-parametric Tilted Bootstrap</i> |
|-----------|----------------------------------------|

---

Description

This function will run an initial bootstrap with equal resampling probabilities (if required) and will use the output of the initial run to find resampling probabilities which put the value of the statistic at required values. It then runs an importance resampling bootstrap using the calculated probabilities as the resampling distribution.

Usage

```
tilt.boot(data, statistic, R, sim = "ordinary", stype = "i",
 strata = rep(1, n), L = NULL, theta = NULL,
 alpha = c(0.025, 0.975), tilt = TRUE, width = 0.5,
 index = 1, ...)
```

Arguments

|           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| data      | The data as a vector, matrix or data frame. If it is a matrix or data frame then each row is considered as one (multivariate) observation.                                                                                                                                                                                                                                                                                                                                           |
| statistic | A function which when applied to data returns a vector containing the statistic(s) of interest. It must take at least two arguments. The first argument will always be data and the second should be a vector of indices, weights or frequencies describing the bootstrap sample. Any other arguments must be supplied to tilt.boot and will be passed unchanged to statistic each time it is called.                                                                                |
| R         | The number of bootstrap replicates required. This will generally be a vector, the first value stating how many uniform bootstrap simulations are to be performed at the initial stage. The remaining values of R are the number of simulations to be performed resampling from each reweighted distribution. The first value of R must always be present, a value of 0 implying that no uniform resampling is to be carried out. Thus length(R) should always equal 1+length(theta). |
| sim       | This is a character string indicating the type of bootstrap simulation required. There are only two possible values that this can take: "ordinary" and "balanced". If other simulation types are required for the initial un-weighted bootstrap then it will be necessary to run boot, calculate the weights appropriately, and run boot again using the calculated weights.                                                                                                         |

|        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| stype  | A character string indicating the type of second argument expected by <code>statistic</code> . The possible values that <code>stype</code> can take are "i" (indices), "w" (weights) and "f" (frequencies).                                                                                                                                                                                                                                                                                                                      |
| strata | An integer vector or factor representing the strata for multi-sample problems.                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| L      | The empirical influence values for the statistic of interest. They are used only for exponential tilting when <code>tilt</code> is TRUE. If <code>tilt</code> is TRUE and they are not supplied then <code>tilt.boot</code> uses <code>empinf</code> to calculate them.                                                                                                                                                                                                                                                          |
| theta  | The required parameter value(s) for the tilted distribution(s). There should be one value of <code>theta</code> for each of the non-uniform distributions. If <code>R[1]</code> is 0 <code>theta</code> is a required argument. Otherwise <code>theta</code> values can be estimated from the initial uniform bootstrap and the values in <code>alpha</code> .                                                                                                                                                                   |
| alpha  | The alpha level to which tilting is required. This parameter is ignored if <code>R[1]</code> is 0 or if <code>theta</code> is supplied, otherwise it is used to find the values of <code>theta</code> as quantiles of the initial uniform bootstrap. In this case <code>R[1]</code> should be large enough that <code>min(c(alpha, 1-alpha)) * R[1] &gt; 5</code> , if this is not the case then a warning is generated to the effect that the <code>theta</code> are extreme values and so the tilted output may be unreliable. |
| tilt   | A logical variable which if TRUE (the default) indicates that exponential tilting should be used, otherwise local frequency smoothing ( <code>smooth.f</code> ) is used. If <code>tilt</code> is FALSE then <code>R[1]</code> must be positive. In fact in this case the value of <code>R[1]</code> should be fairly large (in the region of 500 or more).                                                                                                                                                                       |
| width  | This argument is used only if <code>tilt</code> is FALSE, in which case it is passed unchanged to <code>smooth.f</code> as the standardized bandwidth for the smoothing operation. The value should generally be in the range (0.2, 1). See <code>smooth.f</code> for more details.                                                                                                                                                                                                                                              |
| index  | The index of the statistic of interest in the output from <code>statistic</code> . By default the first element of the output of <code>statistic</code> is used.                                                                                                                                                                                                                                                                                                                                                                 |
| ...    | Any additional arguments required by <code>statistic</code> . These are passed unchanged to <code>statistic</code> each time it is called.                                                                                                                                                                                                                                                                                                                                                                                       |

## Value

An object of class "boot" with the following components

|           |                                                                                                                                                                                                                                                                          |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| t0        | The observed value of the statistic on the original data.                                                                                                                                                                                                                |
| t         | The values of the bootstrap replicates of the statistic. There will be <code>sum(R)</code> of these, the first <code>R[1]</code> corresponding to the uniform bootstrap and the remainder to the tilted bootstrap(s).                                                    |
| R         | The input vector of the number of bootstrap replicates.                                                                                                                                                                                                                  |
| data      | The original data as supplied.                                                                                                                                                                                                                                           |
| statistic | The <code>statistic</code> function as supplied.                                                                                                                                                                                                                         |
| sim       | The simulation type used in the bootstrap(s), it can either be "ordinary" or "balanced".                                                                                                                                                                                 |
| stype     | The type of statistic supplied, it is the same as the input value <code>stype</code> .                                                                                                                                                                                   |
| call      | A copy of the original call to <code>tilt.boot</code> .                                                                                                                                                                                                                  |
| strata    | The strata as supplied.                                                                                                                                                                                                                                                  |
| weights   | The matrix of weights used. If <code>R[1]</code> is greater than 0 then the first row will be the uniform weights and each subsequent row the tilted weights. If <code>R[1]</code> equals 0 then the uniform weights are omitted and only the tilted weights are output. |

`theta`            The values of `theta` used for the tilted distributions. These are either the input values or the values derived from the uniform bootstrap and `alpha`.

## Examples

```
Note that these examples can take a while to run.

Example 9.9 of Davison and Hinkley (1997).
grav1 <- gravity[as.numeric(gravity[,2]) >= 7,]
grav.fun <- function(dat, w, orig) {
 strata <- tapply(dat[, 2], as.numeric(dat[, 2]))
 d <- dat[, 1]
 ns <- tabulate(strata)
 w <- w/tapply(w, strata, sum)[strata]
 mns <- as.vector(tapply(d * w, strata, sum)) # drop names
 mn2 <- tapply(d * d * w, strata, sum)
 s2hat <- sum((mn2 - mns^2)/ns)
 c(mns[2]-mns[1], s2hat, (mns[2]-mns[1]-orig)/sqrt(s2hat))
}
grav.z0 <- grav.fun(grav1, rep(1, 26), 0)
tilt.boot(grav1, grav.fun, R = c(249, 375, 375), stype = "w",
 strata = grav1[,2], tilt = TRUE, index = 3, orig = grav.z0[1])

Example 9.10 of Davison and Hinkley (1997) requires a balanced
importance resampling bootstrap to be run. In this example we
show how this might be run.
acme.fun <- function(data, i, bhat) {
 d <- data[i,]
 n <- nrow(d)
 d.lm <- glm(d$acme~d$market)
 beta.b <- coef(d.lm)[2]
 d.diag <- boot::glm.diag(d.lm)
 SSx <- (n-1)*var(d$market)
 tmp <- (d$market-mean(d$market))*d.diag$res*d.diag$sd
 sr <- sqrt(sum(tmp^2))/SSx
 c(beta.b, sr, (beta.b-bhat)/sr)
}
acme.b <- acme.fun(acme, 1:nrow(acme), 0)
acme.boot1 <- tilt.boot(acme, acme.fun, R = c(499, 250, 250),
 stype = "i", sim = "balanced", alpha = c(0.05, 0.95),
 tilt = TRUE, index = 3, bhat = acme.b[1])
```

**Description**

Generate R bootstrap replicates of a statistic applied to a time series. The replicate time series can be generated using fixed or random block lengths or can be model based replicates.

**Usage**

```
tsboot(tseries, statistic, R, l = NULL, sim = "model",
 endcorr = TRUE, n.sim = NROW(tseries), orig.t = TRUE,
 ran.gen, ran.args = NULL, norm = TRUE, ...,
 parallel = c("no", "multicore", "snow"),
 ncpus = getOption("boot.ncpus", 1L), cl = NULL)
```

**Arguments**

|                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>tseries</code>   | A univariate or multivariate time series.                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <code>statistic</code> | A function which when applied to <code>tseries</code> returns a vector containing the statistic(s) of interest. Each time <code>statistic</code> is called it is passed a time series of length <code>n.sim</code> which is of the same class as the original <code>tseries</code> . Any other arguments which <code>statistic</code> takes must remain constant for each bootstrap replicate and should be supplied through the <code>...</code> argument to <code>tsboot</code> .                       |
| <code>R</code>         | A positive integer giving the number of bootstrap replicates required.                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>sim</code>       | The type of simulation required to generate the replicate time series. The possible input values are "model" (model based resampling), "fixed" (block resampling with fixed block lengths of 1), "geom" (block resampling with block lengths having a geometric distribution with mean 1) or "scramble" (phase scrambling).                                                                                                                                                                               |
| <code>l</code>         | If <code>sim</code> is "fixed" then <code>l</code> is the fixed block length used in generating the replicate time series. If <code>sim</code> is "geom" then <code>l</code> is the mean of the geometric distribution used to generate the block lengths. <code>l</code> should be a positive integer less than the length of <code>tseries</code> . This argument is not required when <code>sim</code> is "model" but it is required for all other simulation types.                                   |
| <code>endcorr</code>   | A logical variable indicating whether end corrections are to be applied when <code>sim</code> is "fixed". When <code>sim</code> is "geom", <code>endcorr</code> is automatically set to TRUE; <code>endcorr</code> is not used when <code>sim</code> is "model" or "scramble".                                                                                                                                                                                                                            |
| <code>n.sim</code>     | The length of the simulated time series. Typically this will be equal to the length of the original time series but there are situations when it will be larger. One obvious situation is if prediction is required. Another situation in which <code>n.sim</code> is larger than the original length is if <code>tseries</code> is a residual time series from fitting some model to the original time series. In this case, <code>n.sim</code> would usually be the length of the original time series. |
| <code>orig.t</code>    | A logical variable which indicates whether <code>statistic</code> should be applied to <code>tseries</code> itself as well as the bootstrap replicate series. If <code>statistic</code> is expecting a longer time series than <code>tseries</code> or if applying <code>statistic</code> to <code>tseries</code> will not yield any useful information then <code>orig.t</code> should be set to FALSE.                                                                                                  |

|                                  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|----------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>ran.gen</code>             | This is a function of three arguments. The first argument is a time series. If <code>sim</code> is "model" then it will always be <code>tseries</code> that is passed. For other simulation types it is the result of selecting <code>n.sim</code> observations from <code>tseries</code> by some scheme and converting the result back into a time series of the same form as <code>tseries</code> (although of length <code>n.sim</code> ). The second argument to <code>ran.gen</code> is always the value <code>n.sim</code> , and the third argument is <code>ran.args</code> , which is used to supply any other objects needed by <code>ran.gen</code> . If <code>sim</code> is "model" then the generation of the replicate time series will be done in <code>ran.gen</code> (for example through use of <code>arima.sim</code> ). For the other simulation types <code>ran.gen</code> is used for 'post-blackening'. The default is that the function simply returns the time series passed to it. |
| <code>ran.args</code>            | This will be supplied to <code>ran.gen</code> each time it is called. If <code>ran.gen</code> needs any extra arguments then they should be supplied as components of <code>ran.args</code> . Multiple arguments may be passed by making <code>ran.args</code> a list. If <code>ran.args</code> is <code>NULL</code> then it should not be used within <code>ran.gen</code> but note that <code>ran.gen</code> must still have its third argument.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <code>norm</code>                | A logical argument indicating whether normal margins should be used for phase scrambling. If <code>norm</code> is <code>FALSE</code> then margins corresponding to the exact empirical margins are used.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>...</code>                 | Extra named arguments to <code>statistic</code> may be supplied here. Beware of partial matching to the arguments of <code>tsboot</code> listed above.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>parallel, ncpus, cl</code> | See the help for <code>boot</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

## Details

If `sim` is "fixed" then each replicate time series is found by taking blocks of length `l`, from the original time series and putting them end-to-end until a new series of length `n.sim` is created. When `sim` is "geom" a similar approach is taken except that now the block lengths are generated from a geometric distribution with mean 1. Post-blackening can be carried out on these replicate time series by including the function `ran.gen` in the call to `tsboot` and having `tseries` as a time series of residuals.

Model based resampling is very similar to the parametric bootstrap and all simulation must be in one of the user specified functions. This avoids the complicated problem of choosing the block length but relies on an accurate model choice being made.

Phase scrambling is described in Section 8.2.4 of Davison and Hinkley (1997). The types of statistic for which this method produces reasonable results is very limited and the other methods seem to do better in most situations. Other types of resampling in the frequency domain can be accomplished using the function `boot` with the argument `sim = "parametric"`.

## Value

An object of class "boot" with the following components.

|                        |                                                                                                                                                            |
|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>t0</code>        | If <code>orig.t</code> is <code>TRUE</code> then <code>t0</code> is the result of <code>statistic(tseries, ...)</code> otherwise it is <code>NULL</code> . |
| <code>t</code>         | The results of applying <code>statistic</code> to the replicate time series.                                                                               |
| <code>R</code>         | The value of <code>R</code> as supplied to <code>tsboot</code> .                                                                                           |
| <code>tseries</code>   | The original time series.                                                                                                                                  |
| <code>statistic</code> | The function <code>statistic</code> as supplied.                                                                                                           |

|                       |                                                                                                                                                                                                                              |
|-----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>sim</code>      | The simulation type used in generating the replicates.                                                                                                                                                                       |
| <code>endcorr</code>  | The value of <code>endcorr</code> used. The value is meaningful only when <code>sim</code> is "fixed"; it is ignored for model based simulation or phase scrambling and is always set to TRUE if <code>sim</code> is "geom". |
| <code>n.sim</code>    | The value of <code>n.sim</code> used.                                                                                                                                                                                        |
| <code>l</code>        | The value of <code>l</code> used for block based resampling. This will be NULL if block based resampling was not used.                                                                                                       |
| <code>ran.gen</code>  | The <code>ran.gen</code> function used for generating the series or for 'post-blackening'.                                                                                                                                   |
| <code>ran.args</code> | The extra arguments passed to <code>ran.gen</code> .                                                                                                                                                                         |
| <code>call</code>     | The original call to <code>tsboot</code> .                                                                                                                                                                                   |

## Examples

```
lynx.fun <- function(tsb) {
 ar.fit <- ar(tsb, order.max = 25)
 c(ar.fit$order, mean(tsb), tsb)
}

the stationary bootstrap with mean block length 20
lynx.1 <- tsboot(log(lynx), lynx.fun, R = 99, l = 20, sim = "geom")

the fixed block bootstrap with length 20
lynx.2 <- tsboot(log(lynx), lynx.fun, R = 99, l = 20, sim = "fixed")

Now for model based resampling we need the original model
Note that for all of the bootstraps which use the residuals as their
data, we set orig.t to FALSE since the function applied to the residual
time series will be meaningless.
lynx.ar <- ar(log(lynx))
lynx.model <- list(order = c(lynx.ar$order, 0, 0), ar = lynx.ar$ar)
lynx.res <- lynx.ar$resid[!is.na(lynx.ar$resid)]
lynx.res <- lynx.res - mean(lynx.res)

lynx.sim <- function(res, n.sim, ran.args) {
 # random generation of replicate series using arima.sim
 rgl <- function(n, res) sample(res, n, replace = TRUE)
 ts.orig <- ran.args$ts
 ts.mod <- ran.args$model
 mean(ts.orig) + ts(arima.sim(model = ts.mod, n = n.sim,
 rand.gen = rgl, res = as.vector(res)))
}
```

```

}

lynx.3 <- tsboot(lynx.res, lynx.fun, R = 99, sim = "model", n.sim = 114,
 orig.t = FALSE, ran.gen = lynx.sim,
 ran.args = list(ts = log(lynx), model = lynx.model))

For "post-blackening" we need to define another function
lynx.black <- function(res, n.sim, ran.args) {
 ts.orig <- ran.args$ts
 ts.mod <- ran.args$model
 mean(ts.orig) + ts(arima.sim(model = ts.mod, n = n.sim, innov = res))
}

Now we can run apply the two types of block resampling again but this
time applying post-blackening.
lynx.1b <- tsboot(lynx.res, lynx.fun, R = 99, l = 20, sim = "fixed",
 n.sim = 114, orig.t = FALSE, ran.gen = lynx.black,
 ran.args = list(ts = log(lynx), model = lynx.model))

lynx.2b <- tsboot(lynx.res, lynx.fun, R = 99, l = 20, sim = "geom",
 n.sim = 114, orig.t = FALSE, ran.gen = lynx.black,
 ran.args = list(ts = log(lynx), model = lynx.model))

To compare the observed order of the bootstrap replicates we
proceed as follows.
table(lynx.1$t[, 1])
table(lynx.1b$t[, 1])
table(lynx.2$t[, 1])
table(lynx.2b$t[, 1])
table(lynx.3$t[, 1])
Notice that the post-blackened and model-based bootstraps preserve
the true order of the model (11) in many more cases than the others.

```

---

tuna

---

### *Tuna Sighting Data*

---

## Description

The tuna data frame has 64 rows and 1 columns.

The data come from an aerial line transect survey of Southern Bluefin Tuna in the Great Australian Bight. An aircraft with two spotters on board flies randomly allocated line transects. Each school of tuna sighted is counted and its perpendicular distance from the transect measured. The survey was conducted in summer when tuna tend to stay on the surface.

## Usage

```
tuna
```

## Format

This data frame contains the following column:

- y The perpendicular distance, in miles, from the transect for 64 independent sightings of tuna schools.

**Source**

The data were obtained from

Chen, S.X. (1996) Empirical likelihood confidence intervals for nonparametric density estimation. *Biometrika*, **83**, 329–341.

**References**

Davison, A.C. and Hinkley, D.V. (1997) *Bootstrap Methods and Their Application*. Cambridge University Press.

---

urine

*Urine Analysis Data*

---

**Description**

The `urine` data frame has 79 rows and 7 columns.

79 urine specimens were analyzed in an effort to determine if certain physical characteristics of the urine might be related to the formation of calcium oxalate crystals.

**Usage**

`urine`

**Format**

This data frame contains the following columns:

`r` Indicator of the presence of calcium oxalate crystals.

`gravity` The specific gravity of the urine.

`ph` The pH reading of the urine.

`osmo` The osmolarity of the urine. Osmolarity is proportional to the concentration of molecules in solution.

`cond` The conductivity of the urine. Conductivity is proportional to the concentration of charged ions in solution.

`urea` The urea concentration in millimoles per litre.

`calc` The calcium concentration in millimoles per litre.

**Source**

The data were obtained from

Andrews, D.F. and Herzberg, A.M. (1985) *Data: A Collection of Problems from Many Fields for the Student and Research Worker*. Springer-Verlag.

**References**

Davison, A.C. and Hinkley, D.V. (1997) *Bootstrap Methods and Their Application*. Cambridge University Press.

|                         |                                 |
|-------------------------|---------------------------------|
| <code>var.linear</code> | <i>Linear Variance Estimate</i> |
|-------------------------|---------------------------------|

---

**Description**

Estimates the variance of a statistic from its empirical influence values.

**Usage**

```
var.linear(L, strata = NULL)
```

**Arguments**

|                     |                                                                                                                              |
|---------------------|------------------------------------------------------------------------------------------------------------------------------|
| <code>L</code>      | Vector of the empirical influence values of a statistic. These will usually be calculated by a call to <code>empinf</code> . |
| <code>strata</code> | A numeric vector or factor specifying which observations (and hence empirical influence values) come from which strata.      |

**Value**

The variance estimate calculated from `L`.

**References**

Davison, A. C. and Hinkley, D. V. (1997) *Bootstrap Methods and Their Application*. Cambridge University Press.

**Examples**

```
To estimate the variance of the ratio of means for the city data.
ratio <- function(d,w) sum(d$x * w)/sum(d$u * w)
var.linear(empinf(data = city, statistic = ratio))
```

---

|                   |                                        |
|-------------------|----------------------------------------|
| <code>wool</code> | <i>Australian Relative Wool Prices</i> |
|-------------------|----------------------------------------|

---

**Description**

`wool` is a time series of class "ts" and contains 309 observations.

Each week that the market is open the Australian Wool Corporation set a floor price which determines their policy on intervention and is therefore a reflection of the overall price of wool for the week in question. Actual prices paid can vary considerably about the floor price. The series here is the log of the ratio between the price for fine grade wool and the floor price, each market week between July 1976 and Jun 1984.

### Source

The data were obtained from

Diggle, P.J. (1990) *Time Series: A Biostatistical Introduction*. Oxford University Press.

### References

## Chapter 19

# The `class` package

---

`batchSOM`

*Self-Organizing Maps: Batch Algorithm*

---

### Description

Kohonen's Self-Organizing Maps are a crude form of multidimensional scaling.

### Usage

```
batchSOM(data, grid = somgrid(), radii, init)
```

### Arguments

|                    |                                                                                                                   |
|--------------------|-------------------------------------------------------------------------------------------------------------------|
| <code>data</code>  | a matrix or data frame of observations, scaled so that Euclidean distance is appropriate.                         |
| <code>grid</code>  | A grid for the representatives: see <a href="#">somgrid</a> .                                                     |
| <code>radii</code> | the radii of the neighbourhood to be used for each pass: one pass is run for each element of <code>radii</code> . |
| <code>init</code>  | the initial representatives. If missing, chosen (without replacement) randomly from <code>data</code> .           |

### Details

The batch SOM algorithm of Kohonen(1995, section 3.14) is used.

### Value

An object of class "`SOM`" with components

|                    |                                                        |
|--------------------|--------------------------------------------------------|
| <code>grid</code>  | the grid, an object of class " <code>somgrid</code> ". |
| <code>codes</code> | a matrix of representatives.                           |

 as.character(crabs.grp))
```

---

condense

---

*Condense training set for k-NN classifier*

---

**Description**

Condense training set for k-NN classifier

**Usage**

```
condense(train, class, store, trace = TRUE)
```

**Arguments**

|                    |                                                                    |
|--------------------|--------------------------------------------------------------------|
| <code>train</code> | matrix for training set                                            |
| <code>class</code> | vector of classifications for test set                             |
| <code>store</code> | initial store set. Default one randomly chosen element of the set. |
| <code>trace</code> | logical. Trace iterations?                                         |

**Details**

The store set is used to 1-NN classify the rest, and misclassified patterns are added to the store set. The whole set is checked until no additions occur.

**Value**

Index vector of cases to be retained (the final store set).

|-----|--------------------------------------------|
| knn | <i>k</i> -Nearest Neighbour Classification |
|-----|--------------------------------------------|

---

## Description

*k*-nearest neighbour classification for test set from training set. For each row of the test set, the *k* nearest (in Euclidean distance) training set vectors are found, and the classification is decided by majority vote, with ties broken at random. If there are ties for the *k*th nearest vector, all candidates are included in the vote.

## Usage

```
knn(train, test, cl, k = 1, l = 0, prob = FALSE, use.all = TRUE)
```

## Arguments

|                      |                                                                                                                                                                                                                   |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>train</code>   | matrix or data frame of training set cases.                                                                                                                                                                       |
| <code>test</code>    | matrix or data frame of test set cases. A vector will be interpreted as a row vector for a single case.                                                                                                           |
| <code>cl</code>      | factor of true classifications of training set                                                                                                                                                                    |
| <code>k</code>       | number of neighbours considered.                                                                                                                                                                                  |
| <code>l</code>       | minimum vote for definite decision, otherwise <code>doubt</code> . (More precisely, less than <i>k</i> –1 dissenting votes are allowed, even if <i>k</i> is increased by ties.)                                   |
| <code>prob</code>    | If this is true, the proportion of the votes for the winning class are returned as attribute <code>prob</code> .                                                                                                  |
| <code>use.all</code> | controls handling of ties. If true, all distances equal to the <i>k</i> th largest are included. If false, a random selection of distances equal to the <i>k</i> th is chosen to use exactly <i>k</i> neighbours. |

**Value**

Factor of classifications of test set. `doubt` will be returned as NA.

knn.cv

*k-Nearest Neighbour Cross-Validatory Classification*

---

**Description**

k-nearest neighbour cross-validatory classification from training set.

**Usage**

```
knn.cv(train, cl, k = 1, l = 0, prob = FALSE, use.all = TRUE)
```

**Arguments**

|                      |                                                                                                                                                                                                    |
|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>train</code>   | matrix or data frame of training set cases.                                                                                                                                                        |
| <code>cl</code>      | factor of true classifications of training set                                                                                                                                                     |
| <code>k</code>       | number of neighbours considered.                                                                                                                                                                   |
| <code>l</code>       | minimum vote for definite decision, otherwise <code>doubt</code> . (More precisely, less than $k-1$ dissenting votes are allowed, even if $k$ is increased by ties.)                               |
| <code>prob</code>    | If this is true, the proportion of the votes for the winning class are returned as attribute <code>prob</code> .                                                                                   |
| <code>use.all</code> | controls handling of ties. If true, all distances equal to the $k$ th largest are included. If false, a random selection of distances equal to the $k$ th is chosen to use exactly $k$ neighbours. |

**Details**

This uses leave-one-out cross validation. For each row of the training set `train`, the  $k$  nearest (in Euclidean distance) other training set vectors are found, and the classification is decided by majority vote, with ties broken at random. If there are ties for the  $k$ th nearest vector, all candidates are included in the vote.

**Value**

Factor of classifications of training set. `doubt` will be returned as NA.

attributes(.Last.value)
```

---

knn1

---

*1-Nearest Neighbour Classification*

---

**Description**

Nearest neighbour classification for test set from training set. For each row of the test set, the nearest (by Euclidean distance) training set vector is found, and its classification used. If there is more than one nearest, a majority vote is used with ties broken at random.

**Usage**

```
knn1(train, test, cl)
```

**Arguments**

|                    |                                                                                                         |
|--------------------|---------------------------------------------------------------------------------------------------------|
| <code>train</code> | matrix or data frame of training set cases.                                                             |
| <code>test</code>  | matrix or data frame of test set cases. A vector will be interpreted as a row vector for a single case. |
| <code>cl</code>    | factor of true classification of training set.                                                          |

**Value**

Factor of classifications of test set.

**References**

knn1(train, test, cl)
```

lvq1

*Learning Vector Quantization I***Description**

Moves examples in a codebook to better represent the training set.

**Usage**

```
lvq1(x, cl, codebk, niter = 100 * nrow(codebk$x), alpha = 0.03)
```

**Arguments**

|                     |                                                        |
|---------------------|--------------------------------------------------------|
| <code>x</code>      | a matrix or data frame of examples                     |
| <code>cl</code>     | a vector or factor of classifications for the examples |
| <code>codebk</code> | a codebook                                             |
| <code>niter</code>  | number of iterations                                   |
| <code>alpha</code>  | constant for training                                  |

**Details**

Selects `niter` examples at random with replacement, and adjusts the nearest example in the codebook for each.

**Value**

A codebook, represented as a list with components `x` and `cl` giving the examples and classes.

**Examples**

```

train <- rbind(iris3[1:25,,1], iris3[1:25,,2], iris3[1:25,,3])
test <- rbind(iris3[26:50,,1], iris3[26:50,,2], iris3[26:50,,3])
cl <- factor(c(rep("s",25), rep("c",25), rep("v",25)))
cd <- lvqinit(train, cl, 10)
lvqtest(cd, train)
cd0 <- olvq1(train, cl, cd)
lvqtest(cd0, train)
cd1 <- lvq1(train, cl, cd0)
lvqtest(cd1, train)

```

lvq2

*Learning Vector Quantization 2.1***Description**

Moves examples in a codebook to better represent the training set.

**Usage**

```

lvq2(x, cl, codebk, niter = 100 * nrow(codebk$x), alpha = 0.03,
 win = 0.3)

```

**Arguments**

|                     |                                                           |
|---------------------|-----------------------------------------------------------|
| <code>x</code>      | a matrix or data frame of examples                        |
| <code>cl</code>     | a vector or factor of classifications for the examples    |
| <code>codebk</code> | a codebook                                                |
| <code>niter</code>  | number of iterations                                      |
| <code>alpha</code>  | constant for training                                     |
| <code>win</code>    | a tolerance for the closeness of the two nearest vectors. |

**Details**

Selects `niter` examples at random with replacement, and adjusts the nearest two examples in the codebook if one is correct and the other incorrect.

**Value**

A codebook, represented as a list with components `x` and `cl` giving the examples and classes.

**References**

```

---

lvq3

*Learning Vector Quantization 3*

---

**Description**

Moves examples in a codebook to better represent the training set.

**Usage**

```
lvq3(x, cl, codebk, niter = 100*nrow(codebk$x), alpha = 0.03,
 win = 0.3, epsilon = 0.1)
```

**Arguments**

|                      |                                                           |
|----------------------|-----------------------------------------------------------|
| <code>x</code>       | a matrix or data frame of examples                        |
| <code>cl</code>      | a vector or factor of classifications for the examples    |
| <code>codebk</code>  | a codebook                                                |
| <code>niter</code>   | number of iterations                                      |
| <code>alpha</code>   | constant for training                                     |
| <code>win</code>     | a tolerance for the closeness of the two nearest vectors. |
| <code>epsilon</code> | proportion of move for correct vectors                    |

**Details**

Selects `niter` examples at random with replacement, and adjusts the nearest two examples in the codebook for each.

**Value**

A codebook, represented as a list with components `x` and `cl` giving the examples and classes.

|---------|----------------------------------|
| lvqinit | <i>Initialize a LVQ Codebook</i> |
|---------|----------------------------------|

---

## Description

Construct an initial codebook for LVQ methods.

## Usage

```
lvqinit(x, cl, size, prior, k = 5)
```

## Arguments

- |                    |                                                                                                                                             |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>     | a matrix or data frame of training examples, $n$ by $p$ .                                                                                   |
| <code>cl</code>    | the classifications for the training examples. A vector or factor of length $n$ .                                                           |
| <code>size</code>  | the size of the codebook. Defaults to $\min(\text{round}(0.4 \cdot n_g \cdot (n_g - 1 + p/2), 0), n)$ where $n_g$ is the number of classes. |
| <code>prior</code> | Probabilities to represent classes in the codebook. Default proportions in the training set.                                                |
| <code>k</code>     | $k$ used for $k$ -NN test of correct classification. Default is 5.                                                                          |

## Details

Selects `size` examples from the training set without replacement with proportions proportional to the prior or the original proportions.

## Value

A codebook, represented as a list with components `x` and `cl` giving the examples and classes.

|---------|--------------------------------------------|
| lvqtest | <i>Classify Test Set from LVQ Codebook</i> |
|---------|--------------------------------------------|

---

Description

Classify a test set by 1-NN from a specified LVQ codebook.

Usage

```
lvqtest(codebk, test)
```

Arguments

|        |                                                |
|--------|------------------------------------------------|
| codebk | codebook object returned by other LVQ software |
| test   | matrix of test examples                        |

Details

Uses 1-NN to classify each test example against the codebook.

Value

Factor of classification for each row of x

References

multiedit

*Multiedit for k-NN Classifier*

---

**Description**

Multiedit for k-NN classifier

**Usage**

```
multiedit(x, class, k = 1, V = 3, I = 5, trace = TRUE)
```

**Arguments**

|       |                                           |
|-------|-------------------------------------------|
| x     | matrix of training set.                   |
| class | vector of classification of training set. |
| k     | number of neighbours used in k-NN.        |
| V     | divide training set into V parts.         |
| I     | number of null passes before quitting.    |
| trace | logical for statistics at each pass.      |

**Value**

Index vector of cases to be retained.

```

---

 olvq1

*Optimized Learning Vector Quantization 1*

---

## Description

Moves examples in a codebook to better represent the training set.

## Usage

```
olvq1(x, cl, codebk, niter = 40 * nrow(codebk$x), alpha = 0.3)
```

## Arguments

|                     |                                                        |
|---------------------|--------------------------------------------------------|
| <code>x</code>      | a matrix or data frame of examples                     |
| <code>cl</code>     | a vector or factor of classifications for the examples |
| <code>codebk</code> | a codebook                                             |
| <code>niter</code>  | number of iterations                                   |
| <code>alpha</code>  | constant for training                                  |

## Details

Selects `niter` examples at random with replacement, and adjusts the nearest example in the codebook for each.

## Value

A codebook, represented as a list with components `x` and `cl` giving the examples and classes.

reduce.nn

*Reduce Training Set for a k-NN Classifier*

---

**Description**

Reduce training set for a k-NN classifier. Used after `condense`.

**Usage**

```
reduce.nn(train, ind, class)
```

**Arguments**

|                    |                                                                            |
|--------------------|----------------------------------------------------------------------------|
| <code>train</code> | matrix for training set                                                    |
| <code>ind</code>   | Initial list of members of the training set (from <code>condense</code> ). |
| <code>class</code> | vector of classifications for test set                                     |

**Details**

All the members of the training set are tried in random order. Any which when dropped do not cause any members of the training set to be wrongly classified are dropped.

**Value**

Index vector of cases to be retained.

cl <- factor(c(rep("s",25), rep("c",25), rep("v",25)))
keep <- condense(train, cl)
knn(train[keep,], test, cl[keep])
keep2 <- reduce.nn(train, keep, cl)
knn(train[keep2,], test, cl[keep2])

```

SOM

*Self-Organizing Maps: Online Algorithm***Description**

Kohonen's Self-Organizing Maps are a crude form of multidimensional scaling.

**Usage**

```
SOM(data, grid = somgrid(), rlen = 10000, alpha, radii, init)
```

**Arguments**

|                    |                                                                                                                                                                                       |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>data</code>  | a matrix or data frame of observations, scaled so that Euclidean distance is appropriate.                                                                                             |
| <code>grid</code>  | A grid for the representatives: see <a href="#">somgrid</a> .                                                                                                                         |
| <code>rlen</code>  | the number of updates: used only in the defaults for <code>alpha</code> and <code>radii</code> .                                                                                      |
| <code>alpha</code> | the amount of change: one update is done for each element of <code>alpha</code> . Default is to decline linearly from 0.05 to 0 over <code>rlen</code> updates.                       |
| <code>radii</code> | the radii of the neighbourhood to be used for each update: must be the same length as <code>alpha</code> . Default is to decline linearly from 4 to 1 over <code>rlen</code> updates. |
| <code>init</code>  | the initial representatives. If missing, chosen (without replacement) randomly from <code>data</code> .                                                                               |

**Details**

`alpha` and `radii` can also be lists, in which case each component is used in turn, allowing two- or more phase training.

**Value**

An object of class "SOM" with components

|                    |                                         |
|--------------------|-----------------------------------------|
| <code>grid</code>  | the grid, an object of class "somgrid". |
| <code>codes</code> | a matrix of representatives.            |

## References

## See Also

[somgrid](#), [batchSOM](#)

## Examples

```
require(graphics)
data(crabs, package = "MASS")

lcrabs <- log(crabs[, 4:8])
crabs.grp <- factor(c("B", "b", "O", "o")[rep(1:4, rep(50,4))])
gr <- somgrid(topo = "hexagonal")
crabs.som <- SOM(lcrabs, gr)
plot(crabs.som)

2-phase training
crabs.som2 <- SOM(lcrabs, gr,
 alpha = list(seq(0.05, 0, len = 1e4), seq(0.02, 0, len = 1e5)),
 radii = list(seq(8, 1, len = 1e4), seq(4, 1, len = 1e5)))
plot(crabs.som2)
```

---

somgrid

*Plot SOM Fits*

---

## Description

Plotting functions for SOM results.

## Usage

```
somgrid(xdim = 8, ydim = 6, topo = c("rectangular", "hexagonal"))

S3 method for class 'somgrid'
plot(x, type = "p", ...)

S3 method for class 'SOM'
plot(x, ...)
```

## Arguments

|                         |                                                     |
|-------------------------|-----------------------------------------------------|
| <code>xdim, ydim</code> | dimensions of the grid                              |
| <code>topo</code>       | the topology of the grid.                           |
| <code>x</code>          | an object inheriting from class "somgrid" or "SOM". |
| <code>type, ...</code>  | graphical parameters.                               |

**Details**

The class "somgrid" records the coordinates of the grid to be used for (batch or on-line) SOM: this has a plot method.

The plot method for class "SOM" plots a [stars](#) plot of the representative at each grid point.

**Value**

For somgrid, an object of class "somgrid", a list with components

pts                    a two-column matrix giving locations for the grid points.  
xdim, ydim, topo      as in the arguments to somgrid.

## Chapter 20

# The `cluster` package

---

`agnes`

*Agglomerative Nesting (Hierarchical Clustering)*

---

### Description

Computes agglomerative hierarchical clustering of the dataset.

### Usage

```
agnes(x, diss = inherits(x, "dist"), metric = "euclidean",
 stand = FALSE, method = "average", par.method,
 keep.diss = n < 100, keep.data = !diss, trace.lev = 0)
```

### Arguments

|                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>      | <p>data matrix or data frame, or dissimilarity matrix, depending on the value of the <code>diss</code> argument.</p> <p>In case of a matrix or data frame, each row corresponds to an observation, and each column corresponds to a variable. All variables must be numeric. Missing values (NAs) are allowed.</p> <p>In case of a dissimilarity matrix, <code>x</code> is typically the output of <code>daisy</code> or <code>dist</code>. Also a vector with length <math>n*(n-1)/2</math> is allowed (where <math>n</math> is the number of observations), and will be interpreted in the same way as the output of the above-mentioned functions. Missing values (NAs) are not allowed.</p> |
| <code>diss</code>   | <p>logical flag: if TRUE (default for <code>dist</code> or <code>dissimilarity</code> objects), then <code>x</code> is assumed to be a dissimilarity matrix. If FALSE, then <code>x</code> is treated as a matrix of observations by variables.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>metric</code> | <p>character string specifying the metric to be used for calculating dissimilarities between observations. The currently available options are "euclidean" and "manhattan". Euclidean distances are root sum-of-squares of differences, and manhattan distances are the sum of absolute differences. If <code>x</code> is already a dissimilarity matrix, then this argument will be ignored.</p>                                                                                                                                                                                                                                                                                               |
| <code>stand</code>  | <p>logical flag: if TRUE, then the measurements in <code>x</code> are standardized before calculating the dissimilarities. Measurements are standardized for each variable</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

|                                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-----------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                   | (column), by subtracting the variable's mean value and dividing by the variable's mean absolute deviation. If $x$ is already a dissimilarity matrix, then this argument will be ignored.                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>method</code>               | character string defining the clustering method. The six methods implemented are "average" (unweighted pair-group [arithMetic] average method, aka 'UPGMA'), "single" (single linkage), "complete" (complete linkage), "ward" (Ward's method), "weighted" (weighted average linkage, aka 'WPGMA'), its generalization "flexible" which uses (a constant version of) the Lance-Williams formula and the <code>par.method</code> argument, and "gaverage" a generalized "average" aka "flexible UPGMA" method also using the Lance-Williams formula and <code>par.method</code> .<br>The default is "average". |
| <code>par.method</code>           | If <code>method</code> is "flexible" or "gaverage", a numeric vector of length 1, 3, or 4, (with a default for "gaverage"), see in the details section.                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>keep.diss, keep.data</code> | logicals indicating if the dissimilarities and/or input data $x$ should be kept in the result. Setting these to FALSE can give much smaller results and hence even save memory allocation <i>time</i> .                                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>trace.lev</code>            | integer specifying a trace level for printing diagnostics during the algorithm. Default 0 does not print anything; higher values print increasingly more.                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

## Details

`agnes` is fully described in chapter 5 of Kaufman and Rousseeuw (1990). Compared to other agglomerative clustering methods such as `hclust`, `agnes` has the following features: (a) it yields the agglomerative coefficient (see `agnes.object`) which measures the amount of clustering structure found; and (b) apart from the usual tree it also provides the banner, a novel graphical display (see `plot.agnes`).

The `agnes`-algorithm constructs a hierarchy of clusterings.

At first, each observation is a small cluster by itself. Clusters are merged until only one large cluster remains which contains all the observations. At each stage the two *nearest* clusters are combined to form one larger cluster.

For `method="average"`, the distance between two clusters is the average of the dissimilarities between the points in one cluster and the points in the other cluster.

In `method="single"`, we use the smallest dissimilarity between a point in the first cluster and a point in the second cluster (nearest neighbor method).

When `method="complete"`, we use the largest dissimilarity between a point in the first cluster and a point in the second cluster (furthest neighbor method).

The `method="flexible"` allows (and requires) more details: The Lance-Williams formula specifies how dissimilarities are computed when clusters are agglomerated (equation (32) in K&R(1990), p.237). If clusters  $C_1$  and  $C_2$  are agglomerated into a new cluster, the dissimilarity between their union and another cluster  $Q$  is given by

$$D(C_1 \cup C_2, Q) = \alpha_1 * D(C_1, Q) + \alpha_2 * D(C_2, Q) + \beta * D(C_1, C_2) + \gamma * |D(C_1, Q) - D(C_2, Q)|,$$

where the four coefficients  $(\alpha_1, \alpha_2, \beta, \gamma)$  are specified by the vector `par.method`, either directly as vector of length 4, or (more conveniently) if `par.method` is of length 1, say  $= \alpha$ , `par.method` is extended to give the "Flexible Strategy" (K&R(1990), p.236 f) with Lance-Williams coefficients  $(\alpha_1 = \alpha_2 = \alpha, \beta = 1 - 2\alpha, \gamma = 0)$ .

Also, if `length(par.method) == 3`,  $\gamma = 0$  is set.

**Care** and expertise is probably needed when using `method = "flexible"` particularly for the case when `par.method` is specified of longer length than one. Since **cluster** version 2.0, choices leading to invalid merge structures now signal an error (from the C code already). The *weighted average* (`method = "weighted"`) is the same as `method = "flexible", par.method = 0.5`. Further, `method = "single"` is equivalent to `method = "flexible", par.method = c(.5, .5, 0, -.5)`, and `method = "complete"` is equivalent to `method = "flexible", par.method = c(.5, .5, 0, +.5)`.

The `method = "gaverage"` is a generalization of "average", aka "flexible UPGMA" method, and is (a generalization of the approach) detailed in Belbin et al. (1992). As "flexible", it uses the Lance-Williams formula above for dissimilarity updating, but with  $\alpha_1$  and  $\alpha_2$  not constant, but *proportional* to the sizes  $n_1$  and  $n_2$  of the clusters  $C_1$  and  $C_2$  respectively, i.e.,

$$\alpha_j = \alpha'_j \frac{n_1}{n_1 + n_2},$$

where  $\alpha'_1, \alpha'_2$  are determined from `par.method`, either directly as  $(\alpha_1, \alpha_2, \beta, \gamma)$  or  $(\alpha_1, \alpha_2, \beta)$  with  $\gamma = 0$ , or (less flexibly, but more conveniently) as follows:

Belbin et al proposed "flexible beta", i.e. the user would only specify  $\beta$  (as `par.method`), sensibly in

$$-1 \leq \beta < 1,$$

and  $\beta$  determines  $\alpha'_1$  and  $\alpha'_2$  as

$$\alpha'_j = 1 - \beta,$$

and  $\gamma = 0$ .

This  $\beta$  may be specified by `par.method` (as length 1 vector), and if `par.method` is not specified, a default value of -0.1 is used, as Belbin et al recommend taking a  $\beta$  value around -0.1 as a general agglomerative hierarchical clustering strategy.

Note that `method = "gaverage", par.method = 0` (or `par.method = c(1, 1, 0, 0)`) is equivalent to the `agnes()` default method "average".

## Value

an object of class "agnes" (which extends "twins") representing the clustering. See [agnes.object](#) for details, and methods applicable.

## BACKGROUND

Cluster analysis divides a dataset into groups (clusters) of observations that are similar to each other.

**Hierarchical methods** like `agnes`, `diana`, and `mona` construct a hierarchy of clusterings, with the number of clusters ranging from one to the number of observations.

**Partitioning methods** like `pam`, `clara`, and `fanny` require that the number of clusters be given by the user.

## Author(s)

Method "gaverage" has been contributed by Pierre Roudier, Landcare Research, New Zealand.

## Examples

```
data(votes.repub)
agn1 <- agnes(votes.repub, metric = "manhattan", stand = TRUE)
agn1
plot(agn1)

op <- par(mfrow=c(2,2))
agn2 <- agnes(daisy(votes.repub), diss = TRUE, method = "complete")
plot(agn2)
alpha = 0.625 ==> beta = -1/4 is "recommended" by some
agnS <- agnes(votes.repub, method = "flexible", par.meth = 0.625)
plot(agnS)
par(op)

"show" equivalence of three "flexible" special cases
d.vr <- daisy(votes.repub)
a.wgt <- agnes(d.vr, method = "weighted")
a.sing <- agnes(d.vr, method = "single")
a.comp <- agnes(d.vr, method = "complete")
iC <- -(6:7) # not using 'call' and 'method' for comparisons
stopifnot(
 all.equal(a.wgt[iC], agnes(d.vr, method="flexible", par.method = 0.5)[iC]) ,
 all.equal(a.sing[iC], agnes(d.vr, method="flex", par.method= c(.5,.5,0, -.5))[iC]),
 all.equal(a.comp[iC], agnes(d.vr, method="flex", par.method= c(.5,.5,0, +.5))[iC]))

Exploring the dendrogram structure
(d2 <- as.dendrogram(agn2)) # two main branches
d2[[1]] # the first branch
d2[[2]] # the 2nd one { 8 + 42 = 50 }
d2[[1]][[1]]# first sub-branch of branch 1 .. and shorter form
identical(d2[[c(1,1)]],
 d2[[1]][[1]])
a "textual picture" of the dendrogram :
str(d2)

data(agriculture)
```

```
Plot similar to Figure 7 in ref
Not run: plot(agnes(agriculture), ask = TRUE)

data(animals)
aa.a <- agnes(animals) # default method = "average"
aa.ga <- agnes(animals, method = "gaverage")
op <- par(mfcol=1:2, mgp=c(1.5, 0.6, 0), mar=c(.1+ c(4,3,2,1)),
 cex.main=0.8)
plot(aa.a, which.plot = 2)
plot(aa.ga, which.plot = 2)
par(op)

Show how "gaverage" is a "generalized average":
aa.ga.0 <- agnes(animals, method = "gaverage", par.method = 0)
stopifnot(all.equal(aa.ga.0[iC], aa.a[iC]))
```

agnes.object

*Agglomerative Nesting (AGNES) Object*

---

## Description

The objects of class "agnes" represent an agglomerative hierarchical clustering of a dataset.

## Value

A legitimate agnes object is a list with the following components:

|           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| order     | a vector giving a permutation of the original observations to allow for plotting, in the sense that the branches of a clustering tree will not cross.                                                                                                                                                                                                                                                                                                                                                                                                             |
| order.lab | a vector similar to order, but containing observation labels instead of observation numbers. This component is only available if the original observations were labelled.                                                                                                                                                                                                                                                                                                                                                                                         |
| height    | a vector with the distances between merging clusters at the successive stages.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| ac        | the agglomerative coefficient, measuring the clustering structure of the dataset. For each observation $i$ , denote by $m(i)$ its dissimilarity to the first cluster it is merged with, divided by the dissimilarity of the merger in the final step of the algorithm. The <code>ac</code> is the average of all $1 - m(i)$ . It can also be seen as the average width (or the percentage filled) of the banner plot. Because <code>ac</code> grows with the number of observations, this measure should not be used to compare datasets of very different sizes. |
| merge     | an $(n-1)$ by 2 matrix, where $n$ is the number of observations. Row $i$ of <code>merge</code> describes the merging of clusters at step $i$ of the clustering. If a number $j$ in the row is negative, then the single observation $ j $ is merged at this stage. If $j$ is positive, then the merger is with the cluster formed at stage $j$ of the algorithm.                                                                                                                                                                                                  |
| diss      | an object of class "dissimilarity" (see <a href="#">dissimilarity.object</a> ), representing the total dissimilarity matrix of the dataset.                                                                                                                                                                                                                                                                                                                                                                                                                       |
| data      | a matrix containing the original or standardized measurements, depending on the <code>stand</code> option of the function <code>agnes</code> . If a dissimilarity matrix was given as input structure, then this component is not available.                                                                                                                                                                                                                                                                                                                      |

GENERATION

This class of objects is returned from `agnes`.

METHODS

The "agnes" class has methods for the following generic functions: `print`, `summary`, `plot`, and `as.dendrogram`.  
In addition, `cutree(x, *)` can be used to “cut” the dendrogram in order to produce cluster assignments.

INHERITANCE

The class "agnes" inherits from "twins". Therefore, the generic functions `pltree` and `as.hclust` are available for agnes objects. After applying `as.hclust()`, all *its* methods are available, of course.

See Also

`agnes`, `diana`, `as.hclust`, `hclust`, `plot.agnes`, `twins.object`, `cutree`.

Examples

```
data(agriculture)
ag.ag <- agnes(agriculture)
class(ag.ag)
pltree(ag.ag) # the dendrogram

cut the dendrogram -> get cluster assignments:
(ck3 <- cutree(ag.ag, k = 3))
(ch6 <- cutree(as.hclust(ag.ag), h = 6))
stopifnot(identical(unname(ch6), ck3))
```

---

|             |                                               |
|-------------|-----------------------------------------------|
| agriculture | <i>European Union Agricultural Workforces</i> |
|-------------|-----------------------------------------------|

---

Description

Gross National Product (GNP) per capita and percentage of the population working in agriculture for each country belonging to the European Union in 1993.

Usage

```
data(agriculture)
```

Format

A data frame with 12 observations on 2 variables:

|        |   |         |                           |
|--------|---|---------|---------------------------|
| [ , 1] | x | numeric | per capita GNP            |
| [ , 2] | y | numeric | percentage in agriculture |

The row names of the data frame indicate the countries.

### Details

The data seem to show two clusters, the “more agricultural” one consisting of Greece, Portugal, Spain, and Ireland.

### Source

Eurostat (European Statistical Agency, 1994): *Cijfers en feiten: Een statistisch portret van de Europese Unie*.

### References

see those in [agnes](#).

### See Also

[agnes](#), [daisy](#), [diana](#).

### Examples

```
data(agriculture)

Compute the dissimilarities using Euclidean metric and without
standardization
daisy(agriculture, metric = "euclidean", stand = FALSE)

2nd plot is similar to Figure 3 in Struyf et al (1996)
plot(pam(agriculture, 2))

Plot similar to Figure 7 in Struyf et al (1996)
Not run: plot(agnes(agriculture), ask = TRUE)

Plot similar to Figure 8 in Struyf et al (1996)
Not run: plot(diana(agriculture), ask = TRUE)
```

---

animals

*Attributes of Animals*

---

### Description

This data set considers 6 binary attributes for 20 animals.

### Usage

```
data(animals)
```

**Format**

A data frame with 20 observations on 6 variables:

|        |     |                |
|--------|-----|----------------|
| [ , 1] | war | warm-blooded   |
| [ , 2] | fly | can fly        |
| [ , 3] | ver | vertebrate     |
| [ , 4] | end | endangered     |
| [ , 5] | gro | live in groups |
| [ , 6] | hai | have hair      |

All variables are encoded as 1 = 'no', 2 = 'yes'.

**Details**

This dataset is useful for illustrating monothetic (only a single variable is used for each split) hierarchical clustering.

**Source**

Leonard Kaufman and Peter J. Rousseeuw (1990): *Finding Groups in Data* (pp 297ff). New York: Wiley.

**References**

see Struyf, Hubert & Rousseeuw (1996), in [agnes](#).

**Examples**

```
data(animals)
apply(animals, 2, table) # simple overview

ma <- mona(animals)
ma
Plot similar to Figure 10 in Struyf et al (1996)
plot(ma)
```

---

bannerplot

*Plot Banner (of Hierarchical Clustering)*

---

**Description**

Draws a “banner”, i.e. basically a horizontal [barplot](#) visualizing the (agglomerative or divisive) hierarchical clustering or an other binary dendrogram structure.

**Usage**

```
bannerplot(x, w = rev(x$height), fromLeft = TRUE,
 main=NULL, sub=NULL, xlab = "Height", adj = 0,
 col = c(2, 0), border = 0, axes = TRUE, frame.plot = axes,
 rev.xax = !fromLeft, xax.pretty = TRUE,
 labels = NULL, nmax.lab = 35, max.strlen = 5,
 yax.do = axes && length(x$order) <= nmax.lab,
 yaxRight = fromLeft, y.mar = 2.4 + max.strlen/2.5, ...)
```

**Arguments**

|                         |                                                                                                                                                                                   |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>          | a list with components <code>order</code> , <code>order.lab</code> and <code>height</code> when <code>w</code> , the next argument is not specified.                              |
| <code>w</code>          | non-negative numeric vector of bar widths.                                                                                                                                        |
| <code>fromLeft</code>   | logical, indicating if the banner is from the left or not.                                                                                                                        |
| <code>main, sub</code>  | main and sub titles, see <a href="#">title</a> .                                                                                                                                  |
| <code>xlab</code>       | x axis label (with ‘correct’ default e.g. for <code>plot.agnes</code> ).                                                                                                          |
| <code>adj</code>        | passed to <a href="#">title</a> ( <code>main, sub</code> ) for string adjustment.                                                                                                 |
| <code>col</code>        | vector of length 2, for two horizontal segments.                                                                                                                                  |
| <code>border</code>     | color for bar border; now defaults to background (no border).                                                                                                                     |
| <code>axes</code>       | logical indicating if axes (and labels) should be drawn at all.                                                                                                                   |
| <code>frame.plot</code> | logical indicating the banner should be framed; mainly used when <code>border = 0</code> (as per default).                                                                        |
| <code>rev.xax</code>    | logical indicating if the x axis should be reversed (as in <code>plot.diana</code> ).                                                                                             |
| <code>xax.pretty</code> | logical or integer indicating if <a href="#">pretty()</a> should be used for the x axis. <code>xax.pretty = FALSE</code> is mainly for back compatibility.                        |
| <code>labels</code>     | labels to use on y-axis; the default is constructed from <code>x</code> .                                                                                                         |
| <code>nmax.lab</code>   | integer indicating the number of labels which is considered too large for single-name labelling the banner plot.                                                                  |
| <code>max.strlen</code> | positive integer giving the length to which strings are truncated in banner plot labeling.                                                                                        |
| <code>yax.do</code>     | logical indicating if a y axis and banner labels should be drawn.                                                                                                                 |
| <code>yaxRight</code>   | logical indicating if the y axis is on the right or left.                                                                                                                         |
| <code>y.mar</code>      | positive number specifying the margin width to use when banners are labeled (along a y-axis). The default adapts to the string width and optimally would also depend on the font. |
| <code>...</code>        | graphical parameters (see <a href="#">par</a> ) may also be supplied as arguments to this function.                                                                               |

**Note**

This is mainly a utility called from [plot.agnes](#), [plot.diana](#) and [plot.mona](#).

**Author(s)**

Martin Maechler (from original code of Kaufman and Rousseeuw).

**Examples**

```
data(agriculture)
bannerplot(agnes(agriculture), main = "Bannerplot")
```

---

chorSub*Subset of C-horizon of Kola Data*

---

## Description

This is a small rounded subset of the C-horizon data [chorizon](#) from package **mvoutlier**.

## Usage

```
data(chorSub)
```

## Format

A data frame with 61 observations on 10 variables. The variables contain scaled concentrations of chemical elements.

## Details

This data set was produced from `chorizon` via these statements:

```
data(chorizon, package = "mvoutlier")
chorSub <- round(100*scale(chorizon[,101:110]))[190:250,]
storage.mode(chorSub) <- "integer"
colnames(chorSub) <- gsub("_.*", "", colnames(chorSub))
```

## Source

Kola Project (1993-1998)

## See Also

[chorizon](#) in package **mvoutlier** and other Kola data in the same package.

## Examples

```
data(chorSub)
summary(chorSub)
pairs(chorSub, gap= .1)# some outliers
```

---

|       |                               |
|-------|-------------------------------|
| clara | Clustering Large Applications |
|-------|-------------------------------|

---

**Description**

Computes a "clara" object, a `list` representing a clustering of the data into  $k$  clusters.

**Usage**

```
clara(x, k, metric = c("euclidean", "manhattan", "jaccard"),
 stand = FALSE, cluster.only = FALSE, samples = 5,
 sampsize = min(n, 40 + 2 * k), trace = 0, medoids.x = TRUE,
 keep.data = medoids.x, rngR = FALSE, pamLike = FALSE, correct.d = TRUE)
```

**Arguments**

|                           |                                                                                                                                                                                                                                                                                                                                                                                                |
|---------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>            | data matrix or data frame, each row corresponds to an observation, and each column corresponds to a variable. All variables must be numeric. Missing values (NAs) are allowed.                                                                                                                                                                                                                 |
| <code>k</code>            | integer, the number of clusters. It is required that $0 < k < n$ where $n$ is the number of observations (i.e., $n = \text{nrow}(x)$ ).                                                                                                                                                                                                                                                        |
| <code>metric</code>       | character string specifying the metric to be used for calculating dissimilarities between observations. The currently available options are "euclidean", "manhattan", and "jaccard".<br>Euclidean distances are root sum-of-squares of differences, and manhattan distances are the sum of absolute differences.                                                                               |
| <code>stand</code>        | logical, indicating if the measurements in <code>x</code> are standardized before calculating the dissimilarities. Measurements are standardized for each variable (column), by subtracting the variable's mean value and dividing by the variable's mean absolute deviation.                                                                                                                  |
| <code>cluster.only</code> | logical; if true, only the clustering will be computed and returned, see details.                                                                                                                                                                                                                                                                                                              |
| <code>samples</code>      | integer, say $N$ , the number of samples to be drawn from the dataset. The default, $N = 5$ , is rather small for historical (and now back compatibility) reasons and we <i>recommend to set samples an order of magnitude larger</i> .                                                                                                                                                        |
| <code>sampsize</code>     | integer, say $j$ , the number of observations in each sample. <code>sampsize</code> should be higher than the number of clusters ( $k$ ) and at most the number of observations ( $n = \text{nrow}(x)$ ). While computational effort is proportional to $j^2$ , see note below, it may still be advisable to set $j = \text{sampsize}$ to a <i>larger</i> value than the (historical) default. |
| <code>trace</code>        | integer indicating a <i>trace level</i> for diagnostic output during the algorithm.                                                                                                                                                                                                                                                                                                            |
| <code>medoids.x</code>    | logical indicating if the medoids should be returned, identically to some rows of the input data <code>x</code> . If FALSE, <code>keep.data</code> must be false as well, and the medoid indices, i.e., row numbers of the medoids will still be returned ( <code>i.med</code> component), and the algorithm saves space by needing one copy less of <code>x</code> .                          |
| <code>keep.data</code>    | logical indicating if the ( <i>scaled</i> if <code>stand</code> is true) data should be kept in the result.<br>Setting this to FALSE saves memory (and hence time), but disables <code>clusplot()</code> ing of the result. Use <code>medoids.x = FALSE</code> to save even more memory.                                                                                                       |

|                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>rngR</code>      | logical indicating if R's random number generator should be used instead of the primitive <code>clara()</code> -builtin one. If true, this also means that each call to <code>clara()</code> returns a different result – though only slightly different in good situations.                                                                                                                                                                                                                                              |
| <code>pamLike</code>   | logical indicating if the “swap” phase (see <a href="#">pam</a> , in C code) should use the same algorithm as <code>pam()</code> . Note that from Kaufman and Rousseeuw's description this <i>should</i> have been true always, but as the original Fortran code and the subsequent port to C has always contained a small one-letter change (a typo according to Martin Maechler) with respect to PAM, the default, <code>pamLike = FALSE</code> has been chosen to remain back compatible rather than “PAM compatible”. |
| <code>correct.d</code> | logical or integer indicating that—only in the case of NAs present in <code>x</code> —the correct distance computation should be used instead of the wrong formula which has been present in the original Fortran code and been in use up to early 2016.<br>Because the new correct formula is not back compatible, for the time being, a warning is signalled in this case, unless the user explicitly specifies <code>correct.d</code> .                                                                                |

### Details

`clara` is fully described in chapter 3 of Kaufman and Rousseeuw (1990). Compared to other partitioning methods such as `pam`, it can deal with much larger datasets. Internally, this is achieved by considering sub-datasets of fixed size (`sampsize`) such that the time and storage requirements become linear in  $n$  rather than quadratic.

Each sub-dataset is partitioned into  $k$  clusters using the same algorithm as in [pam](#).

Once  $k$  representative objects have been selected from the sub-dataset, each observation of the entire dataset is assigned to the nearest medoid.

The mean (equivalent to the sum) of the dissimilarities of the observations to their closest medoid is used as a measure of the quality of the clustering. The sub-dataset for which the mean (or sum) is minimal, is retained. A further analysis is carried out on the final partition.

Each sub-dataset is forced to contain the medoids obtained from the best sub-dataset until then. Randomly drawn observations are added to this set until `sampsize` has been reached.

When `cluster.only` is true, the result is simply a (possibly named) integer vector specifying the clustering, i.e.,

`clara(x, k, cluster.only=TRUE)` is the same as  
`clara(x, k)$clustering` but computed more efficiently.

### Value

If `cluster.only` is false (as by default), an object of class "`clara`" representing the clustering. See [clara.object](#) for details.

If `cluster.only` is true, the result is the "clustering", an integer vector of length  $n$  with entries from  $1:k$ .

### Note

By default, the random sampling is implemented with a *very* simple scheme (with period  $2^{16} = 65536$ ) inside the Fortran code, independently of R's random number generation, and as a matter of fact, deterministically. Alternatively, we recommend setting `rngR = TRUE` which uses R's random number generators. Then, `clara()` results are made reproducible typically by using [set.seed\(\)](#) before calling `clara`.

The storage requirement of clara computation (for small  $k$ ) is about  $O(n \times p) + O(j^2)$  where  $j = \text{sampsiz}$ e, and  $(n, p) = \text{dim}(x)$ . The CPU computing time (again assuming small  $k$ ) is about  $O(n \times p \times j^2 \times N)$ , where  $N = \text{samples}$ .

For “small” datasets, the function `pam` can be used directly. What can be considered *small*, is really a function of available computing power, both memory (RAM) and speed. Originally (1990), “small” meant less than 100 observations; in 1997, the authors said “*small (say with fewer than 200 observations)*”; as of 2006, you can use `pam` with several thousand observations.

### Author(s)

Kaufman and Rousseeuw (see `agnes`), originally. Metric “jaccard”: Kamil Kozłowski (@ownedoutcomes.com) and Kamil Jadeszko. All arguments from `trace` on, and most R documentation and all tests by Martin Maechler.

### See Also

`agnes` for background and references; `clara.object`, `pam`, `partition.object`, `plot.partition`.

### Examples

```
generate 500 objects, divided into 2 clusters.
x <- rbind(cbind(rnorm(200,0,8), rnorm(200,0,8)),
 cbind(rnorm(300,50,8), rnorm(300,50,8)))
clarax <- clara(x, 2, samples=50)
clarax
clarax$clusinfo
using pamLike=TRUE gives the same (apart from the 'call'):
all.equal(clarax[-8],
 clara(x, 2, samples=50, pamLike = TRUE)[-8])
plot(clarax)

cluster.only = TRUE -- save some memory/time :
clclus <- clara(x, 2, samples=50, cluster.only = TRUE)
stopifnot(identical(clclus, clarax$clustering))

'xclara' is an artificial data set with 3 clusters of 1000 bivariate
objects each.
data(xclara)
(clx3 <- clara(xclara, 3))
"better" number of samples
cl.3 <- clara(xclara, 3, samples=100)
but that did not change the result here:
stopifnot(cl.3$clustering == clx3$clustering)
Plot similar to Figure 5 in Struyf et al (1996)
Not run: plot(clx3, ask = TRUE)

Try 100 times *different* random samples -- for reliability:
nSim <- 100
nCl <- 3 # = no.classes
set.seed(421) # (reproducibility)
cl <- matrix(NA, nrow(xclara), nSim)
for(i in 1:nSim)
 cl[,i] <- clara(xclara, nCl, medoids.x = FALSE, rngR = TRUE)$cluster
```

```

tcl <- apply(cl,1, tabulate, nbins = nCl)
those that are not always in same cluster (5 out of 3000 for this seed):
(iDoubt <- which(apply(tcl,2, function(n) all(n < nSim))))
if(length(iDoubt)) { # (not for all seeds)
 tabD <- tcl[,iDoubt, drop=FALSE]
 dimnames(tabD) <- list(cluster = paste(1:nCl), obs = format(iDoubt))
 t(tabD) # how many times in which clusters
}

```

---

clara.object

---

*Clustering Large Applications (CLARA) Object*

---

## Description

The objects of class "clara" represent a partitioning of a large dataset into clusters and are typically returned from [clara](#).

## Value

A legitimate clara object is a list with the following components:

|            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| sample     | labels or case numbers of the observations in the best sample, that is, the sample used by the clara algorithm for the final partition.                                                                                                                                                                                                                                                                                                                                                                                                       |
| medoids    | the medoids or representative objects of the clusters. It is a matrix with in each row the coordinates of one medoid. Possibly NULL, namely when the object resulted from <code>clara(*, medoids.x=FALSE)</code> . Use the following <code>i.med</code> in that case.                                                                                                                                                                                                                                                                         |
| i.med      | the <i>indices</i> of the medoids above: <code>medoids &lt;- x[i.med, ]</code> where <code>x</code> is the original data matrix in <code>clara(x, *)</code> .                                                                                                                                                                                                                                                                                                                                                                                 |
| clustering | the clustering vector, see <a href="#">partition.object</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| objective  | the objective function for the final clustering of the entire dataset.                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| clusinfo   | matrix, each row gives numerical information for one cluster. These are the cardinality of the cluster (number of observations), the maximal and average dissimilarity between the observations in the cluster and the cluster's medoid. The last column is the maximal dissimilarity between the observations in the cluster and the cluster's medoid, divided by the minimal dissimilarity between the cluster's medoid and the medoid of any other cluster. If this ratio is small, the cluster is well-separated from the other clusters. |
| diss       | dissimilarity (maybe NULL), see <a href="#">partition.object</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| silinfo    | list with silhouette width information for the best sample, see <a href="#">partition.object</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| call       | generating call, see <a href="#">partition.object</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| data       | matrix, possibly standardized, or NULL, see <a href="#">partition.object</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

## Methods, Inheritance

The "clara" class has methods for the following generic functions: `print`, `summary`.

The class "clara" inherits from "partition". Therefore, the generic functions `plot` and `clusplot` can be used on a clara object.

clusGap

*Gap Statistic for Estimating the Number of Clusters***Description**

`clusGap()` calculates a goodness of clustering measure, the “gap” statistic. For each number of clusters  $k$ , it compares  $\log(W(k))$  with  $E^*[\log(W(k))]$  where the latter is defined via bootstrapping, i.e., simulating from a reference ( $H_0$ ) distribution, a uniform distribution on the hypercube determined by the ranges of  $x$ , after first centering, and then `svd` (aka ‘PCA’)-rotating them when (as by default) `spaceH0 = "scaledPCA"`.

`maxSE(f, SE.f)` determines the location of the **maximum** of  $f$ , taking a “1-SE rule” into account for the `*SE*` methods. The default method `"firstSEmax"` looks for the smallest  $k$  such that its value  $f(k)$  is not more than 1 standard error away from the first local maximum. This is similar but not the same as `"Tibs2001SEmax"`, Tibshirani et al’s recommendation of determining the number of clusters from the gap statistics and their standard deviations.

**Usage**

```
clusGap(x, FUNcluster, K.max, B = 100, d.power = 1,
 spaceH0 = c("scaledPCA", "original"),
 verbose = interactive(), ...)

maxSE(f, SE.f,
 method = c("firstSEmax", "Tibs2001SEmax", "globalSEmax",
 "firstmax", "globalmax"),
 SE.factor = 1)

S3 method for class 'clusGap'
print(x, method = "firstSEmax", SE.factor = 1, ...)

S3 method for class 'clusGap'
plot(x, type = "b", xlab = "k", ylab = expression(Gap[k]),
 main = NULL, do.arrows = TRUE,
 arrowArgs = list(col="red3", length=1/16, angle=90, code=3), ...)
```

**Arguments**

|                         |                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>          | numeric matrix or <a href="#">data.frame</a> .                                                                                                                                                                                                                                                                                                                                                                  |
| <code>FUNcluster</code> | a <a href="#">function</a> which accepts as first argument a (data) matrix like <code>x</code> , second argument, say $k$ , $k \geq 2$ , the number of clusters desired, and returns a <a href="#">list</a> with a component named (or shortened to) <code>cluster</code> which is a vector of length $n = \text{nrow}(x)$ of integers in $1:k$ determining the clustering or grouping of the $n$ observations. |
| <code>K.max</code>      | the maximum number of clusters to consider, must be at least two.                                                                                                                                                                                                                                                                                                                                               |
| <code>B</code>          | integer, number of Monte Carlo (“bootstrap”) samples.                                                                                                                                                                                                                                                                                                                                                           |

|                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| d.power                | a positive integer specifying the power $p$ which is applied to the euclidean distances ( <code>dist</code> ) before they are summed up to give $W(k)$ . The default, <code>d.power = 1</code> , corresponds to the “historical” R implementation, whereas <code>d.power = 2</code> corresponds to what Tibshirani et al had proposed. This was found by Juan Gonzalez, in 2016-02.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| spaceH0                | a <code>character</code> string specifying the space of the $H_0$ distribution (of <i>no</i> cluster). Both <code>"scaledPCA"</code> and <code>"original"</code> use a uniform distribution in a hyper cube and had been mentioned in the reference; <code>"original"</code> been added after a proposal (including code) by Juan Gonzalez.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| verbose                | integer or logical, determining if “progress” output should be printed. The default prints one bit per bootstrap sample.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| ...                    | (for <code>clusGap()</code> ) optionally further arguments for <code>FUNcluster()</code> , see <code>kmeans</code> example below.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| f                      | numeric vector of ‘function values’, of length $K$ , whose (“1 SE respected”) maximum we want.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| SE.f                   | numeric vector of length $K$ of standard errors of <code>f</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| method                 | <p>character string indicating how the “optimal” number of clusters, <math>\hat{k}</math>, is computed from the gap statistics (and their standard deviations), or more generally how the location <math>\hat{k}</math> of the maximum of <math>f_k</math> should be determined.</p> <p><code>"globalmax"</code>: simply corresponds to the global maximum, i.e., is <code>which.max(f)</code></p> <p><code>"firstmax"</code>: gives the location of the first <i>local</i> maximum.</p> <p><code>"Tibs2001SEmax"</code>: uses the criterion, Tibshirani et al (2001) proposed: “the smallest <math>k</math> such that <math>f(k) \geq f(k+1) - s_{k+1}</math>”. Note that this chooses <math>k = 1</math> when all standard deviations are larger than the differences <math>f(k+1) - f(k)</math>.</p> <p><code>"firstSEmax"</code>: location of the first <math>f()</math> value which is not smaller than the first <i>local</i> maximum minus <code>SE.factor * SE.f[]</code>, i.e, within an “f S.E.” range of that maximum (see also <code>SE.factor</code>).</p> <p>This, the default, has been proposed by Martin Maechler in 2012, when adding <code>clusGap()</code> to the <b>cluster</b> package, after having seen the <code>"globalSEmax"</code> proposal (in code) and read the <code>"Tibs2001SEmax"</code> proposal.</p> <p><code>"globalSEmax"</code>: (used in Dudoit and Fridlyand (2002), supposedly following Tibshirani’s proposition): location of the first <math>f()</math> value which is not smaller than the <i>global</i> maximum minus <code>SE.factor * SE.f[]</code>, i.e, within an “f S.E.” range of that maximum (see also <code>SE.factor</code>).</p> <p>See the examples for a comparison in a simple case.</p> |
| SE.factor              | [When <code>method</code> contains <code>"SE"</code> ] Determining the optimal number of clusters, Tibshirani et al. proposed the “1 S.E.”-rule. Using an <code>SE.factor f</code> , the “f S.E.”-rule is used, more generally.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

## Details

The main result `<res>$Tab[, "gap"]` of course is from bootstrapping aka Monte Carlo simulation and hence random, or equivalently, depending on the initial random seed (see `set.seed()`). On the other hand, in our experience, using `B = 500` gives quite precise results such that the gap plot is basically unchanged after an another run.

## Value

`clusGap(.)` returns an object of S3 class `"clusGap"`, basically a list with components

|                         |                                                                                                                                                                                                                                                                                                                                                                    |

| <code>FUNcluster</code> | input function <code>FUNcluster</code>                                                                                                                                                                                                                                                                                                                             |

## Author(s)

This function is originally based on the functions `gap` of (Bioconductor) package **SAGx** by Per Broberg, `gapStat()` from former package **SLmisc** by Matthias Kohl and ideas from `gap()` and its methods of package **lga** by Justin Harrington.

The current implementation is by Martin Maechler.

The implementation of `spaceH0 = "original"` is based on code proposed by Juan Gonzalez.

[silhouette](#) for a much simpler less sophisticated goodness of clustering measure.

`cluster.stats()` in package **fpc** for alternative measures.

**Examples**

```

--- maxSE() methods -----
(mets <- eval(formals(maxSE)$method))
fk <- c(2,3,5,4,7,8,5,4)
sk <- c(1,1,2,1,1,3,1,1)/2
use plot.clusGap():
plot(structure(class="clusGap", list(Tab = cbind(gap=fk, SE.sim=sk))))
Note that 'firstmax' and 'globalmax' are always at 3 and 6 :
sapply(c(1/4, 1,2,4), function(SEf)
 sapply(mets, function(M) maxSE(fk, sk, method = M, SE.factor = SEf)))

--- clusGap() -----
ridiculously nicely separated clusters in 3 D :
x <- rbind(matrix(rnorm(150, sd = 0.1), ncol = 3),
 matrix(rnorm(150, mean = 1, sd = 0.1), ncol = 3),
 matrix(rnorm(150, mean = 2, sd = 0.1), ncol = 3),
 matrix(rnorm(150, mean = 3, sd = 0.1), ncol = 3))

Slightly faster way to use pam (see below)
pam1 <- function(x,k) list(cluster = pam(x,k, cluster.only=TRUE))

We do not recommend using hier.clustering here, but if you want,
there is factoextra::hcut () or a cheap version of it
hclusCut <- function(x, k, d.meth = "euclidean", ...)
 list(cluster = cutree(hclust(dist(x, method=d.meth), ...), k=k))

You can manually set it before running this : doExtras <- TRUE # or FALSE
if(!(exists("doExtras") && is.logical(doExtras)))
 doExtras <- cluster::doExtras()

if(doExtras) {
 ## Note we use B = 60 in the following examples to keep them "speedy".
 ## ---- rather keep the default B = 500 for your analysis!

 ## note we can pass 'nstart = 20' to kmeans() :
 gskmn <- clusGap(x, FUN = kmeans, nstart = 20, K.max = 8, B = 60)
 gskmn #-> its print() method
 plot(gskmn, main = "clusGap(., FUN = kmeans, n.start=20, B= 60)")
 set.seed(12); system.time(
 gsPam0 <- clusGap(x, FUN = pam, K.max = 8, B = 60)
)
 set.seed(12); system.time(
 gsPam1 <- clusGap(x, FUN = pam1, K.max = 8, B = 60)
)
 ## and show that it gives the "same":
 not.eq <- c("call", "FUNcluster"); n <- names(gsPam0)
 eq <- n[!(n %in% not.eq)]
 stopifnot(identical(gsPam1[eq], gsPam0[eq]))
 print(gsPam1, method="globalSEmax")
 print(gsPam1, method="globalmax")

 print(gsHc <- clusGap(x, FUN = hclusCut, K.max = 8, B = 60))
}# end {doExtras}

gs.pam.RU <- clusGap(ruspini, FUN = pam1, K.max = 8, B = 60)

```

```

gs.pam.RU
plot(gs.pam.RU, main = "Gap statistic for the 'ruspini' data")
mtext("k = 4 is best .. and k = 5 pretty close")

This takes a minute..
No clustering ==> k = 1 ("one cluster") should be optimal:
Z <- matrix(rnorm(256*3), 256, 3)
gsP.Z <- clusGap(Z, FUN = pam1, K.max = 8, B = 200)
plot(gsP.Z, main = "clusGap(<iid_rnorm_p=3>) ==> k = 1 cluster is optimal")
gsP.Z

```

clusplot

*Bivariate Cluster Plot (of a Partitioning Object)*

## Description

Draws a 2-dimensional “clusplot” (clustering plot) on the current graphics device. The generic function has a default and a partition method.

## Usage

```

clusplot(x, ...)

S3 method for class 'partition'
clusplot(x, main = NULL, dist = NULL, ...)

```

## Arguments

|                   |                                                                                                                                                                                                                                                                      |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>    | an R object, here, specifically an object of class "partition", e.g. created by one of the functions <a href="#">pam</a> , <a href="#">clara</a> , or <a href="#">fanny</a> .                                                                                        |
| <code>main</code> | title for the plot; when NULL (by default), a title is constructed, using <code>x\$call</code> .                                                                                                                                                                     |
| <code>dist</code> | when <code>x</code> does not have a <code>diss</code> nor a <code>data</code> component, e.g., for <a href="#">pam</a> ( <code>dist(*)</code> , <code>keep.diss=FALSE</code> ), <code>dist</code> must specify the dissimilarity for the clusplot.                   |
| <code>...</code>  | optional arguments passed to methods, notably the <a href="#">clusplot.default</a> method (except for the <code>diss</code> one) may also be supplied to this function. Many graphical parameters (see <a href="#">par</a> ) may also be supplied as arguments here. |

## Details

The `clusplot.partition()` method relies on [clusplot.default](#).

If the clustering algorithms [pam](#), [fanny](#) and [clara](#) are applied to a data matrix of observations-by-variables then a clusplot of the resulting clustering can always be drawn. When the data matrix contains missing values and the clustering is performed with [pam](#) or [fanny](#), the dissimilarity matrix will be given as input to `clusplot`. When the clustering algorithm [clara](#) was applied to a data matrix with NAs then `clusplot` will replace the missing values as described in [clusplot.default](#), because a dissimilarity matrix is not available.

**Value**

For the partition (and default) method: An invisible list with components `Distances` and `Shading`, as for `clusplot.default`, see there.

**Side Effects**

a 2-dimensional clusplot is created on the current graphics device.

**See Also**

`clusplot.default` for references; `partition.object`, `pam`, `pam.object`, `clara`, `clara.object`, `fanny`, `fanny.object`, `par`.

**Examples**

```
For more, see ?clusplot.default

generate 25 objects, divided into 2 clusters.
x <- rbind(cbind(rnorm(10,0,0.5), rnorm(10,0,0.5)),
 cbind(rnorm(15,5,0.5), rnorm(15,5,0.5)))
clusplot(pam(x, 2))
add noise, and try again :
x4 <- cbind(x, rnorm(25), rnorm(25))
clusplot(pam(x4, 2))
```

|                               |                                                         |
|-------------------------------|---------------------------------------------------------|
| <code>clusplot.default</code> | <i>Bivariate Cluster Plot (clusplot) Default Method</i> |
|-------------------------------|---------------------------------------------------------|

---

**Description**

Creates a bivariate plot visualizing a partition (clustering) of the data. All observation are represented by points in the plot, using principal components or multidimensional scaling. Around each cluster an ellipse is drawn.

**Usage**

```
Default S3 method:
clusplot(x, clus, diss = FALSE,
 s.x.2d = mkCheckX(x, diss), stand = FALSE,
 lines = 2, shade = FALSE, color = FALSE,
 labels = 0, plotchar = TRUE,
 col.p = "dark green", col.txt = col.p,
 col.clus = if(color) c(2, 4, 6, 3) else 5, cex = 1, cex.txt = cex,
 span = TRUE,
 add = FALSE,
 xlim = NULL, ylim = NULL,
 main = paste("CLUSPLOT(", deparse(substitute(x)), ")"),
 sub = paste("These two components explain",
 round(100 * var.dec, digits = 2), "% of the point variability."),
 xlab = "Component 1", ylab = "Component 2",
 verbose = getOption("verbose"),
 ...)
```

## Arguments

|                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>      | <p>matrix or data frame, or dissimilarity matrix, depending on the value of the <code>diss</code> argument.</p> <p>In case of a matrix (alike), each row corresponds to an observation, and each column corresponds to a variable. All variables must be numeric. Missing values (NAs) are allowed. They are replaced by the median of the corresponding variable. When some variables or some observations contain only missing values, the function stops with a warning message.</p> <p>In case of a dissimilarity matrix, <code>x</code> is the output of <code>daisy</code> or <code>dist</code> or a symmetric matrix. Also, a vector of length <math>n * (n - 1) / 2</math> is allowed (where <math>n</math> is the number of observations), and will be interpreted in the same way as the output of the above-mentioned functions. Missing values (NAs) are not allowed.</p>                                                                                                                                                                               |
| <code>clus</code>   | <p>a vector of length <math>n</math> representing a clustering of <code>x</code>. For each observation the vector lists the number or name of the cluster to which it has been assigned. <code>clus</code> is often the clustering component of the output of <code>pam</code>, <code>fanny</code> or <code>clara</code>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <code>diss</code>   | <p>logical indicating if <code>x</code> will be considered as a dissimilarity matrix or a matrix of observations by variables (see <code>x</code> argument above).</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| plotchar     | logical flag: if TRUE, then the plotting symbols differ for points belonging to different clusters.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| span         | logical flag: if TRUE, then each cluster is represented by the ellipse with smallest area containing all its points. (This is a special case of the minimum volume ellipsoid.)<br>If FALSE, the ellipse is based on the mean and covariance matrix of the same points. While this is faster to compute, it often yields a much larger ellipse.<br>There are also some special cases: When a cluster consists of only one point, a tiny circle is drawn around it. When the points of a cluster fall on a straight line, <code>span=FALSE</code> draws a narrow ellipse around it and <code>span=TRUE</code> gives the exact line segment. |
| add          | logical indicating if ellipses (and labels if <code>labels</code> is true) should be <i>added</i> to an already existing plot. If false, neither a <code>title</code> or sub title, see <code>sub</code> , is written.                                                                                                                                                                                                                                                                                                                                                                                                                    |
| col.p        | color code(s) used for the observation points.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| col.txt      | color code(s) used for the labels (if <code>labels &gt;= 2</code> ).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| col.clus     | color code for the ellipses (and their labels); only one if <code>color</code> is false (as per default).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| cex, cex.txt | character <b>expansion</b> (size), for the point symbols and point labels, respectively.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| xlim, ylim   | numeric vectors of length 2, giving the x- and y- ranges as in <code>plot.default</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| main         | main title for the plot; by default, one is constructed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| sub          | sub title for the plot; by default, one is constructed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| xlab, ylab   | x- and y- axis labels for the plot, with defaults.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| verbose      | a logical indicating, if there should be extra diagnostic output; mainly for ‘debugging’.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| ...          | Further graphical parameters may also be supplied, see <code>par</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

### Details

`clusplot` uses function calls `princomp(*, cor = (ncol(x) > 2))` or `cmdscale(*, add=TRUE)`, respectively, depending on `diss` being false or true. These functions are data reduction techniques to represent the data in a bivariate plot.

Ellipses are then drawn to indicate the clusters. The further layout of the plot is determined by the optional arguments.

### Value

An invisible list with components:

|           |                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Distances | When <code>lines</code> is 1 or 2 we obtain a $k$ by $k$ matrix ( $k$ is the number of clusters). The element in $[i, j]$ is the distance between ellipse $i$ and ellipse $j$ .<br>If <code>lines = 0</code> , then the value of this component is NA.                                                                                                                                                                                                 |
| Shading   | A vector of length $k$ (where $k$ is the number of clusters), containing the amount of shading per cluster. Let $y$ be a vector where element $i$ is the ratio between the number of points in cluster $i$ and the area of ellipse $i$ . When the cluster $i$ is a line segment, $y[i]$ and the density of the cluster are set to NA. Let $z$ be the sum of all the elements of $y$ without the NAs. Then we put <code>shading = y/z * 37 + 3</code> . |

### Side Effects

a visual display of the clustering is plotted on the current graphics device.

**Note**

When we have 4 or fewer clusters, then the `color=TRUE` gives every cluster a different color. When there are more than 4 clusters, `clusplot` uses the function `pam` to cluster the densities into 4 groups such that ellipses with nearly the same density get the same color. `col.clus` specifies the colors used.

The `col.p` and `col.txt` arguments, added for R, are recycled to have length the number of observations. If `col.p` has more than one value, using `color = TRUE` can be confusing because of a mix of point and ellipse colors.

**Examples**

```
plotting votes.diss(dissimilarity) in a bivariate plot and
partitioning into 2 clusters
data(votes.repub)
votes.diss <- daisy(votes.repub)
pamv <- pam(votes.diss, 2, diss = TRUE)
clusplot(pamv, shade = TRUE)
is the same as
votes.clus <- pamv$clustering
clusplot(votes.diss, votes.clus, diss = TRUE, shade = TRUE)
Now look at components 3 and 2 instead of 1 and 2:
str(cMDS <- cmdscale(votes.diss, k=3, add=TRUE))
clusplot(pamv, s.x.2d = list(x=cMDS$points[, c(3,2)],
 labs=rownames(votes.repub), var.dec=NA),
 shade = TRUE, col.p = votes.clus,
 sub="", xlab = "Component 3", ylab = "Component 2")

clusplot(pamv, col.p = votes.clus, labels = 4) # color points and label ellipses
"simple" cheap ellipses: larger than minimum volume:
here they are *added* to the previous plot:
clusplot(pamv, span = FALSE, add = TRUE, col.clus = "midnightblue")

Setting a small *label* size:
clusplot(votes.diss, votes.clus, diss = TRUE, labels = 3, cex.txt = 0.6)

if(dev.interactive()) { # uses identify() *interactively* :
 clusplot(votes.diss, votes.clus, diss = TRUE, shade = TRUE, labels = 1)
 clusplot(votes.diss, votes.clus, diss = TRUE, labels = 5) # ident. only points
}
```

```
plotting iris (data frame) in a 2-dimensional plot and partitioning
into 3 clusters.
data(iris)
iris.x <- iris[, 1:4]
cl3 <- pam(iris.x, 3)$clustering
op <- par(mfrow= c(2,2))
clusplot(iris.x, cl3, color = TRUE)
U <- par("usr")
zoom in :
rect(0,-1, 2,1, border = "orange", lwd=2)

coef.hclust

*Agglomerative / Divisive Coefficient for 'hclust' Objects*

## Description

Computes the “agglomerative coefficient” (aka “divisive coefficient” for [diana](#)), measuring the clustering structure of the dataset.

For each observation  $i$ , denote by  $m(i)$  its dissimilarity to the first cluster it is merged with, divided by the dissimilarity of the merger in the final step of the algorithm. The agglomerative coefficient is the average of all  $1 - m(i)$ . It can also be seen as the average width (or the percentage filled) of the banner plot.

`coefHier()` directly interfaces to the underlying C code, and “proves” that *only* `object$heights` is needed to compute the coefficient.

Because it grows with the number of observations, this measure should not be used to compare datasets of very different sizes.

## Usage

```
coefHier(object)
coef.hclust(object, ...)
S3 method for class 'hclust'
coef(object, ...)
S3 method for class 'twins'
coef(object, ...)
```

## Arguments

`object` an object of class "hclust" or "twins", i.e., typically the result of [hclust\(.\)](#), [agnes\(.\)](#), or [diana\(.\)](#).

Since `coef.hclust` only uses `object$heights`, and `object$merge`, `object` can be any list-like object with appropriate merge and heights components.

For `coefHier`, even only `object$heights` is needed.

... currently unused potential further arguments

### Value

a number specifying the *agglomerative* (or *divisive* for `diana` objects) coefficient as defined by Kaufman and Rousseeuw, see `agnes.object` \$ `ac` or `diana.object` \$ `dc`.

### Examples

```
data(agriculture)
aa <- agnes(agriculture)
coef(aa) # really just extracts aa$ac
coef(as.hclust(aa)) # recomputes
coefHier(aa) # ditto
```

---

daisy

Dissimilarity Matrix Calculation

---

### Description

Compute all the pairwise dissimilarities (distances) between observations in the data set. The original variables may be of mixed types. In that case, or whenever `metric = "gower"` is set, a generalization of Gower's formula is used, see 'Details' below.

### Usage

```
daisy(x, metric = c("euclidean", "manhattan", "gower"),
 stand = FALSE, type = list(), weights = rep.int(1, p),
 warnBin = warnType, warnAsym = warnType, warnConst = warnType,
 warnType = TRUE)
```

### Arguments

|                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>      | numeric matrix or data frame, of dimension $n \times p$ , say. Dissimilarities will be computed between the rows of <code>x</code> . Columns of mode <code>numeric</code> (i.e. all columns when <code>x</code> is a matrix) will be recognized as interval scaled variables, columns of class <code>factor</code> will be recognized as nominal variables, and columns of class <code>ordered</code> will be recognized as ordinal variables. Other variable types should be specified with the <code>type</code> argument. Missing values (NAs) are allowed.                                                                                                          |
| <code>metric</code> | character string specifying the metric to be used. The currently available options are "euclidean" (the default), "manhattan" and "gower". Euclidean distances are root sum-of-squares of differences, and manhattan distances are the sum of absolute differences.<br><br>"Gower's distance" is chosen by metric "gower" or automatically if some columns of <code>x</code> are not numeric. Also known as Gower's coefficient (1971), expressed as a dissimilarity, this implies that a particular standardisation will be applied to each variable, and the "distance" between two units is the sum of all the variable-specific distances, see the details section. |

|                                                                       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-----------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>stand</code>                                                    | <p>logical flag: if TRUE, then the measurements in <code>x</code> are standardized before calculating the dissimilarities. Measurements are standardized for each variable (column), by subtracting the variable's mean value and dividing by the variable's mean absolute deviation.</p> <p>If not all columns of <code>x</code> are numeric, <code>stand</code> will be ignored and Gower's standardization (based on the <code>range</code>) will be applied in any case, see argument <code>metric</code>, above, and the details section.</p>                                                                                                                      |
| <code>type</code>                                                     | <p>list for specifying some (or all) of the types of the variables (columns) in <code>x</code>. The list may contain the following components: <code>"ordratio"</code> (ratio scaled variables to be treated as ordinal variables), <code>"logratio"</code> (ratio scaled variables that must be logarithmically transformed), <code>"asymm"</code> (asymmetric binary) and <code>"symm"</code> (symmetric binary variables). Each component's value is a vector, containing the names or the numbers of the corresponding columns of <code>x</code>. Variables not mentioned in the <code>type</code> list are interpreted as usual (see argument <code>x</code>).</p> |
| <code>weights</code>                                                  | <p>an optional numeric vector of length <math>p(=n\text{col}(x))</math>; to be used in "case 2" (mixed variables, or <code>metric = "gower"</code>), specifying a weight for each variable (<code>x[, k]</code>) instead of 1 in Gower's original formula.</p>                                                                                                                                                                                                                                                                                                                                                                                                          |
| <code>warnBin</code> , <code>warnAsym</code> , <code>warnConst</code> | <p>logicals indicating if the corresponding type checking warnings should be signalled (when found).</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>warnType</code>                                                 | <p>logical indicating if <i>all</i> the type checking warnings should be active or not.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

## Details

The original version of `daisy` is fully described in chapter 1 of Kaufman and Rousseeuw (1990). Compared to `dist` whose input must be numeric variables, the main feature of `daisy` is its ability to handle other variable types as well (e.g. nominal, ordinal, (a)symmetric binary) even when different types occur in the same data set.

The handling of nominal, ordinal, and (a)symmetric binary data is achieved by using the general dissimilarity coefficient of Gower (1971). If `x` contains any columns of these data-types, both arguments `metric` and `stand` will be ignored and Gower's coefficient will be used as the metric. This can also be activated for purely numeric data by `metric = "gower"`. With that, each variable (column) is first standardized by dividing each entry by the range of the corresponding variable, after subtracting the minimum value; consequently the rescaled variable has range  $[0, 1]$ , exactly.

Note that setting the type to `symm` (symmetric binary) gives the same dissimilarities as using `nominal` (which is chosen for non-ordered factors) only when no missing values are present, and more efficiently.

Note that `daisy` signals a warning when 2-valued numerical variables do not have an explicit `type` specified, because the reference authors recommend to consider using `"asymm"`; the warning may be silenced by `warnBin = FALSE`.

In the `daisy` algorithm, missing values in a row of `x` are not included in the dissimilarities involving that row. There are two main cases,

1. If all variables are interval scaled (and `metric` is *not* `"gower"`), the metric is "euclidean", and  $n_g$  is the number of columns in which neither row  $i$  and  $j$  have NAs, then the dissimilarity  $d(i,j)$  returned is  $\sqrt{p/n_g}$  ( $p = n\text{col}(x)$ ) times the Euclidean distance between the two vectors of length  $n_g$  shortened to exclude NAs. The rule is similar for the "manhattan" metric, except that the coefficient is  $p/n_g$ . If  $n_g = 0$ , the dissimilarity is NA.
2. When some variables have a type other than interval scaled, or if `metric = "gower"` is specified, the dissimilarity between two rows is the weighted mean of the contributions of

each variable. Specifically,

$$d_{ij} = d(i, j) = \frac{\sum_{k=1}^p w_k \delta_{ij}^{(k)} d_{ij}^{(k)}}{\sum_{k=1}^p w_k \delta_{ij}^{(k)}}.$$

In other words,  $d_{ij}$  is a weighted mean of  $d_{ij}^{(k)}$  with weights  $w_k \delta_{ij}^{(k)}$ , where  $w_k = \text{weights}[k]$ ,  $\delta_{ij}^{(k)}$  is 0 or 1, and  $d_{ij}^{(k)}$ , the  $k$ -th variable contribution to the total distance, is a distance between  $x[i, k]$  and  $x[j, k]$ , see below.

The 0-1 weight  $\delta_{ij}^{(k)}$  becomes zero when the variable  $x[, k]$  is missing in either or both rows ( $i$  and  $j$ ), or when the variable is asymmetric binary and both values are zero. In all other situations it is 1.

The contribution  $d_{ij}^{(k)}$  of a nominal or binary variable to the total dissimilarity is 0 if both values are equal, 1 otherwise. The contribution of other variables is the absolute difference of both values, divided by the total range of that variable. Note that “standard scoring” is applied to ordinal variables, i.e., they are replaced by their integer codes  $1 : K$ . Note that this is not the same as using their ranks (since there typically are ties).

As the individual contributions  $d_{ij}^{(k)}$  are in  $[0, 1]$ , the dissimilarity  $d_{ij}$  will remain in this range.

If all weights  $w_k \delta_{ij}^{(k)}$  are zero, the dissimilarity is set to [NA](#).

## Value

an object of class "dissimilarity" containing the dissimilarities among the rows of  $x$ . This is typically the input for the functions `pam`, `fanny`, `agnes` or `diana`. For more details, see [dissimilarity.object](#).

## Background

Dissimilarities are used as inputs to cluster analysis and multidimensional scaling. The choice of metric may have a large impact.

## Author(s)

Anja Struyf, Mia Hubert, and Peter and Rousseeuw, for the original version.

Martin Maechler improved the [NA](#) handling and type specification checking, and extended functionality to `metric = "gower"` and the optional `weights` argument.

## Examples

```
data(agriculture)
Example 1 in ref:
Dissimilarities using Euclidean metric and without standardization
d.agr <- daisy(agriculture, metric = "euclidean", stand = FALSE)
d.agr
as.matrix(d.agr)[,"DK"] # via as.matrix.dist(.)
compare with
as.matrix(daisy(agriculture, metric = "gower"))

data(flower)
Example 2 in ref
summary(df11 <- daisy(flower, type = list(asymm = 3)))
summary(df12 <- daisy(flower, type = list(asymm = c(1, 3), ordratio = 7)))
this failed earlier:
summary(df13 <- daisy(flower,
 type = list(asymm = c("V1", "V3"), symm= 2,
 ordratio= 7, logratio= 8)))
```

---

diana

---

*Divisive ANALysis Clustering*

---

## Description

Computes a divisive hierarchical clustering of the dataset returning an object of class `diana`.

## Usage

```
diana(x, diss = inherits(x, "dist"), metric = "euclidean", stand = FALSE,
 stop.at.k = FALSE,
 keep.diss = n < 100, keep.data = !diss, trace.lev = 0)
```

## Arguments

|                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>      | <p>data matrix or data frame, or dissimilarity matrix or object, depending on the value of the <code>diss</code> argument.</p> <p>In case of a matrix or data frame, each row corresponds to an observation, and each column corresponds to a variable. All variables must be numeric. Missing values (NAs) <i>are</i> allowed.</p> <p>In case of a dissimilarity matrix, <code>x</code> is typically the output of <code>daisy</code> or <code>dist</code>. Also a vector of length <math>n*(n-1)/2</math> is allowed (where <math>n</math> is the number of observations), and will be interpreted in the same way as the output of the above-mentioned functions. Missing values (NAs) <i>are not</i> allowed.</p> |
| <code>diss</code>   | <p>logical flag: if TRUE (default for <code>dist</code> or dissimilarity objects), then <code>x</code> will be considered as a dissimilarity matrix. If FALSE, then <code>x</code> will be considered as a matrix of observations by variables.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>metric</code> | <p>character string specifying the metric to be used for calculating dissimilarities between observations.</p> <p>The currently available options are "euclidean" and "manhattan". Euclidean distances are root sum-of-squares of differences, and manhattan distances are the</p>                                                                                                                                                                                                                                                                                                                                                                                                                                    |

|                                   |                                                                                                                                                                                                                                                                                                                                             |
|-----------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                   | sum of absolute differences. If $x$ is already a dissimilarity matrix, then this argument will be ignored.                                                                                                                                                                                                                                  |
| <code>stand</code>                | logical; if true, the measurements in $x$ are standardized before calculating the dissimilarities. Measurements are standardized for each variable (column), by subtracting the variable's mean value and dividing by the variable's mean absolute deviation. If $x$ is already a dissimilarity matrix, then this argument will be ignored. |
| <code>stop.at.k</code>            | logical or integer, FALSE by default. Otherwise must be integer, say $k$ , in $\{1, 2, \dots, n\}$ , specifying that the <code>diana</code> algorithm should stop early.<br>Non-default NOT YET IMPLEMENTED.                                                                                                                                |
| <code>keep.diss, keep.data</code> | logicals indicating if the dissimilarities and/or input data $x$ should be kept in the result. Setting these to FALSE can give much smaller results and hence even save memory allocation <i>time</i> .                                                                                                                                     |
| <code>trace.lev</code>            | integer specifying a trace level for printing diagnostics during the algorithm. Default 0 does not print anything; higher values print increasingly more.                                                                                                                                                                                   |

## Details

`diana` is fully described in chapter 6 of Kaufman and Rousseeuw (1990). It is probably unique in computing a divisive hierarchy, whereas most other software for hierarchical clustering is agglomerative. Moreover, `diana` provides (a) the divisive coefficient (see `diana.object`) which measures the amount of clustering structure found; and (b) the banner, a novel graphical display (see `plot.diana`).

The `diana`-algorithm constructs a hierarchy of clusterings, starting with one large cluster containing all  $n$  observations. Clusters are divided until each cluster contains only a single observation. At each stage, the cluster with the largest diameter is selected. (The diameter of a cluster is the largest dissimilarity between any two of its observations.)

To divide the selected cluster, the algorithm first looks for its most disparate observation (i.e., which has the largest average dissimilarity to the other observations of the selected cluster). This observation initiates the "splinter group". In subsequent steps, the algorithm reassigns observations that are closer to the "splinter group" than to the "old party". The result is a division of the selected cluster into two new clusters.

## Value

an object of class "`diana`" representing the clustering; this class has methods for the following generic functions: `print`, `summary`, `plot`.

Further, the class "`diana`" inherits from "`twins`". Therefore, the generic function `pltree` can be used on a `diana` object, and `as.hclust` and `as.dendrogram` methods are available.

A legitimate `diana` object is a list with the following components:

|                        |                                                                                                                                                                                         |
|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>order</code>     | a vector giving a permutation of the original observations to allow for plotting, in the sense that the branches of a clustering tree will not cross.                                   |
| <code>order.lab</code> | a vector similar to <code>order</code> , but containing observation labels instead of observation numbers. This component is only available if the original observations were labelled. |
| <code>height</code>    | a vector with the diameters of the clusters prior to splitting.                                                                                                                         |
| <code>dc</code>        | the divisive coefficient, measuring the clustering structure of the dataset. For each observation $i$ , denote by $d(i)$ the diameter of the last cluster to which it                   |

|                    |                                                                                                                                                                                                                                                                                                                                                                                                    |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                    | belongs (before being split off as a single observation), divided by the diameter of the whole dataset. The <code>dc</code> is the average of all $1 - d(i)$ . It can also be seen as the average width (or the percentage filled) of the banner plot. Because <code>dc</code> grows with the number of observations, this measure should not be used to compare datasets of very different sizes. |
| <code>merge</code> | an (n-1) by 2 matrix, where n is the number of observations. Row i of <code>merge</code> describes the split at step n-i of the clustering. If a number j in row r is negative, then the single observation  j  is split off at stage n-r. If j is positive, then the cluster that will be splitted at stage n-j (described by row j), is split off at stage n-r.                                  |
| <code>diss</code>  | an object of class "dissimilarity", representing the total dissimilarity matrix of the dataset.                                                                                                                                                                                                                                                                                                    |
| <code>data</code>  | a matrix containing the original or standardized measurements, depending on the <code>stand</code> option of the function <code>agnes</code> . If a dissimilarity matrix was given as input structure, then this component is not available.                                                                                                                                                       |

### See Also

`agnes` also for background and references; `cutree` (and `as.hclust`) for grouping extraction; `daisy`, `dist`, `plot.diana`, `twins.object`.

### Examples

```
data(votes.repub)
dv <- diana(votes.repub, metric = "manhattan", stand = TRUE)
print(dv)
plot(dv)

Cut into 2 groups:
dv2 <- cutree(as.hclust(dv), k = 2)
table(dv2) # 8 and 42 group members
rownames(votes.repub)[dv2 == 1]

For two groups, does the metric matter ?
dv0 <- diana(votes.repub, stand = TRUE) # default: Euclidean
dv.2 <- cutree(as.hclust(dv0), k = 2)
table(dv2 == dv.2) ## identical group assignments

str(as.dendrogram(dv0)) # {via as.dendrogram.twins() method}

data(agriculture)
Plot similar to Figure 8 in ref
Not run: plot(diana(agriculture), ask = TRUE)
```

---

dissimilarity.object

*Dissimilarity Matrix Object*

---

### Description

Objects of class "dissimilarity" representing the dissimilarity matrix of a dataset.

**Value**

The dissimilarity matrix is symmetric, and hence its lower triangle (column wise) is represented as a vector to save storage space. If the object, is called `do`, and `n` the number of observations, i.e., `n <- attr(do, "Size")`, then for  $i < j \leq n$ , the dissimilarity between (row)  $i$  and  $j$  is `do[n*(i-1) - i*(i-1)/2 + j-i]`. The length of the vector is  $n * (n - 1) / 2$ , i.e., of order  $n^2$ .

"dissimilarity" objects also inherit from class `dist` and can use `dist` methods, in particular, `as.matrix`, such that  $d_{ij}$  from above is just `as.matrix(do)[i, j]`.

The object has the following attributes:

|            |                                                                                                                                                                                                                                                                                                                                                   |
|------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Size       | the number of observations in the dataset.                                                                                                                                                                                                                                                                                                        |
| Metric     | the metric used for calculating the dissimilarities. Possible values are "euclidean", "manhattan", "mixed" (if variables of different types were present in the dataset), and "unspecified".                                                                                                                                                      |
| Labels     | optionally, contains the labels, if any, of the observations of the dataset.                                                                                                                                                                                                                                                                      |
| NA.message | optionally, if a dissimilarity could not be computed, because of too many missing values for some observations of the dataset.                                                                                                                                                                                                                    |
| Types      | when a mixed metric was used, the types for each variable as one-letter codes (as in the book, e.g. p.54):<br><br><b>A</b> Asymmetric binary<br><b>S</b> Symmetric binary<br><b>N</b> Nominal (factor)<br><b>O</b> Ordinal (ordered factor)<br><b>I</b> Interval scaled (numeric)<br><b>T</b> raTio to be log transformed (positive numeric)<br>. |

**GENERATION**

`daisy` returns this class of objects. Also the functions `pam`, `clara`, `fanny`, `agnes`, and `diana` return a dissimilarity object, as one component of their return objects.

**METHODS**

The "dissimilarity" class has methods for the following generic functions: `print`, `summary`.

**See Also**

`daisy`, `dist`, `pam`, `clara`, `fanny`, `agnes`, `diana`.

ellipsoidhull

*Compute the Ellipsoid Hull or Spanning Ellipsoid of a Point Set***Description**

Compute the “ellipsoid hull” or “spanning ellipsoid”, i.e. the ellipsoid of minimal volume (‘area’ in 2D) such that all given points lie just inside or on the boundary of the ellipsoid.

**Usage**

```
ellipsoidhull(x, tol=0.01, maxit=5000,
 ret.wt = FALSE, ret.sqdist = FALSE, ret.pr = FALSE)
S3 method for class 'ellipsoid'
print(x, digits = max(1, getOption("digits") - 2), ...)
```

**Arguments**

**x** the  $n$   $p$ -dimensional points as numeric  $n \times p$  matrix.

**tol** convergence tolerance for Titterton’s algorithm. Setting this to much smaller values may drastically increase the number of iterations needed, and you may want to increase **maxit** as well.

**maxit** integer giving the maximal number of iteration steps for the algorithm.

**ret.wt, ret.sqdist, ret.pr** logicals indicating if additional information should be returned, **ret.wt** specifying the *weights*, **ret.sqdist** the *squared distances* and **ret.pr** the final **probabilities** in the algorithms.

**digits, ...** the usual arguments to `print` methods.

**Details**

The “spanning ellipsoid” algorithm is said to stem from Titterton(1976), in Pison et al (1999) who use it for `clusplot.default`.

The problem can be seen as a special case of the “Min.Vol.” ellipsoid of which a more flexible and general implementation is `cov.mve` in the MASS package.

**Value**

an object of class "ellipsoid", basically a `list` with several components, comprising at least

**cov**  $p \times p$  covariance matrix description the ellipsoid.

**loc**  $p$ -dimensional location of the ellipsoid center.

**d2** average squared radius. Further,  $d2 = t^2$ , where  $t$  is “the value of a t-statistic on the ellipse boundary” (from `ellipse` in the **ellipse** package), and hence, more usefully,  $d2 = qchisq(alpha, df = p)$ , where  $alpha$  is the confidence level for  $p$ -variate normally distributed data with location and covariance **loc** and **cov** to lie inside the ellipsoid.

**wt** the vector of weights iff **ret.wt** was true.

**sqdist** the vector of squared distances iff **ret.sqdist** was true.

**prob** the vector of algorithm probabilities iff **ret.pr** was true.

|                         |                                                                                                           |
|-------------------------|-----------------------------------------------------------------------------------------------------------|
| <code>it</code>         | number of iterations used.                                                                                |
| <code>tol, maxit</code> | just the input argument, see above.                                                                       |
| <code>eps</code>        | the achieved tolerance which is the maximal squared radius minus $p$ .                                    |
| <code>ierr</code>       | error code as from the algorithm; 0 means <i>ok</i> .                                                     |
| <code>conv</code>       | logical indicating if the converged. This is defined as <code>it &lt; maxit &amp;&amp; ierr == 0</code> . |

### Author(s)

Martin Maechler did the present class implementation; Rousseeuw et al did the underlying original code.

`predict.ellipsoid` which is also the `predict` method for `ellipsoid` objects. `volume.ellipsoid` for an example of ‘manual’ `ellipsoid` object construction; further `ellipse` from package `ellipse` and `ellipsePoints` from package `sfsmisc`.

`chull` for the convex hull, `clusplot` which makes use of this; `cov.mve`.

### Examples

```
x <- rnorm(100)
xy <- unname(cbind(x, rnorm(100) + 2*x + 10))
exy. <- ellipsoidhull(xy)
exy. # >> calling print.ellipsoid()

plot(xy, main = "ellipsoidhull(<Gauss data>) -- 'spanning points'")
lines(predict(exy.), col="blue")
points(rbind(exy.$loc), col = "red", cex = 3, pch = 13)

exy <- ellipsoidhull(xy, tol = 1e-7, ret.wt = TRUE, ret.sq = TRUE)
str(exy) # had small 'tol', hence many iterations
(ii <- which(zapsmall(exy $ wt) > 1e-6))
--> only about 4 to 6 "spanning ellipsoid" points
round(exy$wt[ii], 3); sum(exy$wt[ii]) # weights summing to 1
points(xy[ii,], pch = 21, cex = 2,
 col="blue", bg = adjustcolor("blue", 0.25))
```

## Description

Computes a fuzzy clustering of the data into  $k$  clusters.

## Usage

```
fanny(x, k, diss = inherits(x, "dist"), memb.exp = 2,
 metric = c("euclidean", "manhattan", "SqEuclidean"),
 stand = FALSE, iniMem.p = NULL, cluster.only = FALSE,
 keep.diss = !diss && !cluster.only && n < 100,
 keep.data = !diss && !cluster.only,
 maxit = 500, tol = 1e-15, trace.lev = 0)
```

## Arguments

|                       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>        | <p>data matrix or data frame, or dissimilarity matrix, depending on the value of the <code>diss</code> argument.</p> <p>In case of a matrix or data frame, each row corresponds to an observation, and each column corresponds to a variable. All variables must be numeric. Missing values (NAs) are allowed.</p> <p>In case of a dissimilarity matrix, <code>x</code> is typically the output of <code>daisy</code> or <code>dist</code>. Also a vector of length <math>n*(n-1)/2</math> is allowed (where <math>n</math> is the number of observations), and will be interpreted in the same way as the output of the above-mentioned functions. Missing values (NAs) are not allowed.</p> |
| <code>k</code>        | integer giving the desired number of clusters. It is required that $0 < k < n/2$ where $n$ is the number of observations.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>diss</code>     | logical flag: if TRUE (default for <code>dist</code> or dissimilarity objects), then <code>x</code> is assumed to be a dissimilarity matrix. If FALSE, then <code>x</code> is treated as a matrix of observations by variables.                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>memb.exp</code> | number $r$ strictly larger than 1 specifying the <i>membership exponent</i> used in the fit criterion; see the ‘Details’ below. Default: 2 which used to be hardwired inside FANNY.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>metric</code>   | <p>character string specifying the metric to be used for calculating dissimilarities between observations. Options are "euclidean" (default), "manhattan", and "SqEuclidean". Euclidean distances are root sum-of-squares of differences, and manhattan distances are the sum of absolute differences, and "SqEuclidean", the <i>squared</i> euclidean distances are sum-of-squares of differences. Using this last option is equivalent (but somewhat slower) to computing so called “fuzzy C-means”.</p> <p>If <code>x</code> is already a dissimilarity matrix, then this argument will be ignored.</p>                                                                                    |
| <code>stand</code>    | logical; if true, the measurements in <code>x</code> are standardized before calculating the dissimilarities. Measurements are standardized for each variable (column), by subtracting the variable’s mean value and dividing by the variable’s mean absolute deviation. If <code>x</code> is already a dissimilarity matrix, then this argument will be ignored.                                                                                                                                                                                                                                                                                                                             |

|                                   |                                                                                                                                                                                                                                                         |
|-----------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>iniMem.p</code>             | numeric $n \times k$ matrix or NULL (by default); can be used to specify a starting membership matrix, i.e., a matrix of non-negative numbers, each row summing to one.                                                                                 |
| <code>cluster.only</code>         | logical; if true, no silhouette information will be computed and returned, see details.                                                                                                                                                                 |
| <code>keep.diss, keep.data</code> | logicals indicating if the dissimilarities and/or input data $x$ should be kept in the result. Setting these to FALSE can give smaller results and hence also save memory allocation <i>time</i> .                                                      |
| <code>maxit, tol</code>           | maximal number of iterations and default tolerance for convergence (relative convergence of the fit criterion) for the FANNY algorithm. The defaults <code>maxit</code> = 500 and <code>tol</code> = $1e-15$ used to be hardwired inside the algorithm. |
| <code>trace.lev</code>            | integer specifying a trace level for printing diagnostics during the C-internal algorithm. Default 0 does not print anything; higher values print increasingly more.                                                                                    |

## Details

In a fuzzy clustering, each observation is “spread out” over the various clusters. Denote by  $u_{iv}$  the membership of observation  $i$  to cluster  $v$ .

The memberships are nonnegative, and for a fixed observation  $i$  they sum to 1. The particular method `fanny` stems from chapter 4 of Kaufman and Rousseeuw (1990) (see the references in [daisy](#)) and has been extended by Martin Maechler to allow user specified `memb.exp`, `iniMem.p`, `maxit`, `tol`, etc.

Fanny aims to minimize the objective function

$$\sum_{v=1}^k \frac{\sum_{i=1}^n \sum_{j=1}^n u_{iv}^r u_{jv}^r d(i, j)}{2 \sum_{j=1}^n u_{jv}^r}$$

where  $n$  is the number of observations,  $k$  is the number of clusters,  $r$  is the membership exponent `memb.exp` and  $d(i, j)$  is the dissimilarity between observations  $i$  and  $j$ .

Note that  $r \rightarrow 1$  gives increasingly crisper clusterings whereas  $r \rightarrow \infty$  leads to complete fuzzyness. K&R(1990), p.191 note that values too close to 1 can lead to slow convergence. Further note that even the default,  $r = 2$  can lead to complete fuzzyness, i.e., memberships  $u_{iv} \equiv 1/k$ . In that case a warning is signalled and the user is advised to chose a smaller `memb.exp` ( $= r$ ).

Compared to other fuzzy clustering methods, `fanny` has the following features: (a) it also accepts a dissimilarity matrix; (b) it is more robust to the `spherical cluster` assumption; (c) it provides a novel graphical display, the silhouette plot (see [plot.partition](#)).

## Value

an object of class "fanny" representing the clustering. See [fanny.object](#) for details.

## See Also

[agnes](#) for background and references; [fanny.object](#), [partition.object](#), [plot.partition](#), [daisy](#), [dist](#).

## Examples

```
generate 10+15 objects in two clusters, plus 3 objects lying
between those clusters.
x <- rbind(cbind(rnorm(10, 0, 0.5), rnorm(10, 0, 0.5)),
 cbind(rnorm(15, 5, 0.5), rnorm(15, 5, 0.5)),
 cbind(rnorm(3,3.2,0.5), rnorm(3,3.2,0.5)))
fannyx <- fanny(x, 2)
Note that observations 26:28 are "fuzzy" (closer to # 2):
fannyx
summary(fannyx)
plot(fannyx)

(fan.x.15 <- fanny(x, 2, memb.exp = 1.5)) # 'crispier' for obs. 26:28
(fanny(x, 2, memb.exp = 3)) # more fuzzy in general

data(ruspini)
f4 <- fanny(ruspini, 4)
stopifnot(rle(f4$clustering)$lengths == c(20,23,17,15))
plot(f4, which = 1)
Plot similar to Figure 6 in Stryuf et al (1996)
plot(fanny(ruspini, 5))
```

fanny.object

*Fuzzy Analysis (FANNY) Object*

## Description

The objects of class "fanny" represent a fuzzy clustering of a dataset.

## Value

A legitimate fanny object is a list with the following components:

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| membership  | matrix containing the memberships for each pair consisting of an observation and a cluster.                                                                                                                                                                                                                                                                                                                                                                                                               |
| memb.exp    | the membership exponent used in the fitting criterion.                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| coeff       | Dunn's partition coefficient $F(k)$ of the clustering, where $k$ is the number of clusters. $F(k)$ is the sum of all <i>squared</i> membership coefficients, divided by the number of observations. Its value is between $1/k$ and 1.<br>The normalized form of the coefficient is also given. It is defined as $(F(k) - 1/k)/(1 - 1/k)$ , and ranges between 0 and 1. A low value of Dunn's coefficient indicates a very fuzzy clustering, whereas a value close to 1 indicates a near-crisp clustering. |
| clustering  | the clustering vector of the nearest crisp clustering, see <a href="#">partition.object</a> .                                                                                                                                                                                                                                                                                                                                                                                                             |
| k.crisp     | integer ( $\leq k$ ) giving the number of <i>crisp</i> clusters; can be less than $k$ , where it's recommended to decrease memb.exp.                                                                                                                                                                                                                                                                                                                                                                      |
| objective   | named vector containing the minimal value of the objective function reached by the FANNY algorithm and the relative convergence tolerance tol used.                                                                                                                                                                                                                                                                                                                                                       |
| convergence | named vector with iterations, the number of iterations needed and converged indicating if the algorithm converged (in maxit iterations within convergence tolerance tol).                                                                                                                                                                                                                                                                                                                                 |

- diss            an object of class "dissimilarity", see [partition.object](#).
- call            generating call, see [partition.object](#).
- silinfo        list with silhouette information of the nearest crisp clustering, see [partition.object](#).
- data            matrix, possibly standardized, or NULL, see [partition.object](#).

**GENERATION**

These objects are returned from [fanny](#).

**METHODS**

The "fanny" class has methods for the following generic functions: print, summary.

**INHERITANCE**

The class "fanny" inherits from "partition". Therefore, the generic functions plot and clusplot can be used on a fanny object.

**See Also**

[fanny](#),    [print.fanny](#),    [dissimilarity.object](#),    [partition.object](#),  
[plot.partition](#).

---

|        |                               |
|--------|-------------------------------|
| flower | <i>Flower Characteristics</i> |
|--------|-------------------------------|

---

**Description**

8 characteristics for 18 popular flowers.

**Usage**

`data(flower)`

**Format**

A data frame with 18 observations on 8 variables:

|           |         |            |
|-----------|---------|------------|
| [ , "V1"] | factor  | winters    |
| [ , "V2"] | factor  | shadow     |
| [ , "V3"] | factor  | tubers     |
| [ , "V4"] | factor  | color      |
| [ , "V5"] | ordered | soil       |
| [ , "V6"] | ordered | preference |
| [ , "V7"] | numeric | height     |
| [ , "V8"] | numeric | distance   |

- V1** winters, is binary and indicates whether the plant may be left in the garden when it freezes.  
**V2** shadow, is binary and shows whether the plant needs to stand in the shadow.

- V3** tubers, is asymmetric binary and distinguishes between plants with tubers and plants that grow in any other way.
- V4** color, is nominal and specifies the flower's color (1 = white, 2 = yellow, 3 = pink, 4 = red, 5 = blue).
- V5** soil, is ordinal and indicates whether the plant grows in dry (1), normal (2), or wet (3) soil.
- V6** preference, is ordinal and gives someone's preference ranking going from 1 to 18.
- V7** height, is interval scaled, the plant's height in centimeters.
- V8** distance, is interval scaled, the distance in centimeters that should be left between the plants.

## References

```
lower.to.upper.tri.inds
```

*Permute Indices for Triangular Matrices*

---

## Description

Compute index vectors for extracting or reordering of lower or upper triangular matrices that are stored as contiguous vectors.

## Usage

```
lower.to.upper.tri.inds(n)
upper.to.lower.tri.inds(n)
```

## Arguments

**n** integer larger than 1.

## Value

integer vector containing a permutation of  $1:N$  where  $N = n(n-1)/2$ .

## See Also

[upper.tri](#), [lower.tri](#) with a related purpose.

## Examples

```
m5 <- matrix(NA, 5, 5)
m <- m5; m[lower.tri(m)] <- upper.to.lower.tri.inds(5); m
m <- m5; m[upper.tri(m)] <- lower.to.upper.tri.inds(5); m

stopifnot(lower.to.upper.tri.inds(2) == 1,
 lower.to.upper.tri.inds(3) == 1:3,
 upper.to.lower.tri.inds(3) == 1:3,
 sort(upper.to.lower.tri.inds(5)) == 1:10,
 sort(lower.to.upper.tri.inds(6)) == 1:15)
```

mona

*MONothetic Analysis Clustering of Binary Variables*

## Description

Returns a list representing a divisive hierarchical clustering of a dataset with binary variables only.

## Usage

```
mona(x, trace.lev = 0)
```

## Arguments

|                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>         | data matrix or data frame in which each row corresponds to an observation, and each column corresponds to a variable. All variables must be binary. A limited number of missing values (NAs) is allowed. Every observation must have at least one value different from <a href="#">NA</a> . No variable should have half of its values missing. There must be at least one variable which has no missing values. A variable with all its non-missing values identical is not allowed. |
| <code>trace.lev</code> | logical or integer indicating if (and how much) the algorithm should produce progress output.                                                                                                                                                                                                                                                                                                                                                                                         |

## Details

`mona` is fully described in chapter 7 of Kaufman and Rousseeuw (1990). It is “monothetic” in the sense that each division is based on a single (well-chosen) variable, whereas most other hierarchical methods (including `agnes` and `diana`) are “polythetic”, i.e. they use all variables together.

The `mona`-algorithm constructs a hierarchy of clusterings, starting with one large cluster. Clusters are divided until all observations in the same cluster have identical values for all variables.

At each stage, all clusters are divided according to the values of one variable. A cluster is divided into one cluster with all observations having value 1 for that variable, and another cluster with all observations having value 0 for that variable.

The variable used for splitting a cluster is the variable with the maximal total association to the other variables, according to the observations in the cluster to be splitted. The association between variables  $f$  and  $g$  is given by  $a(f,g)*d(f,g) - b(f,g)*c(f,g)$ , where  $a(f,g)$ ,  $b(f,g)$ ,  $c(f,g)$ , and  $d(f,g)$  are the numbers in the contingency table of  $f$  and  $g$ . [That is,  $a(f,g)$  (resp.  $d(f,g)$ ) is the number of observations for which  $f$  and  $g$  both have value 0 (resp. value 1);  $b(f,g)$  (resp.  $c(f,g)$ ) is the number of observations for which  $f$  has value 0 (resp. 1) and  $g$  has value 1 (resp. 0).] The total association of a variable  $f$  is the sum of its associations to all variables.

**Value**

an object of class "mona" representing the clustering. See [mona.object](#) for details.

**Missing Values (NAs)**

The mona-algorithm requires “pure” 0-1 values. However, `mona(x)` allows `x` to contain (not too many) NAs. In a preliminary step, these are “imputed”, i.e., all missing values are filled in. To do this, the same measure of association between variables is used as in the algorithm. When variable `f` has missing values, the variable `g` with the largest absolute association to `f` is looked up. When the association between `f` and `g` is positive, any missing value of `f` is replaced by the value of `g` for the same observation. If the association between `f` and `g` is negative, then any missing value of `f` is replaced by the value of `1-g` for the same observation.

**Note**

In **cluster** versions before 2.0.6, the algorithm entered an infinite loop in the boundary case of one variable, i.e., `ncol(x) == 1`, which currently signals an error (because the algorithm now in C, has not correctly taken account of this special case).

**See Also**

[agnes](#) for background and references; [mona.object](#), [plot.mona](#).

**Examples**

```
data(animals)
ma <- mona(animals)
ma
Plot similar to Figure 10 in Struyf et al (1996)
plot(ma)

One place to see if/how error messages are *translated* (to 'de' / 'pl'):
ani.NA <- animals; ani.NA[4,] <- NA
aniNA <- within(animals, { end[2:9] <- NA })
aniN2 <- animals; aniN2[cbind(1:6, c(3, 1, 4:6, 2))] <- NA
ani.non2 <- within(animals, end[7] <- 3)
ani.idNA <- within(animals, end[!is.na(end)] <- 1)
try(mona(ani.NA)) ## error: .. object with all values missing
try(mona(aniNA)) ## error: .. more than half missing values
try(mona(aniN2)) ## error: all have at least one missing
try(mona(ani.non2)) ## error: all must be binary
try(mona(ani.idNA)) ## error: ditto
```

---

mona.object

---

*Monothetic Analysis (MONA) Object*

---

**Description**

The objects of class "mona" represent the divisive hierarchical clustering of a dataset with only binary variables (measurements). This class of objects is returned from [mona](#).

**Value**

A legitimate `mona` object is a list with the following components:

|                        |                                                                                                                                                                                         |
|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>data</code>      | matrix with the same dimensions as the original data matrix, but with factors coded as 0 and 1, and all missing values replaced.                                                        |
| <code>order</code>     | a vector giving a permutation of the original observations to allow for plotting, in the sense that the branches of a clustering tree will not cross.                                   |
| <code>order.lab</code> | a vector similar to <code>order</code> , but containing observation labels instead of observation numbers. This component is only available if the original observations were labelled. |
| <code>variable</code>  | vector of length <code>n-1</code> where <code>n</code> is the number of observations, specifying the variables used to separate the observations of <code>order</code> .                |
| <code>step</code>      | vector of length <code>n-1</code> where <code>n</code> is the number of observations, specifying the separation steps at which the observations of <code>order</code> are separated.    |

**METHODS**

The "mona" class has methods for the following generic functions: `print`, `summary`, `plot`.

**See Also**

[mona](#) for examples etc, [plot.mona](#).

---

|     |                                    |
|-----|------------------------------------|
| pam | <i>Partitioning Around Medoids</i> |
|-----|------------------------------------|

---

**Description**

Partitioning (clustering) of the data into `k` clusters “around medoids”, a more robust version of K-means.

**Usage**

```
pam(x, k, diss = inherits(x, "dist"),
 metric = c("euclidean", "manhattan"),
 medoids = if(is.numeric(nstart)) "random",
 nstart = if(variant == "faster") 1 else NA,
 stand = FALSE, cluster.only = FALSE,
 do.swap = TRUE,
 keep.diss = !diss && !cluster.only && n < 100,
 keep.data = !diss && !cluster.only,
 variant = c("original", "o_1", "o_2", "f_3", "f_4", "f_5", "faster"),
 pamonce = FALSE, trace.lev = 0)
```

## Arguments

|                                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-----------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>                    | <p>data matrix or data frame, or dissimilarity matrix or object, depending on the value of the <code>diss</code> argument.</p> <p>In case of a matrix or data frame, each row corresponds to an observation, and each column corresponds to a variable. All variables must be numeric. Missing values (NAs) are allowed—as long as every pair of observations has at least one case not missing.</p> <p>In case of a dissimilarity matrix, <code>x</code> is typically the output of <code>daisy</code> or <code>dist</code>. Also a vector of length <math>n*(n-1)/2</math> is allowed (where <math>n</math> is the number of observations), and will be interpreted in the same way as the output of the above-mentioned functions. Missing values (NAs) are <i>not</i> allowed.</p> |
| <code>k</code>                    | positive integer specifying the number of clusters, less than the number of observations.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <code>diss</code>                 | logical flag: if TRUE (default for <code>dist</code> or dissimilarity objects), then <code>x</code> will be considered as a dissimilarity matrix. If FALSE, then <code>x</code> will be considered as a matrix of observations by variables.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>metric</code>               | <p>character string specifying the metric to be used for calculating dissimilarities between observations.</p> <p>The currently available options are "euclidean" and "manhattan". Euclidean distances are root sum-of-squares of differences, and manhattan distances are the sum of absolute differences. If <code>x</code> is already a dissimilarity matrix, then this argument will be ignored.</p>                                                                                                                                                                                                                                                                                                                                                                               |
| <code>medoids</code>              | NULL (default) or length- <code>k</code> vector of integer indices (in $1:n$ ) specifying initial medoids instead of using the 'build' algorithm.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>nstart</code>               | used only when <code>medoids = "random"</code> : specifies the <i>number</i> of random "starts"; this argument corresponds to the one of <code>kmeans()</code> (from R's package <b>stats</b> ).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <code>stand</code>                | logical; if true, the measurements in <code>x</code> are standardized before calculating the dissimilarities. Measurements are standardized for each variable (column), by subtracting the variable's mean value and dividing by the variable's mean absolute deviation. If <code>x</code> is already a dissimilarity matrix, then this argument will be ignored.                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>cluster.only</code>         | logical; if true, only the clustering will be computed and returned, see details.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>do.swap</code>              | logical indicating if the <b>swap</b> phase should happen. The default, TRUE, correspond to the original algorithm. On the other hand, the <b>swap</b> phase is much more computer intensive than the <b>build</b> one for large $n$ , so can be skipped by <code>do.swap = FALSE</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>keep.diss, keep.data</code> | logicals indicating if the dissimilarities and/or input data <code>x</code> should be kept in the result. Setting these to FALSE can give much smaller results and hence even save memory allocation <i>time</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>pamonce</code>              | logical or integer in $0:6$ specifying algorithmic short cuts as proposed by Reynolds et al. (2006), and Schubert and Rousseeuw (2019, 2021) see below.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>variant</code>              | a <code>character</code> string denoting the variant of PAM algorithm to use; a more self-documenting version of <code>pamonce</code> which should be used preferably; note that "faster" not only uses <code>pamonce = 6</code> but also <code>nstart = 1</code> and hence <code>medoids = "random"</code> by default.                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>trace.lev</code>            | integer specifying a trace level for printing diagnostics during the build and swap phase of the algorithm. Default 0 does not print anything; higher values print increasingly more.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

## Details

The basic `pam` algorithm is fully described in chapter 2 of Kaufman and Rousseeuw(1990). Compared to the `k-means` approach in `kmeans`, the function `pam` has the following features: (a) it also accepts a dissimilarity matrix; (b) it is more robust because it minimizes a sum of dissimilarities instead of a sum of squared euclidean distances; (c) it provides a novel graphical display, the silhouette plot (see `plot.partition`) (d) it allows to select the number of clusters using `mean(silhouette(pr)[, "sil_width"])` on the result `pr <- pam(..)`, or directly its component `pr$silinfo$avg.width`, see also [pam.object](#).

When `cluster.only` is true, the result is simply a (possibly named) integer vector specifying the clustering, i.e.,

`pam(x, k, cluster.only=TRUE)` is the same as  
`pam(x, k)$clustering` but computed more efficiently.

The `pam`-algorithm is based on the search for  $k$  representative objects or medoids among the observations of the dataset. These observations should represent the structure of the data. After finding a set of  $k$  medoids,  $k$  clusters are constructed by assigning each observation to the nearest medoid. The goal is to find  $k$  representative objects which minimize the sum of the dissimilarities of the observations to their closest representative object.

By default, when medoids are not specified, the algorithm first looks for a good initial set of medoids (this is called the **build** phase). Then it finds a local minimum for the objective function, that is, a solution such that there is no single switch of an observation with a medoid (i.e. a ‘swap’) that will decrease the objective (this is called the **swap** phase).

When the medoids are specified (or randomly generated), their order does *not* matter; in general, the algorithms have been designed to not depend on the order of the observations.

The `pamonce` option, new in cluster 1.14.2 (Jan. 2012), has been proposed by Matthias Studer, University of Geneva, based on the findings by Reynolds et al. (2006) and was extended by Erich Schubert, TU Dortmund, with the FastPAM optimizations.

The default FALSE (or integer 0) corresponds to the original “swap” algorithm, whereas `pamonce = 1` (or TRUE), corresponds to the first proposal .... and `pamonce = 2` additionally implements the second proposal as well.

The key ideas of ‘FastPAM’ (Schubert and Rousseeuw, 2019) are implemented except for the linear approximate build as follows:

`pamonce = 3`: reduces the runtime by a factor of  $O(k)$  by exploiting that points cannot be closest to all current medoids at the same time.

`pamonce = 4`: additionally allows executing multiple swaps per iteration, usually reducing the number of iterations.

`pamonce = 5`: adds minor optimizations copied from the `pamonce = 2` approach, and is expected to be the fastest of the ‘FastPam’ variants included.

‘FasterPAM’ (Schubert and Rousseeuw, 2021) is implemented via

`pamonce = 6`: execute each swap which improves results immediately, and hence typically multiple swaps per iteration; this swapping algorithm runs in  $O(n^2)$  rather than  $O(n(n - k)k)$  time which is much faster for all but small  $k$ .

In addition, ‘FasterPAM’ uses *random* initialization of the medoids (instead of the ‘*build*’ phase) to avoid the  $O(n^2k)$  initialization cost of the build algorithm. In particular for large  $k$ , this yields a much faster algorithm, while preserving a similar result quality.

One may decide to use *repeated* random initialization by setting `nstart > 1`.

**Value**

an object of class "pam" representing the clustering. See `?pam.object` for details.

**Note**

For large datasets, pam may need too much memory or too much computation time since both are  $O(n^2)$ . Then, `clara()` is preferable, see its documentation.

There is hard limit currently,  $n \leq 65536$ , at  $2^{16}$  because for larger  $n$ ,  $n(n-1)/2$  is larger than the maximal integer (`.Machine$integer.max =  $2^{31} - 1$` ).

**Author(s)**

Kaufman and Rousseeuw's original Fortran code was translated to C and augmented in several ways, e.g. to allow `cluster.only=TRUE` or `do.swap=FALSE`, by Martin Maechler.  
Matthias Studer, Univ.Geneva provided the `pamonce` (1 and 2) implementation.  
Erich Schubert, TU Dortmund contributed the `pamonce` (3 to 6) implementation.

**Examples**

```
generate 25 objects, divided into 2 clusters.
x <- rbind(cbind(rnorm(10,0,0.5), rnorm(10,0,0.5)),
 cbind(rnorm(15,5,0.5), rnorm(15,5,0.5)))
pamx <- pam(x, 2)
pamx # Medoids: '7' and '25' ...
summary(pamx)
plot(pamx)
use obs. 1 & 16 as starting medoids -- same result (typically)
(p2m <- pam(x, 2, medoids = c(1,16)))
no _build_ *and* no _swap_ phase: just cluster all obs. around (1, 16):
p2.s <- pam(x, 2, medoids = c(1,16), do.swap = FALSE)
p2.s

p3m <- pam(x, 3, trace = 2)
rather stupid initial medoids:
(p3m. <- pam(x, 3, medoids = 3:1, trace = 1))

pam(daisy(x, metric = "manhattan"), 2, diss = TRUE)
```

```
data(ruspini)
Plot similar to Figure 4 in Stryuf et al (1996)
Not run: plot(pam(ruspini, 4), ask = TRUE)
```

pam.object

*Partitioning Around Medoids (PAM) Object***Description**

The objects of class "pam" represent a partitioning of a dataset into clusters.

**Value**

A legitimate pam object is a [list](#) with the following components:

|            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| medoids    | the medoids or representative objects of the clusters. If a dissimilarity matrix was given as input to pam, then a vector of numbers or labels of observations is given, else medoids is a <a href="#">matrix</a> with in each row the coordinates of one medoid.                                                                                                                                                                                                                                                       |
| id.med     | integer vector of <i>indices</i> giving the medoid observation numbers.                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| clustering | the clustering vector, see <a href="#">partition.object</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| objective  | the objective function after the first and second step of the pam algorithm.                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| isolation  | vector with length equal to the number of clusters, specifying which clusters are isolated clusters (L- or L*-clusters) and which clusters are not isolated.<br>A cluster is an L*-cluster iff its diameter is smaller than its separation. A cluster is an L-cluster iff for each observation i the maximal dissimilarity between i and any other observation of the cluster is smaller than the minimal dissimilarity between i and any observation of another cluster. Clearly each L*-cluster is also an L-cluster. |
| clusinfo   | matrix, each row gives numerical information for one cluster. These are the cardinality of the cluster (number of observations), the maximal and average dissimilarity between the observations in the cluster and the cluster's medoid, the diameter of the cluster (maximal dissimilarity between two observations of the cluster), and the separation of the cluster (minimal dissimilarity between an observation of the cluster and an observation of another cluster).                                            |
| silinfo    | list with silhouette width information, see <a href="#">partition.object</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| diss       | dissimilarity (maybe NULL), see <a href="#">partition.object</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| call       | generating call, see <a href="#">partition.object</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| data       | (possibly standardized) see <a href="#">partition.object</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

**GENERATION**

These objects are returned from [pam](#).

**METHODS**

The "pam" class has methods for the following generic functions: `print`, `summary`.

## INHERITANCE

The class "pam" inherits from "partition". Therefore, the generic functions `plot` and `clusplot` can be used on a pam object.

## See Also

[pam](#), [dissimilarity.object](#), [partition.object](#), [plot.partition](#).

## Examples

```
Use the silhouette widths for assessing the best number of clusters,
following a one-dimensional example from Christian Hennig :
##
x <- c(rnorm(50), rnorm(50,mean=5), rnorm(30,mean=15))
asw <- numeric(20)
Note that "k=1" won't work!
for (k in 2:20)
 asw[k] <- pam(x, k) $ silinfo $ avg.width
k.best <- which.max(asw)
cat("silhouette-optimal number of clusters:", k.best, "\n")

plot(1:20, asw, type="h", main = "pam() clustering assessment",
 xlab= "k (# clusters)", ylab = "average silhouette width")
axis(1, k.best, paste("best",k.best,sep="\n"), col = "red", col.axis = "red")
```

---

partition.object      *Partitioning Object*

---

## Description

The objects of class "partition" represent a partitioning of a dataset into clusters.

## Value

a "partition" object is a list with the following (and typically more) components:

- |            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| clustering | the clustering vector. An integer vector of length $n$ , the number of observations, giving for each observation the number ('id') of the cluster to which it belongs.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| call       | the matched <a href="#">call</a> generating the object.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| silinfo    | <p>a list with all <i>silhouette</i> information, only available when the number of clusters is non-trivial, i.e., <math>1 &lt; k &lt; n</math> and then has the following components, see <a href="#">silhouette</a></p> <p><b>widths</b> an <math>(n \times 3)</math> matrix, as returned by <a href="#">silhouette()</a>, with for each observation <math>i</math> the cluster to which <math>i</math> belongs, as well as the neighbor cluster of <math>i</math> (the cluster, not containing <math>i</math>, for which the average dissimilarity between its observations and <math>i</math> is minimal), and the silhouette width <math>s(i)</math> of the observation.</p> <p><b>clus.avg.widths</b> the average silhouette width per cluster.</p> <p><b>avg.width</b> the average silhouette width for the dataset, i.e., simply the average of <math>s(i)</math> over all observations <math>i</math>.</p> |

|                        |                                                                                                                                                                                   |
|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                        | This information is also needed to construct a <i>silhouette plot</i> of the clustering, see <code>plot.partition</code> .                                                        |
|                        | Note that <code>avg.width</code> can be maximized over different clusterings (e.g. with varying number of clusters) to choose an <i>optimal</i> clustering.                       |
| <code>objective</code> | value of criterion maximized during the partitioning algorithm, may more than one entry for different stages.                                                                     |
| <code>diss</code>      | an object of class "dissimilarity", representing the total dissimilarity matrix of the dataset (or relevant subset, e.g. for <code>clara</code> ).                                |
| <code>data</code>      | a matrix containing the original or standardized data. This might be missing to save memory or when a dissimilarity matrix was given as input structure to the clustering method. |

## GENERATION

These objects are returned from `pam`, `clara` or `fanny`.

## METHODS

The "partition" class has a method for the following generic functions: `plot`, `clusplot`.

## INHERITANCE

The following classes inherit from class "partition": "pam", "clara" and "fanny".

See `pam.object`, `clara.object` and `fanny.object` for details.

## See Also

`pam`, `clara`, `fanny`.

---

plantTraits

*Plant Species Traits Data*

---

## Description

This dataset constitutes a description of 136 plant species according to biological attributes (morphological or reproductive)

## Usage

```
data(plantTraits)
```

## Format

A data frame with 136 observations on the following 31 variables.

`pdias` Diaspore mass (mg)

`longindex` Seed bank longevity

`durflow` Flowering duration

`height` Plant height, an ordered factor with levels 1 < 2 < ... < 8.

`begflow` Time of first flowering, an ordered factor with levels 1 < 2 < 3 < 4 < 5 < 6 < 7 < 8 < 9

mycor Mycorrhizas, an ordered factor with levels 0never < 1 sometimes< 2always

vegaer aerial vegetative propagation, an ordered factor with levels 0never < 1 present but limited< 2important.

vegsout underground vegetative propagation, an ordered factor with 3 levels identical to vegaer above.

autopoll selfing pollination, an ordered factor with levels 0never < 1rare < 2 often< the rule3

insects insect pollination, an ordered factor with 5 levels 0 < ... < 4.

wind wind pollination, an ordered factor with 5 levels 0 < ... < 4.

lign a binary factor with levels 0:1, indicating if plant is woody.

piq a binary factor indicating if plant is thorny.

ros a binary factor indicating if plant is rosette.

semiros semi-rosette plant, a binary factor (0: no; 1: yes).

leafy leafy plant, a binary factor.

suman summer annual, a binary factor.

winan winter annual, a binary factor.

monocarp monocarpic perennial, a binary factor.

polycarp polycarpic perennial, a binary factor.

seasaes seasonal aestival leaves, a binary factor.

seashiv seasonal hibernal leaves, a binary factor.

seasver seasonal vernal leaves, a binary factor.

everalw leaves always evergreen, a binary factor.

everparti leaves partially evergreen, a binary factor.

elaio fruits with an elaiosome (dispersed by ants), a binary factor.

endozoo endozoochorous fruits, a binary factor.

epizoo epizoochorous fruits, a binary factor.

aquat aquatic dispersal fruits, a binary factor.

windgl wind dispersed fruits, a binary factor.

unsp unspecialized mechanism of seed dispersal, a binary factor.

### Details

Most of factor attributes are not disjunctive. For example, a plant can be usually pollinated by insects but sometimes self-pollination can occurred.

## Examples

```
data(plantTraits)

Calculation of a dissimilarity matrix
library(cluster)
dai.b <- daisy(plantTraits,
 type = list(ordratio = 4:11, symm = 12:13, asymm = 14:31))

Hierarchical classification
agn.trts <- agnes(dai.b, method="ward")
plot(agn.trts, which.plots = 2, cex= 0.6)
plot(agn.trts, which.plots = 1)
cutree6 <- cutree(agn.trts, k=6)
cutree6

Principal Coordinate Analysis
cmds dai.b <- cmdscale(dai.b, k=6)
plot(cmdsdai.b[, 1:2], asp = 1, col = cutree6)
```

---

plot.agnes

---

*Plots of an Agglomerative Hierarchical Clustering*

---

## Description

Creates plots for visualizing an agnes object.

## Usage

```
S3 method for class 'agnes'
plot(x, ask = FALSE, which.plots = NULL, main = NULL,
 sub = paste("Agglomerative Coefficient = ", round(x$ac, digits = 2)),
 adj = 0, nmax.lab = 35, max.strlen = 5, xax.pretty = TRUE, ...)
```

## Arguments

|             |                                                                                                                                                                                                    |
|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x           | an object of class "agnes", typically created by <a href="#">agnes()</a> .                                                                                                                         |
| ask         | logical; if true and which.plots is NULL, plot.agnes operates in interactive mode, via <a href="#">menu</a> .                                                                                      |
| which.plots | integer vector or NULL (default), the latter producing both plots. Otherwise, which.plots must contain integers of 1 for a <i>banner</i> plot or 2 for a dendrogram or “clustering tree”.          |
| main, sub   | main and sub title for the plot, with convenient defaults. See documentation for these arguments in <a href="#">plot.default</a> .                                                                 |
| adj         | for label adjustment in <a href="#">bannerplot()</a> .                                                                                                                                             |
| nmax.lab    | integer indicating the number of labels which is considered too large for single-name labelling the banner plot.                                                                                   |
| max.strlen  | positive integer giving the length to which strings are truncated in banner plot labeling.                                                                                                         |
| xax.pretty  | logical or integer indicating if <a href="#">pretty()</a> should be used for the x axis. xax.pretty = FALSE is for back compatibility.                                                             |
| ...         | graphical parameters (see <a href="#">par</a> ) may also be supplied and are passed to <a href="#">bannerplot()</a> or <a href="#">pltree()</a> (see <a href="#">pltree.twins</a> ), respectively. |

## Details

When `ask = TRUE`, rather than producing each plot sequentially, `plot.agnes` displays a menu listing all the plots that can be produced. If the menu is not desired but a pause between plots is still wanted one must set `par(ask= TRUE)` before invoking the plot command.

The banner displays the hierarchy of clusters, and is equivalent to a tree. See Rousseeuw (1986) or chapter 5 of Kaufman and Rousseeuw (1990). The banner plots distances at which observations and clusters are merged. The observations are listed in the order found by the `agnes` algorithm, and the numbers in the `height` vector are represented as bars between the observations.

The leaves of the clustering tree are the original observations. Two branches come together at the distance between the two clusters being merged.

For more customization of the plots, rather call `bannerplot` and `pltree()`, i.e., its method `pltree.twins`, respectively.

directly with corresponding arguments, e.g., `xlab` or `ylab`.

## Side Effects

Appropriate plots are produced on the current graphics device. This can be one or both of the following choices:

Banner  
Clustering tree

## Note

In the banner plot, observation labels are only printed when the number of observations is limited less than `nmax.lab` (35, by default), for readability. Moreover, observation labels are truncated to maximally `max.strlen` (5) characters.

For the dendrogram, more flexibility than via `pltree()` is provided by `dg <- as.dendrogram(x)` and plotting `dg` via `plot.dendrogram`.

`agnes` and `agnes.object`; `bannerplot`, `pltree.twins`, and `par`.

## Examples

```
Can also pass 'labels' to pltree() and bannerplot():
data(iris)
cS <- as.character(Sp <- iris$Species)
cS[Sp == "setosa"] <- "S"
cS[Sp == "versicolor"] <- "V"
cS[Sp == "virginica"] <- "G"
```

```
ai <- agnes(iris[, 1:4])
plot(ai, labels = cS, nmax = 150) # bannerplot labels are mess
```

plot.diana

*Plots of a Divisive Hierarchical Clustering*

## Description

Creates plots for visualizing a diana object.

## Usage

```
S3 method for class 'diana'
plot(x, ask = FALSE, which.plots = NULL, main = NULL,
 sub = paste("Divisive Coefficient = ", round(x$dc, digits = 2)),
 adj = 0, nmax.lab = 35, max.strlen = 5, xax.pretty = TRUE, ...)
```

## Arguments

|             |                                                                                                                                                                                           |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x           | an object of class "diana", typically created by <a href="#">diana(.)</a> .                                                                                                               |
| ask         | logical; if true and which.plots is NULL, plot.diana operates in interactive mode, via <a href="#">menu</a> .                                                                             |
| which.plots | integer vector or NULL (default), the latter producing both plots. Otherwise, which.plots must contain integers of 1 for a <i>banner</i> plot or 2 for a dendrogram or “clustering tree”. |
| main, sub   | main and sub title for the plot, each with a convenient default. See documentation for these arguments in <a href="#">plot.default</a> .                                                  |
| adj         | for label adjustment in <a href="#">bannerplot()</a> .                                                                                                                                    |
| nmax.lab    | integer indicating the number of labels which is considered too large for single-name labelling the banner plot.                                                                          |
| max.strlen  | positive integer giving the length to which strings are truncated in banner plot labeling.                                                                                                |
| xax.pretty  | logical or integer indicating if <a href="#">pretty(*, n = xax.pretty)</a> should be used for the x axis. xax.pretty = FALSE is for back compatibility.                                   |
| ...         | graphical parameters (see <a href="#">par</a> ) may also be supplied and are passed to <a href="#">bannerplot()</a> or <a href="#">pltree()</a> , respectively.                           |

## Details

When `ask = TRUE`, rather than producing each plot sequentially, `plot.diana` displays a menu listing all the plots that can be produced. If the menu is not desired but a pause between plots is still wanted one must set `par(ask = TRUE)` before invoking the plot command.

The banner displays the hierarchy of clusters, and is equivalent to a tree. See Rousseeuw (1986) or chapter 6 of Kaufman and Rousseeuw (1990). The banner plots the diameter of each cluster being splitted. The observations are listed in the order found by the `diana` algorithm, and the numbers in the `height` vector are represented as bars between the observations.

The leaves of the clustering tree are the original observations. A branch splits up at the diameter of the cluster being splitted.

### Side Effects

An appropriate plot is produced on the current graphics device. This can be one or both of the following choices:

Banner

Clustering tree

### Note

In the banner plot, observation labels are only printed when the number of observations is limited less than `nmax.lab` (35, by default), for readability. Moreover, observation labels are truncated to maximally `max.strlen` (5) characters.

```
example(diana)# -> dv <- diana(...)

plot(dv, which = 1, nmax.lab = 100)

wider labels :
op <- par(mar = par("mar") + c(0, 2, 0, 0))
plot(dv, which = 1, nmax.lab = 100, max.strlen = 12)
par(op)
```

---

plot.mona

*Banner of Monothetic Divisive Hierarchical Clusterings*

---

### Description

Creates the banner of a `mona` object.

### Usage

```
S3 method for class 'mona'
plot(x, main = paste("Banner of ", deparse(x$call)),
 sub = NULL, xlab = "Separation step",
 col = c(2, 0), axes = TRUE, adj = 0,
 nmax.lab = 35, max.strlen = 5, ...)
```

**Arguments**

|                         |                                                                                                              |
|-------------------------|--------------------------------------------------------------------------------------------------------------|
| <code>x</code>          | an object of class "mona", typically created by <code>mona ( . )</code> .                                    |
| <code>main, sub</code>  | main and sub titles for the plot, with convenient defaults. See documentation in <code>plot.default</code> . |
| <code>xlab</code>       | x axis label, see <code>title</code> .                                                                       |
| <code>col, adj</code>   | graphical parameters passed to <code>bannerplot ( )</code> .                                                 |
| <code>axes</code>       | logical, indicating if (labeled) axes should be drawn.                                                       |
| <code>nmax.lab</code>   | integer indicating the number of labels which is considered too large for labeling.                          |
| <code>max.strlen</code> | positive integer giving the length to which strings are truncated in labeling.                               |
| <code>...</code>        | further graphical arguments are passed to <code>bannerplot ( )</code> and <code>text</code> .                |

**Details**

Plots the separation step at which clusters are splitted. The observations are given in the order found by the `mona` algorithm, the numbers in the `step` vector are represented as bars between the observations.

When a long bar is drawn between two observations, those observations have the same value for each variable. See chapter 7 of Kaufman and Rousseeuw (1990).

**Side Effects**

A banner is plotted on the current graphics device.

**Note**

In the banner plot, observation labels are only printed when the number of observations is limited less than `nmax.lab` (35, by default), for readability. Moreover, observation labels are truncated to maximally `max.strlen` (5) characters.

**References**

see those in `plot.agnes`.

`mona`, `mona.object`, `par`.

---

`plot.partition`

*Plot of a Partition of the Data Set*

---

**Description**

Creates plots for visualizing a `partition` object.

## Usage

```
S3 method for class 'partition'
plot(x, ask = FALSE, which.plots = NULL,
 nmax.lab = 40, max.strlen = 5, data = x$data, dist = NULL,
 stand = FALSE, lines = 2,
 shade = FALSE, color = FALSE, labels = 0, plotchar = TRUE,
 span = TRUE, xlim = NULL, ylim = NULL, main = NULL, ...)
```

## Arguments

|                                                                                        |                                                                                                                                                                                                                                   |
|----------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>                                                                         | an object of class "partition", typically created by the functions <a href="#">pam</a> , <a href="#">clara</a> , or <a href="#">fanny</a> .                                                                                       |
| <code>ask</code>                                                                       | logical; if true and <code>which.plots</code> is NULL, <code>plot.partition</code> operates in interactive mode, via <a href="#">menu</a> .                                                                                       |
| <code>which.plots</code>                                                               | integer vector or NULL (default), the latter producing both plots. Otherwise, <code>which.plots</code> must contain integers of 1 for a <i>clusplot</i> or 2 for <i>silhouette</i> .                                              |
| <code>nmax.lab</code>                                                                  | integer indicating the number of labels which is considered too large for single-name labeling the silhouette plot.                                                                                                               |
| <code>max.strlen</code>                                                                | positive integer giving the length to which strings are truncated in silhouette plot labeling.                                                                                                                                    |
| <code>data</code>                                                                      | numeric matrix with the scaled data; per default taken from the partition object <code>x</code> , but can be specified explicitly.                                                                                                |
| <code>dist</code>                                                                      | when <code>x</code> does not have a <code>diss</code> component as for <a href="#">pam</a> (*, keep.diss=FALSE), <code>dist</code> must be the dissimilarity if a <i>clusplot</i> is desired.                                     |
| <code>stand, lines, shade, color, labels, plotchar, span, xlim, ylim, main, ...</code> | All optional arguments available for the <a href="#">clusplot.default</a> function (except for the <code>diss</code> one) and graphical parameters (see <a href="#">par</a> ) may also be supplied as arguments to this function. |

## Details

When `ask=TRUE`, rather than producing each plot sequentially, `plot.partition` displays a menu listing all the plots that can be produced. If the menu is not desired but a pause between plots is still wanted, call `par(ask=TRUE)` before invoking the plot command.

The *clusplot* of a cluster partition consists of a two-dimensional representation of the observations, in which the clusters are indicated by ellipses (see [clusplot.partition](#) for more details).

The *silhouette plot* of a nonhierarchical clustering is fully described in Rousseeuw (1987) and in chapter 2 of Kaufman and Rousseeuw (1990). For each observation *i*, a bar is drawn, representing its silhouette width *s(i)*, see [silhouette](#) for details. Observations are grouped per cluster, starting with cluster 1 at the top. Observations with a large *s(i)* (almost 1) are very well clustered, a small *s(i)* (around 0) means that the observation lies between two clusters, and observations with a negative *s(i)* are probably placed in the wrong cluster.

A clustering can be performed for several values of *k* (the number of clusters). Finally, choose the value of *k* with the largest overall average silhouette width.

## Side Effects

An appropriate plot is produced on the current graphics device. This can be one or both of the following choices:

Clusplot  
Silhouette plot

### Note

In the silhouette plot, observation labels are only printed when the number of observations is less than `nmax.lab` (40, by default), for readability. Moreover, observation labels are truncated to maximally `max.strlen` (5) characters.

For more flexibility, use `plot(silhouette(x), ...)`, see [plot.silhouette](#).

### References

Rousseeuw, P.J. (1987) Silhouettes: A graphical aid to the interpretation and validation of cluster analysis. *J. Comput. Appl. Math.*, **20**, 53–65.

Further, the references in [plot.agnes](#).

### See Also

[partition.object](#), [clusplot.partition](#), [clusplot.default](#), [pam](#),  
[pam.object](#), [clara](#), [clara.object](#), [fanny](#), [fanny.object](#), [par](#).

### Examples

```
generate 25 objects, divided into 2 clusters.
x <- rbind(cbind(rnorm(10,0,0.5), rnorm(10,0,0.5)),
 cbind(rnorm(15,5,0.5), rnorm(15,5,0.5)))
plot(pam(x, 2))

Save space not keeping data in clus.object, and still clusplot() it:
data(xclara)
cx <- clara(xclara, 3, keep.data = FALSE)
cx$data # is NULL
plot(cx, data = xclara)
```

---

pltree

---

*Plot Clustering Tree of a Hierarchical Clustering*

---

### Description

`pltree()` Draws a clustering tree (“dendrogram”) on the current graphics device. We provide the `twins` method draws the tree of a `twins` object, i.e., hierarchical clustering, typically resulting from [agnes\(\)](#) or [diana\(\)](#).

### Usage

```
pltree(x, ...)
S3 method for class 'twins'
pltree(x, main = paste("Dendrogram of ", deparse(x$call)),
 labels = NULL, ylab = "Height", ...)
```

**Arguments**

|                     |                                                                                                                                                                                                 |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>      | in general, an R object for which a <code>pltree</code> method is defined; specifically, an object of class "twins", typically created by either <code>agnes()</code> or <code>diana()</code> . |
| <code>main</code>   | main title with a sensible default.                                                                                                                                                             |
| <code>labels</code> | labels to use; the default is constructed from <code>x</code> .                                                                                                                                 |
| <code>ylab</code>   | label for y-axis.                                                                                                                                                                               |
| <code>...</code>    | graphical parameters (see <code>par</code> ) may also be supplied as arguments to this function.                                                                                                |

**Details**

Creates a plot of a clustering tree given a `twins` object. The leaves of the tree are the original observations. In case of an agglomerative clustering, two branches come together at the distance between the two clusters being merged. For a divisive clustering, a branch splits up at the diameter of the cluster being splitted.

Note that currently the method function simply calls `plot(as.hclust(x), ...)`, which dispatches to `plot.hclust(.)`. If more flexible plots are needed, consider `xx <- as.dendrogram(as.hclust(x))` and plotting `xx`, see `plot.dendrogram`.

**Value**

a NULL value is returned.

**See Also**

`agnes`, `agnes.object`, `diana`, `diana.object`, `hclust`, `par`, `plot.agnes`, `plot.diana`.

**Examples**

```
data(votes.repub)
agn <- agnes(votes.repub)
pltree(agn)

dagn <- as.dendrogram(as.hclust(agn))
dagn2 <- as.dendrogram(as.hclust(agn), hang = 0.2)
op <- par(mar = par("mar") + c(0,0,0, 2)) # more space to the right
plot(dagn2, horiz = TRUE)
plot(dagn, horiz = TRUE, center = TRUE,
 nodePar = list(lab.cex = 0.6, lab.col = "forest green", pch = NA),
 main = deparse(agn$call))
par(op)
```

---

pluton

*Isotopic Composition Plutonium Batches*

---

**Description**

The `pluton` data frame has 45 rows and 4 columns, containing percentages of isotopic composition of 45 Plutonium batches.

**Usage**

```
data(pluton)
```

**Format**

This data frame contains the following columns:

**Pu238** the percentages of  $^{238}\text{Pu}$ , always less than 2 percent.

**Pu239** the percentages of  $^{239}\text{Pu}$ , typically between 60 and 80 percent (from neutron capture of Uranium,  $^{238}\text{U}$ ).

**Pu240** percentage of the plutonium 240 isotope.

**Pu241** percentage of the plutonium 241 isotope.

**Details**

Note that the percentage of plutonium-242 can be computed from the other four percentages, see the examples.

In the reference below it is explained why it is very desirable to combine these plutonium patches in three groups of similar size.

**Source**

Available as ‘pluton.dat’ from the archive of the University of Antwerpen,  
‘.../datasets/clusplot-examples.tar.gz’, no longer available.

**References**

Rousseeuw, P.J. and Kaufman, L and Trauwaert, E. (1996) Fuzzy clustering using scatter matrices, *Computational Statistics and Data Analysis* **23**(1), 135–151.

**Examples**

```
data(pluton)

hist(apply(pluton,1,sum), col = "gray") # between 94% and 100%
pu5 <- pluton
pu5$Pu242 <- 100 - apply(pluton,1,sum) # the remaining isotope.
pairs(pu5)
```

---

predict.ellipsoid    *Predict Method for Ellipsoid Objects*

---

**Description**

Compute points on the ellipsoid boundary, mostly for drawing.

**Usage**

```
predict.ellipsoid(object, n.out=201, ...)
S3 method for class 'ellipsoid'
predict(object, n.out=201, ...)
ellipsoidPoints(A, d2, loc, n.half = 201)
```

## Arguments

|                            |                                                                                                                                                                         |
|----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code>        | an object of class <code>ellipsoid</code> , typically from <code>ellipsoidhull()</code> ; alternatively any list-like object with proper components, see details below. |
| <code>n.out, n.half</code> | half the number of points to create.                                                                                                                                    |
| <code>A, d2, loc</code>    | arguments of the auxiliary <code>ellipsoidPoints</code> , see below.                                                                                                    |
| <code>...</code>           | passed to and from methods.                                                                                                                                             |

## Details

Note `ellipsoidPoints` is the workhorse function of `predict.ellipsoid` a standalone function and method for `ellipsoid` objects, see `ellipsoidhull`. The class of `object` is not checked; it must solely have valid components `loc` (length  $p$ ), the  $p \times p$  matrix `cov` (corresponding to `A`) and `d2` for the center, the shape (“covariance”) matrix and the squared average radius (or distance) or `qchisq(*, p)` quantile.

Unfortunately, this is only implemented for  $p = 2$ , currently; contributions for  $p \geq 3$  are *very welcome*.

## Value

a numeric matrix of dimension  $2 * n.out$  times  $p$ .

## See Also

`ellipsoidhull`, `volume.ellipsoid`.

## Examples

```
see also example(ellipsoidhull)

Robust vs. L.S. covariance matrix
set.seed(143)
x <- rt(200, df=3)
y <- 3*x + rt(200, df=2)
plot(x,y, main="non-normal data (N=200)")
mtext("with classical and robust cov.matrix ellipsoids")
X <- cbind(x,y)
C.ls <- cov(X) ; m.ls <- colMeans(X)
d2.99 <- qchisq(0.99, df = 2)
lines(ellipsoidPoints(C.ls, d2.99, loc=m.ls), col="green")
if(require(MASS)) {
 Cxy <- cov.rob(cbind(x,y))
 lines(ellipsoidPoints(Cxy$cov, d2 = d2.99, loc=Cxy$center), col="red")
}# MASS

|-------------|---------------------------------------|
| print.agnes | <i>Print Method for AGNES Objects</i> |
|-------------|---------------------------------------|

---

**Description**

Prints the call, agglomerative coefficient, ordering of objects and distances between merging clusters ('Height') of an `agnes` object.

This is a method for the generic `print()` function for objects inheriting from class `agnes`, see `agnes.object`.

**Usage**

```
S3 method for class 'agnes'
print(x, ...)
```

**Arguments**

|                  |                                                    |
|------------------|----------------------------------------------------|
| <code>x</code>   | an <code>agnes</code> object.                      |
| <code>...</code> | potential further arguments (required by generic). |

**See Also**

`summary.agnes` producing more output; `agnes`, `agnes.object`, `print`, `print.default`.

|-------------|---------------------------------------|
| print.clara | <i>Print Method for CLARA Objects</i> |
|-------------|---------------------------------------|

---

**Description**

Prints the best sample, medoids, clustering vector and objective function of `clara` object.

This is a method for the function `print()` for objects inheriting from class `clara`.

**Usage**

```
S3 method for class 'clara'
print(x, ...)
```

**Arguments**

|                  |                                                   |
|------------------|---------------------------------------------------|
| <code>x</code>   | a <code>clara</code> object.                      |
| <code>...</code> | potential further arguments (require by generic). |

**See Also**

`summary.clara` producing more output; `clara`, `clara.object`, `print`, `print.default`.

---

```
print.diana
```

---

*Print Method for DIANA Objects*

---

### Description

Prints the ordering of objects, diameters of splitted clusters, and divisive coefficient of a `diana` object.

This is a method for the function `print()` for objects inheriting from class `diana`.

### Usage

```
S3 method for class 'diana'
print(x, ...)
```

### Arguments

`x`                      a `diana` object.  
`...`                    potential further arguments (require by generic).

### See Also

`diana`, `diana.object`, `print`, `print.default`.

---

```
print.dissimilarity
```

---

*Print and Summary Methods for Dissimilarity Objects*

---

### Description

Print or summarize the distances and the attributes of a `dissimilarity` object.

These are methods for the functions `print()` and `summary()` for `dissimilarity` objects. See `print`, `print.default`, or `summary` for the general behavior of these.

### Usage

```
S3 method for class 'dissimilarity'
print(x, diag = NULL, upper = NULL,
 digits = getOption("digits"), justify = "none", right = TRUE, ...)
S3 method for class 'dissimilarity'
summary(object,
 digits = max(3, getOption("digits") - 2), ...)
S3 method for class 'summary.dissimilarity'
print(x, ...)
```

**Arguments**

`x, object` a dissimilarity object or a `summary.dissimilarity` one for `print.summary.dissimilarity()`.

`digits` the number of digits to use, see `print.default`.

`diag, upper, justify, right` optional arguments specifying how the triangular dissimilarity matrix is printed; see `print.dist`.

`...` potential further arguments (require by generic).

**See Also**

`daisy`, `dissimilarity.object`, `print`, `print.default`, `print.dist`.

**Examples**

```
See example(daisy)

sd <- summary(daisy(matrix(rnorm(100), 20, 5)))
sd # -> print.summary.dissimilarity(.)
str(sd)
```

---

`print.fanny`

*Print and Summary Methods for FANNY Objects*

---

**Description**

Prints the objective function, membership coefficients and clustering vector of `fanny` object.

This is a method for the function `print()` for objects inheriting from class `fanny`.

**Usage**

```
S3 method for class 'fanny'
print(x, digits = getOption("digits"), ...)
S3 method for class 'fanny'
summary(object, ...)
S3 method for class 'summary.fanny'
print(x, digits = getOption("digits"), ...)
```

**Arguments**

`x, object` a `fanny` object.

`digits` number of significant digits for printing, see `print.default`.

`...` potential further arguments (required by generic).

**See Also**

`fanny`, `fanny.object`, `print`, `print.default`.

---

`print.mona`*Print Method for MONA Objects*

---

**Description**

Prints the ordering of objects, separation steps, and used variables of a `mona` object.

This is a method for the function `print()` for objects inheriting from class `mona`.

**Usage**

```
S3 method for class 'mona'
print(x, ...)
```

**Arguments**

|                  |                                                   |
|------------------|---------------------------------------------------|
| <code>x</code>   | a <code>mona</code> object.                       |
| <code>...</code> | potential further arguments (require by generic). |

**See Also**

`mona`, `mona.object`, `print`, `print.default`.

---

`print.pam`*Print Method for PAM Objects*

---

**Description**

Prints the medoids, clustering vector and objective function of `pam` object.

This is a method for the function `print()` for objects inheriting from class `pam`.

**Usage**

```
S3 method for class 'pam'
print(x, ...)
```

**Arguments**

|                  |                                                   |
|------------------|---------------------------------------------------|
| <code>x</code>   | a <code>pam</code> object.                        |
| <code>...</code> | potential further arguments (require by generic). |

---

`ruspini`*Ruspini Data*

---

**Description**

The Ruspini data set, consisting of 75 points in four groups that is popular for illustrating clustering techniques.

**Usage**

```
data(ruspini)
```

**Format**

A data frame with 75 observations on 2 variables giving the x and y coordinates of the points, respectively.

**Source**

E. H. Ruspini (1970) Numerical methods for fuzzy clustering. *Inform. Sci.* **2**, 319–350.

**References**

see those in [agnes](#).

**Examples**

```
data(ruspini)

Plot similar to Figure 4 in Stryuf et al (1996)
Not run: plot(pam(ruspini, 4), ask = TRUE)

Plot similar to Figure 6 in Stryuf et al (1996)
plot(fanny(ruspini, 5))
```

---

`silhouette`*Compute or Extract Silhouette Information from Clustering*

---

**Description**

Compute silhouette information according to a given clustering in  $k$  clusters.

## Usage

```

silhouette(x, ...)
Default S3 method:
 silhouette(x, dist, dmatrix, ...)
S3 method for class 'partition'
silhouette(x, ...)
S3 method for class 'clara'
silhouette(x, full = FALSE, subset = NULL, ...)

sortSilhouette(object, ...)
S3 method for class 'silhouette'
summary(object, FUN = mean, ...)
S3 method for class 'silhouette'
plot(x, nmax.lab = 40, max.strlen = 5,
 main = NULL, sub = NULL, xlab = expression("Silhouette width " * s[i]),
 col = "gray", do.col.sort = length(col) > 1, border = 0,
 cex.names = par("cex.axis"), do.n.k = TRUE, do.clus.stat = TRUE, ...)

```

## Arguments

|                                     |                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>                      | an object of appropriate class; for the default method an integer vector with $k$ different integer cluster codes or a list with such an <code>x\$clustering</code> component. Note that silhouette statistics are only defined if $2 \leq k \leq n - 1$ .                                                                                                                                                           |
| <code>dist</code>                   | a dissimilarity object inheriting from class <code>dist</code> or coercible to one. If not specified, <code>dmatrix</code> must be.                                                                                                                                                                                                                                                                                  |
| <code>dmatrix</code>                | a symmetric dissimilarity matrix ( $n \times n$ ), specified instead of <code>dist</code> , which can be more efficient.                                                                                                                                                                                                                                                                                             |
| <code>full</code>                   | logical or number in $[0, 1]$ specifying if a <i>full</i> silhouette should be computed for <code>clara</code> object. When a number, say $f$ , for a random <code>sample.int</code> ( <code>n</code> , <code>size = f*n</code> ) of the data the silhouette values are computed. This requires $O((f*n)^2)$ memory, since the full dissimilarity of the (sub)sample (see <code>daisy</code> ) is needed internally. |
| <code>subset</code>                 | a subset from <code>1:n</code> , specified instead of <code>full</code> to specify the indices of the observations to be used for the silhouette computations.                                                                                                                                                                                                                                                       |
| <code>object</code>                 | an object of class <code>silhouette</code> .                                                                                                                                                                                                                                                                                                                                                                         |
| <code>...</code>                    | further arguments passed to and from methods.                                                                                                                                                                                                                                                                                                                                                                        |
| <code>FUN</code>                    | function used to summarize silhouette widths.                                                                                                                                                                                                                                                                                                                                                                        |
| <code>nmax.lab</code>               | integer indicating the number of labels which is considered too large for single-name labeling the silhouette plot.                                                                                                                                                                                                                                                                                                  |
| <code>max.strlen</code>             | positive integer giving the length to which strings are truncated in silhouette plot labeling.                                                                                                                                                                                                                                                                                                                       |
| <code>main, sub, xlab</code>        | arguments to <code>title</code> ; have a sensible non-NULL default here.                                                                                                                                                                                                                                                                                                                                             |
| <code>col, border, cex.names</code> | arguments passed <code>barplot()</code> ; note that the default used to be <code>col = heat.colors(n)</code> , <code>border = par("fg")</code> instead. <code>col</code> can also be a color vector of length $k$ for clusterwise coloring, see also <code>do.col.sort</code> :                                                                                                                                      |

`do.col.sort` logical indicating if the colors `col` should be sorted “along” the silhouette; this is useful for casewise or clusterwise coloring.

`do.n.k` logical indicating if  $n$  and  $k$  “title text” should be written.

`do.clus.stat` logical indicating if cluster size and averages should be written right to the silhouettes.

## Details

For each observation  $i$ , the *silhouette width*  $s(i)$  is defined as follows:

Put  $a(i)$  = average dissimilarity between  $i$  and all other points of the cluster to which  $i$  belongs (if  $i$  is the *only* observation in its cluster,  $s(i) := 0$  without further calculations). For all *other* clusters  $C$ , put  $d(i, C)$  = average dissimilarity of  $i$  to all observations of  $C$ . The smallest of these  $d(i, C)$  is  $b(i) := \min_C d(i, C)$ , and can be seen as the dissimilarity between  $i$  and its “neighbor” cluster, i.e., the nearest one to which it does *not* belong. Finally,

$$s(i) := \frac{b(i) - a(i)}{\max(a(i), b(i))}.$$

`silhouette.default()` is now based on C code donated by Romain Francois (the R version being still available as `cluster::silhouette.default.R`).

Observations with a large  $s(i)$  (almost 1) are very well clustered, a small  $s(i)$  (around 0) means that the observation lies between two clusters, and observations with a negative  $s(i)$  are probably placed in the wrong cluster.

## Value

`silhouette()` returns an object, `sil`, of class `silhouette` which is an  $n \times 3$  matrix with attributes. For each observation  $i$ , `sil[i, ]` contains the cluster to which  $i$  belongs as well as the neighbor cluster of  $i$  (the cluster, not containing  $i$ , for which the average dissimilarity between its observations and  $i$  is minimal), and the silhouette width  $s(i)$  of the observation. The `colnames` correspondingly are `c("cluster", "neighbor", "sil_width")`.

`summary(sil)` returns an object of class `summary.silhouette`, a list with components

`sil.summary`: numerical `summary` of the individual silhouette widths  $s(i)$ .

`clus.avg.widths`: numeric (rank 1) array of clusterwise *means* of silhouette widths where `mean = FUN` is used.

`avg.width`: the total mean `FUN(s)` where  $s$  are the individual silhouette widths.

`clus.sizes`: `table` of the  $k$  cluster sizes.

`call`: if available, the `call` creating `sil`.

`Ordered`: logical identical to `attr(sil, "Ordered")`, see below.

`sortSilhouette(sil)` orders the rows of `sil` as in the silhouette plot, by cluster (increasingly) and decreasing silhouette width  $s(i)$ .

`attr(sil, "Ordered")` is a logical indicating if `sil` is ordered as by `sortSilhouette()`. In that case, `rownames(sil)` will contain case labels or numbers, and `attr(sil, "iOrd")` the ordering index vector.

## Note

While `silhouette()` is *intrinsic* to the `partition` clusterings, and hence has a (trivial) method for these, it is straightforward to get silhouettes from hierarchical clusterings from `silhouette.default()` with `cutree()` and distance as input.

By default, for `clara()` partitions, the silhouette is just for the best random *subset* used. Use `full = TRUE` to compute (and later possibly plot) the full silhouette.

`partition.object`, `plot.partition`.

## Examples

```
data(ruspini)
pr4 <- pam(ruspini, 4)
str(si <- silhouette(pr4))
(ssi <- summary(si))
plot(si) # silhouette plot
plot(si, col = c("red", "green", "blue", "purple")) # with cluster-wise coloring

si2 <- silhouette(pr4$clustering, dist(ruspini, "canberra"))
summary(si2) # has small values: "canberra"'s fault
plot(si2, nmax= 80, cex.names=0.6)

op <- par(mfrow= c(3,2), oma= c(0,0, 3, 0),
 mgp= c(1.6, .8, 0), mar= .1+c(4,2,2,2))
for(k in 2:6)
 plot(silhouette(pam(ruspini, k=k)), main = paste("k = ",k), do.n.k=FALSE)
mtext("PAM(Ruspini) as in Kaufman & Rousseeuw, p.101",
 outer = TRUE, font = par("font.main"), cex = par("cex.main")); frame()

the same with cluster-wise colours:
c6 <- c("tomato", "forest green", "dark blue", "purple2", "goldenrod4", "gray20")
for(k in 2:6)
 plot(silhouette(pam(ruspini, k=k)), main = paste("k = ",k), do.n.k=FALSE,
 col = c6[1:k])
par(op)

clara(): standard silhouette is just for the best random subset
data(xclara)
set.seed(7)
str(xclk <- xclara[sample(nrow(xclara), size = 1000) ,]) # rownames == indices
cl3 <- clara(xclk, 3)
plot(silhouette(cl3)) # only of the "best" subset of 46
The full silhouette: internally needs large (36 MB) dist object:
sf <- silhouette(cl3, full = TRUE) ## this is the same as
s.full <- silhouette(cl3$clustering, daisy(xclk))
stopifnot(all.equal(sf, s.full, check.attributes = FALSE, tolerance = 0))
color dependent on original "3 groups of each 1000": % __FIXME ??__
```

```

plot(sf, col = 2+ as.integer(names(cl3$clustering)) %% 1000,
 main ="plot(silhouette(clara(.), full = TRUE))")

Silhouette for a hierarchical clustering:
ar <- agnes(ruspini)
si3 <- silhouette(cutree(ar, k = 5), # k = 4 gave the same as pam() above
 daisy(ruspini))
plot(si3, nmax = 80, cex.names = 0.5)
2 groups: Agnes() wasn't too good:
si4 <- silhouette(cutree(ar, k = 2), daisy(ruspini))
plot(si4, nmax = 80, cex.names = 0.5)

```

sizeDiss

*Sample Size of Dissimilarity Like Object***Description**

Returns the number of observations (*sample size*) corresponding to a dissimilarity like object, or equivalently, the number of rows or columns of a matrix when only the lower or upper triangular part (without diagonal) is given.

It is nothing else but the inverse function of  $f(n) = n(n-1)/2$ .

**Usage**

```
sizeDiss(d)
```

**Arguments**

`d` any R object with length (typically)  $n(n-1)/2$ .

**Value**

a number;  $n$  if `length(d) == n(n-1)/2`, NA otherwise.

**See Also**

[dissimilarity.object](#) and also [as.dist](#) for class dissimilarity and dist objects which have a `Size` attribute.

**Examples**

```

sizeDiss(1:10) # 5, since 10 == 5 * (5 - 1) / 2
sizeDiss(1:9) # NA

n <- 1:100
stopifnot(n == sapply(n*(n-1)/2, function(n) sizeDiss(logical(n))))

```

---

`summary.agnes`*Summary Method for 'agnes' Objects*

---

**Description**

Returns (and prints) a summary list for an `agnes` object. Printing gives more output than the corresponding `print.agnes` method.

**Usage**

```
S3 method for class 'agnes'
summary(object, ...)
S3 method for class 'summary.agnes'
print(x, ...)
```

**Arguments**

`x, object`      a `agnes` object.  
`...`            potential further arguments (require by generic).

**See Also**

`agnes`, `agnes.object`.

**Examples**

```
data(agriculture)
summary(agnes(agriculture))
```

---

`summary.clara`*Summary Method for 'clara' Objects*

---

**Description**

Returns (and prints) a summary list for a `clara` object. Printing gives more output than the corresponding `print.clara` method.

**Usage**

```
S3 method for class 'clara'
summary(object, ...)
S3 method for class 'summary.clara'
print(x, ...)
```

**Arguments**

`x, object`      a `clara` object.  
`...`            potential further arguments (require by generic).

**See Also**

[clara.object](#)

**Examples**

```
generate 2000 objects, divided into 5 clusters.
set.seed(47)
x <- rbind(cbind(rnorm(400, 0,4), rnorm(400, 0,4)),
 cbind(rnorm(400,10,8), rnorm(400,40,6)),
 cbind(rnorm(400,30,4), rnorm(400, 0,4)),
 cbind(rnorm(400,40,4), rnorm(400,20,2)),
 cbind(rnorm(400,50,4), rnorm(400,50,4))
)
clx5 <- clara(x, 5)
Mis'classification' table:

table(rep(1:5, rep(400,5)), clx5$clust) # -> 1 "error"
summary(clx5)

Graphically:
par(mfrow = c(3,1), mgp = c(1.5, 0.6, 0), mar = par("mar") - c(0,0,2,0))

plot(x, col = rep(2:6, rep(400,5)))
plot(clx5)
```

---

summary.diana

*Summary Method for 'diana' Objects*

---

**Description**

Returns (and prints) a summary list for a diana object.

**Usage**

```
S3 method for class 'diana'
summary(object, ...)
S3 method for class 'summary.diana'
print(x, ...)
```

**Arguments**

`x, object`      a [diana](#) object.

`...`            potential further arguments (require by generic).

**See Also**

[diana](#), [diana.object](#).

---

`summary.mona`*Summary Method for 'mona' Objects*

---

**Description**

Returns (and prints) a summary list for a `mona` object.

**Usage**

```
S3 method for class 'mona'
summary(object, ...)
S3 method for class 'summary.mona'
print(x, ...)
```

**Arguments**

`x, object`      a [mona](#) object.  
`...`            potential further arguments (require by generic).

**See Also**

[mona](#), [mona.object](#).

---

`summary.pam`*Summary Method for PAM Objects*

---

**Description**

Summarize a [pam](#) object and return an object of class `summary.pam`. There's a [print](#) method for the latter.

**Usage**

```
S3 method for class 'pam'
summary(object, ...)
S3 method for class 'summary.pam'
print(x, ...)
```

**Arguments**

`x, object`      a [pam](#) object.  
`...`            potential further arguments (require by generic).

**See Also**

[pam](#), [pam.object](#).

---

|              |                                       |
|--------------|---------------------------------------|
| twins.object | <i>Hierarchical Clustering Object</i> |
|--------------|---------------------------------------|

---

**Description**

The objects of class "twins" represent an agglomerative or divisive (polythetic) hierarchical clustering of a dataset.

**Value**

See [agnes.object](#) and [diana.object](#) for details.

**GENERATION**

This class of objects is returned from `agnes` or `diana`.

**METHODS**

The "twins" class has a method for the following generic function: `pltree`.

**INHERITANCE**

The following classes inherit from class "twins": "agnes" and "diana".

**See Also**

[agnes,diana](#).

---

|                  |                                             |
|------------------|---------------------------------------------|
| volume.ellipsoid | <i>Compute the Volume (of an Ellipsoid)</i> |
|------------------|---------------------------------------------|

---

**Description**

Compute the volume of geometric R object. This is a generic function and has a method for `ellipsoid` objects (typically resulting from [ellipsoidhull\(\)](#)).

**Usage**

```
volume(object, ...)
S3 method for class 'ellipsoid'
volume(object, log = FALSE, ...)
```

**Arguments**

|                     |                                                                                                                                                                     |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code> | an R object the volume of which is wanted; for the <code>ellipsoid</code> method, an object of that class (see <a href="#">ellipsoidhull</a> or the example below). |
| <code>log</code>    | <a href="#">logical</a> indicating if the volume should be returned in log scale. Maybe needed in largish dimensions.                                               |
| <code>...</code>    | potential further arguments of methods, e.g. <code>log</code> .                                                                                                     |

**Value**

a number, the volume  $V$  (or  $\log(V)$  if `log = TRUE`) of the given object.

**Author(s)**

Martin Maechler (2002, extracting from former `clusplot` code); Keefe Murphy (2019) provided code for dimensions  $d > 2$ .

**See Also**

`ellipsoidhull` for spanning ellipsoid computation.

**Examples**

```
example(ellipsoidhull) # which defines 'ellipsoid' object <namefoo>

myEl <- structure(list(cov = rbind(c(3,1),1:2), loc = c(0,0), d2 = 10),
 class = "ellipsoid")
volume(myEl) # i.e. "area" here (d = 2)
myEl # also mentions the "volume"

set.seed(1)
d5 <- matrix(rt(500, df=3), 100, 5)
e5 <- ellipsoidhull(d5)
```

---

votes.repub

*Votes for Republican Candidate in Presidential Elections*

---

**Description**

A data frame with the percents of votes given to the republican candidate in presidential elections from 1856 to 1976. Rows represent the 50 states, and columns the 31 elections.

**Usage**

```
data(votes.repub)
```

**Source**

S. Peterson (1973): *A Statistical History of the American Presidential Elections*. New York: Frederick Ungar Publishing Co.

Data from 1964 to 1976 is from R. M. Scammon, *American Votes 12*, Congressional Quarterly.

xclara

*Bivariate Data Set with 3 Clusters***Description**

An artificial data set consisting of 3000 points in 3 quite well-separated clusters.

**Usage**

```
data(xclara)
```

**Format**

A data frame with 3000 observations on 2 numeric variables (named V1 and V2) giving the  $x$  and  $y$  coordinates of the points, respectively.

**Note**

Our version of the `xclara` is slightly more rounded than the one from `read.table("xclara.dat")` and the relative difference measured by `all.equal` is  $1.15\text{e-}7$  for V1 and  $1.17\text{e-}7$  for V2 which suggests that our version has been the result of a `options(digits = 7)` formatting.

Previously (before May 2017), it was claimed the three cluster were each of size 1000, which is clearly wrong. `pam(*, 3)` gives cluster sizes of 899, 1149, and 952, which apart from seven “outliers” (or “mislabellings”) correspond to observation indices  $\{1 : 900\}$ ,  $\{901 : 2050\}$ , and  $\{2051 : 3000\}$ , see the example.

**Source**

Sample data set accompanying the reference below (file ‘xclara.dat’ in side ‘clus\_examples.tar.gz’).

**References**

Anja Struyf, Mia Hubert & Peter J. Rousseeuw (1996) Clustering in an Object-Oriented Environment. *Journal of Statistical Software* **1**. doi: [10.18637/jss.v001.i04](https://doi.org/10.18637/jss.v001.i04)

**Examples**

```
Visualization: Assuming groups are defined as {1:1000}, {1001:2000}, {2001:3000}
plot(xclara, cex = 3/4, col = rep(1:3, each=1000))
p.ID <- c(78, 1411, 2535) ## PAM's medoid indices == pam(xclara, 3)$id.med
text(xclara[p.ID,], labels = 1:3, cex=2, col=1:3)

px <- pam(xclara, 3) ## takes ~2 seconds
cxcl <- px$clustering ; iCl <- split(seq_along(cxcl), cxcl)
boxplot(iCl, range = 0.7, horizontal=TRUE,
 main = "Indices of the 3 clusters of pam(xclara, 3)")

Look more closely now:
bxCl <- boxplot(iCl, range = 0.7, plot=FALSE)
We see 3 + 2 + 2 = 7 clear "outlier"s or "wrong group" observations:
with(bxCl, rbind(out, group))
```

```
out 1038 1451 1610 30 327 562 770
group 1 1 1 2 2 3 3
Apart from these, what are the robust ranges of indices? -- Robust range:
t(iR <- bxCl$stats[c(1,5),])
1 900
901 2050
2051 3000
gc <- adjustcolor("gray20",1/2)
abline(v = iR, col = gc, lty=3)
axis(3, at = c(0, iR[2,]), padj = 1.2, col=gc, col.axis=gc)
```

## Chapter 21

# The codetools package

---

checkUsage

*Check R Code for Possible Problems*

---

### Description

Check R code for possible problems.

### Usage

```
checkUsage(fun, name = "<anonymous>", report = cat, all = FALSE,
 suppressLocal = FALSE, suppressParamAssigns = !all,
 suppressParamUnused = !all, suppressFundefMismatch = FALSE,
 suppressLocalUnused = FALSE, suppressNoLocalFun = !all,
 skipWith = FALSE, suppressUndefined = dfltSuppressUndefined,
 suppressPartialMatchArgs = TRUE)
checkUsageEnv(env, ...)
checkUsagePackage(pack, ...)
```

### Arguments

|                      |                                                           |
|----------------------|-----------------------------------------------------------|
| fun                  | closure.                                                  |
| name                 | character; name of closure.                               |
| env                  | environment containing closures to check.                 |
| pack                 | character naming package to check.                        |
| ...                  | options to be passed to checkUsage.                       |
| report               | function to use to report possible problems.              |
| all                  | logical; report all possible problems if TRUE.            |
| suppressLocal        | suppress all local variable warnings.                     |
| suppressParamAssigns | suppress warnings about assignments to formal parameters. |
| suppressParamUnused  | suppress warnings about unused formal parameters.         |

```

suppressFundefMismatch
 suppress warnings about multiple local function definitions with different formal
 argument lists
suppressLocalUnused
 suppress warnings about unused local variables
suppressNoLocalFun
 suppress warnings about using local variables as functions with no apparent
 local function definition
skipWith logical; if true, do not examine code portion of with expressions.
suppressUndefined
 suppress warnings about undefined global functions and variables.
suppressPartialMatchArgs
 suppress warnings about partial argument matching

```

### Details

`checkUsage` checks a single R closure. Options control which possible problems to report. The default settings are moderately verbose. A first pass might use `suppressLocal=TRUE` to suppress all information related to local variable usage. The `suppressXYZ` values can either be scalar logicals or character vectors; then they are character vectors they only suppress problem reports for the variables with names in the vector.

`checkUsageEnv` and `checkUsagePackage` are convenience functions that apply `checkUsage` to all closures in an environment or a package. `checkUsagePackage` requires that the package be loaded. If the package has a name space then the internal name space frame is checked.

### Author(s)

Luke Tierney

### Examples

```

checkUsage(checkUsage)
checkUsagePackage("codetools", all=TRUE)
Not run: checkUsagePackage("base", suppressLocal=TRUE)

```

---

codetools

*Low Level Code Analysis Tools for R*

---

### Description

These functions provide some tools for analysing R code. Mainly intended to support the other tools in this package and byte code compilation.

### Usage

```

collectLocals(e, collect)
collectUsage(fun, name = "<anonymous>", ...)
constantFold(e, env = NULL, fail = NULL)
findFuncLocals(formals, body)
findLocals(e, envir = .BaseEnv)

```

```
findLocalsList(elist, envir = .BaseEnv)
flattenAssignment(e)
getAssignedVar(e)
isConstantValue(v, w)
makeCodeWalker(..., handler, call, leaf)
makeLocalsCollector(..., leaf, handler, isLocal, exit, collect)
makeUsageCollector(fun, ..., name, enterLocal, enterGlobal, enterInternal,
 startCollectLocals, finishCollectLocals, warn,
 signal)
walkCode(e, w = makeCodeWalker())
```

### Arguments

|                     |                                 |
|---------------------|---------------------------------|
| e                   | R expression.                   |
| elist               | list of R expressions.          |
| v                   | R object.                       |
| fun                 | closure.                        |
| formals             | formal arguments of a closure.  |
| body                | body of a closure.              |
| name                | character.                      |
| env                 | character.                      |
| envir               | environment.                    |
| w                   | code walker.                    |
| ...                 | extra elements for code walker. |
| collect             | function.                       |
| fail                | function.                       |
| handler             | function.                       |
| call                | function.                       |
| leaf                | function.                       |
| isLocal             | function.                       |
| exit                | function.                       |
| enterLocal          | function.                       |
| enterGlobal         | function.                       |
| enterInternal       | function.                       |
| startCollectLocals  | function.                       |
| finishCollectLocals | function.                       |
| warn                | function.                       |
| signal              | function.                       |

### Author(s)

Luke Tierney

---

|             |                                                              |
|-------------|--------------------------------------------------------------|
| findGlobals | <i>Find Global Functions and Variables Used by a Closure</i> |
|-------------|--------------------------------------------------------------|

---

**Description**

Finds global functions and variables used by a closure.

**Usage**

```
findGlobals(fun, merge = TRUE)
```

**Arguments**

|       |                                     |
|-------|-------------------------------------|
| fun   | function object; usually a closure. |
| merge | logical                             |

**Details**

The result is an approximation. R semantics only allow variables that might be local to be identified (and event that assumes no use of `assign` and `rm`).

**Value**

Character vector if `merge` is true; otherwise, a list with `functions` and `variables` character vector components. Character vectors are of length zero For non-closures.

**Author(s)**

Luke Tierney

**Examples**

```
findGlobals(findGlobals)
findGlobals(findGlobals, merge = FALSE)
```

---

|          |                                                        |
|----------|--------------------------------------------------------|
| showTree | <i>Print Lisp-Style Representation of R Expression</i> |
|----------|--------------------------------------------------------|

---

**Description**

Prints a Lisp-style representation of R expression. This can be useful for understanding how some things are parsed.

**Usage**

```
showTree(e, write = cat)
```

**Arguments**

|       |                                               |
|-------|-----------------------------------------------|
| e     | R expression.                                 |
| write | function of one argument to write the result. |

**Author(s)**

Luke Tierney

**Examples**

```
showTree(quote(-3))
showTree(quote("x"<-1))
showTree(quote("f"(x)))
```

## Chapter 22

# The foreign package

---

`lookup.xport`

*Lookup Information on a SAS XPORT Format Library*

---

### Description

Scans a file as a SAS XPORT format library and returns a list containing information about the SAS library.

### Usage

```
lookup.xport (file)
```

### Arguments

|                   |                                                                                             |
|-------------------|---------------------------------------------------------------------------------------------|
| <code>file</code> | character variable with the name of the file to read. The file must be in SAS XPORT format. |
|-------------------|---------------------------------------------------------------------------------------------|

### Value

A list with one component for each dataset in the XPORT format library.

### Author(s)

Saikat DebRoy

### References

SAS Technical Support document TS-140: “The Record Layout of a Data Set in SAS Transport (XPORT) Format” available as <https://support.sas.com/techsup/technote/ts140.pdf>.

### See Also

### Examples

```
Not run: ## no XPORT file is installed.
lookup.xport("test.xpt")

End(Not run)
```

---

read.arff

*Read Data from ARFF Files*

---

### Description

Reads data from Weka Attribute-Relation File Format (ARFF) files.

### Usage

```
read.arff(file)
```

### Arguments

`file` a character string with the name of the ARFF file to read from, or a [connection](#) which will be opened if necessary, and if so closed at the end of the function call.

### Value

A data frame containing the data from the ARFF file.

### References

Attribute-Relation File Format [https://waikato.github.io/weka-wiki/formats\\_and\\_processing/arff/](https://waikato.github.io/weka-wiki/formats_and_processing/arff/).

### See Also

[write.arff](#); functions `write.arff` and `read.arff` in package **RWeka** which provide some support for logicals via conversion to or from factors.

---

read.dbf

*Read a DBF File*

---

### Description

The function reads a DBF file into a data frame, converting character fields to factors, and trying to respect NULL fields.

The DBF format is documented but not much adhered to. There is no guarantee this will read all DBF files.

### Usage

```
read.dbf(file, as.is = FALSE)
```

## Arguments

|                    |                                                       |
|--------------------|-------------------------------------------------------|
| <code>file</code>  | name of input file                                    |
| <code>as.is</code> | should character vectors not be converted to factors? |

## Details

DBF is the extension used for files written for the 'XBASE' family of database languages, 'covering the dBase, Clipper, FoxPro, and their Windows equivalents Visual dBase, Visual Objects, and Visual FoxPro, plus some older products' (<https://www.clicketyclick.dk/databases/xbase/format/>). Most of these follow the file structure used by Ashton-Tate's dBase II, III or 4 (later owned by Borland).

`read.dbf` is based on C code from <http://shapelib.maptools.org/> which implements the 'XBASE' specification. It can convert fields of type "L" (logical), "N" and "F" (numeric and float) and "D" (dates): all other field types are read as-is as character vectors. A numeric field is read as an R integer vector if it is encoded to have no decimals, otherwise as a numeric vector. However, if the numbers are too large to fit into an integer vector, it is changed to numeric. Note that is possible to read integers that cannot be represented exactly even as doubles: this sometimes occurs if IDs are incorrectly coded as numeric.

## Value

A data frame of data from the DBF file; note that the field names are adjusted to use in R using `make.names` (`unique=TRUE`).

There is an attribute "data\_type" giving the single-character dBase types for each field.

## Note

Not to be able to read a particular 'DBF' file is not a bug: this is a convenience function especially for shapefiles.

## Author(s)

Nicholas Lewin-Koh and Roger Bivand; shapelib by Frank Warmerdam

## References

<http://shapelib.maptools.org/>.

## See Also

`write.dbf`

## Examples

```
x <- read.dbf(system.file("files/sids.dbf", package="foreign"))[1:]
str(x)
summary(x)
```

read.dta

*Read Stata Binary Files***Description**

Reads a file in Stata version 5–12 binary format into a data frame.

Frozen: will not support Stata formats after 12.

**Usage**

```
read.dta(file, convert.dates = TRUE, convert.factors = TRUE,
 missing.type = FALSE,
 convert.underscore = FALSE, warn.missing.labels = TRUE)
```

**Arguments**

`file` a filename or URL as a character string.

`convert.dates` Convert Stata dates to Date class, and date-times to POSIXct class?

`convert.factors` Use Stata value labels to create factors? (Version 6.0 or later).

`missing.type` For version 8 or later, store information about different types of missing data?

`convert.underscore` Convert "\_" in Stata variable names to "." in R names?

`warn.missing.labels` Warn if a variable is specified with value labels and those value labels are not present in the file.

**Details**

If the filename appears to be a URL (of schemes 'http:', 'ftp:' or 'https:') the URL is first downloaded to a temporary file and then read. ('https:' is only supported on some platforms.)

The variables in the Stata data set become the columns of the data frame. Missing values are correctly handled. The data label, variable labels, timestamp, and variable/dataset characteristics are stored as attributes of the data frame.

By default Stata dates (%d and %td formats) are converted to R's Date class, and variables with Stata value labels are converted to factors. Ordinarily, `read.dta` will not convert a variable to a factor unless a label is present for every level. Use `convert.factors = NA` to override this. In any case the value label and format information is stored as attributes on the returned data frame. Stata's date formats are sketchily documented: if necessary use `convert.dates = FALSE` and examine the attributes to work out how to post-process the dates.

Stata 8 introduced a system of 27 different missing data values. If `missing.type` is TRUE a separate list is created with the same variable names as the loaded data. For string variables the list value is NULL. For other variables the value is NA where the observation is not missing and 0–26 when the observation is missing. This is attached as the "missing" attribute of the returned value.

The default file format for Stata 13, `format-115`, is substantially different from those for Stata 5–12.

**Value**

A data frame with attributes. These will include "datalabel", "time.stamp", "formats", "types", "val.labels", "var.labels" and "version" and may include "label.table" and "expansion.table". Possible versions are 5, 6, 7, -7 (Stata 7SE, 'format-111'), 8 (Stata 8 and 9, 'format-113'), 10 (Stata 10 and 11, 'format-114'), and 12 (Stata 12, 'format-115').

The value labels in attribute "val.labels" name a table for each variable, or are an empty string. The tables are elements of the named list attribute "label.table": each is an integer vector with names.

**Author(s)**

Thomas Lumley and R-core members: support for value labels by Brian Quistorff.

**References**

Stata Users Manual (versions 5 & 6), Programming manual (version 7), or online help (version 8 and later) describe the format of the files. Or directly at [https://www.stata.com/help.cgi?dta\\_114](https://www.stata.com/help.cgi?dta_114) and [https://www.stata.com/help.cgi?dta\\_113](https://www.stata.com/help.cgi?dta_113), but note that these have been changed since first published.

**See Also**

Different approaches are available in package **memisc** (see its help for `Stata.file`), function `read_dta` in package **haven** and package **readstata13**.

`write.dta`, `attributes`, `Date`, `factor`

**Examples**

```
write.dta(swiss, swissfile <- tempfile())
read.dta(swissfile)
```

---

`read.epiinfo`*Read Epi Info Data Files*

---

**Description**

Reads data files in the .REC format used by Epi Info versions 6 and earlier and by EpiData. Epi Info is a public domain database and statistics package produced by the US Centers for Disease Control and EpiData is a freely available data entry and validation system.

**Usage**

```
read.epiinfo(file, read.deleted = FALSE, guess.broken.dates = FALSE,
 thisyear = NULL, lower.case.names = FALSE)
```

## Arguments

|                                 |                                                                               |
|---------------------------------|-------------------------------------------------------------------------------|
| <code>file</code>               | A filename, URL, or connection.                                               |
| <code>read.deleted</code>       | Deleted records are read if TRUE, omitted if FALSE or replaced with NA if NA. |
| <code>guess.broken.dates</code> | Attempt to convert dates with 0 or 2 digit year information (see 'Details').  |
| <code>thisyear</code>           | A 4-digit year to use for dates with no year. Defaults to the current year.   |
| <code>lower.case.names</code>   | Convert variable names to lowercase?                                          |

## Details

Epi Info allows dates to be specified with no year or with a 2 or 4 digits. Dates with four-digit years are always converted to `Date` class. With the `guess.broken.dates` option the function will attempt to convert two-digit years using the operating system's default method (see [Date](#)) and will use the current year or the `thisyear` argument for dates with no year information.

If `read.deleted` is TRUE the "deleted" attribute of the data frame indicates the deleted records.

## Value

A data frame.

## Note

Some later versions of Epi Info use the Microsoft Access file format to store data. That may be readable with the **RODBC** package.

## Examples

```
Not run: ## That file is not available
read.epiinfo("oswego.rec", guess.broken.dates = TRUE, thisyear = "1972")

End(Not run)
```

---

`read.mtp`*Read a Minitab Portable Worksheet*

---

## Description

Return a list with the data stored in a file as a Minitab Portable Worksheet.

## Usage

```
read.mtp(file)
```

## Arguments

|                   |                                                                                                              |
|-------------------|--------------------------------------------------------------------------------------------------------------|
| <code>file</code> | character variable with the name of the file to read. The file must be in Minitab Portable Worksheet format. |
|-------------------|--------------------------------------------------------------------------------------------------------------|

## Value

A list with one component for each column, matrix, or constant stored in the Minitab worksheet.

## Note

This function was written around 1990 for the format current then. Later versions of Minitab appear to have added to the format.

## Examples

```
Not run:
read.mtp("ex1-10.mtp")

End (Not run)
```

---

read.octave

*Read Octave Text Data Files*

---

### Description

Read a file in Octave text data format into a list.

### Usage

```
read.octave(file)
```

### Arguments

`file` a character string with the name of the file to read.

### Details

This function is used to read in files in Octave text data format, as created by `save -text` in Octave. It knows about most of the common types of variables, including the standard atomic (real and complex scalars, matrices, and  $N$ -d arrays, strings, ranges, and boolean scalars and matrices) and recursive (structs, cells, and lists) ones, but has no guarantee to read all types. If a type is not recognized, a warning indicating the unknown type is issued, it is attempted to skip the unknown entry, and `NULL` is used as its value. Note that this will give incorrect results, and maybe even errors, in the case of unknown recursive data types.

As Octave can read MATLAB binary files, one can make the contents of such files available to R by using Octave's load and save (as text) facilities as an intermediary step.

### Value

A list with one named component for each variable in the file.

read.spss

*Read an SPSS Data File*

---

### Description

`read.spss` reads a file stored by the SPSS `save` or `export` commands.

This was originally written in 2000 and has limited support for changes in SPSS formats since (which have not been many).

## Usage

```
read.spss(file, use.value.labels = TRUE, to.data.frame = FALSE,
 max.value.labels = Inf, trim.factor.names = FALSE,
 trim_values = TRUE, reencode = NA, use.missings = to.data.frame,
 sub = ".", add.undeclared.levels = c("sort", "append", "no"),
 duplicated.value.labels = c("append", "condense"),
 duplicated.value.labels.infix = "_duplicated_", ...)
```

## Arguments

|                                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|--------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>file</code>                    | character string: the name of the file or URL to read.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <code>use.value.labels</code>        | logical: convert variables with value labels into R factors with those levels? This is only done if there are at least as many labels as values of the variable (when values without a matching label are returned as NA).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <code>to.data.frame</code>           | logical: return a data frame?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>max.value.labels</code>        | logical: only variables with value labels and at most this many unique values will be converted to factors if TRUE.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>trim.factor.names</code>       | logical: trim trailing spaces from factor levels?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| <code>reencode</code>                | logical: should character strings be re-encoded to the current locale. The default, NA, means to do so in UTF-8 or latin-1 locales, only. Alternatively a character string specifying an encoding to assume for the file.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>use.missings</code>            | logical: should information on user-defined missing values be used to set the corresponding values to NA?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>sub</code>                     | character string: If not NA it is used by <code>iconv</code> to replace any non-convertible bytes in character/factor input. Default is ".". For back compatibility with <b>foreign</b> versions <= 0.8-68 use <code>sub=NA</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <code>add.undeclared.levels</code>   | character: specify how to handle variables with at least one value label and further non-missing values that have no value label (like a factor levels in R). For "sort" (the default) it adds undeclared factor levels to the already declared levels (and labels) and sort them according to level, for "append" it appends undeclared factor levels to declared levels (and labels) without sorting, and for "no" this does not convert to factor in case of numeric SPSS levels (not labels), and still converts to factor if the SPSS levels are characters and <code>to.data.frame=TRUE</code> . For back compatibility with <b>foreign</b> versions <= 0.8-68 use <code>add.undeclared.levels="no"</code> (not recommended as this may convert some values with missing corresponding value labels to NA). |
| <code>duplicated.value.labels</code> | character: what to do with duplicated value labels for different levels. For "append" (the default), the first original value label is kept while further duplicated labels are renamed to <code>paste0(label, duplicated.value.labels.infix, level)</code> , for "condense", all levels with identical labels are condensed into exactly the first of these levels in R. Back compatibility with <b>foreign</b> versions <= 0.8-68 is not given as R versions >= 3.4.0 no longer support duplicated factor labels.                                                                                                                                                                                                                                                                                               |

```

duplicated.value.labels.infix
 character: the infix used for labels of factor levels with du-
 plicated value labels in SPSS (default "_duplicated_") if
 duplicated.value.labels="append".
...
 passed to as.data.frame if to.data.frame = TRUE.

```

## Details

This uses modified code from the PSPP project (<http://www.gnu.org/software/pspp/> for reading the SPSS formats.

If the filename appears to be a URL (of schemes 'http:', 'ftp:' or 'https:') the URL is first downloaded to a temporary file and then read. ('https:' is supported where supported by `download.file` with its current default method.)

Occasionally in SPSS, value labels will be added to some values of a continuous variable (e.g. to distinguish different types of missing data), and you will not want these variables converted to factors. By setting `max.value.labels` you can specify that variables with a large number of distinct values are not converted to factors even if they have value labels.

If SPSS variable labels are present, they are returned as the `"variable.labels"` attribute of the answer.

Fixed length strings (including value labels) are padded on the right with spaces by SPSS, and so are read that way by R. The default argument `trim_values=TRUE` causes trailing spaces to be ignored when matching to value labels, as examples have been seen where the strings and the value labels had different amounts of padding. See the examples for `sub` for ways to remove trailing spaces in character data.

URL <https://docs.microsoft.com/en-us/windows/win32/intl/code-page-identifiers> provides a list of translations from Windows codepage numbers to encoding names that `iconv` is likely to know about and so suitable values for `reencode`. Automatic re-encoding is attempted for apparent codepages of 200 or more in a UTF-8 or latin-1 locale: some other high-numbered codepages can be re-encoded on most systems, but the encoding names are platform-dependent (see `iconvlist`).

## Value

A list (or optionally a data frame) with one component for each variable in the saved data set.

If what looks like a Windows codepage was recorded in the SPSS file, it is attached (as a number) as attribute `"codepage"` to the result.

There may be attributes `"label.table"` and `"variable.labels"`. Attribute `"label.table"` is a named list of value labels with one element per variable, either `NULL` or a named character vector. Attribute `"variable.labels"` is a named character vector with names the short variable names and elements the long names.

If there are user-defined missing values, there will be a attribute `"Missings"`. This is a named list with one list element per variable. Each element has an element `type`, a length-one character vector giving the type of missingness, and may also have an element `value` with the values corresponding to missingness. This is a complex subject (where the R and C source code for `read.spss` is the main documentation), but the simplest cases are types `"one"`, `"two"` and `"three"` with a corresponding number of (real or string) values whose labels can be found from the `"label.table"` attribute. Other possibilities are a finite or semi-infinite range, possibly plus a single value. See also [http://www.gnu.org/software/pspp/manual/html\\_node/Missing-Observations.html#Missing-Observations](http://www.gnu.org/software/pspp/manual/html_node/Missing-Observations.html#Missing-Observations).

**Note**

If SPSS value labels are converted to factors the underlying numerical codes will not in general be the same as the SPSS numerical values, since the numerical codes in R are always 1, 2, 3, ...

You may see warnings about the file encoding for SPSS save files: it is possible such files contain non-ASCII character data which need re-encoding. The most common occurrence is Windows codepage 1252, a superset of Latin-1. The encoding is recorded (as an integer) in attribute "codepage" of the result if it looks like a Windows codepage. Automatic re-encoding is done only in UTF-8 and latin-1 locales: see argument `reencode`.

**Author(s)**

Saikat DebRoy and the R-core team

**See Also**

A different interface also based on the PSPP codebase is available in package **memisc**: see its help for `spss.system.file`.

**Examples**

```
(sav <- system.file("files", "electric.sav", package = "foreign"))
dat <- read.spss(file=sav)
str(dat) # list structure with attributes

dat <- read.spss(file=sav, to.data.frame=TRUE)
str(dat) # now a data.frame

Now we use an example file that is not very well structured and
hence may need some special treatment with appropriate argument settings.
Expect lots of warnings as value labels (corresponding to R factor labels) are uncom
and an unsupported long string variable is present in the data
(sav <- system.file("files", "testdata.sav", package = "foreign"))

Examples for add.undeclared.levels:
add.undeclared.levels = "sort" (default):
x.sort <- read.spss(file=sav, to.data.frame = TRUE)
add.undeclared.levels = "append":
x.append <- read.spss(file=sav, to.data.frame = TRUE,
 add.undeclared.levels = "append")
add.undeclared.levels = "no":
x.no <- read.spss(file=sav, to.data.frame = TRUE,
 add.undeclared.levels = "no")

levels(x.sort$factor_n_undeclared)
levels(x.append$factor_n_undeclared)
str(x.no$factor_n_undeclared)

Examples for duplicated.value.labels:
duplicated.value.labels = "append" (default)
x.append <- read.spss(file=sav, to.data.frame=TRUE)
duplicated.value.labels = "condense"
x.condense <- read.spss(file=sav, to.data.frame=TRUE,
 duplicated.value.labels = "condense")
```

```

levels(x.append$factor_n_duplicated)
levels(x.condense$factor_n_duplicated)

as.numeric(x.append$factor_n_duplicated)
as.numeric(x.condense$factor_n_duplicated)

Long Strings (>255 chars) are imported in consecutive separate variables
(see warning about subtype 14):
x <- read.spss(file=sav, to.data.frame=TRUE, stringsAsFactors=FALSE)

cat.long.string <- function(x, w=70) cat(paste(strwrap(x, width=w), "\n"))

first part: x$string_500:
cat.long.string(x$string_500)
second part: x$STRIN0:
cat.long.string(x$STRIN0)
complete long string:
long.string <- apply(x[,c("string_500", "STRIN0")], 1, paste, collapse="")
cat.long.string(long.string)

```

---

read.ssd

---

*Obtain a Data Frame from a SAS Permanent Dataset, via read.xport*

---

## Description

Generates a SAS program to convert the ssd contents to SAS transport format and then uses read.xport to obtain a data frame.

## Usage

```

read.ssd(libname, sectionnames,
 tmpXport=tempfile(), tmpProgLoc=tempfile(), sascmd="sas")

```

## Arguments

|              |                                                                                                                                                                                                                                      |
|--------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| libname      | character string defining the SAS library (usually a directory reference)                                                                                                                                                            |
| sectionnames | character vector giving member names. These are files in the libname directory. They will usually have a .ssd0x or .sas7bdat extension, which should be omitted. Use of ASCII names of at most 8 characters is strongly recommended. |
| tmpXport     | character string: location where temporary xport format archive should reside – defaults to a randomly named file in the session temporary directory, which will be removed.                                                         |
| tmpProgLoc   | character string: location where temporary conversion SAS program should reside – defaults to a randomly named file in session temporary directory, which will be removed on successful operation.                                   |
| sascmd       | character string giving full path to SAS executable.                                                                                                                                                                                 |

## Details

Creates a SAS program and runs it.

Error handling is primitive.

## Value

A data frame if all goes well, or `NULL` with warnings and some enduring side effects (log file for auditing)

## Note

**This requires SAS to be available.** If you have a SAS dataset without access to SAS you will need another product to convert it to a format such as `.csv`, for example ‘Stat/Transfer’ or ‘DBMS/Copy’ or the ‘SAS System Viewer’ (Windows only).

SAS requires section names to be no more than 8 characters. This is worked by the use of symbolic links: these are barely supported on Windows.

## Author(s)

For Unix: VJ Carey <stvjc@channing.harvard.edu>

## Examples

```
if there were some files on the web we could get a real
runnable example
Not run:
R> list.files("trialdata")
[1] "baseline.sas7bdat" "form11.sas7bdat" "form12.sas7bdat"
[4] "form13.sas7bdat" "form22.sas7bdat" "form23.sas7bdat"
[7] "form3.sas7bdat" "form4.sas7bdat" "form48.sas7bdat"
[10] "form50.sas7bdat" "form51.sas7bdat" "form71.sas7bdat"
[13] "form72.sas7bdat" "form8.sas7bdat" "form9.sas7bdat"
[16] "form90.sas7bdat" "form91.sas7bdat"
R> baseline <- read.ssd("trialdata", "baseline")
R> form90 <- read.ssd("trialdata", "form90")

Or for a Windows example
sashome <- "/Program Files/SAS/SAS 9.1"
read.ssd(file.path(sashome, "core", "sashelp"), "retail",
 sascmd = file.path(sashome, "sas.exe"))

End(Not run)
```

---

`read.systat`*Obtain a Data Frame from a Systat File*

---

### Description

`read.systat` reads a rectangular data file stored by the Systat `SAVE` command as (legacy) `*.sys` or more recently `*.syd` files.

### Usage

```
read.systat(file, to.data.frame = TRUE)
```

### Arguments

|                            |                                                      |
|----------------------------|------------------------------------------------------|
| <code>file</code>          | character variable with the name of the file to read |
| <code>to.data.frame</code> | return a data frame (otherwise a list)               |

### Details

The function only reads those Systat files that are rectangular data files (`mtype = 1`), and warns when files have non-standard variable name codings. The files tested were produced on MS-DOS and Windows: files for the Mac version of Systat have a completely different format.

The C code was originally written for an add-on module for Systat described in Bivand (1992 paper). Variable names retain the trailing dollar in the list returned when `to.data.frame` is `FALSE`, and in that case character variables are returned as is and filled up to 12 characters with blanks on the right. The original function was limited to reading Systat files with up to 256 variables (a Systat limitation); it will now read up to 8192 variables.

If there is a user comment in the header this is returned as attribute `"comment"`. Such comments are always a multiple of 72 characters (with a maximum of 720 chars returned), normally padded with trailing spaces.

### Value

A data frame (or list) with one component for each variable in the saved data set.

### Author(s)

Roger Bivand

**Examples**

```
summary(iris)
iris.s <- read.systat(system.file("files/Iris.syd", package="foreign")[1])
str(iris.s)
summary(iris.s)
```

read.xport

*Read a SAS XPORT Format Library***Description**

Reads a file as a SAS XPORT format library and returns a list of data.frames.

**Usage**

```
read.xport(file, ...)
```

**Arguments**

|      |                                                                                             |
|------|---------------------------------------------------------------------------------------------|
| file | character variable with the name of the file to read. The file must be in SAS XPORT format. |
| ...  | passed to <code>as.data.frame</code> when creating the data frames.                         |

**Value**

If there is a more than one dataset in the XPORT format library, a named list of data frames, otherwise a data frame. The columns of the data frames will be either numeric (corresponding to numeric in SAS) or factor (corresponding to character in SAS). All SAS numeric missing values (including special missing values represented by .\_, .A to .Z by SAS) are mapped to R NA.

Trailing blanks are removed from character columns before conversion to a factor. Some sources claim that character missing values in SAS are represented by ' ' or ' ': these are not treated as R missing values.

**Examples**

```
Not run: ## no XPORT file is installed
read.xport("test.xpt")

End(Not run)
```

---

S3 read functions    *Read an S3 Binary or data.dump File*

---

**Description**

Reads binary data files or `data.dump` files that were produced in S version 3.

**Usage**

```
data.restore(file, print = FALSE, verbose = FALSE, env = .GlobalEnv)
read.S(file)
```

**Arguments**

|                      |                                                                   |
|----------------------|-------------------------------------------------------------------|
| <code>file</code>    | the filename of the S-PLUS <code>data.dump</code> or binary file. |
| <code>print</code>   | whether to print the name of each object as read from the file.   |
| <code>verbose</code> | whether to print the name of every subitem within each object.    |
| <code>env</code>     | environment within which to create the restored object(s).        |

**Details**

`read.S` can read the binary files produced in some older versions of S-PLUS on either Windows (versions 3.x, 4.x, 2000) or Unix (version 3.x with 4 byte integers). It automatically detects whether the file was produced on a big- or little-endian machine and adapts itself accordingly.

`data.restore` can read a similar range of files produced by `data.dump` and for newer versions of S-PLUS, those from `data.dump(..., oldStyle=TRUE)`.

Not all S3 objects can be handled in the current version. The most frequently encountered exceptions are functions and expressions; you will also have trouble with objects that contain model formulas. In particular, comments will be lost from function bodies, and the argument lists of functions will often be changed.

**Value**

For `read.S`, an R version of the S3 object.

For `data.restore`, the name of the file.

**Author(s)**

Duncan Murdoch

**Examples**

```
if you have an S-PLUS _Data file containing 'myobj'
Not run: read.S(file.path("_Data", "myobj"))
data.restore("dumpdata", print = TRUE)

End(Not run)
```

---

`write.arff`*Write Data into ARFF Files*

---

## Description

Writes data into Weka Attribute-Relation File Format (ARFF) files.

## Usage

```
write.arff(x, file, eol = "\n", relation = deparse(substitute(x)))
```

## Arguments

|                       |                                                                                                                  |
|-----------------------|------------------------------------------------------------------------------------------------------------------|
| <code>x</code>        | the data to be written, preferably a matrix or data frame. If not, coercion to a data frame is attempted.        |
| <code>file</code>     | either a character string naming a file, or a connection. "" indicates output to the standard output connection. |
| <code>eol</code>      | the character(s) to print at the end of each line (row).                                                         |
| <code>relation</code> | The name of the relation to be written in the file.                                                              |

## Details

`relation` will be passed through `make.names` before writing to the file, in an attempt to it them acceptable to Weka, and column names what do not start with an alphabetic character will have `x` prepended.

However, the references say that ARFF files are ASCII files, and that encoding is not enforced.

## See Also

`read.arff`; functions `write.arff` and `read.arff` in package **RWeka** which provide some support for logicals via conversion to or from factors.

## Examples

```
write.arff(iris, file = "")
```

write.dbf

*Write a DBF File***Description**

The function tries to write a data frame to a DBF file.

**Usage**

```
write.dbf(dataframe, file, factor2char = TRUE, max_nchar = 254)
```

**Arguments**

|             |                                                                                                                                         |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| dataframe   | a data frame object.                                                                                                                    |
| file        | a file name to be written to.                                                                                                           |
| factor2char | logical, default TRUE, convert factor columns to character: otherwise they are written as the internal integer codes.                   |
| max_nchar   | The maximum number of characters allowed in a character field. Strings which exceed this will be truncated with a warning. See Details. |

**Details**

Dots in column names are replaced by underlines in the DBF file, and names are truncated to 11 characters.

Only vector columns of classes "logical", "numeric", "integer", "character", "factor" and "Date" can be written. Other columns should be converted to one of these.

Maximum precision (number of digits including minus sign and decimal sign) for numeric is 19 - scale (digits after the decimal sign) which is calculated internally based on the number of digits before the decimal sign.

The original DBASE format limited character fields to 254 bytes. It is said that Clipper and FoxPro can read up to 32K, and it is possible to write a reader that could accept up to 65535 bytes. (The documentation suggests that only ASCII characters can be assumed to be supported.) Readers expecting the older standard (which includes Excel 2003, Access 2003 and OpenOffice 2.0) will truncate the field to the maximum width modulo 256, so increase `max_nchar` only if you are sure the intended reader supports wider character fields.

**Value**

Invisible NULL.

**Note**

Other applications have varying abilities to read the data types used here. Microsoft Access reads "numeric", "integer", "character" and "Date" fields, including recognizing missing values, but not "logical" (read as 0, -1). Microsoft Excel understood all possible types but did not interpret missing values in character fields correctly (showing them as character nuls).

**Author(s)**

Nicholas J. Lewin-Koh, modified by Roger Bivand and Brian Ripley; shapelib by Frank Warmerdam.

---

write.dta

*Write Files in Stata Binary Format*

---

## Description

Writes the data frame to file in the Stata binary format. Does not write array variables unless they can be [drop](#)-ed to a vector.

Frozen: will not support Stata formats after 10 (also used by Stata 11).

## Usage

```
write.dta(dataframe, file, version = 7L,
 convert.dates = TRUE, tz = "GMT",
 convert.factors = c("labels", "string", "numeric", "codes"))
```

## Arguments

|                 |                                                                                       |
|-----------------|---------------------------------------------------------------------------------------|
| dataframe       | a data frame.                                                                         |
| file            | character string giving filename.                                                     |
| version         | integer: Stata version: 6, 7, 8 and 10 are supported, and 9 is mapped to 8, 11 to 10. |
| convert.dates   | logical: convert Date and POSIXct objects: see section ‘Dates’.                       |
| tz              | timezone for date conversion.                                                         |
| convert.factors | how to handle factors.                                                                |

## Details

The major difference between supported file formats in Stata versions is that version 7.0 and later allow 32-character variable names (5 and 6 were restricted to 8-character names). The `abbreviate` function is used to trim variable names to the permitted length. A warning is given if this is needed and it is an error for the abbreviated names not to be unique. Each version of Stata is claimed to be able to read all earlier formats.

The columns in the data frame become variables in the Stata data set. Missing values are handled correctly.

There are four options for handling factors. The default is to use Stata 'value labels' for the factor levels. With `convert.factors = "string"`, the factor levels are written as strings (the name of the value label is taken from the `"val.labels"` attribute if it exists or the variable name otherwise). With `convert.factors = "numeric"` the numeric values of the levels are written, or NA if they cannot be coerced to numeric. Finally, `convert.factors = "codes"` writes the underlying integer codes of the factors. This last used to be the only available method and is provided largely for backwards compatibility.

If the `"label.table"` attribute contains value labels with names not already attached to a variable (not the variable name or name from `"val.labels"`) then these will be written out as well.

If the `"datalabel"` attribute contains a string, it is written out as the dataset label otherwise the dataset label is `"Written by R."`.

If the `"expansion.table"` attribute exists expansion fields are written. This attribute should contain a `list` where each element is a `character` vector of length three. The first vector element contains the name of a variable or `"_dta"` (meaning the dataset). The second element contains the characteristic name. The third contains the associated data.

If the `"val.labels"` attribute contains a `character` vector with a string label for each value then this is written as the value labels. Otherwise the variable names are used.

If the `"var.labels"` attribute contains a `character` vector with a string label for each variable then this is written as the variable labels. Otherwise the variable names are repeated as variable labels.

For Stata 8 or later use the default `version = 7` – the only advantage of Stata 8 format over 7 is that it can represent multiple different missing value types, and R doesn't have them. Stata 10/11 allows longer format lists, but R does not make use of them.

Note that the Stata formats are documented to use ASCII strings – R does not enforce this, but use of non-ASCII character strings will not be portable as the encoding is not recorded. Up to 244 bytes are allowed in character data, and longer strings will be truncated with a warning.

Stata uses some large numerical values to represent missing values. This function does not currently check, and hence integers greater than 2147483620 and doubles greater than  $8.988e+307$  may be misinterpreted by Stata.

## Value

NULL

## Dates

Unless disabled by argument `convert.dates = FALSE`, R date and date-time objects (`POSIXt` classes) are converted into the Stata date format, the number of days since 1960-01-01. (For date-time objects this may lose information.) Stata can be told that these are dates by

```
format xdate %td;
```

It is possible to pass objects of class `POSIXct` to Stata to be treated as one of its versions of date-times. Stata uses the number of milliseconds since 1960-01-01, either excluding (format `%tc`) or counting (format `%tC`) leap seconds. So either an object of class `POSIXct` can be passed to Stata with `convert.dates = FALSE` and converted in Stata, or 315619200 should be added and then multiplied by 1000 before passing to `write.dta` and assigning format `%tc`. Stata's comments on the first route are at <https://www.stata.com/manuals13/ddatetime.pdf>, but at the time of writing were wrong: R uses POSIX conventions and hence does not count leap seconds.

```

---

write.foreign

*Write Text Files and Code to Read Them*

---

### Description

This function exports simple data frames to other statistical packages by writing the data as free-format text and writing a separate file of instructions for the other package to read the data.

### Usage

```
write.foreign(df, datafile, codefile,
 package = c("SPSS", "Stata", "SAS"), ...)
```

### Arguments

|                       |                                                                        |
|-----------------------|------------------------------------------------------------------------|
| <code>df</code>       | A data frame                                                           |
| <code>datafile</code> | Name of file for data output                                           |
| <code>codefile</code> | Name of file for code output                                           |
| <code>package</code>  | Name of package                                                        |
| <code>...</code>      | Other arguments for the individual <code>writeForeign</code> functions |

## Details

The work for this function is done by `foreign::writeForeignStata`, `foreign::writeForeignSAS` and `foreign::writeForeignSPSS`. To add support for another package, eg Systat, create a function `writeForeignSystat` with the same first three arguments as `write.foreign`. This will be called from `write.foreign` when `package="Systat"`.

Numeric variables and factors are supported for all packages: dates and times (`Date`, `dates`, `date`, and `POSIXt` classes) and logical vectors are also supported for SAS and characters are supported for SPSS.

For `package="SAS"` there are optional arguments `dataname = "rdata"` taking a string that will be the SAS data set name, `validvarname` taking either `"V6"` or `"V7"`, and `libpath = NULL` taking a string that will be the directory where the target SAS dataset will be written when the generated SAS code been run.

For `package="SPSS"` there is an optional argument `maxchars = 32L` taking an integer that causes the variable names (not variable labels) to be abbreviated to not more than `maxchars` chars. For compatibility with SPSS version 12 and before, change this to `maxchars = 8L`. In single byte locales with SPSS versions 13 or later, this can be set to `maxchars = 64L`.

For `package="SPSS"`, as a side effect, the decimal indicator is always set by `SET DECIMAL=DOT.` which may override user settings of the indicator or its default derived from the current locale.

## Value

Invisible `NULL`.

## Author(s)

Thomas Lumley and Stephen Weigand

## Examples

```
Not run:
datafile <- tempfile()
codefile <- tempfile()
write.foreign(esoph, datafile, codefile, package="SPSS")
file.show(datafile)
file.show(codefile)
unlink(datafile)
unlink(codefile)

End(Not run)
```

## Chapter 23

# The `lattice` package

---

A\_01\_Lattice

*Lattice Graphics*

---

### Description

The **lattice** add-on package is an implementation of Trellis graphics for R. It is a powerful and elegant high-level data visualization system with an emphasis on multivariate data. It is designed to meet most typical graphics needs with minimal tuning, but can also be easily extended to handle most nonstandard requirements.

### Details

Trellis Graphics, originally developed for S and S-PLUS at the Bell Labs, is a framework for data visualization developed by R. A. Becker, W. S. Cleveland, et al, extending ideas presented in Cleveland's 1993 book *Visualizing Data*. The Lattice API is based on the original design in S, but extends it in many ways.

The Lattice user interface primarily consists of several 'high-level' generic functions (listed below in the "See Also" section), each designed to create a particular type of display by default. Although the functions produce different output, they share many common features, reflected in several common arguments that affect the resulting displays in similar ways. These arguments are extensively (sometimes only) documented in the help page for `xyplot`, which also includes a discussion of the important topics of *conditioning* and control of the Trellis layout. Features specific to other high-level functions are documented in their respective help pages.

Lattice employs an extensive system of user-controllable settings to determine the look and feel of the displays it produces. To learn how to use and customize the graphical parameters used by lattice, see `trellis.par.set`. For other settings, see `lattice.options`. The default graphical settings are (potentially) different for different graphical devices. To learn how to initialize new devices with the desired settings or change the settings of the current device, see `trellis.device`.

It is usually unnecessary, but sometimes important to be able to plot multiple lattice plots on a single page. Such capabilities are described in the `print.trellis` help page. See `update.trellis` to learn about manipulating a "trellis" object. Tools to augment lattice plots after they are drawn (including *locator*-like functionality) are described in the `trellis.focus` help page.

The online documentation accompanying the package is complete, and effort has been made to present the help pages in a logical sequence, so that one can learn how to use lattice by reading the

PDF reference manual available at <https://cran.r-project.org/package=lattice>. However, the format in which the online documentation is written and the breadth of topics covered necessarily makes it somewhat terse and less than ideal as a first introduction. For a more gentle introduction, a book on lattice is available as part of Springer's 'Use R' series; see the "References" section below.

### Note

High-level **lattice** functions like `xyplot` are different from traditional R graphics functions in that they do not perform any plotting themselves. Instead, they return an object, of class "trellis", which has to be then `print`-ed or `plot`-ted to create the actual plot. Due to R's automatic printing rule, it is usually not necessary to explicitly carry out the second step, and **lattice** functions appear to behave like their traditional counterparts. However, the automatic plotting is suppressed when the high-level functions are called inside another function (most often `source`) or in other contexts where automatic printing is suppressed (e.g., `for` or `while` loops). In such situations, an explicit call to `print` or `plot` is required.

The **lattice** package is based on the Grid graphics engine and requires the **grid** add-on package. One consequence of this is that it is not (readily) compatible with traditional R graphics tools. In particular, changing `par()` settings usually has no effect on Lattice plots; **lattice** provides its own interface for querying and modifying an extensive set of graphical and non-graphical settings.

### See Also

The following is a list of high-level functions in the **lattice** package and their default displays. In all cases, the actual display is produced by the so-called "panel" function, which has a suitable default, but can be substituted by an user defined function to create customized displays. In many cases, the default panel function will itself have many optional arguments to customize its output. The default panel functions are named as "panel." followed by the name of the corresponding high-level function; i.e., the default panel function for `xyplot` is `panel.xyplot`, the one for `histogram` is `panel.histogram`, etc. Each default panel function has a separate help page, linked from the help pages of the corresponding high-level function. Although documented separately, arguments to these panel functions can be supplied directly to the high-level functions, which will pass on the arguments appropriately.

#### Univariate:

`barchart`: Bar plots.

`bwplot`: Box-and-whisker plots.  
`densityplot`: Kernel density estimates.  
`dotplot`: Cleveland dot plots.  
`histogram`: Histograms.  
`qqmath`: Theretical quantile plots.  
`stripplot`: One-dimensional scatterplots.

#### **Bivariate:**

`qq`: Quantile plots for comparing two distributions.  
`xypplot`: Scatterplots and time-series plots (and potentially a lot more).

#### **Trivariate:**

`levelplot`: Level plots (similar to `image` plots).  
`contourplot`: Contour plots.  
`cloud`: Three-dimensional scatter plots.  
`wireframe`: Three-dimensional surface plots (similar to `persp` plots).

#### **Hypervariate:**

`splom`: Scatterplot matrices.  
`parallel`: Parallel coordinate plots.

#### **Miscellaneous:**

`rfs`: Residual and fitted value plots (also see `oneway`).  
`tmd`: Tukey Mean-Difference plots.

In addition, there are several panel functions that do little by themselves, but can be useful components of custom panel functions. These are documented in `panel.functions`. Lattice also provides a collection of convenience functions that correspond to the traditional graphics primitives `lines`, `points`, etc. These are implemented using Grid graphics, but try to be as close to the traditional versions as possible in terms of their argument list. These functions have names like `llines` or `panel.lines` and are often useful when writing (or porting from S-PLUS code) nontrivial panel functions.

Finally, many useful enhancements that extend the Lattice system are available in the **latticeExtra** package.

### **Examples**

```
Not run:

Show brief history of changes to lattice, including
a summary of new features.

RShowDoc("NEWS", package = "lattice")

End(Not run)
```

## Description

This help page documents several commonly used high-level Lattice functions. `xyplot` produces bivariate scatterplots or time-series plots, `bwplot` produces box-and-whisker plots, `dotplot` produces Cleveland dot plots, `barchart` produces bar plots, and `stripplot` produces one-dimensional scatterplots. All these functions, along with other high-level Lattice functions, respond to a common set of arguments that control conditioning, layout, aspect ratio, legends, axis annotation, and many other details in a consistent manner. These arguments are described extensively in this help page, and should be used as the reference for other high-level functions as well.

For control and customization of the actual display in each panel, the help page of the respective default panel function will often be more informative. In particular, these help pages describe many arguments commonly used when calling the corresponding high-level function but are specific to them.

## Usage

```
xyplot(x, data, ...)
dotplot(x, data, ...)
barchart(x, data, ...)
stripplot(x, data, ...)
bwplot(x, data, ...)

 default.prepanel = lattice.getOption("prepanel.default.bwplot"),
 subscripts = !is.null(groups),
 subset = TRUE)

```

## Arguments

**x** All high-level function in **lattice** are generic. **x** is the object on which method dispatch is carried out.  
For the "formula" methods, **x** must be a formula describing the primary vari-

ables (used for the per-panel display) and the optional conditioning variables (which define the subsets plotted in different panels) to be used in the plot. Conditioning is described in the “Details” section below.

For the functions documented here, the formula is generally of the form  $y \sim x \mid g1 * g2 * \dots$  (or equivalently,  $y \sim x \mid g1 + g2 + \dots$ ), indicating that plots of  $y$  (on the y-axis) versus  $x$  (on the x-axis) should be produced conditional on the variables  $g1, g2, \dots$ . Here  $x$  and  $y$  are the primary variables, and  $g1, g2, \dots$  are the conditioning variables. The conditioning variables may be omitted to give a formula of the form  $y \sim x$ , in which case the plot will consist of a single panel with the full dataset. The formula can also involve expressions, e.g., `sqrt()`, `log()`, etc. See the `data` argument below for rules regarding evaluation of the terms in the formula.

With the exception of `xyplot`, the functions documented here may also be supplied a formula of the form  $\sim x \mid g1 * g2 * \dots$ . In that case,  $y$  defaults to `names(x)` if  $x$  is named, and a factor with a single level otherwise.

Cases where  $x$  is not a formula is handled by appropriate methods. The numeric methods are equivalent to a call with no left hand side and no conditioning variables in the formula. For `barchart` and `dotplot`, non-trivial methods exist for tables and arrays, documented at [barchart.table](#).

The conditioning variables  $g1, g2, \dots$  must be either factors or shingles. Shingles provide a way of using numeric variables for conditioning; see the help page of [shingle](#) for details. Like factors, they have a “levels” attribute, which is used in producing the conditional plots. If necessary, numeric conditioning variables are converted to shingles using the `shingle` function; however, using `equal.count` may be more appropriate in many cases. Character variables are coerced to factors.

**Extended formula interface:** As a useful extension of the interface described above, the primary variable terms (both the LHS  $y$  and RHS  $x$ ) may consist of multiple terms separated by a “+” sign, e.g.,  $y1 + y2 \sim x \mid a * b$ . This formula would be taken to mean that the user wants to plot both  $y1 \sim x \mid a * b$  and  $y2 \sim x \mid a * b$ , but with the  $y1 \sim x$  and  $y2 \sim x$  superposed in each panel. The two groups will be distinguished by different graphical parameters. This is essentially what the `groups` argument (see below) would produce, if  $y1$  and  $y2$  were concatenated to produce a longer vector, with the `groups` argument being an indicator of which rows come from which variable. In fact, this is exactly what is done internally using the `reshape` function. This feature cannot be used in conjunction with the `groups` argument.

To interpret  $y1 + y2$  as a sum, one can either set `allow.multiple=FALSE` or use `I(y1+y2)`.

A variation on this feature is when the `outer` argument is set to `TRUE`. In that case, the plots are not superposed in each panel, but instead separated into different panels (as if a new conditioning variable had been added).

**Primary variables:** The  $x$  and  $y$  variables should both be numeric in `xyplot`, and an attempt is made to coerce them if not. However, if either is a factor, the levels of that factor are used as axis labels. In the other four functions documented here, exactly one of  $x$  and  $y$  should be numeric, and the other a factor or shingle. Which of these will happen is determined by the `horizontal` argument — if `horizontal=TRUE`, then  $y$  will be coerced to be a factor or shingle, otherwise  $x$ . The default value of `horizontal` is `FALSE` if  $x$  is a factor or shingle, `TRUE` otherwise. (The functionality provided by `horizontal=FALSE` is not S-compatible.)

Note that the `x` argument used to be called `formula` in earlier versions (when the high-level functions were not generic and the `formula` method was essentially the only method). This is no longer allowed. It is recommended that this argument not be named in any case, but instead be the first (unnamed) argument.

`data` For the `formula` methods, a data frame (or more precisely, anything that is a valid `envir` argument in `eval`, e.g., a list or an environment) containing values for any variables in the formula, as well as `groups` and `subset` if applicable. If not found in `data`, or if `data` is unspecified, the variables are looked for in the environment of the formula. For other methods (where `x` is not a formula), `data` is usually ignored, often with a warning if it is explicitly specified.

`allow.multiple`

Logical flag specifying whether the extended formula interface described above should be in effect. Defaults to `TRUE` whenever sensible.

`outer`

Logical flag controlling what happens with formulas using the extended interface described above (see the entry for `x` for details). Defaults to `FALSE`, except when `groups` is explicitly specified or grouping does not make sense for the default panel function.

`box.ratio`

Applicable to `barchart` and `bwplot`. Specifies the ratio of the width of the rectangles to the inter-rectangle space. See also the `box.width` argument in the respective default panel functions.

`horizontal`

Logical flag applicable to `bwplot`, `dotplot`, `barchart`, and `stripplot`. Determines which of `x` and `y` is to be a factor or shingle (`y` if `TRUE`, `x` otherwise). Defaults to `FALSE` if `x` is a factor or shingle, `TRUE` otherwise. This argument is used to process the arguments to these high-level functions, but more importantly, it is passed as an argument to the panel function, which is expected to use it as appropriate.

A potentially useful component of `scales` in this case may be `abbreviate = TRUE`, in which case long labels which would usually overlap will be abbreviated. `scales` could also contain a `minlength` argument in this case, which would be passed to the `abbreviate` function.

**Common arguments:** The following arguments are common to all the functions documented here, as well as most other high-level Trellis functions. These are not documented elsewhere, except to override the usage given here.

`panel`

Once the subset of rows defined by each unique combination of the levels of the grouping variables are obtained (see “Details”), the corresponding `x` and `y` variables (or other variables, as appropriate, in the case of other high-level functions) are passed on to be plotted in each panel. The actual plotting is done by the function specified by the `panel` argument. The argument may be a function object or a character string giving the name of a predefined function. Each high-level function has its own default panel function, named as “`panel.`” followed by the name of the corresponding high-level function (e.g., `panel.xyplot`, `panel.barchart`, etc).

Much of the power of Trellis Graphics comes from the ability to define customized panel functions. A panel function appropriate for the functions described here would usually expect arguments named `x` and `y`, which would be provided by the conditioning process. It can also have other arguments. It is useful to know in this context that all arguments passed to a high-level Lattice function (such as `xyplot`) that are not recognized by it are passed through to the panel function. It is thus generally good practice when defining panel functions to allow a `...` argument. Such extra arguments typically control graphical

parameters, but other uses are also common. See documentation for individual panel functions for specifics.

Note that unlike in S-PLUS, it is not guaranteed that panel functions will be supplied only numeric vectors for the `x` and `y` arguments; they can be factors as well (but not shingles). Panel functions need to handle this case, which in most cases can be done by simply coercing them to numeric.

Technically speaking, panel functions must be written using Grid graphics functions. However, knowledge of Grid is usually not necessary to construct new custom panel functions, as there are several predefined panel functions which can help; for example, `panel.grid`, `panel.loess`, etc. There are also some grid-compatible replacements of commonly used traditional graphics functions useful for this purpose. For example, `lines` can be replaced by `llines` (or equivalently, `panel.lines`). Note that traditional graphics functions like `lines` will not work in a lattice panel function.

One case where a bit more is required of the panel function is when the `groups` argument is not `NULL`. In that case, the panel function should also accept arguments named `groups` and `subscripts` (see below for details). A useful panel function predefined for use in such cases is `panel.superpose`, which can be combined with different `panel.groups` functions to determine what is plotted for each group. See the “Examples” section for an interaction plot constructed in this way. Several other panel functions can also handle the `groups` argument, including the default ones for `xyplot`, `barchart`, `dotplot`, and `stripplot`.

Even when `groups` is not present, the panel function can have `subscripts` as a formal argument. In either case, the `subscripts` argument passed to the panel function are the indices of the `x` and `y` data for that panel in the original data, BEFORE taking into account the effect of the `subset` argument. Note that `groups` remains unaffected by any subsetting operations, so `groups[subscripts]` gives the values of `groups` that correspond to the data in that panel.

This interpretation of `subscripts` does not hold when the extended formula interface is in use (i.e., when `allow.multiple` is in effect). A comprehensive description would be too complicated (details can be found in the source code of the function `latticeParseFormula`), but in short, the extended interface works by creating an artificial grouping variable that is longer than the original data frame, and consequently, `subscripts` needs to refer to rows beyond those in the original data. To further complicate matters, the artificial grouping variable is created after any effect of `subset`, in which case `subscripts` may have no relationship with corresponding rows in the original data frame.

One can also use functions called `panel.number` and `packet.number`, representing panel order and packet order respectively, inside the panel function (as well as the `strip` function or while interacting with a lattice display using `trellis.focus` etc). Both provide a simple integer index indicating which panel is currently being drawn, but differ in how the count is calculated. The panel number is a simple incremental counter that starts with 1 and is incremented each time a panel is drawn. The packet number on the other hand indexes the combination of levels of the conditioning variables that is represented by that panel. The two indices coincide unless the order of conditioning variables is permuted and/or the plotting order of levels within one or more conditioning variables is altered (using `perm.cond` and `index.cond` respectively), in which case `packet.number` gives the index corresponding to the ‘natural’

ordering of that combination of levels of the conditioning variables.

`panel.xyplot` has an argument called `type` which is worth mentioning here because it is quite frequently used (and as mentioned above, can be passed to `xyplot` directly). In the event that a `groups` variable is used, `panel.xyplot` calls `panel.superpose`, arguments of which can also be passed directly to `xyplot`. Panel functions for `bwplot` and friends should have an argument called `horizontal` to account for the cases when `x` is the factor or shingle.

`aspect`

This argument controls the physical aspect ratio of the panels, which is usually the same for all the panels. It can be specified as a ratio (vertical size/horizontal size) or as a character string. In the latter case, legitimate values are `"fill"` (the default) which tries to make the panels as big as possible to fill the available space; `"xy"`, which computes the aspect ratio based on the 45 degree banking rule (see `banking`); and `"iso"` for isometric scales, where the relation between physical distance on the device and distance in the data scale are forced to be the same for both axes.

If a `prepanel` function is specified and it returns components `dx` and `dy`, these are used for banking calculations. Otherwise, values from the default `prepanel` function are used. Not all default `prepanel` functions produce sensible banking calculations.

`groups`

A variable or expression to be evaluated in `data`, expected to act as a grouping variable within each panel, typically used to distinguish different groups by varying graphical parameters like color and line type. Formally, if `groups` is specified, then `groups` along with `subscripts` is passed to the panel function, which is expected to handle these arguments. For high level functions where grouping is appropriate, the default panel functions can handle grouping.

It is very common to use a key (legend) when a grouping variable is specified. See entries for `key`, `auto.key` and `simpleKey` for how to draw a key.

`auto.key`

A logical, or a list containing components to be used as arguments to `simpleKey`. `auto.key=TRUE` is equivalent to `auto.key=list()`, in which case `simpleKey` is called with a set of default arguments (which may depend on the relevant high-level function). Most valid components to the `key` argument can be specified in this manner, as `simpleKey` will simply add unrecognized arguments to the list it produces.

`auto.key` is typically used to automatically produce a suitable legend in conjunction with a grouping variable. If `auto.key=TRUE`, a suitable legend will be drawn if a `groups` argument is also provided, and not otherwise. In list form, `auto.key` will modify the default legend thus produced. For example, `auto.key=list(columns=2)` will create a legend split into two columns (`columns` is documented in the entry for `key`).

More precisely, if `auto.key` is not `FALSE`, `groups` is non-null, and there is no `key` or `legend` argument specified in the call, a key is created with `simpleKey` with `levels(groups)` as the first (`text`) argument. (Note: this may not work in all high-level functions, but it does work for the ones where grouping makes sense with the default panel function). If `auto.key` is provided as a list and includes a `text` component, then that is used instead as the text labels in the key, and the key is drawn even if `groups` is not specified.

Note that `simpleKey` uses the default settings (see `trellis.par.get`) to determine the graphical parameters in the key, so the resulting legend will be meaningful only if the same settings are used in the plot as well. The

`par.settings` argument, possibly in conjunction with [simpleTheme](#), may be useful to temporarily modify the default settings for this purpose.

One disadvantage to using `key` (or even `simpleKey`) directly is that the graphical parameters used in the key are absolutely determined at the time when the "trellis" object is created. Consequently, if a plot once created is re-plotted with different settings, the original parameter settings will be used for the key even though the new settings are used for the actual display. However, with `auto.key`, the key is actually created at plotting time, so the settings will match.

`prepanel`

A function that takes the same arguments as the `panel` function and returns a list, possibly containing components named `xlim`, `ylim`, `dx`, and `dy` (and less frequently, `xat` and `yat`). The return value of a user-supplied `prepanel` function need not contain all these components; in case some are missing, they are replaced by the component-wise defaults.

The `xlim` and `ylim` components are similar to the high level `xlim` and `ylim` arguments (i.e., they are usually a numeric vector of length 2 defining a range, or a character vector representing levels of a factor). If the `xlim` and `ylim` arguments are not explicitly specified (possibly as components in `scales`) in the high-level call, then the actual limits of the panels are guaranteed to include the limits returned by the `prepanel` function. This happens globally if the `relation` component of `scales` is "same", and on a per-panel basis otherwise.

The `dx` and `dy` components are used for banking computations in case `aspect` is specified as "xy". See documentation of [banking](#) for details.

If `xlim` or `ylim` is a character vector (which is appropriate when the corresponding variable is a factor), this implicitly indicates that the scale should include the first `n` integers, where `n` is the length of `xlim` or `ylim`, as the case may be. The elements of the character vector are used as the default labels for these `n` integers. Thus, to make this information consistent between panels, the `xlim` or `ylim` values should represent all the levels of the corresponding factor, even if some are not used within that particular panel.

In such cases, an additional component `xat` or `yat` may be returned by the `prepanel` function, which should be a subset of `1:n`, indicating which of the `n` values (levels) are actually represented in the panel. This is useful when calculating the limits with `relation="free"` or `relation="sliced"` in `scales`.

The `prepanel` function is responsible for providing a meaningful return value when the `x`, `y` (etc.) variables are zero-length vectors. When nothing else is appropriate, values of `NA` should be returned for the `xlim` and `ylim` components.

`strip`

A logical flag or function. If `FALSE`, strips are not drawn. Otherwise, strips are drawn using the `strip` function, which defaults to `strip.default`. See documentation of [strip.default](#) to see the arguments that are available to the `strip` function. This description also applies to the `strip.left` argument (see . . . below), which can be used to draw strips on the left of each panel (useful for wide short panels, e.g., in time-series plots).

`xlab`

Character or expression (or a "grob") giving label(s) for the x-axis. Generally defaults to the expression for `x` in the formula defining the plot. Can be specified as `NULL` to omit the label altogether. Finer control is possible, as described in the entry for `main`, with the modification that if the `label` component is omitted from the list, it is replaced by the default `xlab`.

**ylab** Character or expression (or "grob") giving label for the y-axis. Generally defaults to the expression for *y* in the formula defining the plot. Finer control is possible, see entries for *main* and *xlab*.

**scales** Generally a list determining how the x- and y-axes (tick marks and labels) are drawn. The list contains parameters in *name=value* form, and may also contain two other lists called *x* and *y* of the same form (described below). Components of *x* and *y* affect the respective axes only, while those in *scales* affect both. When parameters are specified in both lists, the values in *x* or *y* are used. Note that certain high-level functions have defaults that are specific to a particular axis (e.g., *bwplot* has *alternating=FALSE* for the categorical axis only); these can only be overridden by an entry in the corresponding component of *scales*.

As a special exception, *scales* (or its *x* and *y* components) can also be a character string, in which case it is interpreted as the *relation* component.

The possible components are :

**relation** A character string that determines how axis limits are calculated for each panel. Possible values are "same" (default), "free" and "sliced". For *relation="same"*, the same limits, usually large enough to encompass all the data, are used for all the panels. For *relation="free"*, limits for each panel is determined by just the points in that panel. Behavior for *relation="sliced"* is similar, except that the length (max - min) of the scales are constrained to remain the same across panels.

The determination of what axis limits are suitable for each panel can be controlled by the *prepanel* function, which can be overridden by *xlim*, *ylim* or *scales\$limits* (except when *relation="sliced"*, in which case explicitly specified limits are ignored with a warning). When *relation* is "free", *xlim* or *ylim* can be a list, in which case it is treated as if its components were the limit values obtained from the *prepanel* calculations for each panel (after being replicated if necessary).

**tick.number** An integer, giving the suggested number of intervals between ticks. This is ignored for a factor, shingle, or character vector, for in these cases there is no natural rule for leaving out some of the labels. But see *xlim*.

**draw** A logical flag, defaulting to TRUE, that determines whether to draw the axis (i.e., tick marks and labels) at all.

**alternating** Usually a logical flag specifying whether axis labels should alternate from one side of the group of panels to the other. For finer control, *alternating* can also be a vector (replicated to be as long as the number of rows or columns per page) consisting of the following numbers

- 0: do not draw tick labels
- 1: bottom/left
- 2: top/right
- 3: both.

*alternating* applies only when *relation="same"*. The default is TRUE, or equivalently, *c(1, 2)*

**limits** Same as *xlim* and *ylim*.

**at** The location of tick marks along the axis (in native coordinates), or a list as long as the number of panels describing tick locations for each panel.

**labels** Vector of labels (characters or expressions) to go along with *at*. Can also be a list like *at*.

- cex** A numeric multiplier to control character sizes for axis labels. Can be a vector of length 2, to control left/bottom and right/top labels separately.
- font, fontface, fontfamily** Specifies the font to be used for axis labels.
- lineheight** Specifies the line height parameter (height of line as a multiple of the size of text); relevant for multi-line labels. (This is currently ignored for `cloud`.)
- tck** Usually a numeric scalar controlling the length of tick marks. Can also be a vector of length 2, to control the length of left/bottom and right/top tick marks separately.
- col** Color of tick marks and labels.
- rot** Angle (in degrees) by which the axis labels are to be rotated. Can be a vector of length 2, to control left/bottom and right/top axes separately.
- abbreviate** A logical flag, indicating whether to abbreviate the labels using the `abbreviate` function. Can be useful for long labels (e.g., in factors), especially on the x-axis.
- minlength** Argument passed to `abbreviate` if `abbreviate=TRUE`.
- log** Controls whether the corresponding variable (x or y) will be log transformed before being passed to the panel function. Defaults to `FALSE`, in which case the data are not transformed. Other possible values are any number that works as a base for taking logarithm, `TRUE` (which is equivalent to 10), and `"e"` (for the natural logarithm). As a side effect, the corresponding axis is labeled differently. Note that this is in reality a transformation of the data, not the axes. Other than the axis labeling, using this feature is no different than transforming the data in the formula; e.g., `scales=list(x = list(log = 2))` is equivalent to  $y \sim \log_2(x)$ . See entry for `equispaced.log` below for details on how to control axis labeling.
- equispaced.log** A logical flag indicating whether tick mark locations should be equispaced when 'log scales' are in use. Defaults to `TRUE`. Tick marks are always labeled in the original (untransformed) scale, but this makes the choice of tick mark locations nontrivial. If `equispaced.log` is `FALSE`, the choice made is similar to how log scales are annotated in traditional graphics. If `TRUE`, tick mark locations are chosen as 'pretty' equispaced values in the transformed scale, and labeled in the form `"base^loc"`, where `base` is the base of the logarithm transformation, and `loc` are the locations in the transformed scale. See also `xscale.components.logpower` in the **latticeExtra** package.
- format** The format to use for POSIXct variables. See `strptime` for description of valid values.
- axis** A character string, `"r"` (default) or `"i"`. In the latter case, the axis limits are calculated as the exact data range, instead of being padded on either side. (May not always work as expected.)

Note that much of the function of `scales` is accomplished by `pscales` in `splom`.

- subscripts** A logical flag specifying whether or not a vector named `subscripts` should be passed to the panel function. Defaults to `FALSE`, unless `groups` is specified, or if the panel function accepts an argument named `subscripts`. This argument is useful if one wants the subscripts to be passed on even if these conditions do not hold; a typical example is when one wishes to augment a Lattice plot after it has been drawn, e.g., using `panel.identify`.

|                                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|---------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>subset</code>             | An expression that evaluates to a logical or integer indexing vector. Like groups, it is evaluated in data. Only the resulting rows of data are used for the plot. If <code>subscripts</code> is <code>TRUE</code> , the subscripts provided to the panel function will be indices referring to the rows of data prior to the subsetting. Whether levels of factors in the data frame that are unused after the subsetting will be dropped depends on the <code>drop.unused.levels</code> argument.                                                                                                                                                                                                                                                                                        |
| <code>xlim</code>               | Normally a numeric vector (or a <code>DateTime</code> object) of length 2 giving left and right limits for the x-axis, or a character vector, expected to denote the levels of <code>x</code> . The latter form is interpreted as a range containing <code>c(1, length(xlim))</code> , with the character vector determining labels at tick positions <code>1:length(xlim)</code> .<br><br><code>xlim</code> could also be a list, with as many components as the number of panels (recycled if necessary), with each component as described above. This is meaningful only when <code>scales\$x\$relation</code> is <code>"free"</code> , in which case these are treated as if they were the corresponding limit components returned by <code>prepanel</code> calculations.              |
| <code>ylim</code>               | Similar to <code>xlim</code> , applied to the y-axis.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>drop.unused.levels</code> | A logical flag indicating whether the unused levels of factors will be dropped, usually relevant when a subsetting operation is performed or an <a href="#">interaction</a> is created. Unused levels are usually dropped, but it is sometimes appropriate to suppress dropping to preserve a useful layout. For finer control, this argument could also be list containing components <code>cond</code> and <code>data</code> , both logical, indicating desired behavior for conditioning variables and primary variables respectively. The default is given by <code>lattice.getOption("drop.unused.levels")</code> , which is initially set to <code>TRUE</code> for both components. Note that this argument does not control dropping of levels of the <code>groups</code> argument. |
| <code>default.scales</code>     | A list giving the default values of <code>scales</code> for a particular high-level function. This is rarely of interest to the end-user, but may be helpful when defining other functions that act as a wrapper to one of the high-level Lattice functions.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>default.prepanel</code>   | A function or character string giving the name of a function that serves as the (component-wise) fallback <code>prepanel</code> function when the <code>prepanel</code> argument is not specified, or does not return all necessary components. The main purpose of this argument is to enable the defaults to be overridden through the use of <a href="#">lattice.options</a> .                                                                                                                                                                                                                                                                                                                                                                                                          |
| <code>lattice.options</code>    | A list that could be supplied to <a href="#">lattice.options</a> . These options are applied temporarily for the duration of the call, after which the settings revert back to what they were before. The options are retained along with the object and reused during plotting. This enables the user to attach options settings to the trellis object itself rather than change the settings globally. See also the <code>par.settings</code> argument described below for a similar treatment of graphical settings.                                                                                                                                                                                                                                                                    |
| <code>...</code>                | Further arguments, usually not directly processed by the high-level functions documented here, but instead passed on to other functions. Such arguments can be broadly categorized into two types: those that affect all high-level Lattice functions in a similar manner, and those that are meant for the specific panel function being used.<br><br>The first group of arguments are processed by a common, unexported function called <code>trellis.skeleton</code> . These arguments affect all high-level functions,                                                                                                                                                                                                                                                                 |

but are only documented here (except to override the behaviour described here). All other arguments specified in a high-level call, specifically those neither described here nor in the help page of the relevant high-level function, are passed unchanged to the panel function used. By convention, the default panel function used for any high-level function is named as “panel.” followed by the name of the high-level function; for example, the default panel function for `bwplot` is `panel.bwplot`. In practical terms, this means that in addition to the help page of the high-level function being used, the user should also consult the help page of the corresponding panel function for arguments that may be specified in the high-level call.

The effect of the first group of common arguments are as follows:

**as.table:** A logical flag that controls the order in which panels should be displayed: if `FALSE` (the default), panels are drawn left to right, bottom to top (as in a graph); if `TRUE`, left to right, top to bottom (as in a table).

**between:** A list with components `x` and `y` (both usually 0 by default), numeric vectors specifying the space between the panels (units are character heights). `x` and `y` are repeated to account for all panels in a page and any extra components are ignored. The result is used for all pages in a multi page display. In other words, it is not possible to use different `between` values for different pages.

**key:** A list that defines a legend to be drawn on the plot. This list is used as an argument to the `draw.key` function, which produces a “grob” (grid object) eventually plotted by the print method for “trellis” objects. The structure of the legend is constrained in the ways described below.

Although such a list can be and often is created explicitly, it is also possible to generate such a list using the `simpleKey` function; the latter is more convenient but less flexible. The `auto.key` argument can be even more convenient for the most common situation where legends are used, namely, in conjunction with a grouping variable. To use more than one legend, or to have arbitrary legends not constrained by the structure imposed by `key`, use the `legend` argument.

The position of the key can be controlled in either of two possible ways. If a component called `space` is present, the key is positioned outside the plot region, in one of the four sides, determined by the value of `space`, which can be one of “top”, “bottom”, “left” and “right”. Alternatively, the key can be positioned inside the plot region by specifying components `x`, `y` and `corner`. `x` and `y` determine the location of the corner of the key given by `corner`, which is usually one of `c(0, 0)`, `c(1, 0)`, `c(1, 1)` and `c(0, 1)`, which denote the corners of the unit square. Fractional values are also allowed, in which case `x` and `y` determine the position of an arbitrary point inside (or outside for values outside the unit interval) the key.

`x` and `y` should be numbers between 0 and 1, giving coordinates with respect to the “display area”. Depending on the value of the “`legend.bbox`” option (see `lattice.getOption`), this can be either the full figure region (“full”), or just the region that bounds the panels and strips (“panel”).

The key essentially consists of a number of columns, possibly divided into blocks, each containing some rows. The contents of the key are determined by (possibly repeated) components named “`rectangles`”, “`lines`”, “`points`” or “`text`”. Each of these must be lists with relevant graphical parameters (see later) controlling their appearance. The `key` list itself

can contain graphical parameters, these would be used if relevant graphical components are omitted from the other components.

The length (number of rows) of each such column (except "text"s) is taken to be the largest of the lengths of the graphical components, including the ones specified outside (see the entry for `rep` below for details on this). The "text" component must have a character or expression vector as its first component, to be used as labels. The length of this vector determines the number of rows.

The graphical components that can be included in `key` and also in the components named "text", "lines", "points" and "rectangles" (as appropriate) are:

- `cex=1` (text, lines, points)
- `col="black"` (text, rectangles, lines, points)
- `alpha=1` (text, rectangles, lines, points)
- `fill="transparent"` (lines, points)
- `lty=1` (lines)
- `lwd=1` (lines, points)
- `font=1` (text, points)
- `fontface` (text, points)
- `fontfamily` (text, points)
- `pch=8` (lines, points)
- `adj=0` (text)
- `type="l"` (lines)
- `size=5` (rectangles, lines)
- `height=1` (rectangles)
- `lineheight=1` (text)
- `angle=0` (rectangles, but ignored)
- `density=-1` (rectangles, but ignored)

In addition, the component `border` can be included inside the "rect" component to control the border color of the rectangles; when specified at the top level, `border` controls the border of the entire key (see below).

`angle` and `density` are unimplemented. `size` determines the width of columns of rectangles and lines in character widths. `type` is relevant for lines; "l" denotes a line, "p" denotes a point, and "b" and "o" both denote both together. `height` gives heights of rectangles as a fraction of the default.

Other possible components of `key` are:

`reverse.rows` Logical flag, defaulting to `FALSE`. If `TRUE`, all components are reversed *after* being replicated (the details of which may depend on the value of `rep`). This is useful in certain situations, e.g., with a grouped barchart with `stack = TRUE` with the categorical variable on the vertical axis, where the bars in the plot will usually be ordered from bottom to top, but the corresponding legend will have the levels from top to bottom unless `reverse.rows = TRUE`. Note that in this case, unless all columns have the same number of rows, they will no longer be aligned.

`between` Numeric vector giving the amount of space (character widths) surrounding each column (split equally on both sides).

`title` String or expression giving a title for the key.

- `rep` Logical flag, defaults to `TRUE`. By default, it is assumed that all columns in the key (except the "text"s) will have the same number of rows, and all components are replicated to be as long as the longest. This can be suppressed by specifying `rep=FALSE`, in which case the length of each column will be determined by components of that column alone.
- `cex.title` Zoom factor for the title.
- `lines.title` The amount of vertical space to be occupied by the title in lines (in multiples of itself). Defaults to 2.
- `padding.text` The amount of space (padding) to be used above and below each row containing text, in multiples of the default, which is currently  $0.2 * \text{"lines"}$ . This padding is in addition to the normal height of any row that contains text, which is the minimum amount necessary to contain all the text entries.
- `background` Background color for the legend. Defaults to the global background color.
- `alpha.background` An alpha transparency value between 0 and 1 for the background.
- `border` Either a color for the border, or a logical flag. In the latter case, the border color is black if `border` is `TRUE`, and no border is drawn if it is `FALSE` (the default).
- `transparent=FALSE` Logical flag, whether legend should have a transparent background.
- `just` A character or numeric vector of length one or two giving horizontal and vertical justification for the placement of the legend. See [grid.layout](#) for more precise details.
- `columns` The number of column-blocks (drawn side by side) the legend is to be divided into.
- `between.columns` Space between column blocks, in addition to between.
- `divide` Number of point symbols to divide each line when `type` is "b" or "o" in lines.
- legend:** The legend argument can be useful if one wants to place more than one key. It also allows the use of arbitrary "grob"s (grid objects) as legends.
- If used, `legend` must be a list, with an arbitrary number of components. Each component must be named one of "left", "right", "top", "bottom", or "inside". The name "inside" can be repeated, but not the others. This name will be used to determine the location for that component, and is similar to the `space` component of `key`. If `key` (or `colorkey` for [levelplot](#) and [wireframe](#)) is specified, their `space` component must not conflict with the name of any component of `legend`. Each component of `legend` must have a component called `fun`. This can be a "grob", or a function (or the name of a function) that produces a "grob" when called. If this function expects any arguments, they must be supplied as a list in another component called `args`. For components named "inside", there can be additional components called `x`, `y` and `corner`, which work in the same way as for `key`.
- page:** A function of one argument (page number) to be called after drawing each page. The function must be 'grid-compliant', and is called with the whole display area as the default viewport.

`xlab.top`, `ylab.right`: Labels for the x-axis on top, and y-axis on the right. Similar to `xlab` and `ylab`, but less commonly used.

`main`: Typically a character string or expression describing the main title to be placed on top of each page. Defaults to `NULL`.

`main` (as well as `xlab`, `ylab` and `sub`) is usually a character string or an expression that gets used as the label, but can also be a list that controls further details. Expressions are treated as specification of LaTeX-like markup as described in [plotmath](#). The label can be a vector, in which case the components will be spaced out horizontally (or vertically for `ylab`). This feature can be used to provide column or row labels rather than a single axis label.

When `main` (etc.) is a list, the actual label should be specified as the `label` component (which may be unnamed if it is the first component). The label can be missing, in which case the default will be used (`xlab` and `ylab` usually have defaults, but `main` and `sub` do not). Further named arguments are passed on to `textGrob`; this can include arguments controlling positioning like `just` and `rot` as well as graphical parameters such as `col` and `font` (see [gpar](#) for a full list).

`main`, `sub`, `xlab`, `ylab`, `xlab.top`, and `ylab.right` can also be arbitrary "grob"s (grid graphical objects).

`sub`: Character string or expression (or a list or "grob") for a subtitle to be placed at the bottom of each page. See entry for `main` for finer control options.

`par.strip.text`: A list of parameters to control the appearance of strip text. Notable components are `col`, `cex`, `font`, and `lines`. The first three control graphical parameters while the last is a means of altering the height of the strips. This can be useful, for example, if the strip labels (derived from factor levels, say) are double height (i.e., contains "`\n`"-s) or if the default height seems too small or too large.

Additionally, the `lineheight` component can control the space between multiple lines. The labels can be abbreviated when shown by specifying `abbreviate = TRUE`, in which case the components `minlength` and `dot` (passed along to the [abbreviate](#) function) can be specified to control the details of how this is done.

`layout`: In general, a conditioning plot in Lattice consists of several panels arranged in a rectangular array, possibly spanning multiple pages. `layout` determines this arrangement.

`layout` is a numeric vector of length 2 or 3 giving the number of columns, rows, and pages (optional) in a multipanel display. By default, the number of columns is the number of levels of the first conditioning variable and the number of rows is the number of levels of the second conditioning variable. If there is only one conditioning variable, the default layout vector is `c(0, n)`, where `n` is the number of levels of the given vector. Any time the first value in the layout vector is 0, the second value is used as the desired number of panels per page and the actual layout is computed from this, taking into account the aspect ratio of the panels and the device dimensions (via `par("din")`). If `NA` is specified for the number of rows or columns (but not both), that dimension will be filled out according to the number of panels.

The number of pages is by default set to as many as is required to plot all the panels, and so rarely needs to be specified. However, in certain situations the default calculation may be incorrect, and in that case the number of

pages needs to be specified explicitly.

**skip:** A logical vector (default `FALSE`), replicated to be as long as the number of panels (spanning all pages). For elements that are `TRUE`, the corresponding panel position is skipped; i.e., nothing is plotted in that position. The panel that was supposed to be drawn there is now drawn in the next available panel position, and the positions of all the subsequent panels are bumped up accordingly. This may be useful for arranging plots in an informative manner.

**strip.left:** `strip.left` can be used to draw strips on the left of each panel, which can be useful for wide short panels, as in time-series (or similar) plots. See the entry for `strip` for detailed usage.

**xlab.default, ylab.default:** Fallback default for `xlab` and `ylab` when they are not specified. If `NULL`, the defaults are parsed from the Trellis formula. This is rarely useful for the end-user, but can be helpful when developing new Lattice functions.

**xscale.components, yscale.components:** Functions that determine axis annotation for the x and y axes respectively. See documentation for `xscale.components.default`, the default values of these arguments, to learn more.

**axis:** Function responsible for drawing axis annotation. See documentation for `axis.default`, the default value of this argument, to learn more.

**perm.cond:** An integer vector, a permutation of `1:n`, where `n` is the number of conditioning variables. By default, the order in which panels are drawn depends on the order of the conditioning variables specified in the formula. `perm.cond` can modify this order. If the trellis display is thought of as an `n`-dimensional array, then during printing, its dimensions are permuted using `perm.cond` as the `perm` argument does in `aperm`.

**index.cond:** Whereas `perm.cond` permutes the dimensions of the multi-dimensional array of panels, `index.cond` can be used to subset (or reorder) margins of that array. `index.cond` can be a list or a function, with behavior in each case described below.

The panel display order within each conditioning variable depends on the order of their levels. `index.cond` can be used to choose a ‘subset’ (in the R sense) of these levels, which is then used as the display order for that variable. If `index.cond` is a list, it has to be as long as the number of conditioning variables, and the `i`-th component has to be a valid indexing vector for `levels(g_i)`, where `g_i` is the `i`-th conditioning variable in the plot (note that these levels may not contain all levels of the original variable, depending on the effects of the `subset` and `drop.unused.levels` arguments). In particular, this indexing may repeat levels, or drop some altogether. The result of this indexing determines the order of panels within that conditioning variable. To keep the order of a particular variable unchanged, the corresponding component must be set to `TRUE`.

Note that the components of `index.cond` are interpreted in the order of the conditioning variables in the original call, and is not affected by `perm.cond`.

Another possibility is to specify `index.cond` as a function. In this case, this function is called once for each panel, potentially with all arguments that are passed to the panel function for that panel. (More specifically, if this function has a `...` argument, then all panel arguments are passed, otherwise, only named arguments that match are passed.) If there is only one conditioning variable, the levels of that variable are then sorted so that

these values are in ascending order. For multiple conditioning variables, the order for each variable is determined by first taking the average over all other conditioning variables.

Although they can be supplied in high-level function calls directly, it is more typical to use `perm.cond` and `index.cond` to update an existing "trellis" object, thus allowing it to be displayed in a different arrangement without re-calculating the data subsets that go into each panel. In the `update.trellis` method, both can be set to `NULL`, which reverts these back to their defaults.

`par.settings`: A list that could be supplied to `trellis.par.set`. When the resulting object is plotted, these options are applied temporarily for the duration of the plotting, after which the settings revert back to what they were before. This enables the user to attach some display settings to the trellis object itself rather than change the settings globally. See also the `lattice.options` argument described above for a similar treatment of non-graphical options.

`plot.args`: A list containing possible arguments to `plot.trellis`, which will be used by the `plot` or `print` methods when drawing the object, unless overridden explicitly. This enables the user to attach such arguments to the trellis object itself. Partial matching is not performed.

## Details

The high-level functions documented here, as well as other high-level Lattice functions, are generic, with the `formula` method usually doing the most substantial work. The structure of the plot that is produced is mostly controlled by the formula (implicitly in the case of the non-formula methods). For each unique combination of the levels of the conditioning variables `g1, g2, . . .`, a separate "packet" is produced, consisting of the points  $(x, y)$  for the subset of the data defined by that combination. The display can be thought of as a three-dimensional array of panels, consisting of one two-dimensional matrix per page. The dimensions of this array are determined by the `layout` argument. If there are no conditioning variables, the plot produced consists of a single packet. Each packet usually corresponds to one panel, but this is not strictly necessary (see the entry for `index.cond` above).

The coordinate system used by **lattice** by default is like a graph, with the origin at the bottom left, with axes increasing to the right and top. In particular, panels are by default drawn starting from the bottom left corner, going right and then up, unless `as.table = TRUE`, in which case panels are drawn from the top left corner, going right and then down. It is possible to set a global preference for the table-like arrangement by changing the default to `as.table=TRUE`; this can be done by setting `lattice.options(default.args = list(as.table = TRUE))`. Default values can be set in this manner for the following arguments: `as.table`, `aspect`, `between`, `page`, `main`, `sub`, `par.strip.text`, `layout`, `skip` and `strip`. Note that these global defaults are sometimes overridden by individual functions.

The order of the panels depends on the order in which the conditioning variables are specified, with `g1` varying fastest, followed by `g2`, and so on. Within a conditioning variable, the order depends on the order of the levels (which for factors is usually in alphabetical order). Both of these orders can be modified using the `index.cond` and `perm.cond` arguments, possibly using the `update` (and other related) method(s).

## Value

The high-level functions documented here, as well as other high-level Lattice functions, return an object of class "trellis". The `update` method can be used to subsequently update components

of the object, and the `print` method (usually called by default) will plot it on an appropriate plotting device.

### Note

Most of the arguments documented here are also applicable for the other high-level functions in the **lattice** package. These are not described in any detail elsewhere unless relevant, and this should be considered the canonical documentation for such arguments.

Any arguments passed to these functions and not recognized by them will be passed to the panel function. Most predefined panel functions have arguments that customize its output. These arguments are described only in the help pages for these panel functions, but can usually be supplied as arguments to the high-level plot.

### Examples

```
require(stats)

Tonga Trench Earthquakes

Depth <- equal.count(quakes$depth, number=8, overlap=.1)
xyplot(lat ~ long | Depth, data = quakes)
update(trellis.last.object(),
 strip = strip.custom(strip.names = TRUE, strip.levels = TRUE),
 par.strip.text = list(cex = 0.75),
 aspect = "iso")

Examples with data from 'Visualizing Data' (Cleveland, 1993) obtained
from http://cm.bell-labs.com/cm/ms/departments/sia/wsc/

EE <- equal.count(ethanol$E, number=9, overlap=1/4)

Constructing panel functions on the fly; prepanel
xyplot(NOx ~ C | EE, data = ethanol,
 prepanel = function(x, y) prepanel.loess(x, y, span = 1),
 xlab = "Compression Ratio", ylab = "NOx (micrograms/J)",
 panel = function(x, y) {
 panel.grid(h = -1, v = 2)
 panel.xyplot(x, y)
 panel.loess(x, y, span=1)
 })
```

```

 },
 aspect = "xy")

Extended formula interface

xyplot(Sepal.Length + Sepal.Width ~ Petal.Length + Petal.Width | Species,
 data = iris, scales = "free", layout = c(2, 2),
 auto.key = list(x = .6, y = .7, corner = c(0, 0)))

user defined panel functions

states <- data.frame(state.x77,
 state.name = dimnames(state.x77)[[1]],
 state.region = state.region)
xyplot(Murder ~ Population | state.region, data = states,
 groups = state.name,
 panel = function(x, y, subscripts, groups) {
 ltext(x = x, y = y, labels = groups[subscripts], cex=1,
 fontfamily = "HersheySans")
 })

Stacked bar chart

barchart(yield ~ variety | site, data = barley,
 groups = year, layout = c(1,6), stack = TRUE,
 auto.key = list(space = "right"),
 ylab = "Barley Yield (bushels/acre)",
 scales = list(x = list(rot = 45)))

bwplot(voice.part ~ height, data=singer, xlab="Height (inches)")

dotplot(variety ~ yield | year * site, data=barley)

Grouped dot plot showing anomaly at Morris

dotplot(variety ~ yield | site, data = barley, groups = year,
 key = simpleKey(levels(barley$year), space = "right"),
 xlab = "Barley Yield (bushels/acre) ",
 aspect=0.5, layout = c(1,6), ylab=NULL)

stripplot(voice.part ~ jitter(height), data = singer, aspect = 1,
 jitter.data = TRUE, xlab = "Height (inches)")

Interaction Plot

xyplot(decrease ~ treatment, OrchardSprays, groups = rowpos,
 type = "a",
 auto.key =
 list(space = "right", points = FALSE, lines = TRUE))

longer version with no x-ticks

Not run:
bwplot(decrease ~ treatment, OrchardSprays, groups = rowpos,
 panel = "panel.superpose",
 panel.groups = "panel.linejoin",

```

```

xlab = "treatment",
key = list(lines = Rows(trellis.par.get("superpose.line"),
 c(1:7, 1)),
 text = list(lab = as.character(unique(OrchardSprays$rowpos))),
 columns = 4, title = "Row position"))

End(Not run)

```

B\_01\_xyplot.ts

*Time series plotting methods*

## Description

This function handles time series plotting, including cut-and-stack plots. Examples are given of superposing, juxtaposing and styling different time series.

## Usage

```

S3 method for class 'ts'
xyplot(x, data = NULL,
 screens = if (superpose) 1 else colnames(x),
 ...,
 superpose = FALSE,
 cut = FALSE,
 type = "l",
 col = NULL,
 lty = NULL,
 lwd = NULL,
 pch = NULL,
 cex = NULL,
 fill = NULL,
 auto.key = superpose,
 panel = if (superpose) "panel.superpose"

 par.settings = list(),
 layout = NULL, as.table = TRUE,
 xlab = "Time", ylab = NULL,
 default.scales = list(y = list(relation =
 if (missing(cut)) "free" else "same")))

```

## Arguments

|         |                                                                                                                                                                                                                                   |
|---------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x       | an object of class <code>ts</code> , which may be multi-variate, i.e. have a matrix structure with multiple columns.                                                                                                              |
| data    | not used, and must be left as <code>NULL</code> .                                                                                                                                                                                 |
| ...     | additional arguments passed to <code>xyplot</code> , which may pass them on to <code>panel.xyplot</code> .                                                                                                                        |
| screens | factor (or coerced to factor) whose levels specify which panel each series is to be plotted in. <code>screens = c(1, 2, 1)</code> would plot series 1, 2 and 3 in panels 1, 2 and 1. May also be a named list, see Details below. |

|                                                  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|--------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>superpose</code>                           | overlays all series in one panel (via <code>screens = 1</code> ) and uses grouped style settings (from <code>trellis.par.get("superpose.line")</code> , etc). Note that this is just a convenience argument: its only action is to change the default values of other arguments.                                                                                                                                                                                                                                                                                                                                  |
| <code>cut</code>                                 | defines a cut-and-stack plot. <code>cut</code> can be a list of arguments to the function <code>equal.count</code> , i.e. <code>number</code> (number of intervals to divide into) and <code>overlap</code> (the fraction of overlap between cuts, default 0.5). If <code>cut</code> is numeric this is passed as the <code>number</code> argument.<br><br><code>cut = TRUE</code> tries to choose an appropriate number of cuts (up to a maximum of 6), using <code>banking</code> , and assuming a square plot region. This should have the effect of minimising wasted space when <code>aspect = "xy"</code> . |
| <code>type, col, lty, lwd, pch, cex, fill</code> | graphical arguments, which are processed and eventually passed to <code>panel.xyplot</code> . These arguments can also be vectors or (named) lists, see Details for more information.                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>auto.key</code>                            | a logical, or a list describing how to draw a key. See the <code>auto.key</code> entry in <code>xyplot</code> . The default here is to draw lines, not points, and any specified style arguments should show up automatically.                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>panel</code>                               | the panel function. It is recommended to leave this alone, but one can pass a <code>panel.groups</code> argument which is handled by <code>panel.superpose</code> for each series.                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>par.settings</code>                        | style settings beyond the standard <code>col</code> , <code>lty</code> , <code>lwd</code> , etc; see <code>trellis.par.set</code> and <code>simpleTheme</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <code>layout</code>                              | numeric vector of length 2 specifying number of columns and rows in the plot. The default is to fill columns with up to 6 rows.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>as.table</code>                            | to draw panels from top to bottom. The order is determined by the order of columns in <code>x</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <code>xlab, ylab</code>                          | X axis and Y axis labels; see <code>xyplot</code> . Note in particular that <code>ylab</code> may be a character vector, in which case the labels are spaced out equally, to correspond to the panels; but <i>NOTE</i> in this case the vector should be reversed OR the argument <code>as.table</code> set to <code>FALSE</code> .                                                                                                                                                                                                                                                                               |
| <code>default.scales</code>                      | scales specification. The default is set to have "free" Y axis scales unless <code>cut</code> is given. Note, users should pass the <code>scales</code> argument rather than <code>default.scales</code> .                                                                                                                                                                                                                                                                                                                                                                                                        |

## Details

The handling of several graphical parameters is more flexible for multivariate series. These parameters can be vectors of the same length as the number of series plotted or are recycled if shorter. They can also be (partially) named list, e.g., `list(A = c(1, 2), c(3, 4))` in which `c(3, 4)` is the default value and `c(1, 2)` the value only for series A. The `screens` argument can be specified in a similar way.

Some examples are given below.

## Value

An object of class "trellis". The `update` method can be used to update components of the object and the `print` method (usually called by default) will plot it on an appropriate plotting device.

**Author(s)**

Gabor Grothendieck, Achim Zeileis, Deepayan Sarkar and Felix Andrews  
<felix@nfrac.org>.

The first two authors developed `xyplot.ts` in their **zoo** package, including the `screens` approach. The third author developed a different `xyplot.ts` for cut-and-stack plots in the **lattice-Extra** package. The final author fused these together.

**References**

Sarkar, Deepayan (2008) *Lattice: Multivariate Data Visualization with R*, Springer. <http://lmdvr.r-forge.r-project.org/> (cut-and-stack plots)

**See Also**

`xyplot`, `panel.xyplot`, `plot.ts`, `ts`, `xyplot.zoo` in the **zoo** package.

**Examples**

```
xyplot(ts(c(1:10,10:1)))

Figure 14.1 from Sarkar (2008)
xyplot(sunspot.year, aspect = "xy",
 strip = FALSE, strip.left = TRUE,
 cut = list(number = 4, overlap = 0.05))

A multivariate example; first juxtaposed, then superposed
xyplot(EuStockMarkets, scales = list(y = "same"))
xyplot(EuStockMarkets, superpose = TRUE, aspect = "xy", lwd = 2,
 type = c("l","g"), ylim = c(0, max(EuStockMarkets)))

Examples using screens (these two are identical)
xyplot(EuStockMarkets, screens = c(rep("Continental", 3), "UK"))
xyplot(EuStockMarkets, screens = list(FTSE = "UK", "Continental"))

Automatic group styles
xyplot(EuStockMarkets, screens = list(FTSE = "UK", "Continental"),
 superpose = TRUE)

xyplot(EuStockMarkets, screens = list(FTSE = "UK", "Continental"),
 superpose = TRUE, xlim = extendrange(1996:1998),
 par.settings = standard.theme(color = FALSE))

Specifying styles for series by name
xyplot(EuStockMarkets, screens = list(FTSE = "UK", "Continental"),
 col = list(DAX = "red", FTSE = "blue", "black"), auto.key = TRUE)

xyplot(EuStockMarkets, screens = list(FTSE = "UK", "Continental"),
 col = list(DAX = "red"), lty = list(SMI = 2), lwd = 1:2,
 auto.key = TRUE)

Example with simpler data, few data points
set.seed(1)
z <- ts(cbind(a = 1:5, b = 11:15, c = 21:25) + rnorm(5))
xyplot(z, screens = 1)
xyplot(z, screens = list(a = "primary (a)", "other (b & c)"),
```

```
type = list(a = c("p", "h"), b = c("p", "s"), "o"),
pch = list(a = 2, c = 3), auto.key = list(type = "o"))
```

---

B\_02\_barchart.table

*table methods for barchart and dotplot*

---

## Description

Contingency tables are often displayed using bar charts and dot plots. These methods operate directly on tables, bypassing the need to convert them to data frames for use with the formula interface. Matrices and arrays are also supported, by coercing them to tables.

## Usage

```
S3 method for class 'table'
barchart(x, data, groups = TRUE,
 origin = 0, stack = TRUE, ..., horizontal = TRUE)

S3 method for class 'array'
barchart(x, data, ...)

S3 method for class 'matrix'
barchart(x, data, ...)

S3 method for class 'table'
dotplot(x, data, groups = TRUE, ..., horizontal = TRUE)

S3 method for class 'array'
dotplot(x, data, ...)

S3 method for class 'matrix'
dotplot(x, data, ...)
```

## Arguments

|               |                                                                                                                           |
|---------------|---------------------------------------------------------------------------------------------------------------------------|
| x             | A table, array or matrix object.                                                                                          |
| data          | Should not be specified. If specified, will be ignored with a warning.                                                    |
| groups        | A logical flag, indicating whether to use the last dimension as a grouping variable in the display.                       |
| origin, stack | Arguments to <a href="#">panel.barchart</a> . The defaults for the table method are different.                            |
| horizontal    | Logical flag, indicating whether the plot should be horizontal (with the categorical variable on the y-axis) or vertical. |
| ...           | Other arguments, passed to the underlying formula method.                                                                 |

```

S3 method for class 'numeric'
densityplot(x, data = NULL, xlab, ...)

do.breaks(endpoints, nint)

```

## Arguments

**x** The object on which method dispatch is carried out.

For the `formula` method, `x` can be a formula of the form `~ x | g1 * g2 * ...`, indicating that histograms or kernel density estimates of the `x` variable should be produced conditioned on the levels of the (optional) variables `g1`, `g2`, .... `x` should be numeric (or possibly a factor in the case of `histogram`), and each of `g1`, `g2`, ... should be either factors or shingles.

As a special case, the right hand side of the formula can contain more than one

term separated by '+' signs (e.g.,  $\sim x_1 + x_2 \mid g_1 * g_2$ ). What happens in this case is described in the documentation for [xyplot](#). Note that in either form, all the terms in the formula must have the same length after evaluation.

For the `numeric` and `factor` methods, `x` is the variable whose histogram or Kernel density estimate is drawn. Conditioning is not allowed in these cases.

|                        |                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>data</code>      | For the <code>formula</code> method, an optional data source (usually a data frame) in which variables are to be evaluated (see <a href="#">xyplot</a> for details). <code>data</code> should not be specified for the other methods, and is ignored with a warning if it is.                                                                                                                                                     |
| <code>type</code>      | A character string indicating the type of histogram that is to be drawn. "percent" and "count" give relative frequency and frequency histograms respectively, and can be misleading when breakpoints are not equally spaced. "density" produces a density histogram.<br><br>type defaults to "density" when the breakpoints are unequally spaced, and when <code>breaks</code> is NULL or a function, and to "percent" otherwise. |
| <code>nint</code>      | An integer specifying the number of histogram bins, applicable only when <code>breaks</code> is unspecified or NULL in the call. Ignored when the variable being plotted is a factor.                                                                                                                                                                                                                                             |
| <code>endpoints</code> | A numeric vector of length 2 indicating the range of x-values that is to be covered by the histogram. This applies only when <code>breaks</code> is unspecified and the variable being plotted is not a factor. In <code>do.breaks</code> , this specifies the interval that is to be divided up.                                                                                                                                 |
| <code>breaks</code>    | Usually a numeric vector of length (number of bins + 1) defining the breakpoints of the bins. Note that when breakpoints are not equally spaced, the only value of <code>type</code> that makes sense is <code>density</code> .<br><br>When <code>breaks</code> is unspecified, the value of <code>lattice.getOption("histogram.breaks")</code> is first checked. If this value is NULL, then the default is to use               |

```
breaks = seq_len(1 + nlevels(x)) - 0.5
```

when `x` is a factor, and

```
breaks = do.breaks(endpoints, nint)
```

otherwise. Breakpoints calculated in such a manner are used in all panels. If the retrieved value is not NULL, or if `breaks` is explicitly specified, it affects the display in each panel independently. Valid values are those accepted as the `breaks` argument in [hist](#). In particular, this allows specification of `breaks` as an integer giving the number of bins (similar to `nint`), as a character string denoting a method, or as a function.

When specified explicitly, a special value of `breaks` is NULL, in which case the number of bins is determined by `nint` and then breakpoints are chosen according to the value of `equal.widths`.

|                           |                                                                                                                                                                                                                            |
|---------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>equal.widths</code> | A logical flag, relevant only when <code>breaks=NULL</code> . If TRUE, equally spaced bins will be selected, otherwise, approximately equal area bins will be selected (typically producing unequally spaced breakpoints). |
| <code>n</code>            | Integer, giving the number of points at which the kernel density is to be evaluated. Passed on as an argument to <a href="#">density</a> .                                                                                 |

|                                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>panel</code>                 | A function, called once for each panel, that uses the packet (subset of panel variables) corresponding to the panel to create a display. The default panel functions <code>panel.histogram</code> and <code>panel.densityplot</code> are documented separately, and have arguments that can be used to customize its output in various ways. Such arguments can usually be directly supplied to the high-level function.                                                                                                           |
| <code>allow.multiple, outer</code> | See <code>xyplot</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <code>auto.key</code>              | See <code>xyplot</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| <code>default.prepanel</code>      | Fallback <code>prepanel</code> function. See <code>xyplot</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <code>weights</code>               | <p>numeric vector of weights for the density calculations, evaluated in the non-standard manner used for <code>groups</code> and terms in the formula, if any. If this is specified, it is subsetted using <code>subscripts</code> inside the panel function to match it to the corresponding <code>x</code> values.</p> <p>At the time of writing, <code>weights</code> do not work in conjunction with an extended formula specification (this is not too hard to fix, so just bug the maintainer if you need this feature).</p> |
| <code>bw, adjust, width</code>     | Arguments controlling bandwidth. Passed on as arguments to <code>density</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <code>kernel, window</code>        | The choice of kernel. Passed on as arguments to <code>density</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>give.Rkern</code>            | Logical flag, passed on as argument to <code>density</code> . This argument is made available only for ease of implementation, and will produce an error if <code>TRUE</code> .                                                                                                                                                                                                                                                                                                                                                    |
| <code>from, to, cut</code>         | Controls range over which density is evaluated. Passed on as arguments to <code>density</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>na.rm</code>                 | Logical flag specifying whether NA values should be ignored. Passed on as argument to <code>density</code> , but unlike in <code>density</code> , the default is <code>TRUE</code> .                                                                                                                                                                                                                                                                                                                                               |
| <code>...</code>                   | Further arguments. See corresponding entry in <code>xyplot</code> for non-trivial details.                                                                                                                                                                                                                                                                                                                                                                                                                                         |

## Details

`histogram` draws Conditional Histograms, and `densityplot` draws Conditional Kernel Density Plots. The default panel function uses the `density` function to compute the density estimate, and all arguments accepted by `density` can be specified in the call to `densityplot` to control the output. See documentation of `density` for details.

These and all other high level Trellis functions have several arguments in common. These are extensively documented only in the help page for `xyplot`, which should be consulted to learn more detailed usage.

`do.breaks` is an utility function that calculates breakpoints given an interval and the number of pieces to break it into.

## Value

An object of class "trellis". The `update` method can be used to update components of the object and the `print` method (usually called by default) will plot it on an appropriate plotting device.

## Note

The form of the arguments accepted by the default panel function `panel.histogram` is different from that in S-PLUS. Whereas S-PLUS calculates the heights inside `histogram` and passes only the breakpoints and the heights to the panel function, **lattice** simply passes along the original variable `x` along with the breakpoints. This approach is more flexible; see the example below with an estimated density superimposed over the histogram.

## Examples

```
require(stats)
histogram(~ height | voice.part, data = singer, nint = 17,
 endpoints = c(59.5, 76.5), layout = c(2,4), aspect = 1,
 xlab = "Height (inches)")

histogram(~ height | voice.part, data = singer,
 xlab = "Height (inches)", type = "density",
 panel = function(x, ...) {
 panel.histogram(x, ...)
 panel.mathdensity(dmath = dnorm, col = "black",
 args = list(mean=mean(x), sd=sd(x)))
 })
```

```
densityplot(~ height | voice.part, data = singer, layout = c(2, 4),
 xlab = "Height (inches)", bw = 5)
```

B\_04\_qqmath

*Q-Q Plot with Theoretical Distribution*

## Description

Draw quantile-Quantile plots of a sample against a theoretical distribution, possibly conditioned on other variables.

## Usage

```
qqmath(x, data, ...)

S3 method for class 'formula'
qqmath(x,
 data,
 allow.multiple = is.null(groups) || outer,
 outer = !is.null(groups),
 distribution = qnorm,
 f.value = NULL,
 auto.key = FALSE,
 aspect = "fill",
 panel = lattice.getOption("panel.qqmath"),
 prepanel = NULL,
 scales, strip, groups,
 xlab, xlim, ylab, ylim,
 drop.unused.levels = lattice.getOption("drop.unused.levels"),
 ...,
 lattice.options = NULL,
 default.scales = list(),
 default.prepanel = lattice.getOption("prepanel.default.qqmath"),
 subscripts,
 subset)
S3 method for class 'numeric'
qqmath(x, data = NULL, ylab, ...)
```

## Arguments

- |              |                                                                                                                                                                                                                                                                                                                                                           |
|--------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x            | The object on which method dispatch is carried out.<br>For the "formula" method, x should be a formula of the form <code>~ x   g1 * g2 * ...</code> , where x should be a numeric variable. For the "numeric" method, x should be a numeric vector.                                                                                                       |
| data         | For the formula method, an optional data source (usually a data frame) in which variables are to be evaluated (see <a href="#">xyplot</a> for details). data should not be specified for the other methods, and is ignored with a warning if it is.                                                                                                       |
| distribution | A quantile function that takes a vector of probabilities as argument and produces the corresponding quantiles from a theoretical distribution. Possible values are <a href="#">qnorm</a> , <a href="#">qunif</a> , etc. Distributions with other required arguments need to be provided as user-defined functions (see example with <a href="#">qt</a> ). |

|                                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>f.value</code>               | <p>An optional numeric vector of probabilities, quantiles corresponding to which should be plotted. This can also be a function of a single integer (representing sample size) that returns such a numeric vector. A typical value for this argument is the function <code>ppoints</code>, which is also the S-PLUS default. If specified, the probabilities generated by this function is used for the plotted quantiles, through the <code>quantile</code> function for the sample, and the function specified as the <code>distribution</code> argument for the theoretical distribution.</p> <p><code>f.value</code> defaults to <code>NULL</code>, which has the effect of using <code>ppoints</code> for the quantiles of the theoretical distribution, but the exact data values for the sample. This is similar to what happens for <code>qqnorm</code>, but different from the S-PLUS default of <code>f.value=ppoints</code>.</p> <p>For large <code>x</code>, this argument can be used to restrict the number of points plotted. See also the <code>tails.n</code> argument in <code>panel.qqmath</code>.</p> |
| <code>panel</code>                 | <p>A function, called once for each panel, that uses the <code>packet</code> (subset of panel variables) corresponding to the panel to create a display. The default panel function <code>panel.qqmath</code> is documented separately, and has arguments that can be used to customize its output in various ways. Such arguments can usually be directly supplied to the high-level function.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <code>allow.multiple, outer</code> | See <code>xyplot</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <code>auto.key</code>              | See <code>xyplot</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <code>aspect</code>                | See <code>xyplot</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

## Details

`qqmath` produces Q-Q plots of the given sample against a theoretical distribution. The default behaviour of `qqmath` is different from the corresponding S-PLUS function, but is similar to `qqnorm`. See the entry for `f.value` for specifics.

The implementation details are also different from S-PLUS. In particular, all the important calculations are done by the `panel` (and `prepanel` function) and not `qqmath` itself. In fact, both the

arguments `distribution` and `f.value` are passed unchanged to the panel and prepanel function. This allows, among other things, display of grouped Q-Q plots, which are often useful. See the help page for [panel.qqmath](#) for further details.

This and all other high level Trellis functions have several arguments in common. These are extensively documented only in the help page for [xyplot](#), which should be consulted to learn more detailed usage.

### Value

An object of class "trellis". The [update](#) method can be used to update components of the object and the [print](#) method (usually called by default) will plot it on an appropriate plotting device.

### Examples

```
qqmath(~ rnorm(100), distribution = function(p) qt(p, df = 10))
qqmath(~ height | voice.part, aspect = "xy", data = singer,
 prepanel = prepanel.qqmathline,
 panel = function(x, ...) {
 panel.qqmathline(x, ...)
 panel.qqmath(x, ...)
 })
vp.comb <-
 factor(sapply(strsplit(as.character(singer$voice.part), split = " "),
 "[", 1),
 levels = c("Bass", "Tenor", "Alto", "Soprano"))
vp.group <-
 factor(sapply(strsplit(as.character(singer$voice.part), split = " "),
 "[", 2))
qqmath(~ height | vp.comb, data = singer,
 groups = vp.group, auto.key = list(space = "right"),
 aspect = "xy",
 prepanel = prepanel.qqmathline,
 panel = function(x, ...) {
 panel.qqmathline(x, ...)
 panel.qqmath(x, ...)
 })
```

### Description

Quantile-Quantile plots for comparing two Distributions

**Usage**

```
qq(x, data, ...)

S3 method for class 'formula'
qq(x, data, aspect = "fill",
 panel = lattice.getOption("panel.qq"),
 prepanel, scales, strip,
 groups, xlab, xlim, ylab, ylim, f.value = NULL,
 drop.unused.levels = lattice.getOption("drop.unused.levels"),
 ...,
 lattice.options = NULL,
 qtype = 7,
 default.scales = list(),
 default.prepanel = lattice.getOption("prepanel.default.qq"),
 subscripts,
 subset)
```

**Arguments**

- |          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x        | <p>The object on which method dispatch is carried out.</p> <p>For the "formula" method, x should be a formula of the form <math>y \sim x \mid g1 * g2 * \dots</math>, where x should be a numeric variable, and y a factor, shingle, character, or numeric variable, with the restriction that there must be exactly two levels of y, which divide the values of x into two groups. Quantiles for these groups will be plotted against each other along the two axes.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| data     | <p>For the formula method, an optional data source (usually a data frame) in which variables are to be evaluated (see <a href="#">xyplot</a> for details).</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| f.value  | <p>An optional numeric vector of probabilities, quantiles corresponding to which should be plotted. This can also be a function of a single integer (representing sample size) that returns such a numeric vector. A typical value for this argument is the function <code>ppoints</code>, which is also the S-PLUS default. If specified, the probabilities generated by this function is used for the plotted quantiles, through the <code>quantile</code> function.</p> <p>f.value defaults to NULL, which is equivalent to</p> <pre>f.value = function(n) ppoints(n, a = 1)</pre> <p>This has the effect of including the minimum and maximum data values in the computed quantiles. This is similar to what happens for <code>qqplot</code> but different from the default behaviour of <code>qq</code> in S-PLUS.</p> <p>For large x, this argument can be used to restrict the number of quantiles plotted.</p> |
| panel    | <p>A function, called once for each panel, that uses the packet (subset of panel variables) corresponding to the panel to create a display. The default panel function <code>panel.qq</code> is documented separately, and has arguments that can be used to customize its output in various ways. Such arguments can usually be directly supplied to the high-level function.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| qtype    | <p>The type argument for <a href="#">quantile</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

## Details

`qq` produces Q-Q plots of two samples. The default behaviour of `qq` is different from the corresponding S-PLUS function. See the entry for `f.value` for specifics.

This and all other high level Trellis functions have several arguments in common. These are extensively documented only in the help page for `xyplot`, which should be consulted to learn more detailed usage.

## Value

An object of class `"trellis"`. The [update](#) method can be used to update components of the object and the [print](#) method (usually called by default) will plot it on an appropriate plotting device.

## Author(s)

## Examples

```
qq(voice.part ~ height, aspect = 1, data = singer,
 subset = (voice.part == "Bass 2" | voice.part == "Tenor 1"))
```

B\_06\_levelplot

*Level plots and contour plots***Description**

Draws false color level plots and contour plots.

**Usage**

```

levelplot(x, data, ...)
contourplot(x, data, ...)

S3 method for class 'formula'
levelplot(x,
 data,
 allow.multiple = is.null(groups) || outer,
 outer = TRUE,
 aspect = "fill",
 panel = if (useRaster) lattice.getOption("panel.levelplot.raster")
 else lattice.getOption("panel.levelplot"),
 prepanel = NULL,
 scales = list(),
 strip = TRUE,
 groups = NULL,
 xlab,
 xlim,
 ylab,
 ylim,
 at,
 cuts = 15,
 pretty = FALSE,
 region = TRUE,
 drop.unused.levels =
 lattice.getOption("drop.unused.levels"),
 ...,
 useRaster = FALSE,
 lattice.options = NULL,
 default.scales = list(),
 default.prepanel =
 lattice.getOption("prepanel.default.levelplot"),
 colorkey = region,
 col.regions,
 alpha.regions,
 subset = TRUE)

S3 method for class 'formula'
contourplot(x,
 data,
 panel = lattice.getOption("panel.contourplot"),
 default.prepanel =
 lattice.getOption("prepanel.default.contourplot"),

```

```

cuts = 7,
labels = TRUE,
contour = TRUE,
pretty = TRUE,
region = FALSE,
...)

S3 method for class 'table'
levelplot(x, data = NULL, aspect = "iso", ..., xlim, ylim)

S3 method for class 'table'
contourplot(x, data = NULL, aspect = "iso", ..., xlim, ylim)

S3 method for class 'matrix'
levelplot(x, data = NULL, aspect = "iso",
..., xlim, ylim,
row.values = seq_len(nrow(x)),
column.values = seq_len(ncol(x)))

S3 method for class 'matrix'
contourplot(x, data = NULL, aspect = "iso",
..., xlim, ylim,
row.values = seq_len(nrow(x)),
column.values = seq_len(ncol(x)))

S3 method for class 'array'
levelplot(x, data = NULL, ...)

S3 method for class 'array'
contourplot(x, data = NULL, ...)

```

## Arguments

**x** for the formula method, a formula of the form  $z \sim x * y \mid g1 * g2 * \dots$ , where  $z$  is a numeric response, and  $x, y$  are numeric values evaluated on a rectangular grid.  $g1, g2, \dots$  are optional conditional variables, and must be either factors or shingles if present.

Calculations are based on the assumption that all  $x$  and  $y$  values are evaluated on a grid (defined by their unique values). The function will not return an error if this is not true, but the display might not be meaningful. However, the  $x$  and  $y$  values need not be equally spaced.

Both `levelplot` and `wireframe` have methods for `matrix`, `array`, and `table` objects, in which case  $x$  provides the  $z$  vector described above, while its rows and columns are interpreted as the  $x$  and  $y$  vectors respectively. This is similar to the form used in `filled.contour` and `image`. For higher-dimensional arrays and tables, further dimensions are used as conditioning variables. Note that the `dimnames` may be duplicated; this is handled by calling `make.unique` to make the names unique (although the original labels are used for the  $x$ - and  $y$ -axes).

| <code>data</code>                      | For the formula methods, an optional data frame in which variables in the formula (as well as <code>groups</code> and <code>subset</code> , if any) are to be evaluated. Usually ignored with a warning in other cases.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>row.values, column.values</code> | Optional vectors of values that define the grid when <code>x</code> is a matrix. <code>row.values</code> and <code>column.values</code> must have the same lengths as <code>nrow(x)</code> and <code>ncol(x)</code> respectively. By default, row and column numbers.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>panel</code>                     | panel function used to create the display, as described in <a href="#">xyplot</a>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <code>aspect</code>                    | For the matrix methods, the default aspect ratio is chosen to make each cell square. The usual default is <code>aspect="fill"</code> , as described in <a href="#">xyplot</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <code>at</code>                        | A numeric vector giving breakpoints along the range of <code>z</code> . Contours (if any) will be drawn at these heights, and the regions in between would be colored using <code>col.regions</code> . In the latter case, values outside the range of <code>at</code> will not be drawn at all. This serves as a way to limit the range of the data shown, similar to what a <code>zlim</code> argument might have been used for. However, this also means that when supplying <code>at</code> explicitly, one has to be careful to include values outside the range of <code>z</code> to ensure that all the data are shown.<br><code>at</code> can have length one only if <code>region=FALSE</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <code>col.regions</code>               | color vector to be used if <code>regions</code> is TRUE. The general idea is that this should be a color vector of moderately large length (longer than the number of regions. By default this is 100). It is expected that this vector would be gradually varying in color (so that nearby colors would be similar). When the colors are actually chosen, they are chosen to be equally spaced along this vector. When there are more regions than colors in <code>col.regions</code> , the colors are recycled. The actual color assignment is performed by <a href="#">level.colors</a> , which is documented separately.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>alpha.regions</code>             | numeric, specifying alpha transparency (works only on some devices)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <code>colorkey</code>                  | logical specifying whether a color key is to be drawn alongside the plot, or a list describing the color key. The list may contain the following components:<br><code>space</code> : location of the colorkey, can be one of "left", "right", "top" and "bottom". Defaults to "right".<br><code>x, y</code> : location, currently unused<br><code>col</code> : A color ramp specification, as in the <code>col.regions</code> argument in <a href="#">level.colors</a><br><code>at</code> : numeric vector specifying where the colors change. must be of length 1 more than the <code>col</code> vector.<br><code>tri.lower, tri.upper</code> : Logical or numeric controlling whether the first and last intervals should be triangular instead of rectangular. With the default value (NA), this happens only if the corresponding extreme <code>at</code> values are <code>-Inf</code> or <code>Inf</code> respectively, and the triangles occupy 5% of the total length of the color key. If numeric and between 0 and 0.25, these give the corresponding fraction, which is again 5% when specified as TRUE.<br><code>labels</code> : a character vector for labelling the <code>at</code> values, or more commonly, a list describing characteristics of the labels. This list may include components <code>labels</code> , <code>at</code> , <code>cex</code> , <code>col</code> , <code>rot</code> , <code>font</code> , <code>fontface</code> and <code>fontfamily</code> .<br><code>tick.number</code> : The approximate number of ticks desired.<br><code>tck</code> : A (scalar) multiplier for tick lengths. |

Some are processed by <code>levelplot</code> or <code>contourplot</code> , and those that are unrecognized are passed on to the panel function.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <code>useRaster</code>                                                                                                                                                                                                                          | <p>A logical flag indicating whether raster representations should be used, both for the false color image and the color key (if present). Effectively, setting this to <code>TRUE</code> changes the default panel function from <code>panel.levelplot</code> to <code>panel.levelplot.raster</code>, and sets the default value of <code>colorkey\$raster</code> to <code>TRUE</code>.</p> <p>Note that <code>panel.levelplot.raster</code> provides only a subset of the features of <code>panel.levelplot</code>, but setting <code>useRaster=TRUE</code> will not check whether any of the additional features have been requested.</p> <p>Not all devices support raster images. For devices that appear to lack support, <code>useRaster=TRUE</code> will be ignored with a warning.</p> |

## Details

These and all other high level Trellis functions have several arguments in common. These are extensively documented only in the help page for `xyplot`, which should be consulted to learn more detailed usage.

Other useful arguments are mentioned in the help page for the default panel function `panel.levelplot` (these are formally arguments to the panel function, but can be specified in the high level calls directly).

**Value**

An object of class "trellis". The `update` method can be used to update components of the object and the `print` method (usually called by default) will plot it on an appropriate plotting device.

**Author(s)**

Deepayan Sarkar <Deepayan.Sarkar@R-project.org>

**Examples**

```
x <- seq(pi/4, 5 * pi, length.out = 100)
y <- seq(pi/4, 5 * pi, length.out = 100)
r <- as.vector(sqrt(outer(x^2, y^2, "+")))
grid <- expand.grid(x=x, y=y)
grid$z <- cos(r^2) * exp(-r/(pi^3))
levelplot(z ~ x * y, grid, cuts = 50, scales=list(log="e"), xlab="",
 ylab="", main="Weird Function", sub="with log scales",
 colorkey = FALSE, region = TRUE)
triangular end-points in color key
levelplot(z ~ x * y, grid, col.regions = topo.colors(10),
 at = c(-Inf, seq(-0.8, 0.8, by = 0.2), Inf))

#S-PLUS example
require(stats)
attach(environmental)
ozo.m <- loess((ozone^(1/3)) ~ wind * temperature * radiation,
 parametric = c("radiation", "wind"), span = 1, degree = 2)
w.marginal <- seq(min(wind), max(wind), length.out = 50)
t.marginal <- seq(min(temperature), max(temperature), length.out = 50)
r.marginal <- seq(min(radiation), max(radiation), length.out = 4)
wtr.marginal <- list(wind = w.marginal, temperature = t.marginal,
 radiation = r.marginal)
grid <- expand.grid(wtr.marginal)
grid[, "fit"] <- c(predict(ozo.m, grid))
contourplot(fit ~ wind * temperature | radiation, data = grid,
 cuts = 10, region = TRUE,
 xlab = "Wind Speed (mph)",
 ylab = "Temperature (F)",
 main = "Cube Root Ozone (cube root ppb)")
detach()
```

## Description

Generic functions to draw 3d scatter plots and surfaces. The "formula" methods do most of the actual work.

## Usage

```
cloud(x, data, ...)
wireframe(x, data, ...)

S3 method for class 'formula'
cloud(x,
 data,
 allow.multiple = is.null(groups) || outer,
 outer = FALSE,
 auto.key = FALSE,
 aspect = c(1,1),
 panel.aspect = 1,
 panel = lattice.getOption("panel.cloud"),
 prepanel = NULL,
 scales = list(),
 strip = TRUE,
 groups = NULL,
 xlab,
 ylab,
 zlab,
 xlim = if (is.factor(x)) levels(x) else range(x, finite = TRUE),
 ylim = if (is.factor(y)) levels(y) else range(y, finite = TRUE),
 zlim = if (is.factor(z)) levels(z) else range(z, finite = TRUE),
 at,
 drape = FALSE,
 pretty = FALSE,
 drop.unused.levels,
 ...,
 lattice.options = NULL,
 default.scales =
 list(distance = c(1, 1, 1),
 arrows = TRUE,
 axs = axs.default),
 default.prepanel = lattice.getOption("prepanel.default.cloud"),
 colorkey,
 col.regions,
 alpha.regions,
 cuts = 70,
 subset = TRUE,
 axs.default = "r")

S3 method for class 'formula'
```

```

wireframe(x,
 data,
 panel = lattice.getOption("panel.wireframe"),
 default.prepanel = lattice.getOption("prepanel.default.wireframe"),
 ...)

S3 method for class 'matrix'
cloud(x, data = NULL, type = "h",
 zlab = deparse(substitute(x)), aspect, ...,
 xlim, ylim, row.values, column.values)

S3 method for class 'table'
cloud(x, data = NULL, groups = FALSE,
 zlab = deparse(substitute(x)),
 type = "h", ...)

S3 method for class 'matrix'
wireframe(x, data = NULL,
 zlab = deparse(substitute(x)), aspect, ...,
 xlim, ylim, row.values, column.values)

```

| x                                                                                      | <p>The object on which method dispatch is carried out.</p> <p>For the "formula" methods, a formula of the form <math>z \sim x * y \mid g1 * g2 * \dots</math>, where <math>z</math> is a numeric response, and <math>x, y</math> are numeric values. <math>g1, g2, \dots</math>, if present, are conditioning variables used for conditioning, and must be either factors or shingles. In the case of <code>wireframe</code>, calculations are based on the assumption that the <math>x</math> and <math>y</math> values are evaluated on a rectangular grid defined by their unique values. The grid points need not be equally spaced.</p> <p>For <code>wireframe</code>, <math>x, y</math> and <math>z</math> may also be matrices (of the same dimension), in which case they are taken to represent a 3-D surface parametrized on a 2-D grid (e.g., a sphere). Conditioning is not possible with this feature. See details below.</p> <p>Missing values are allowed, either as NA values in the <math>z</math> vector, or missing rows in the data frame (note however that in that case the <math>X</math> and <math>Y</math> grids will be determined only by the available values). For a grouped display (producing multiple surfaces), missing rows are not allowed, but NA-s in <math>z</math> are.</p> <p>Both <code>wireframe</code> and <code>cloud</code> have methods for <code>matrix</code> objects, in which case <math>x</math> provides the <math>z</math> vector described above, while its rows and columns are interpreted as the <math>x</math> and <math>y</math> vectors respectively. This is similar to the form used in <code>persp</code>.</p> |
| data                                                                                   | <p>for the "formula" methods, an optional data frame in which variables in the formula (as well as <code>groups</code> and <code>subset</code>, if any) are to be evaluated. <code>data</code> should not be specified except when using the "formula" method.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| row.values, column.values                                                              | <p>Optional vectors of values that define the grid when <math>x</math> is a matrix. <code>row.values</code> and <code>column.values</code> must have the same lengths as <code>nrow(x)</code> and <code>ncol(x)</code> respectively. By default, row and column numbers.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

|                      | dimension should be used as a grouping variable as opposed to a conditioning variable. This is only relevant if the table has more than 2 dimensions.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| type                 | type of display in <code>cloud</code> (see <a href="#">panel.3dscatter</a> for details). Defaults to "h" for the <code>matrix</code> method.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| aspect, panel.aspect | <p>Unlike other high level functions, <code>aspect</code> is taken to be a numeric vector of length 2, giving the relative aspects of the y-size/x-size and z-size/x-size of the enclosing cube. The usual role of the <code>aspect</code> argument in determining the aspect ratio of the panel (see <a href="#">xyplot</a> for details) is played by <code>panel.aspect</code>, except that it can only be a numeric value.</p> <p>For the <code>matrix</code> methods, the default y/x aspect is <code>ncol(x) / nrow(x)</code> and the z/x aspect is the smaller of the y/x aspect and 1.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| panel                | panel function used to create the display. See <a href="#">panel.cloud</a> for (non-trivial) details.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| default.prepanel     | Fallback prepanel function. See <a href="#">xyplot</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| scales               | <p>a list describing the scales. As with other high level functions (see <a href="#">xyplot</a> for details), this list can contain parameters in name=value form. It can also contain components with the special names <code>x</code>, <code>y</code> and <code>z</code>, which can be similar lists with axis-specific values overriding the ones specified in <code>scales</code>.</p> <p>The most common use for this argument is to set <code>arrows=FALSE</code>, which causes tick marks and labels to be used instead of arrows being drawn (the default). Both can be suppressed by <code>draw=FALSE</code>. Another special component is <code>distance</code>, which specifies the relative distance of the axis label from the bounding box. If specified as a component of <code>scales</code> (as opposed to one of <code>scales\$z</code> etc), this can be (and is recycled if not) a vector of length 3, specifying distances for the <code>x</code>, <code>y</code> and <code>z</code> labels respectively.</p> <p>Other components that work in the <code>scales</code> argument of <code>xyplot</code> etc. should also work here (as long as they make sense), including explicit specification of tick mark locations and labels. (Not everything is implemented yet, but if you find something that should work but does not, feel free to bug the maintainer.)</p> <p>Note, however, that for these functions <code>scales</code> cannot contain information that is specific to particular panels. If you really need that, consider using the <code>scales.3d</code> argument of <code>panel.cloud</code>.</p> |
| axs.default          | Unlike 2-D display functions, <code>cloud</code> does not expand the bounding box to slightly beyond the range of the data, even though it should. This is primarily because this is the natural behaviour in <code>wireframe</code> , which uses the same code. <code>axs.default</code> is intended to provide a different default for <code>cloud</code> . However, this feature has not yet been implemented.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| zlab                 | Specifies a label describing the <code>z</code> variable in ways similar to <code>xlab</code> and <code>ylab</code> (i.e. "grob", character string, expression or list) in other high level functions. Additionally, if <code>zlab</code> (and <code>xlab</code> and <code>ylab</code> ) is a list, it can contain a component called <code>rot</code> , controlling the rotation for the label                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| zlim                 | limits for the <code>z</code> -axis. Similar to <code>xlim</code> and <code>ylim</code> in other high level functions                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| drape                | logical, whether the wireframe is to be draped in color. If <code>TRUE</code> , the height of a facet is used to determine its color in a manner similar to the coloring scheme used in <a href="#">levelplot</a> . Otherwise, the background color is used to color the facets. This argument is ignored if <code>shade = TRUE</code> (see <a href="#">panel.3dwire</a> ).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

|                                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| ...                            | Any number of other arguments can be specified, and are passed to the panel function. In particular, the arguments <code>distance</code> , <code>perspective</code> , <code>screen</code> and <code>R.mat</code> are very important in determining the 3-D display. The argument <code>shade</code> can be useful for <code>wireframe</code> calls, and controls shading of the rendered surface. These arguments are described in detail in the help page for <a href="#">panel.cloud</a> .<br><br>Additionally, an argument called <code>zoom</code> may be specified, which should be a numeric scalar to be interpreted as a scale factor by which the projection is magnified. This can be useful to get the variable names into the plot. This argument is actually only used by the default <code>prepanel</code> function. |

## Details

These functions produce three dimensional plots in each panel (as long as the default panel functions are used). The orientation is obtained as follows: the data are scaled to fall within a bounding box that is contained in the  $[-0.5, 0.5]$  cube (even smaller for non-default values of `aspect`). The viewing direction is given by a sequence of rotations specified by the `screen` argument, starting from the positive Z-axis. The viewing point (camera) is located at a distance of  $1/\text{distance}$  from the origin. If `perspective=FALSE`, `distance` is set to 0 (i.e., the viewing point is at an infinite distance).

`cloud` draws a 3-D Scatter Plot, while `wireframe` draws a 3-D surface (usually evaluated on a grid). Multiple surfaces can be drawn by `wireframe` using the `groups` argument (although this is of limited use because the display is incorrect when the surfaces intersect). Specifying `groups` with `cloud` results in a `panel.superpose`-like effect (via [panel.3dscatter](#)).

`wireframe` can optionally render the surface as being illuminated by a light source (no shadows though). Details can be found in the help page for [panel.3dwire](#). Note that although arguments controlling these are actually arguments for the panel function, they can be supplied to `cloud` and `wireframe` directly.

For single panel plots, `wireframe` can also plot parametrized 3-D surfaces (i.e., functions of the form  $f(u,v) = (x(u,v), y(u,v), z(u,v))$ , where values of  $(u,v)$  lie on a rectangle. The simplest example of this sort of surface is a sphere parametrized by latitude and longitude. This can be achieved by calling `wireframe` with a formula `x` of the form `z~x*y`, where `x`, `y` and `z` are all matrices of the same dimension, representing the values of  $x(u,v)$ ,  $y(u,v)$  and  $z(u,v)$  evaluated on a discrete rectangular grid (the actual values of  $(u,v)$  are irrelevant).

When this feature is used, the heights used to calculate `drape` colors or shading colors are no longer the `z` values, but the distances of  $(x, y, z)$  from the origin.

Note that this feature does not work with `groups`, `subscripts`, `subset`, etc. Conditioning variables are also not supported in this case.

The algorithm for identifying which edges of the bounding box are ‘behind’ the points doesn’t work in some extreme situations. Also, `panel.cloud` tries to figure out the optimal location of the arrows and axis labels automatically, but can fail on occasion (especially when the view is from ‘below’ the data). This can be manually controlled by the `scpos` argument in `panel.cloud`.

These and all other high level Trellis functions have several other arguments in common. These are extensively documented only in the help page for `xyplot`, which should be consulted to learn more detailed usage.

### Value

An object of class "trellis". The `update` method can be used to update components of the object and the `print` method (usually called by default) will plot it on an appropriate plotting device.

### Note

There is a known problem with grouped wireframe displays when the (x, y) coordinates represented in the data do not represent the full evaluation grid. The problem occurs whether the grouping is specified through the `groups` argument or through the formula interface, and currently causes memory access violations. Depending on the circumstances, this is manifested either as a meaningless plot or a crash. To work around the problem, it should be enough to have a row in the data frame for each grid point, with an NA response (z) in rows that were previously missing.

## Details

`splom` produces Scatter Plot Matrices. The role usually played by `panel` is taken over by `superpanel`, which takes a data frame subset and is responsible for plotting it. It is called with the coordinate system set up to have both `x`- and `y`-limits from `0.5` to `ncol(z) + 0.5`. The only built-in option currently available is [panel.pairs](#), which calls a further `panel` function for each pair  $(i, j)$  of variables in `z` inside a rectangle of unit width and height centered at  $c(i, j)$  (see [panel.pairs](#) for details).

Many of the finer customizations usually done via arguments to high level function like `xyplot` are instead done by `panel.pairs` for `splom`. These include control of axis limits, tick locations and `prepanel` calculations. If you are trying to fine-tune your `splom` plot, definitely look at the [panel.pairs](#) help page. The `scales` argument is usually not very useful in `splom`, and trying to change it may have undesired effects.

[parallelplot](#) draws Parallel Coordinate Plots. (Difficult to describe, see example.)

These and all other high level Trellis functions have several arguments in common. These are extensively documented only in the help page for `xyplot`, which should be consulted to learn more detailed usage.

**Value**

An object of class "trellis". The `update` method can be used to update components of the object and the `print` method (usually called by default) will plot it on an appropriate plotting device.

**See Also**

`xyplot`, `Lattice`, `panel.pairs`, `panel.parallel`.

**Examples**

```
super.sym <- trellis.par.get("superpose.symbol")
splom(~iris[1:4], groups = Species, data = iris,
 panel = panel.superpose,
 key = list(title = "Three Varieties of Iris",
 columns = 3,
 points = list(pch = super.sym$pch[1:3],
 col = super.sym$col[1:3]),
 text = list(c("Setosa", "Versicolor", "Virginica"))))
splom(~iris[1:3] | Species, data = iris,
 layout=c(2,2), pscales = 0,
 varnames = c("Sepal\nLength", "Sepal\nWidth", "Petal\nLength"),
 page = function(...) {
 ltext(x = seq(.6, .8, length.out = 4),
 y = seq(.9, .6, length.out = 4),
 labels = c("Three", "Varieties", "of", "Iris"),
 cex = 2)
 })
parallelplot(~iris[1:4] | Species, iris)
parallelplot(~iris[1:4], iris, groups = Species,
 horizontal.axis = FALSE, scales = list(x = list(rot = 90)))
```

**Description**

`tmd` Creates Tukey Mean-Difference Plots from a trellis object returned by `xyplot`, `qq` or `qqmath`. The `prepanel` and `panel` functions are used as appropriate. The `formula` method for `tmd` is provided for convenience, and simply calls `tmd` on the object created by calling `xyplot` on that formula.

**Usage**

```
tmd(object, ...)

S3 method for class 'trellis'
tmd(object,
 xlab = "mean",
```

```

 ylab = "difference",
 panel,
 prepanel,
 ...)

prepanel.tmd.qqmath(x,
 f.value = NULL,
 distribution = qnorm,
 qtype = 7,
 groups = NULL,
 subscripts, ...)
panel.tmd.qqmath(x,
 f.value = NULL,
 distribution = qnorm,
 qtype = 7,
 groups = NULL,
 subscripts, ...,
 identifier = "tmd")
panel.tmd.default(x, y, groups = NULL, ...,
 identifier = "tmd")
prepanel.tmd.default(x, y, ...)

```

| <code>prepanel</code>                     | prepanel function. See details below.                                                                   |
| <code>f.value, distribution, qtype</code> | see <a href="#">panel.qqmath</a> .                                                                      |
| <code>groups, subscripts</code>           | see <a href="#">xyplot</a> .                                                                            |
| <code>x, y</code>                         | data as passed to panel functions in original call.                                                     |
| <code>...</code>                          | other arguments                                                                                         |
| <code>identifier</code>                   | A character string that is prepended to the names of grobs that are created by this panel function.     |

### Details

The Tukey Mean-difference plot is produced by modifying the (x,y) values of each panel as follows: the new coordinates are given by  $x = (x+y) / 2$  and  $y = y - x$ , which are then plotted. The default panel function(s) add a reference line at  $y=0$  as well.

`tmd` acts on the a "trellis" object, not on the actual plot this object would have produced. As such, it only uses the arguments supplied to the panel function in the original call, and completely ignores what the original panel function might have done with this data. `tmd` uses these panel arguments to set up its own scales (using its `prepanel` argument) and display (using `panel`). It is thus important to provide suitable `prepanel` and `panel` functions to `tmd` depending on the original call.

Such functions currently exist for `xyplot`, `qq` (the ones with `default` in their name) and `qqmath`, as listed in the usage section above. These assume the default displays for the corresponding high-level call. If unspecified, the `prepanel` and `panel` arguments default to suitable choices.

`tmd` uses the `update` method for "trellis" objects, which processes all extra arguments supplied to `tmd`.

### Value

An object of class "trellis". The `update` method can be used to update components of the object and the `print` method (usually called by default) will plot it on an appropriate plotting device.

---

Description

Fits a One-way model to univariate data grouped by a factor, the result often being displayed using `rfs`

Usage

```
oneway(formula, data, location=mean, spread=function(x) sqrt(var(x)))
```

Arguments

- |                       |                                                                                                                                                              |
|-----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>formula</code>  | formula of the form $y \sim x$ where $y$ is the numeric response and $x$ is the grouping factor                                                              |
| <code>data</code>     | data frame in which the model is to be evaluated                                                                                                             |
| <code>location</code> | function or numeric giving the location statistic to be used for centering the observations, e.g. <code>median</code> , <code>0</code> (to avoid centering). |
| <code>spread</code>   | function or numeric giving the spread statistic to be used for scaling the observations, e.g. <code>sd</code> , <code>1</code> (to avoid scaling).           |

Value

- A list with components
- |                               |                                            |
|-------------------------------|--------------------------------------------|
| <code>location</code>         | vector of locations for each group.        |
| <code>spread</code>           | vector of spreads for each group.          |
| <code>fitted.values</code>    | vector of locations for each observation.  |
| <code>residuals</code>        | residuals ( $y - \text{fitted.values}$ ).  |
| <code>scaled.residuals</code> | residuals scaled by spread for their group |

C\_01\_trellis.device

*Initializing Trellis Displays*

---

**Description**

Initialization of a display device with appropriate graphical parameters.

**Usage**

```
trellis.device(device = getOption("device"),
 color = !(dev.name == "postscript"),
 theme = lattice.getOption("default.theme"),
 new = TRUE,
 retain = FALSE,
 ...)

standard.theme(name, color)
canonical.theme(name, color)
col.whitebg()
```

**Arguments**

- |        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| device | function (or the name of one as a character string) that starts a device. Admissible values depend on the platform and how R was compiled (see <a href="#">Devices</a> ), but usually "pdf", "postscript", "png", "jpeg" and at least one of "X11", "windows" and "quartz" will be available.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| color  | logical, whether the initial settings should be color or black and white. Defaults to FALSE for postscript devices, TRUE otherwise. Note that this only applies to the initial choice of colors, which can be overridden using <a href="#">theme</a> or subsequent calls to <a href="#">trellis.par.set</a> (and by arguments supplied directly in high level calls for some settings).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| theme  | list of components that changes the settings of the device opened, or, a function that when called produces such a list. The function name can be supplied as a quoted string. These settings are only used to modify the default settings (determined by other arguments), and need not contain all possible parameters. A possible use of this argument is to change the default settings by specifying <code>lattice.options(default.theme = "col.whitebg")</code> . For back-compatibility, this is initially (when <code>lattice</code> is loaded) set to <code>getOption(lattice.theme)</code> .<br><br>If <code>theme</code> is a function, it will not be supplied any arguments, however, it is guaranteed that a device will already be open when it is called, so one may use <code>.Device</code> inside the function to ascertain what device has been opened. |

|                     |                                                                                                                                                                                                                                                               |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>new</code>    | logical flag indicating whether a new device should be started. If <code>FALSE</code> , the options for the current device are changed to the defaults determined by the other arguments.                                                                     |
| <code>retain</code> | logical. If <code>TRUE</code> and a setting for this device already exists, then that is used instead of the defaults for this device. By default, pre-existing settings are overwritten (and lost).                                                          |
| <code>name</code>   | name of the device for which the setting is required, as returned by <code>.Device</code>                                                                                                                                                                     |
| <code>...</code>    | additional parameters to be passed to the <code>device</code> function, most commonly <code>file</code> for non-screen devices, as well as <code>height</code> , <code>width</code> , etc. See the help file for individual devices for admissible arguments. |

## Details

Trellis Graphics functions obtain the default values of various graphical parameters (colors, line types, fonts, etc.) from a customizable “settings” list. This functionality is analogous to `par` for standard R graphics and, together with `lattice.options`, mostly supplants it (`par` settings are mostly ignored by Lattice). Unlike `par`, Trellis settings can be controlled separately for each different device type (but not concurrently for different instances of the same device). `standard.theme` and `col.whitebg` produce predefined settings (a.k.a. themes), while `trellis.device` provides a high level interface to control which “theme” will be in effect when a new device is opened. `trellis.device` is called automatically when a “trellis” object is plotted, and the defaults can be used to provide sufficient control, so in a properly configured system it is rarely necessary for the user to call `trellis.device` explicitly.

The `standard.theme` function is intended to provide device specific settings (e.g. light colors on a grey background for screen devices, dark colors or black and white for print devices) which were used as defaults prior to R 2.3.0. However, these defaults are not always appropriate, due to the variety of platforms and hardware settings on which R is used, as well as the fact that a plot created on a particular device may be subsequently used in many different ways. For this reason, a “safe” default is used for all devices from R 2.3.0 onwards. The old behaviour can be reinstated by setting `standard.theme` as the default `theme` argument, e.g. by putting `lattice.options(default.theme = "standard.theme")` in a startup script (see the entry for `theme` above for details).

## Value

`standard.theme` returns a list of components defining graphical parameter settings for Lattice displays. It is used internally in `trellis.device`, and can also be used as the `theme` argument to `trellis.par.set`, or even as `theme` in `trellis.device` to use the defaults for another device. `canonical.theme` is an alias for `standard.theme`.

`col.whitebg` returns a similar (but smaller) list that is suitable as the `theme` argument to `trellis.device` and `trellis.par.set`. It contains settings values which provide colors suitable for plotting on a white background. Note that the name `col.whitebg` is somewhat of a misnomer, since it actually sets the background to transparent rather than white.

## Note

Earlier versions of `trellis.device` had a `bg` argument to set the background color, but this is no longer supported. If supplied, the `bg` argument will be passed on to the device function; however, this will have no effect on the Trellis settings. It is rarely meaningful to change the background alone; if you feel the need to change the background, consider using the `theme` argument instead.

[Devices](#) for valid choices of device on your platform.

[trellis.par.get](#) and [trellis.par.set](#) can be used to query and modify the settings *after* a device has been initialized. The `par.settings` argument to high level functions, described in [xyplot](#), can be used to attach transient settings to a "trellis" object.

---

C\_02\_trellis.par.get

*Graphical Parameters for Trellis Displays*

---

**Description**

Functions used to query, display and modify graphical parameters for fine control of Trellis displays. Modifications are made to the settings for the currently active device only.

**Usage**

```
trellis.par.set(name, value, ..., theme, warn = TRUE, strict = FALSE)
trellis.par.get(name = NULL)
show.settings(x = NULL)
```

**Arguments**

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>name</code>  | A character string giving the name of a component. If unspecified in <code>trellis.par.get()</code> , the return value is a named list containing all the current settings (this can be used to get the valid values for <code>name</code> ).                                                                                                                                                                                                                                                                                                           |
| <code>value</code> | a list giving the desired value of the component. Components that are already defined as part of the current settings but are not mentioned in <code>value</code> will remain unchanged.                                                                                                                                                                                                                                                                                                                                                                |
| <code>theme</code> | a list describing how to change the settings, similar to what is returned by <code>trellis.par.get()</code> . This is purely for convenience, allowing multiple calls to <code>trellis.par.set</code> to be condensed into one. The name of each component must be a valid name as described above, with the corresponding value a valid value as described above.<br><br>As in <a href="#">trellis.device</a> , <code>theme</code> can also be a function that produces such a list when called. The function name can be supplied as a quoted string. |
| <code>...</code>   | Multiple settings can be specified in <code>name = value</code> form. Equivalent to calling with <code>theme = list(...)</code>                                                                                                                                                                                                                                                                                                                                                                                                                         |

|        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| warn   | A logical flag, indicating whether a warning should be issued when <code>trellis.par.get</code> is called when no graphics device is open.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| strict | Usually a logical flag, indicating whether the <code>value</code> should be interpreted strictly. Usually, assignment of value to the corresponding named component is fuzzy in the sense that sub-components that are absent from <code>value</code> but not currently <code>NULL</code> are retained. By specifying <code>strict = TRUE</code> , such values will be removed.<br><br>An even stricter interpretation is allowed by specifying <code>strict</code> as a numeric value larger than 1. In that case, top-level components not specified in the call will also be removed. This is primarily for internal use. |
| x      | optional list of components that change the settings (any valid value of <code>theme</code> ). These are used to modify the current settings (obtained by <code>trellis.par.get</code> ) before they are displayed.                                                                                                                                                                                                                                                                                                                                                                                                          |

## Details

The various graphical parameters (color, line type, background etc) that control the look and feel of Trellis displays are highly customizable. Also, R can produce graphics on a number of devices, and it is expected that a different set of parameters would be more suited to different devices. These parameters are stored internally in a variable named `lattice.theme`, which is a list whose components define settings for particular devices. The components are identified by the name of the device they represent (as obtained by `.Device`), and are created as and when new devices are opened for the first time using `trellis.device` (or Lattice plots are drawn on a device for the first time in that session).

The initial settings for each device defaults to values appropriate for that device. In practice, this boils down to three distinct settings, one for screen devices like `x11` and `windows`, one for black and white plots (mostly useful for `postscript`) and one for color printers (`color postscript`, `pdf`).

Once a device is open, its settings can be modified. When another instance of the same device is opened later using `trellis.device`, the settings for that device are reset to its defaults, unless otherwise specified in the call to `trellis.device`. But settings for different devices are treated separately, i.e., opening a `postscript` device will not alter the `x11` settings, which will remain in effect whenever an `x11` device is active.

The functions `trellis.par.*` are meant to be interfaces to the global settings. They always apply on the settings for the currently `ACTIVE` device.

`trellis.par.get`, called without any arguments, returns the full list of settings for the active device. With the `name` argument present, it returns that component only. `trellis.par.get` sets the value of the `name` component of the current active device settings to `value`.

`trellis.par.get` is usually used inside `trellis` functions to get graphical parameters before plotting. Modifications by users via `trellis.par.set` is traditionally done as follows:

```
add.line <- trellis.par.get("add.line")
add.line$col <- "red"
trellis.par.set("add.line", add.line)
```

More convenient (but not S compatible) ways to do this are

```
trellis.par.set(list(add.line = list(col = "red")))
and
trellis.par.set(add.line = list(col = "red"))
```

The actual list of the components in `trellis.settings` has not been finalized, so I'm not attempting to list them here. The current value can be obtained by `print(trellis.par.get())`. Most names should be self-explanatory.

`show.settings` provides a graphical display summarizing some of the values in the current settings.

### Value

`trellis.par.get` returns a list giving parameters for that component. If `name` is missing, it returns the full list.

Most of the settings are graphical parameters that control various elements of a lattice plot. For details, see the examples below. The more unusual settings are described here.

**grid.pars** Grid graphical parameters that are in effect globally unless overridden by specific settings.

**fontsize** A list of two components (each a numeric scalar), `text` and `points`, for text and symbols respectively.

**clip** A list of two components (each a character string, either "on" or "off"), `panel` and `strip`.

**axis.components**

**layout.heights**

**layout.widths**

### Note

In some ways, `trellis.par.get` and `trellis.par.set` together are a replacement for the `par` function used in traditional R graphics. In particular, changing `par` settings has little (if any) effect on lattice output. Since lattice plots are implemented using Grid graphics, its parameter system *does* have an effect unless overridden by a suitable lattice parameter setting. Such parameters can be specified as part of a lattice theme by including them in the `grid.pars` component (see [gpar](#) for a list of valid parameter names).

### Examples

```
show.settings()

tp <- trellis.par.get()

unusual <- c("grid.pars", "fontsize", "clip", "axis.components",
 "layout.heights", "layout.widths")

for (u in unusual) tp[[u]] <- NULL
names.tp <- lapply(tp, names)
unames <- sort(unique(unlist(names.tp)))
```

```

ans <- matrix(0, nrow = length(names.tp), ncol = length(unames))
rownames(ans) <- names(names.tp)
colnames(ans) <- unames
for (i in seq(along = names.tp))
 ans[i,] <- as.numeric(unames %in% names.tp[[i]])
ans <- ans[, order(-colSums(ans))]
ans <- ans[order(rowSums(ans)),]
ans[ans == 0] <- NA

levelplot(t(ans), colorkey = FALSE,
 scales = list(x = list(rot = 90)),
 panel = function(x, y, z, ...) {
 panel.abline(v = unique(as.numeric(x)),
 h = unique(as.numeric(y)),
 col = "darkgrey")
 panel.xyplot(x, y, pch = 16 * z, ...)
 },
 xlab = "Graphical parameters",
 ylab = "Setting names")

```

---

C\_03\_simpleTheme      *Function to generate a simple theme*

---

## Description

Simple interface to generate a list appropriate as a theme, typically used as the `par.settings` argument in a high level call

## Usage

```

simpleTheme(col, alpha,
 cex, pch, lty, lwd, font, fill, border,
 col.points, col.line,
 alpha.points, alpha.line)

```

## Arguments

`col, col.points, col.line`

A color specification. `col` is used for components `"plot.symbol"`, `"plot.line"`, `"plot.polygon"`, `"superpose.symbol"`, `"superpose.line"`, and `"superpose.polygon"`. `col.points` overrides `col`, but is used only for `"plot.symbol"` and `"superpose.symbol"`. Similarly, `col.line` overrides `col` for `"plot.line"` and `"superpose.line"`. The arguments can be vectors, but only the first component is used for scalar targets (i.e., the ones without `"superpose"` in their name).

`alpha, alpha.points, alpha.line`

A numeric alpha transparency specification. The same rules as `col`, etc., apply.

`cex, pch, font`

Parameters for points. Applicable for components `plot.symbol` (for which only the first component is used) and `superpose.symbol` (for which the arguments can be vectors).

|                       |                                                                                                                                                                                               |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>lty, lwd</code> | Parameters for lines. Applicable for components <code>plot.line</code> (for which only the first component is used) and <code>superpose.line</code> (for which the arguments can be vectors). |
| <code>fill</code>     | fill color, applicable for components <code>plot.symbol</code> , <code>plot.polygon</code> , <code>superpose.symbol</code> , and <code>superpose.polygon</code> .                             |
| <code>border</code>   | border color, applicable for components <code>plot.polygon</code> and <code>superpose.polygon</code> .                                                                                        |

### Details

The appearance of a lattice display depends partly on the “theme” active when the display is plotted (see `trellis.device` for details). This theme is used to obtain defaults for various graphical parameters, and in particular, the `auto.key` argument works on the premise that the same source is used for both the actual graphical encoding and the legend. The easiest way to specify custom settings for a particular display is to use the `par.settings` argument, which is usually tedious to construct as it is a nested list. The `simpleTheme` function can be used in such situations as a wrapper that generates a suitable list given parameters in `simple name=value` form, with the nesting made implicit. This is less flexible, but straightforward and sufficient in most situations.

### Value

A list that would work as the `theme` argument to `trellis.device` and `trellis.par.set`, or as the `par.settings` argument to any high level lattice function such as `xyplot`.

### Author(s)

Deepayan Sarkar <Deepayan.Sarkar@R-project.org>, based on a suggestion from John Maindonald.

### See Also

`trellis.device`, `xyplot`, `Lattice`

### Examples

```
str(simpleTheme(pch = 16))

dotplot(variety ~ yield | site, data = barley, groups = year,
 auto.key = list(space = "right"),
 par.settings = simpleTheme(pch = 16),
 xlab = "Barley Yield (bushels/acre) ",
 aspect=0.5, layout = c(1,6))
```

### Description

Functions to handle settings used by lattice. Their main purpose is to make code maintenance easier, and users normally should not need to use these functions. However, fine control at this level maybe useful in certain cases.

## Usage

```
lattice.options(...)
lattice.getOption(name)
```

## Arguments

|      |                                                                                                                                                                                                                                                                                             |
|------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| name | character giving the name of a setting                                                                                                                                                                                                                                                      |
| ...  | new options can be defined, or existing ones modified, using one or more arguments of the form <code>name = value</code> or by passing a list of such tagged values. Existing values can be retrieved by supplying the names (as character strings) of the components as unnamed arguments. |

## Details

These functions are modeled on `options` and `getOption`, and behave similarly for the most part. Some of the available components are documented here, but not all. The purpose of the ones not documented are either fairly obvious, or not of interest to the end-user.

`panel.error` A function, or `NULL`. If the former, every call to the panel function will be wrapped inside `tryCatch` with the specified function as an error handler. The default is to use the `panel.error` function. This prevents the plot from failing due to errors in a single panel, and leaving the grid operations in an unmanageable state. If set to `NULL`, errors in panel functions will not be caught using `tryCatch`.

`save.object` Logical flag indicating whether a "trellis" object should be saved when plotted for subsequent retrieval and further manipulation. Defaults to `TRUE`.

`layout.widths`, `layout.heights` Controls details of the default space allocation in the grid layout created in the course of plotting a "trellis" object. Each named component is a list of arguments to the `grid` function `unit` (x, units, and optionally data).

Usually not of interest to the end-user, who should instead use the similarly named component in the graphical settings, modifiable using `trellis.par.set`.

`drop.unused.levels` A list of two components named `cond` and `data`, both logical flags. The flags indicate whether the unused levels of factors (conditioning variables and primary variables respectively) will be dropped, which is usually relevant when a subsetting operation is performed or an 'interaction' is created. See `xyplot` for more details. Note that this does not control dropping of levels of the 'groups' argument.

`legend.bbox` A character string, either "full" or "panel". This determines the interpretation of `x` and `y` when `space="inside"` in `key` (determining the legend; see `xyplot`): either the full figure region ("full"), or just the region that bounds the panels and strips ("panel").

`default.args` A list giving default values for various standard arguments: `as.table`, `aspect`, `between`, `skip`, `strip`, `xscale.components`, `yscale.components`, and `axis`.

`highlight.gpar` A list giving arguments to `gpar` used to highlight a viewport chosen using `trellis.focus`.

`banking` The banking function. See `banking`.

`axis.padding` List with components named "numeric" and "factor", both scalar numbers. Panel limits are extended by this amount, to provide padding for numeric and factor scales respectively. The value for numeric is multiplicative, whereas factor is additive.

`skip.boundary.labels` Numeric scalar between 0 and 1. Tick marks that are too close to the limits are not drawn unless explicitly requested. The limits are contracted by this proportion, and anything outside is skipped.

`interaction.sep` The separator for creating interactions with the extended formula interface (see [xyplot](#)).

`axis.units` List determining default units for axis components. Should not be of interest to the end-user.

In addition, there is an option for the default prepanel and panel function for each high-level function; e.g., `panel.xyplot` and `prepanel.default.xyplot` for [xyplot](#). The options for the others have similarly patterned names.

### Value

`lattice.getOption` returns the value of a single component, whereas `lattice.options` always returns a list with one or more named components. When changing the values of components, the old values of the modified components are returned by `lattice.options`. If called without any arguments, the full list is returned.

### Examples

```
names(lattice.options())
str(lattice.getOption("layout.widths"), max.level = 2)
```

---

C\_05\_print.trellis *Plot and Summarize Trellis Objects*

---

### Description

The `print` and `plot` methods produce a graph from a "trellis" object. The `print` method is necessary for automatic plotting. `plot` method is essentially an alias, provided for convenience. The `summary` method gives a textual summary of the object. `dim` and `dimnames` describe the cross-tabulation induced by conditioning. `panel.error` is the default handler used when an error occurs while executing the panel function.

### Usage

```
S3 method for class 'trellis'
plot(x, position, split,
 more = FALSE, newpage = TRUE,
 packet.panel = packet.panel.default,
 draw.in = NULL,
 panel.height = lattice.getOption("layout.heights")$panel,
 panel.width = lattice.getOption("layout.widths")$panel,
```

```

 save.object = lattice.getOption("save.object"),
 panel.error = lattice.getOption("panel.error"),
 prefix,
 ...)
S3 method for class 'trellis'
print(x, ...)

S3 method for class 'trellis'
summary(object, ...)

S3 method for class 'trellis'
dim(x)
S3 method for class 'trellis'
dimnames(x)

panel.error(e)

```

### Arguments

|                                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|----------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x, object</code>                 | an object of class "trellis"                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>position</code>                  | a vector of 4 numbers, typically <code>c(xmin, ymin, xmax, ymax)</code> that give the lower-left and upper-right corners of a rectangle in which the Trellis plot of <code>x</code> is to be positioned. The coordinate system for this rectangle is [0-1] in both the <code>x</code> and <code>y</code> directions.                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>split</code>                     | a vector of 4 integers, <code>c(x,y,nx,ny)</code> , that says to position the current plot at the <code>x,y</code> position in a regular array of <code>nx</code> by <code>ny</code> plots. (Note: this has origin at top left)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <code>more</code>                      | A logical specifying whether more plots will follow on this page.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>newpage</code>                   | A logical specifying whether the plot should be on a new page. This option is specific to lattice, and is useful for including lattice plots in an arbitrary grid viewport (see the details section).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <code>packet.panel</code>              | a function that determines which packet (data subset) is plotted in which panel. Panels are always drawn in an order such that columns vary the fastest, then rows and then pages. This function determines, given the column, row and page and other relevant information, the packet (if any) which should be used in that panel. By default, the association is determined by matching panel order with packet order, which is determined by varying the first conditioning variable the fastest, then the second, and so on. This association rule is encoded in the default, namely the function <code>packet.panel.default</code> , whose help page details the arguments supplied to whichever function is specified as the <code>packet.panel</code> argument. |
| <code>draw.in</code>                   | An optional (grid) viewport (used as the <code>name</code> argument in <code>downViewport</code> ) in which the plot is to be drawn. If specified, the <code>newpage</code> argument is ignored. This feature is not well-tested.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>panel.width, panel.height</code> | lists with 2 components, that should be valid <code>x</code> and <code>units</code> arguments to <code>unit()</code> (the <code>data</code> argument cannot be specified currently, but can be considered for addition if needed). The resulting <code>unit</code> object will be the width/height of each panel in the Lattice plot. These arguments can be used to explicitly control the dimensions of the panel, rather than letting them expand to maximize                                                                                                                                                                                                                                                                                                       |

|                          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|--------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                          | available space. Vector widths are allowed, and can specify unequal lengths across rows or columns.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|                          | Note that this option should not be used in conjunction with non-default values of the <code>aspect</code> argument in the original high level call (no error will be produced, but the resulting behaviour is undefined).                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>save.object</code> | logical, specifying whether the object being printed is to be saved. The last object thus saved can be subsequently retrieved. This is an experimental feature that should allow access to a panel's data after the plot is done, making it possible to enhance the plot after the fact. This also allows the user to invoke the <code>update</code> method on the current plot, even if it was not assigned to a variable explicitly. For more details, see <a href="#">trellis.focus</a> .                                                                                                                                                                                                         |
| <code>panel.error</code> | a function, or a character string naming a function, that is to be executed when an error occurs during the execution of the panel function. The error is caught (using <code>tryCatch</code> ) and supplied as the only argument to <code>panel.error</code> . The default behaviour (implemented as the <code>panel.error</code> function) is to print the corresponding error message in the panel and continue. To stop execution on error, use <code>panel.error = stop</code> .<br><br>Normal error recovery and debugging tools are unhelpful when <code>tryCatch</code> is used. <code>tryCatch</code> can be completely bypassed by setting <code>panel.error</code> to <code>NULL</code> . |
| <code>prefix</code>      | A character string acting as a prefix identifying the plot of a "trellis" object, primarily used in constructing viewport and grob names, to distinguish similar viewports if a page contains multiple plots. The default is based on the serial number of the current plot on the current page (specifically, "plot_01", "plot_02", etc.). If supplied explicitly, this must be a valid R symbol name (briefly, it must start with a letter or a period followed by a letter) and must not contain the grid path separator (currently " : ").                                                                                                                                                       |
| <code>e</code>           | an error condition caught by <code>tryCatch</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>...</code>         | extra arguments, ignored by the <code>print</code> method. All arguments to the <code>plot</code> method are passed on to the <code>print</code> method.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

## Details

This is the default print method for objects of class "trellis", produced by calls to functions like `xyplot`, `bwplot` etc. It is usually called automatically when a trellis object is produced. It can also be called explicitly to control plot positioning by means of the arguments `split` and `position`.

When `newpage = FALSE`, the current grid viewport is treated as the plotting area, making it possible to embed a Lattice plot inside an arbitrary grid viewport. The `draw.in` argument provides an alternative mechanism that may be simpler to use.

The print method uses the information in `x` (the object to be printed) to produce a display using the Grid graphics engine. At the heart of the plot is a grid layout, of which the entries of most interest to the user are the ones containing the display panels.

Unlike in older versions of Lattice (and Grid), the grid display tree is retained after the plot is produced, making it possible to access individual viewport locations and make additions to the plot. For more details and a lattice level interface to these viewports, see [trellis.focus](#).

## Note

Unlike S-PLUS, trying to position a multipage display (using `position` and/or `split`) will mess things up.

**Author(s)**

Deepayan Sarkar <Deepayan.Sarkar@R-project.org>

**See Also**

[Lattice](#), [unit](#), [update.trellis](#), [trellis.focus](#), [packet.panel.default](#)

**Examples**

```
p11 <- histogram(~ height | voice.part, data = singer, xlab="Height")
p12 <- densityplot(~ height | voice.part, data = singer, xlab = "Height")
p2 <- histogram(~ height, data = singer, xlab = "Height")

simple positioning by split
print(p11, split=c(1,1,1,2), more=TRUE)
print(p2, split=c(1,2,1,2))

Combining split and position:
print(p11, position = c(0,0,.75,.75), split=c(1,1,1,2), more=TRUE)
print(p12, position = c(0,0,.75,.75), split=c(1,2,1,2), more=TRUE)
print(p2, position = c(.5,.75,1,1), more=FALSE)

Using seekViewport

repeat same plot, with different polynomial fits in each panel
xyplot(Armed.Forces ~ Year, longley, index.cond = list(rep(1, 6)),
 layout = c(3, 2),
 panel = function(x, y, ...)
 {
 panel.xyplot(x, y, ...)
 fm <- lm(y ~ poly(x, panel.number()))
 llines(x, predict(fm))
 })

Not run:
grid::seekViewport(trellis.vpname("panel", 1, 1))
cat("Click somewhere inside the first panel:\n")
ltext(grid::grid.locator(), lab = "linear")

End(Not run)

grid::seekViewport(trellis.vpname("panel", 1, 1))
grid::grid.text("linear")

grid::seekViewport(trellis.vpname("panel", 2, 1))
grid::grid.text("quadratic")

grid::seekViewport(trellis.vpname("panel", 3, 1))
grid::grid.text("cubic")

grid::seekViewport(trellis.vpname("panel", 1, 2))
grid::grid.text("degree 4")

grid::seekViewport(trellis.vpname("panel", 2, 2))
grid::grid.text("degree 5")
```

```
grid::seekViewport(trellis.vpname("panel", 3, 2))
grid::grid.text("degree 6")
```

S3 method for class 'trellis'
```

```
t(x)

S3 method for class 'trellis'
x[i, j, ..., drop = FALSE]

trellis.last.object(..., prefix)
```

### Arguments

|                                                                                                     |                                                                                                                                                                                                                                                                        |
|-----------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object, x</code>                                                                              | The object to be updated, of class "trellis".                                                                                                                                                                                                                          |
| <code>i, j</code>                                                                                   | indices to be used. Names are not currently allowed.                                                                                                                                                                                                                   |
| <code>drop</code>                                                                                   | logical, whether dimensions with only one level are to be dropped. Currently ignored, behaves as if it were FALSE.                                                                                                                                                     |
| <code>panel, aspect, as.table, between, key, auto.key, legend, layout, main, page, par.strip</code> | arguments that will be used to update <code>object</code> . See details below.                                                                                                                                                                                         |
| <code>prefix</code>                                                                                 | A character string acting as a prefix identifying the plot of a "trellis" object. Only relevant when a particular page is occupied by more than one plot. Defaults to the value appropriate for the last "trellis" object printed. See <a href="#">trellis.focus</a> . |

### Details

All high level lattice functions such as `xyplot` produce an object of (S3) class "trellis", which is usually displayed by its `print` method. However, the object itself can be manipulated and modified to a large extent using the `update` method, and then re-displayed as needed.

Most arguments to high level functions can also be supplied to the `update` method as well, with some exceptions. Generally speaking, anything that would need to change the data within each panel is a no-no (this includes the `formula`, `data`, `groups`, `subscripts` and `subset`). Everything else is technically game, though might not be implemented yet. If you find something missing that you wish to have, feel free to make a request.

Not all arguments accepted by a Lattice function are processed by `update`, but the ones listed above should work. The purpose of these arguments are described in the help page for [xyplot](#). Any other argument is added to the list of arguments to be passed to the `panel` function. Because of their somewhat special nature, updates to objects produced by `cloud` and `wireframe` do not work very well yet.

The `"["` method is a convenient shortcut for updating `index.cond`. The `t` method is a convenient shortcut for updating `perm.cond` in the special (but frequent) case where there are exactly two conditioning variables, when it has the effect of switching ('transposing') their order.

The `print` method for "trellis" objects optionally saves the object after printing it. If this feature is enabled, `trellis.last.object` can retrieve it. By default, the last object plotted is retrieved, but if multiple objects are plotted on the current page, then others can be retrieved using the appropriate `prefix` argument. If [trellis.last.object](#) is called with arguments, these are used to update the retrieved object before returning it.

### Value

An object of class `trellis`, by default plotted by `print.trellis`. `trellis.last.object` returns NULL if no saved object is available.

```
spots <- by(sunspots, gl(235, 12, labels = 1749:1983), mean)
old.options <- lattice.options(save.object = TRUE)
xyplot(spots ~ 1749:1983, xlab = "", type = "l",
 scales = list(x = list(alternating = 2)),
 main = "Average Yearly Sunspots")
update(trellis.last.object(), aspect = "xy")
trellis.last.object(xlab = "Year")
lattice.options(old.options)
```

---

C\_07\_shingles

*shingles*

---

**Description**

Functions to handle shingles

**Usage**

```
shingle(x, intervals=sort(unique(x)))
equal.count(x, ...)
as.shingle(x)
is.shingle(x)

S3 method for class 'shingle'
plot(x, panel, xlab, ylab, ...)

S3 method for class 'shingle'
print(x, showValues = TRUE, ...)

S3 method for class 'shingleLevel'
as.character(x, ...)

S3 method for class 'shingleLevel'
print(x, ...)

S3 method for class 'shingle'
summary(object, showValues = FALSE, ...)

S3 method for class 'shingle'
x[subset, drop = FALSE]
as.factorOrShingle(x, subset, drop)
```

**Arguments**

|                                |                                                                                                                                                                                                                                     |
|--------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>                 | numeric variable or R object, <code>shingle</code> in <code>plot.shingle</code> and <code>x[]</code> . An object (list of intervals) of class "shingleLevel" in <code>print.shingleLevel</code>                                     |
| <code>object</code>            | shingle object to be summarized                                                                                                                                                                                                     |
| <code>showValues</code>        | logical, whether to print the numeric part. If FALSE, only the intervals are printed                                                                                                                                                |
| <code>intervals</code>         | numeric vector or matrix with 2 columns                                                                                                                                                                                             |
| <code>subset</code>            | logical vector                                                                                                                                                                                                                      |
| <code>drop</code>              | whether redundant shingle levels are to be dropped                                                                                                                                                                                  |
| <code>panel, xlab, ylab</code> | standard Trellis arguments (see <a href="#">xyplot</a> )                                                                                                                                                                            |
| <code>...</code>               | other arguments, passed down as appropriate. For example, extra arguments to <code>equal.count</code> are passed on to <code>co.intervals</code> . graphical parameters can be passed as arguments to the <code>plot</code> method. |

**Details**

A shingle is a data structure used in Trellis, and is a generalization of factors to ‘continuous’ variables. It consists of a numeric vector along with some possibly overlapping intervals. These intervals are the ‘levels’ of the shingle. The `levels` and `nlevels` functions, usually applicable to factors, also work on shingles. The implementation of shingles is slightly different from S.

There are print methods for shingles, as well as for printing the result of `levels()` applied to a shingle. For use in labelling, the `as.character` method can be used to convert levels of a shingle to character strings.

`equal.count` converts `x` to a shingle using the equal count algorithm. This is essentially a wrapper around `co.intervals`. All arguments are passed to `co.intervals`.

`shingle` creates a shingle using the given `intervals`. If `intervals` is a vector, these are used to form 0 length intervals.

`as.shingle` returns `shingle(x)` if `x` is not a shingle.

`is.shingle` tests whether `x` is a shingle.

`plot.shingle` displays the ranges of shingles via rectangles. `print.shingle` and `summary.shingle` describe the shingle object.

**Value**

`x$intervals` for `levels.shingle(x)`, logical for `is.shingle`, an object of class "trellis" for `plot` (printed by default by `print.trellis`), and an object of class "shingle" for the others.

## Examples

```
z <- equal.count(rnorm(50))
plot(z)
print(z)
print(levels(z))
```

---

|                 |                                                   |
|-----------------|---------------------------------------------------|
| D_draw.colorkey | <i>Produce a colorkey typically for levelplot</i> |
|-----------------|---------------------------------------------------|

---

## Description

Creates (and optionally draws) a grid frame grob representing a color key that can be placed in other grid-based plots. Primarily used by `levelplot` when a color key is requested.

## Usage

```
draw.colorkey(key, draw = FALSE, vp = NULL)
```

## Arguments

|      |                                                                                                                                                                  |
|------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| key  | A list determining the key. See documentation for <code>levelplot</code> , in particular the section describing the <code>colorkey</code> argument, for details. |
| draw | A scalar logical, indicating whether the grob is to be drawn.                                                                                                    |
| vp   | The viewport in which to draw the grob, if applicable.                                                                                                           |

## Value

A grid frame object (that inherits from "grob")

## Author(s)

Deepayan Sarkar <Deepayan.Sarkar@R-project.org>

| D_level.colors | <i>A function to compute false colors representing a numeric or categorical variable</i> |
|----------------|------------------------------------------------------------------------------------------|

---

### Description

Calculates false colors from a numeric variable (including factors, using their numeric codes) given a color scheme and breakpoints.

### Usage

```
level.colors(x, at, col.regions, colors = TRUE, ...)
```

**Arguments**

|                          |                                                                                                                                                                                                                                                                       |
|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>           | A numeric or <code>factor</code> variable.                                                                                                                                                                                                                            |
| <code>at</code>          | A numeric variable of breakpoints defining intervals along the range of <code>x</code> .                                                                                                                                                                              |
| <code>col.regions</code> | A specification of the colors to be assigned to each interval defined by <code>at</code> . This could be either a vector of colors, or a function that produces a vector of colors when called with a single argument giving the number of colors. See details below. |
| <code>colors</code>      | logical indicating whether colors should be computed and returned. If <code>FALSE</code> , only the indices representing which interval (among those defined by <code>at</code> ) each value in <code>x</code> falls into is returned.                                |
| <code>...</code>         | Extra arguments, ignored.                                                                                                                                                                                                                                             |

**Details**

If `at` has length `n`, then it defines `n-1` intervals. Values of `x` outside the range of `at` are not assigned to an interval, and the return value is `NA` for such values.

Colors are chosen by assigning a color to each of the `n-1` intervals. If `col.regions` is a palette function (such as `topo.colors`, or the result of calling `colorRampPalette`), it is called with `n-1` as an argument to obtain the colors. Otherwise, if there are exactly `n-1` colors in `col.regions`, these get assigned to the intervals. If there are fewer than `n-1` colors, `col.regions` gets recycled. If there are more, a more or less equally spaced (along the length of `col.regions`) subset is chosen.

**Value**

A vector of the same length as `x`. Depending on the `colors` argument, this could be either a vector of colors (in a form usable by `R`), or a vector of integer indices representing which interval the values of `x` fall in.

[levelplot](#), [colorRampPalette](#).

**Examples**

```
depth.col <-
 with(quakes,
 level.colors(depth, at = do.breaks(range(depth), 30),
 col.regions = terrain.colors))

xyplot(lat ~ long | equal.count(stations), quakes,
 strip = strip.custom(var.name = "Stations"),
 colours = depth.col,
 panel = function(x, y, colours, subscripts, ...) {
 panel.xyplot(x, y, pch = 21, col = "transparent",
 fill = colours[subscripts], ...)
 })
```

---

`D_make.groups`*Grouped data from multiple vectors*

---

**Description**

Combines two or more vectors, possibly of different lengths, producing a data frame with a second column indicating which of these vectors that row came from. This is mostly useful for getting data into a form suitable for use in high level Lattice functions.

**Usage**

```
make.groups(...)
```

**Arguments**

`...` one or more vectors of the same type (coercion is attempted if not), or one or more data frames with similar columns, with possibly differing number of rows.

**Value**

When all the input arguments are vectors, a data frame with two columns

`data` all the vectors supplied, concatenated

`which` factor indicating which vector the corresponding data value came from

When all the input arguments are data frames, the result of `rbind` applied to them, along with an additional `which` column as described above.

D\_simpleKey

Function to generate a simple key

---

## Description

Simple interface to generate a list appropriate for `draw.key`

## Usage

```
simpleKey(text, points = TRUE,
 rectangles = FALSE,
 lines = FALSE,
 col, cex, alpha, font,
 fontface, fontfamily,
 lineheight, ...)
```

## Arguments

|                                                                      |                                                                                                                                                       |
|----------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>text</code>                                                    | character or expression vector, to be used as labels for levels of the grouping variable                                                              |
| <code>points</code>                                                  | logical                                                                                                                                               |
| <code>rectangles</code>                                              | logical                                                                                                                                               |
| <code>lines</code>                                                   | logical                                                                                                                                               |
| <code>col, cex, alpha, font, fontface, fontfamily, lineheight</code> | Used as top-level components of the list produced, to be used for the text labels. Defaults to the values in <code>trellis.par.get("add.text")</code> |
| <code>...</code>                                                     | further arguments added to the list, eventually passed to <code>draw.key</code>                                                                       |

## Details

A lattice plot can include a legend (key) if an appropriate list is specified as the `key` argument to a high level Lattice function such as `xyplot`. This key can be very flexible, but that flexibility comes at a cost: this list needs to be fairly complicated even in simple situations. `simpleKey` is designed as a useful shortcut in the common case of a key drawn in conjunction with a grouping variable, using the default graphical settings.

The `simpleKey` function produces a suitable `key` argument using a simpler interface. The resulting list will use the `text` argument as a text component, along with at most one set each of points, rectangles, and lines. The number of entries (rows) in the key will be the length of the `text` component. The graphical parameters for the additional components will be derived from the default graphical settings (wherein lies the simplification, as otherwise these would have to be provided explicitly).

Calling `simpleKey` directly is usually unnecessary. It is most commonly invoked (during the plotting of the "trellis" object) when the `auto.key` argument is supplied in a high-level plot with a `groups` argument. In that case, the `text` argument of `simpleKey` defaults to `levels(groups)`, and the defaults for the other arguments depend on the relevant high-level function. Note that these defaults can be overridden by supplying `auto.key` as a list containing the replacement values.

**Value**

A list that would work as the `key` argument to `xyplot`, etc.

**Author(s)**

Deepayan Sarkar <Deepayan.Sarkar@R-project.org>

**See Also**

`Lattice`, `draw.key`, `trellis.par.get`, and `xyplot`, specifically the entry for `auto.key`.

|-----------------|---------------------------------------|
| D_strip.default | <i>Default Trellis Strip Function</i> |
|-----------------|---------------------------------------|

---

**Description**

`strip.default` is the function that draws the strips by default in Trellis plots. Users can write their own strip functions, but most commonly this involves calling `strip.default` with a slightly different arguments. `strip.custom` provides a convenient way to obtain new strip functions that differ from `strip.default` only in the default values of certain arguments.

**Usage**

```
strip.default(which.given,
 which.panel,
 var.name,
 factor.levels,
 shingle.intervals,
 strip.names = c(FALSE, TRUE),
 strip.levels = c(TRUE, FALSE),
 sep = " : ",
 style = 1,
 horizontal = TRUE,
 bg = trellis.par.get("strip.background")$col[which.given],
 fg = trellis.par.get("strip.shingle")$col[which.given],
 par.strip.text = trellis.par.get("add.text"))
strip.custom(...)
```

**Arguments**

|                          |                                                                                                                                                                                                                                                                                                                                                                |
|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>which.given</code> | integer index specifying which of the conditioning variables this strip corresponds to.                                                                                                                                                                                                                                                                        |
| <code>which.panel</code> | vector of integers as long as the number of conditioning variables. The contents are indices specifying the current levels of each of the conditioning variables (thus, this would be unique for each distinct packet). This is identical to the return value of <code>which.packet</code> , which is a more accurate name.                                    |
| <code>var.name</code>    | vector of character strings or expressions as long as the number of conditioning variables. The contents are interpreted as names for the conditioning variables. Whether they are shown on the strip depends on the values of <code>strip.names</code> and <code>style</code> (see below). By default, the names are shown for shingles, but not for factors. |

|                                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|--------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>factor.levels</code>     | vector of character strings or expressions giving the levels of the conditioning variable currently being drawn. For more than one conditioning variable, this will vary with <code>which.given</code> . Whether these levels are shown on the strip depends on the values of <code>strip.levels</code> and <code>style</code> (see below). <code>factor.levels</code> may be specified for both factors and shingles (despite the name), but by default they are shown only for factors. If shown, the labels may optionally be abbreviated by specifying suitable components in <code>par.strip.text</code> (see <code>xyplot</code> )                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <code>shingle.intervals</code> | if the current strip corresponds to a shingle, this should be a 2-column matrix giving the levels of the shingle. (of the form that would be produced by <code>printing.levels(shingle)</code> ). Otherwise, it should be <code>NULL</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>strip.names</code>       | a logical vector of length 2, indicating whether or not the name of the conditioning variable that corresponds to the strip being drawn is to be written on the strip. The two components give the values for factors and shingles respectively. This argument is ignored for a factor when <code>style</code> is not one of 1 and 3.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>strip.levels</code>      | a logical vector of length 2, indicating whether or not the level of the conditioning variable that corresponds to the strip being drawn is to be written on the strip. The two components give the values for factors and shingles respectively.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>sep</code>               | character or expression, serving as a separator if the name and level are both to be shown.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>style</code>             | integer, with values 1, 2, 3, 4 and 5 currently supported, controlling how the current level of a factor is encoded. Ignored for shingles (actually, when <code>shingle.intervals</code> is non-null.<br><br>The best way to find out what effect the value of <code>style</code> has is to try them out. Here is a short description: for a style value of 1, the strip is colored in the background color with the strip text (as determined by other arguments) centered on it. A value of 3 is the same, except that a part of the strip is colored in the foreground color, indicating the current level of the factor. For styles 2 and 4, the part corresponding to the current level remains colored in the foreground color, however, for style = 2, the remaining part is not colored at all, whereas for 4, it is colored with the background color. For both these, the names of all the levels of the factor are placed on the strip from left to right. Styles 5 and 6 produce the same effect (they are subtly different in S, this implementation corresponds to 5), they are similar to style 1, except that the strip text is not centered, it is instead positioned according to the current level.<br><br>Note that unlike S-PLUS, the default value of <code>style</code> is 1. <code>strip.names</code> and <code>strip.levels</code> have no effect if <code>style</code> is not 1 or 3. |
| <code>horizontal</code>        | logical, specifying whether the labels etc should be horizontal. <code>horizontal=FALSE</code> is useful for strips on the left of panels using <code>strip.left=TRUE</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>par.strip.text</code>    | list with parameters controlling the text on each strip, with components <code>col</code> , <code>cex</code> , <code>font</code> , etc.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>bg</code>                | strip background color.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>fg</code>                | strip foreground color.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>...</code>               | arguments to be passed on to <code>strip.default</code> , overriding whatever value it would have normally assumed                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

**Details**

default strip function for trellis functions. Useful mostly because of the `style` argument — non-default styles are often more informative, especially when the names of the levels of the factor `x` are small. Traditional use is as `strip = function(...) strip.default(style=2, ...)`, though this can be simplified by the use of `strip.custom`.

**Value**

`strip.default` is called for its side-effect, which is to draw a strip appropriate for multi-panel Trellis conditioning plots. `strip.custom` returns a function that is similar to `strip.default`, but with different defaults for the arguments specified in the call.

**See Also**

`xyplot`, `Lattice`

**Examples**

```
Traditional use
xyplot(Petal.Length ~ Petal.Width | Species, iris,
 strip = function(..., style) strip.default(..., style = 4))

equivalent call using strip.custom
xyplot(Petal.Length ~ Petal.Width | Species, iris,
 strip = strip.custom(style = 4))

xyplot(Petal.Length ~ Petal.Width | Species, iris,
 strip = FALSE,
 strip.left = strip.custom(style = 4, horizontal = FALSE))
```

D\_trellis.object     *A Trellis Plot Object*

---

**Description**

This class of objects is returned by high level lattice functions, and is usually plotted by default by its `print` method.

**Details**

A trellis object, as returned by high level lattice functions like `xyplot`, is a list with the "class" attribute set to "trellis". Many of the components of this list are simply the arguments to the high level function that produced the object. Among them are: `as.table`, `layout`, `page`, `panel`, `prepanel`, `main`, `sub`, `par.strip.text`, `strip`, `skip`, `xlab` `ylab`, `par.settings`, `lattice.options` and `plot.args`. Some other typical components are:

`formula` the Trellis formula used in the call

`index.cond` list with index for each of the conditioning variables

`perm.cond` permutation of the order of the conditioning variables  
`aspect.fill` logical, whether aspect is "fill"  
`aspect.ratio` numeric, aspect ratio to be used if `aspect.fill` is FALSE  
`call` call that generated the object.  
`condlevels` list with levels of the conditioning variables  
`legend` list describing the legend(s) to be drawn  
`panel.args` a list as long as the number of panels, each element being a list itself, containing the arguments in named form to be passed to the panel function in that panel.  
`panel.args.common` a list containing the arguments common to all the panel functions in name=value form  
`x.scales` list describing x-scale, can consist of several other lists, paralleling `panel.args`, if x-relation is not "same"  
`y.scales` list describing y-scale, similar to `x.scales`  
`x.between` numeric vector of interpanel x-space  
`y.between` numeric vector of interpanel y-space  
`x.limits` numeric vector of length 2 or list, giving x-axis limits  
`y.limits` similar to `x.limits`  
`packet.sizes` array recording the number of observations in each packet

E\_interaction

*Functions to Interact with Lattice Plots*

---

**Description**

The classic Trellis paradigm is to plot the whole object at once, without the possibility of interacting with it afterwards. However, by keeping track of the grid viewports where the panels and strips are drawn, it is possible to go back to them afterwards and enhance them one panel at a time. These functions provide convenient interfaces to help in this. Note that these are still experimental and the exact details may change in future.

**Usage**

```

panel.identify(x, y = NULL,
 subscripts = seq_along(x),
 labels = subscripts,
 n = length(x), offset = 0.5,
 threshold = 18, ## in points, roughly 0.25 inches
 panel.args = trellis.panelArgs(),
 ...)

```

```

panel.identify.qqmath(x, distribution, groups, subscripts, labels,
 panel.args = trellis.panelArgs(),
 ...)
panel.identify.cloud(x, y, z, subscripts,
 perspective, distance,
 xlim, ylim, zlim,
 screen, R.mat, aspect, scales.3d,
 ...,
 panel.3d.identify,
 n = length(subscripts),
 offset = 0.5,
 threshold = 18,
 labels = subscripts,
 panel.args = trellis.panelArgs())
panel.link.splom(threshold = 18, verbose = getOption("verbose"), ...)
panel.brush.splom(threshold = 18, verbose = getOption("verbose"), ...)

trellis.vpname(name = c("position", "split", "split.location", "toplevel",
 "figure", "panel", "strip", "strip.left",
 "legend", "legend.region", "main", "sub",
 "xlab", "ylab", "xlab.top", "ylab.right", "page"),
 column, row,
 side = c("left", "top", "right", "bottom", "inside"),
 clip.off = FALSE, prefix)
trellis.grobname(name,
 type = c("", "panel", "strip", "strip.left",
 "key", "colorkey"),
 group = 0,
 which.given = lattice.getStatus("current.which.given",
 prefix = prefix),
 which.panel = lattice.getStatus("current.which.panel",
 prefix = prefix),
 column = lattice.getStatus("current.focus.column",
 prefix = prefix),
 row = lattice.getStatus("current.focus.row",
 prefix = prefix),
 prefix = lattice.getStatus("current.prefix"))
trellis.focus(name, column, row, side, clip.off,
 highlight = interactive(), ..., prefix,
 guess = TRUE, verbose = getOption("verbose"))
trellis.switchFocus(name, side, clip.off, highlight, ..., prefix)
trellis.unfocus()
trellis.panelArgs(x, packet.number)

```

### Arguments

|                         |                                                                                                                   |
|-------------------------|-------------------------------------------------------------------------------------------------------------------|
| <code>x, y, z</code>    | variables defining the contents of the panel. In the case of <code>trellis.panelArgs</code> , a "trellis" object. |
| <code>n</code>          | the number of points to identify by default (overridden by a right click)                                         |
| <code>subscripts</code> | an optional vector of integer indices associated with each point. See details below.                              |

|                                                                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| labels                                                                    | an optional vector of labels associated with each point. Defaults to subscripts                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| distribution, groups                                                      | typical panel arguments of <code>panel.qqmath</code> . These will usually be obtained from <code>panel.args</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| offset                                                                    | the labels are printed either below, above, to the left or to the right of the identified point, depending on the relative location of the mouse click. The <code>offset</code> specifies (in "char" units) how far from the identified point the labels should be printed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| threshold                                                                 | threshold in grid's "points" units. Points further than these from the mouse click position are not considered                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| panel.args                                                                | list that contains components names <code>x</code> (and usually <code>y</code> ), to be used if <code>x</code> is missing. Typically, when called after <code>trellis.focus</code> , this would appropriately be the arguments passed to that panel.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| perspective, distance, xlim, ylim, zlim, screen, R.mat, aspect, scales.3d | arguments as passed to <code>panel.cloud</code> . These are required to recompute the relevant three-dimensional projections in <code>panel.identify.cloud</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| panel.3d.identify                                                         | the function that is responsible for the actual interaction once the data rescaling and rotation computations have been done. By default, an internal function similar to <code>panel.identify</code> is used.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| name                                                                      | <p>A character string indicating which viewport or grob we are looking for. Although these do not necessarily provide access to all viewports and grobs created by a lattice plot, they cover most of the ones that end-users may find interesting. <code>trellis.vpname</code> and <code>trellis.focus</code> deal with viewport names only, and only accept the values explicitly listed above. <code>trellis.grobname</code> is meant to create names for grobs, and can currently accept any value.</p> <p>If <code>name</code>, as well as <code>column</code> and <code>row</code> is missing in a call to <code>trellis.focus</code>, the user can click inside a panel (or an associated strip) to focus on that panel. Note however that this assumes equal width and height for each panel, and may not work when this is not true.</p> <p>When <code>name</code> is "panel", "strip", or "strip.left", <code>column</code> and <code>row</code> must also be specified. When <code>name</code> is "legend", <code>side</code> must also be specified.</p> |
| column, row                                                               | integers, indicating position of the panel or strip that should be assigned focus in the Trellis layout. Rows are usually calculated from the bottom up, unless the plot was created with <code>as.table=TRUE</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| guess                                                                     | logical. If TRUE, and the display has only one panel, that panel will be automatically selected by a call to <code>trellis.focus</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| side                                                                      | character string, relevant only for legends (i.e., when <code>name="legend"</code> ), indicating their position. Partial specification is allowed, as long as it is unambiguous.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| clip.off                                                                  | logical, whether clipping should be off, relevant when <code>name</code> is "panel" or "strip". This is necessary if axes are to be drawn outside the panel or strip. Note that setting <code>clip.off=FALSE</code> does not necessarily mean that clipping is on; that is determined by conditions in effect during printing.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| type                                                                      | <p>A character string specifying whether the grob is specific to a particular panel or strip.</p> <p>When <code>type</code> is "panel", "strip", or "strip.left", information about the panel is added to the grob name.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

|                                       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|---------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>group</code>                    | <p>An integer specifying whether the grob is specific to a particular group within the plot.</p> <p>When <code>group</code> is greater than zero, information about the group is added to the grob name.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>which.given, which.panel</code> | <p>integers, indicating which conditional variable is being represented (within a strip) and the current levels of the conditional variables.</p> <p>When <code>which.panel</code> has length greater than 1, and the type is "strip" or "strip.left", information about the conditional variable is added to the grob name.</p>                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>prefix</code>                   | <p>A character string acting as a prefix identifying the plot of a "trellis" object, primarily used to distinguish otherwise equivalent viewports in different plots. This only becomes relevant when a particular page is occupied by more than one plot. Defaults to the value appropriate for the last "trellis" object printed, as determined by the <code>prefix</code> argument in <code>print.trellis</code>.</p> <p>Users should not usually need to supply a value for this argument except to interact with an existing plot other than the one plotted last.</p> <p>For <code>switchFocus</code>, ignored except when it does not match the prefix of the currently active plot, in which case an error occurs.</p> |
| <code>highlight</code>                | <p>logical, whether the viewport being assigned focus should be highlighted. For <code>trellis.focus</code>, the default is TRUE in interactive mode, and <code>trellis.switchFocus</code> by default preserves the setting currently active.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <code>packet.number</code>            | <p>integer, which panel to get data from. See <code>packet.number</code> for details on how this is calculated</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>verbose</code>                  | <p>whether details will be printed</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>...</code>                      | <p>For <code>panel.identify.qqmath</code>, extra parameters are passed on to <code>panel.identify</code>. For <code>panel.identify</code>, extra arguments are treated as graphical parameters and are used for labelling. For <code>trellis.focus</code> and <code>trellis.switchFocus</code>, these are used (in combination with <code>lattice.options</code>) for highlighting the chosen viewport if so requested. Graphical parameters can be supplied for <code>panel.link.splom</code>.</p>                                                                                                                                                                                                                            |

## Details

`panel.identify` is similar to `identify`. When called, it waits for the user to identify points (in the panel being drawn) via mouse clicks. Clicks other than left-clicks terminate the procedure. Although it is possible to call it as part of the panel function, it is more typical to use it to identify points after plotting the whole object, in which case a call to `trellis.focus` first is necessary.

`panel.link.splom` is meant for use with `spлом`, and requires a panel to be chosen using `trellis.focus` before it is called. Clicking on a point causes that and the corresponding projections in other pairwise scatter plots to be highlighted. `panel.brush.splom` is a (misnamed) alias for `panel.link.splom`, retained for back-compatibility.

`panel.identify.qqmath` is a specialized wrapper meant for use with the display produced by `qqmath`. `panel.identify.cloud` is a specialized wrapper meant for use with the display produced by `cloud`. It would be unusual to call them except in a context where default panel function arguments are available through `trellis.panelArgs` (see below).

One way in which `panel.identify` etc. are different from `identify` is in how it uses the `subscripts` argument. In general, when one identifies points in a panel, one wants to identify the origin in the data frame used to produce the plot, and not within that particular panel.

This information is available to the panel function, but only in certain situations. One way to ensure that `subscripts` is available is to specify `subscripts = TRUE` in the high level call such as `xyplot`. If `subscripts` is not explicitly specified in the call to `panel.identify`, but is available in `panel.args`, then those values will be used. Otherwise, they default to `seq_along(x)`. In either case, the final return value will be the `subscripts` that were marked.

The process of printing (plotting) a Trellis object builds up a grid layout with named viewports which can then be accessed to modify the plot further. While full flexibility can only be obtained by using grid functions directly, a few lattice functions are available for the more common tasks.

`trellis.focus` can be used to move to a particular panel or strip, identified by its position in the array of panels. It can also be used to focus on the viewport corresponding to one of the labels or a legend, though such usage would be less useful. The exact viewport is determined by the `name` along with the other arguments, not all of which are relevant for all names. Note that when more than one object is plotted on a page, `trellis.focus` will always go to the plot that was created last. For more flexibility, use grid functions directly (see note below).

After a successful call to `trellis.focus`, the desired viewport (typically panel or strip area) will be made the 'current' viewport (plotting area), which can then be enhanced by calls to standard lattice panel functions as well as grid functions.

It is quite common to have the layout of panels chosen when a "trellis" object is drawn, and not before then. Information on the layout (specifically, how many rows and columns, and which packet belongs in which position in this layout) is retained for the last "trellis" object plotted, and is available through `trellis.currentLayout`.

`trellis.unfocus` unsets the focus, and makes the top level viewport the current viewport.

`trellis.switchFocus` is a convenience function to switch from one viewport to another, while preserving the current `row` and `column`. Although the rows and columns only make sense for panels and strips, they would be preserved even when the user switches to some other viewport (where row/column is irrelevant) and then switches back.

Once a panel or strip is in focus, `trellis.panelArgs` can be used to retrieve the arguments that were available to the panel function at that position. In this case, it can be called without arguments as

```
trellis.panelArgs()
```

This usage is also allowed when a "trellis" object is being printed, e.g. inside the panel functions or the axis function (but not inside the `prepanel` function). `trellis.panelArgs` can also retrieve the panel arguments from any "trellis" object. Note that for this usage, one needs to specify the `packet.number` (as described under the `panel` entry in [xyplot](#)) and not the position in the layout, because a layout determines the panel only **after** the object has been printed.

It is usually not necessary to call `trellis.vpname` and `trellis.grobname` directly. However, they can be useful in generating appropriate names in a portable way when using grid functions to interact with the plots directly, as described in the note below.

## Value

`panel.identify` returns an integer vector containing the subscripts of the identified points (see details above). The equivalent of `identify` with `pos=TRUE` is not yet implemented, but can be considered for addition if requested.

`trellis.panelArgs` returns a named list of arguments that were available to the panel function for the chosen panel.

`trellis.vpname` and `trellis.grobname` return character strings.

`trellis.focus` has a meaningful return value only if it has been used to focus on a panel interactively, in which case the return value is a list with components `col` and `row` giving the column and row positions respectively of the chosen panel, unless the choice was cancelled (by a right click), in which case the return value is `NULL`. If click was outside a panel, both `col` and `row` are set to 0.

### Note

The viewports created by `lattice` are accessible to the user through `trellis.focus` as described above. Functions from the `grid` package can also be used directly. For example, `current.vpTree` can be used to inspect the current viewport tree and `seekViewport` or `downViewport` can be used to navigate to these viewports. For such usage, `trellis.vpname` and `trellis.grobname` provides a portable way to access the appropriate viewports and grobs by name.

### Author(s)

Deepayan Sarkar <Deepayan.Sarkar@R-project.org>. Felix Andrews provided initial implementations of `panel.identify.qqmath` and support for focusing on panels interactively.

### Examples

```
Not run:
xyplot(1:10 ~ 1:10)
trellis.focus("panel", 1, 1)
panel.identify()

End(Not run)

xyplot(Petal.Length ~ Sepal.Length | Species, iris, layout = c(2, 2))
Sys.sleep(1)

trellis.focus("panel", 1, 1)
do.call("panel.lmline", trellis.panelArgs())
Sys.sleep(0.5)
trellis.unfocus()

trellis.focus("panel", 2, 1)
do.call("panel.lmline", trellis.panelArgs())
Sys.sleep(0.5)
trellis.unfocus()

trellis.focus("panel", 1, 2)
do.call("panel.lmline", trellis.panelArgs())
Sys.sleep(0.5)
trellis.unfocus()

choosing loess smoothing parameter

p <- xyplot(dist ~ speed, cars)
```

```

panel.loessresid <-
 function(x = panel.args$x,
 y = panel.args$y,
 span,
 panel.args = trellis.panelArgs())
{
 fm <- loess(y ~ x, span = span)
 xgrid <- do.breaks(current.panel.limits()$xlim, 50)
 ygrid <- predict(fm, newdata = data.frame(x = xgrid))
 panel.lines(xgrid, ygrid)
 pred <- predict(fm)
 ## center residuals so that they fall inside panel
 resids <- y - pred + mean(y)
 fm.resid <- loess.smooth(x, resids, span = span)
 ##panel.points(x, resids, col = 1, pch = 4)
 panel.lines(fm.resid, col = 1)
}

spans <- c(0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8)
update(p, index.cond = list(rep(1, length(spans))))
panel.locs <- trellis.currentLayout()

i <- 1

for (row in 1:nrow(panel.locs))
 for (column in 1:ncol(panel.locs))
 if (panel.locs[row, column] > 0)
 {
 trellis.focus("panel", row = row, column = column,
 highlight = FALSE)
 panel.loessresid(span = spans[i])
 grid::grid.text(paste("span = ", spans[i]),
 x = 0.25,
 y = 0.75,
 default.units = "npc")
 trellis.unfocus()
 i <- i + 1
 }
}

```

F\_1\_\_panel.barchart *Default Panel Function for barchart*

---

## Description

Default panel function for barchart.

## Usage

```

panel.barchart(x, y, box.ratio = 1, box.width,
 horizontal = TRUE,

```

```

origin = NULL, reference = TRUE,
stack = FALSE,
groups = NULL,
col = if (is.null(groups)) plot.polygon$col
 else superpose.polygon$col,
border = if (is.null(groups)) plot.polygon$border
 else superpose.polygon$border,
lty = if (is.null(groups)) plot.polygon$lty
 else superpose.polygon$lty,
lwd = if (is.null(groups)) plot.polygon$lwd
 else superpose.polygon$lwd,
..., identifier = "barchart")

```

### Arguments

|                                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>                     | Extent of Bars. By default, bars start at left of panel, unless <code>origin</code> is specified, in which case they start there.                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>y</code>                     | Horizontal location of bars. Possibly a factor.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>box.ratio</code>             | Ratio of bar width to inter-bar space.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>box.width</code>             | Thickness of bars in absolute units; overrides <code>box.ratio</code> . Useful for specifying thickness when the categorical variable is not a factor, as use of <code>box.ratio</code> alone cannot achieve a thickness greater than 1.                                                                                                                                                                                                                                                                                                                    |
| <code>horizontal</code>            | Logical flag. If <code>FALSE</code> , the plot is ‘transposed’ in the sense that the behaviours of <code>x</code> and <code>y</code> are switched. <code>x</code> is now the ‘factor’. Interpretation of other arguments change accordingly. See documentation of <a href="#">bwplot</a> for a fuller explanation.                                                                                                                                                                                                                                          |
| <code>origin</code>                | The origin for the bars. For grouped displays with <code>stack = TRUE</code> , this argument is ignored and the origin set to 0. Otherwise, defaults to <code>NULL</code> , in which case bars start at the left (or bottom) end of a panel. This choice is somewhat unfortunate, as it can be misleading, but is the default for historical reasons. For tabular (or similar) data, <code>origin = 0</code> is usually more appropriate; if not, one should reconsider the use of a bar chart in the first place (dot plots are often a good alternative). |
| <code>reference</code>             | Logical, whether a reference line is to be drawn at the origin.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>stack</code>                 | logical, relevant when <code>groups</code> is non-null. If <code>FALSE</code> (the default), bars for different values of the grouping variable are drawn side by side, otherwise they are stacked.                                                                                                                                                                                                                                                                                                                                                         |
| <code>groups</code>                | Optional grouping variable.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <code>col, border, lty, lwd</code> | Graphical parameters for the bars. By default, the trellis parameter <code>plot.polygon</code> is used if there is no grouping variable, otherwise <code>superpose.polygon</code> is used. <code>col</code> gives the fill color, <code>border</code> the border color, and <code>lty</code> and <code>lwd</code> the line type and width of the borders.                                                                                                                                                                                                   |
| <code>...</code>                   | Extra arguments will be accepted but ignored.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>identifier</code>            | A character string that is prepended to the names of grobs that are created by this panel function.                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

### Details

A barchart is drawn in the panel. Note that most arguments controlling the display can be supplied to the high-level `barchart` call directly.

**Author(s)**

Deepayan Sarkar <Deepayan.Sarkar@R-project.org>

**Examples**

```
barchart(yield ~ variety | site, data = barley,
 groups = year, layout = c(1,6), origin = 0,
 ylab = "Barley Yield (bushels/acre)",
 scales = list(x = list(abbreviate = TRUE,
 minlength = 5)))
```

---

F\_1\_panel.bwplot      *Default Panel Function for bwplot*

---

**Description**

This is the default panel function for bwplot.

**Usage**

```
panel.bwplot(x, y, box.ratio = 1,
 box.width = box.ratio / (1 + box.ratio),
 horizontal = TRUE,
 pch, col, alpha, cex,
 font, fontfamily, fontface,
 fill, varwidth = FALSE,
 notch = FALSE, notch.frac = 0.5,
 ...,
 levels.fos,
 stats = boxplot.stats,
 coef = 1.5,
 do.out = TRUE,
 identifier = "bwplot")
```

**Arguments**

|                         |                                                                                                                                                                                                                                                                                                               |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x, y</code>       | numeric vector or factor. Boxplots drawn for each unique value of <code>y</code> ( <code>x</code> ) if <code>horizontal</code> is <code>TRUE</code> ( <code>FALSE</code> )                                                                                                                                    |
| <code>box.ratio</code>  | ratio of box thickness to inter box space                                                                                                                                                                                                                                                                     |
| <code>box.width</code>  | thickness of box in absolute units; overrides <code>box.ratio</code> . Useful for specifying thickness when the categorical variable is not a factor, as use of <code>box.ratio</code> alone cannot achieve a thickness greater than 1.                                                                       |
| <code>horizontal</code> | logical. If <code>FALSE</code> , the plot is ‘transposed’ in the sense that the behaviours of <code>x</code> and <code>y</code> are switched. <code>x</code> is now the ‘factor’. Interpretation of other arguments change accordingly. See documentation of <a href="#">bwplot</a> for a fuller explanation. |

|                                                               |                                                                                                                                                                                                                                                                                                                                                                                          |
|---------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>pch, col, alpha, cex, font, fontfamily, fontface</code> | graphical parameters controlling the dot. <code>pch=" "</code> is treated specially, by replacing the dot with a line (similar to <code>boxplot</code> )                                                                                                                                                                                                                                 |
| <code>fill</code>                                             | color to fill the boxplot                                                                                                                                                                                                                                                                                                                                                                |
| <code>varwidth</code>                                         | logical. If TRUE, widths of boxplots are proportional to the number of points used in creating it.                                                                                                                                                                                                                                                                                       |
| <code>notch</code>                                            | if <code>notch</code> is TRUE, a notch is drawn in each side of the boxes. If the notches of two plots do not overlap this is 'strong evidence' that the two medians differ (Chambers et al., 1983, p. 62). See <code>boxplot.stats</code> for the calculations used.                                                                                                                    |
| <code>notch.frac</code>                                       | numeric in (0,1). When <code>notch=TRUE</code> , the fraction of the box width that the notches should use.                                                                                                                                                                                                                                                                              |
| <code>stats</code>                                            | a function, defaulting to <code>boxplot.stats</code> , that accepts a numeric vector and returns a list similar to the return value of <code>boxplot.stats</code> . The function must accept arguments <code>coef</code> and <code>do.out</code> even if they do not use them (a <code>...</code> argument is good enough). This function is used to determine the box and whisker plot. |
| <code>coef, do.out</code>                                     | passed to <code>stats</code>                                                                                                                                                                                                                                                                                                                                                             |
| <code>levels.fos</code>                                       | numeric values corresponding to positions of the factor or shingle variable. For internal use.                                                                                                                                                                                                                                                                                           |
| <code>...</code>                                              | further arguments, ignored.                                                                                                                                                                                                                                                                                                                                                              |
| <code>identifier</code>                                       | A character string that is prepended to the names of grobs that are created by this panel function.                                                                                                                                                                                                                                                                                      |

### Details

Creates Box and Whisker plot of `x` for every level of `y` (or the other way round if `horizontal=FALSE`). By default, the actual boxplot statistics are calculated using `boxplot.stats`. Note that most arguments controlling the display can be supplied to the high-level `bwplot` call directly.

Although the graphical parameters for the dot representing the median can be controlled by optional arguments, many others can not. These parameters are obtained from the relevant settings parameters ("`box.rectangle`" for the box, "`box.umbrella`" for the whiskers and "`plot.symbol`" for the outliers).

F\_1\_panel.cloud

*Default Panel Function for cloud*

## Description

These are default panel functions controlling cloud and wireframe displays.

## Usage

```

panel.cloud(x, y, subscripts, z,
 groups = NULL,
 perspective = TRUE,
 distance = if (perspective) 0.2 else 0,
 xlim, ylim, zlim,
 panel.3d.cloud = "panel.3dscatter",
 panel.3d.wireframe = "panel.3dwire",
 screen = list(z = 40, x = -60),
 R.mat = diag(4), aspect = c(1, 1),
 par.box = NULL,
 xlab, ylab, zlab,
 xlab.default, ylab.default, zlab.default,
 scales.3d,
 proportion = 0.6,
 wireframe = FALSE,
 scpos,
 ...,
 at,
 identifier = "cloud")
panel.wireframe(...)
panel.3dscatter(x, y, z, rot.mat, distance,
 groups, type = "p",
 xlim, ylim, zlim,
 xlim.scaled, ylim.scaled, zlim.scaled,
 zero.scaled,
 col, col.point, col.line,
 lty, lwd, cex, pch,
 cross, ..., .scale = FALSE, subscripts,
 identifier = "3dscatter")
panel.3dwire(x, y, z, rot.mat = diag(4), distance,
 shade = FALSE,
 shade.colors.palette = trellis.par.get("shade.colors")$palette,
 light.source = c(0, 0, 1000),
 xlim, ylim, zlim,

```

```

xlim.scaled,
ylim.scaled,
zlim.scaled,
col = if (shade) "transparent" else "black",
lty = 1, lwd = 1,
alpha,
col.groups = superpose.polygon$col,
polynum = 100,
...,
.scale = FALSE,
drape = FALSE,
at,
col.regions = regions$col,
alpha.regions = regions$alpha,
identifier = "3dwire")

```

### Arguments

|                          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|--------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x, y, z</code>     | <p>numeric (or possibly factors) vectors representing the data to be displayed. The interpretation depends on the context. For <code>panel.cloud</code> these are essentially the same as the data passed to the high level plot (except if <code>formula</code> was a matrix, the appropriate <code>x</code> and <code>y</code> vectors are generated). By the time they are passed to <code>panel.3dscatter</code> and <code>panel.3dwire</code>, they have been appropriately subsetting (using <code>subscripts</code>) and scaled (to lie inside a bounding box, usually the <code>[-0.5, 0.5]</code> cube).</p> <p>Further, for <code>panel.3dwire</code>, <code>x</code> and <code>y</code> are shorter than <code>z</code> and represent the sorted locations defining a rectangular grid. Also in this case, <code>z</code> may be a matrix if the display is grouped, with each column representing one surface.</p> <p>In <code>panel.cloud</code> (called from <code>wireframe</code>) and <code>panel.3dwire</code>, <code>x</code>, <code>y</code> and <code>z</code> could also be matrices (of the same dimension) when they represent a 3-D surface parametrized on a 2-D grid.</p> |
| <code>subscripts</code>  | index specifying which points to draw. The same <code>x</code> , <code>y</code> and <code>z</code> values (representing the whole data) are passed to <code>panel.cloud</code> for each panel. <code>subscripts</code> specifies the subset of rows to be used for the particular panel.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>groups</code>      | specification of a grouping variable, passed down from the high level functions.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>perspective</code> | logical, whether to plot a perspective view. Setting this to <code>FALSE</code> is equivalent to setting <code>distance</code> to 0                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <code>distance</code>    | numeric, between 0 and 1, controls amount of perspective. The distance of the viewing point from the origin (in the transformed coordinate system) is <code>1 / distance</code> . This is described in a little more detail in the documentation for <a href="#">cloud</a>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>screen</code>      | A list determining the sequence of rotations to be applied to the data before being plotted. The initial position starts with the viewing point along the positive <code>z</code> -axis, and the <code>x</code> and <code>y</code> axes in the usual position. Each component of the list should be named one of " <code>x</code> ", " <code>y</code> " or " <code>z</code> " (repetitions are allowed), with their values indicating the amount of rotation about that axis in degrees.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>R.mat</code>       | initial rotation matrix in homogeneous coordinates, to be applied to the data before <code>screen</code> rotates the view further.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>par.box</code>     | graphical parameters for box, namely, <code>col</code> , <code>lty</code> and <code>lwd</code> . By default obtained from the parameter <code>box.3d</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

|                                                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| <code>xlim, ylim, zlim</code>                      | limits for the respective axes. As with other lattice functions, these could each be a numeric 2-vector or a character vector indicating levels of a factor.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>panel.3d.cloud, panel.3d.wireframe</code>    | functions that draw the data-driven part of the plot (as opposed to the bounding box and scales) in <code>cloud</code> and <code>wireframe</code> . This function is called after the 'back' of the bounding box is drawn, but before the 'front' is drawn.<br>Any user-defined custom display would probably want to change these functions. The intention is to pass as much information to this function as might be useful (not all of which are used by the defaults). In particular, these functions can expect arguments called <code>xlim</code> , <code>ylim</code> , <code>zlim</code> which give the bounding box ranges in the original data scale and <code>xlim.scaled</code> , <code>ylim.scaled</code> , <code>zlim.scaled</code> which give the bounding box ranges in the transformed scale. More arguments can be considered on request. |
| <code>aspect</code>                                | aspect as in <code>cloud</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>xlab, ylab, zlab</code>                      | Labels, have to be lists. Typically the user will not manipulate these, but instead control this via arguments to <code>cloud</code> directly.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| <code>proportion</code>                            | numeric scalar, gives the length of arrows as a proportion of the sides                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>scpos</code>                                 | A list with three components x, y and z (each a scalar integer), describing which of the 12 sides of the cube the scales should be drawn. The defaults should be OK. Valid values are x: 1, 3, 9, 11; y: 8, 5, 7, 6 and z: 4, 2, 10, 12. (See comments in the source code of <code>panel.cloud</code> to see the details of this enumeration.)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <code>wireframe</code>                             | logical, indicating whether this is a wireframe plot                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <code>drape</code>                                 | logical, whether the facets will be colored by height, in a manner similar to <code>levelplot</code> . This is ignored if <code>shade=TRUE</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>at, col.regions, alpha.regions</code>        | deals with specification of colors when <code>drape=TRUE</code> in <code>wireframe</code> . <code>at</code> can be a numeric vector, <code>col.regions</code> a vector of colors, and <code>alpha.regions</code> a numeric scalar controlling transparency. The resulting behaviour is similar to <code>levelplot</code> , <code>at</code> giving the breakpoints along the z-axis where colors change, and the other two determining the colors of the facets that fall in between.                                                                                                                                                                                                                                                                                                                                                                        |
| <code>rot.mat</code>                               | 4x4 transformation matrix in homogeneous coordinates. This gives the rotation matrix combining the screen and <code>R.mat</code> arguments to <code>panel.cloud</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>type</code>                                  | Character vector, specifying type of cloud plot. Can include one or more of "p", "l", "h" or "b". "p" and "l" mean 'points' and 'lines' respectively, and "b" means 'both'. "h" stands for 'histogram', and causes a line to be drawn from each point to the X-Y plane (i.e., the plane representing $z = 0$ ), or the lower (or upper) bounding box face, whichever is closer.                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>xlim.scaled, ylim.scaled, zlim.scaled</code> | axis limits (after being scaled to the bounding box)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

|                                                                  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>zero.scaled</code>                                         | z-axis location (after being scaled to the bounding box) of the X-Y plane in the original data scale, to which lines will be dropped (if within range) from each point when <code>type = "h"</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <code>cross</code>                                               | <p>logical, defaults to TRUE if <code>pch = "+"</code>. <code>panel.3dscatter</code> can represent each point by a 3d 'cross' of sorts (it's much easier to understand looking at an example than from a description). This is different from the usual <code>pch</code> argument, and reflects the depth of the points and the orientation of the axes. This argument indicates whether this feature will be used.</p> <p>This is useful for two reasons. It can be set to FALSE to use "+" as the plotting character in the regular sense. It can also be used to force this feature in grouped displays.</p>                                                                                                                                      |
| <code>shade</code>                                               | logical, indicating whether the surface is to be colored using an illumination model with a single light source                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>shade.colors.palette</code>                                | <p>a function (or the name of one) that is supposed to calculate the color of a facet when shading is being used. Three pieces of information are available to the function: first, the cosine of the angle between the incident light ray and the normal to the surface (representing foreshortening); second, the cosine of half the angle between the reflected ray and the viewing direction (useful for non-Lambertian surfaces); and third, the scaled (average) height of that particular facet with respect to the total plot z-axis limits.</p> <p>All three numbers should be between 0 and 1. The <code>shade.colors.palette</code> function should return a valid color. The default function is obtained from the trellis settings.</p> |
| <code>light.source</code>                                        | a 3-vector representing (in cartesian coordinates) the light source. This is relative to the viewing point being (0, 0, 1/distance) (along the positive z-axis), keeping in mind that all observations are bounded within the [-0.5, 0.5] cube                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <code>polynum</code>                                             | quadrilateral faces are drawn in batches of <code>polynum</code> at a time. Drawing too few at a time increases the total number of calls to the underlying <code>grid.polygon</code> function, which affects speed. Trying to draw too many at once may be unnecessarily memory intensive. This argument controls the trade-off.                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>col.groups</code>                                          | colors for different groups                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <code>col, col.point, col.line, lty, lwd, cex, pch, alpha</code> | Graphical parameters. Some other arguments (such as <code>lex</code> for line width) may also be passed through the <code>...</code> argument.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <code>...</code>                                                 | other parameters, passed down when appropriate                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <code>.scale</code>                                              | Logical flag, indicating whether x, y, and z should be assumed to be in the original data scale and hence scaled before being plotted. x, y, and z are usually already scaled. However, setting <code>.scale=TRUE</code> may be helpful for calls to <code>panel.3dscatter</code> and <code>panel.3dwire</code> in user-supplied panel functions.                                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>identifier</code>                                          | A character string that is prepended to the names of grobs that are created by this panel function.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

## Details

These functions together are responsible for the content drawn inside each panel in `cloud` and `wireframe`. `panel.wireframe` is a wrapper to `panel.cloud`, which does the actual work. `panel.cloud` is responsible for drawing the content that does not depend on the data, namely, the bounding box, the arrows/scales, etc. At some point, depending on whether `wireframe` is TRUE,

it calls either `panel.3d.wireframe` or `panel.3d.cloud`, which draws the data-driven part of the plot.

The arguments accepted by these two functions are different, since they have essentially different purposes. For `cloud`, the data is unstructured, and `x`, `y` and `z` are all passed to the `panel.3d.cloud` function. For `wireframe`, on the other hand, `x` and `y` are increasing vectors with unique values, defining a rectangular grid. `z` must be a matrix with `length(x) * length(y)` rows, and as many columns as the number of groups.

`panel.3dscatter` is the default `panel.3d.cloud` function. It has a `type` argument similar to `panel.xyplot`, and supports grouped displays. It tries to honour depth ordering, i.e., points and lines closer to the camera are drawn later, overplotting more distant ones. (Of course there is no absolute ordering for line segments, so an ad hoc ordering is used. There is no hidden point removal.)

`panel.3dwire` is the default `panel.3d.wireframe` function. It calculates polygons corresponding to the facets one by one, but waits till it has collected information about `polynum` facets, and draws them all at once. This avoids the overhead of drawing `grid.polygon` repeatedly, speeding up the rendering considerably. If `shade = TRUE`, these attempt to color the surface as being illuminated from a light source at `light.source`. `palette.shade` is a simple function that provides the default shading colors

Multiple surfaces are drawn if `groups` is non-null in the call to `wireframe`, however, the algorithm is not sophisticated enough to render intersecting surfaces correctly.

*Default Panel Function for densityplot*

---

### Description

This is the default panel function for `densityplot`.

### Usage

```
panel.densityplot(x, darg, plot.points = "jitter", ref = FALSE,
 groups = NULL, weights = NULL,
 jitter.amount, type, ...,
 identifier = "density")
```

### Arguments

|                   |                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>    | data points for which density is to be estimated                                                                                                                                                                                                                                                                                                                                                                                |
| <code>darg</code> | list of arguments to be passed to the <code>density</code> function. Typically, this should be a list with zero or more of the following components : <code>bw</code> , <code>adjust</code> , <code>kernel</code> , <code>window</code> , <code>width</code> , <code>give.Rkern</code> , <code>n</code> , <code>from</code> , <code>to</code> , <code>cut</code> , <code>na.rm</code> (see <a href="#">density</a> for details) |

|                            |                                                                                                                                                                                                                                                                                                                                                                                          |
|----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>plot.points</code>   | logical specifying whether or not the data points should be plotted along with the estimated density. Alternatively, a character string specifying how the points should be plotted. Meaningful values are "rug", in which case <code>panel.rug</code> is used to plot a 'rug', and "jitter", in which case the points are jittered vertically to better distinguish overlapping points. |
| <code>ref</code>           | logical, whether to draw x-axis                                                                                                                                                                                                                                                                                                                                                          |
| <code>groups</code>        | an optional grouping variable. If present, <code>panel.superpose</code> will be used instead to display each subgroup                                                                                                                                                                                                                                                                    |
| <code>weights</code>       | numeric vector of weights for the density calculations. If this is specified, the <code>...</code> part must also include a <code>subscripts</code> argument that matches the weights to <code>x</code> .                                                                                                                                                                                |
| <code>jitter.amount</code> | when <code>plot.points="jitter"</code> , the value to use as the <code>amount</code> argument to <code>jitter</code> .                                                                                                                                                                                                                                                                   |
| <code>type</code>          | type argument used to plot points, if requested. This is not expected to be useful, it is available mostly to protect a <code>type</code> argument, if specified, from affecting the density curve.                                                                                                                                                                                      |
| <code>...</code>           | extra graphical parameters. Note that additional arguments to <code>panel.rug</code> cannot be passed on through <code>panel.densityplot</code> .                                                                                                                                                                                                                                        |
| <code>identifier</code>    | A character string that is prepended to the names of grobs that are created by this panel function.                                                                                                                                                                                                                                                                                      |

F\_1\_panel.dotplot    *Default Panel Function for dotplot*

---

**Description**

Default panel function for `dotplot`.

**Usage**

```
panel.dotplot(x, y, horizontal = TRUE,
 pch, col, lty, lwd,
 col.line, levels.fos,
 groups = NULL,
 ...,
 identifier = "dotplot")
```

**Arguments**

|                                           |                                                                                                                                                                                                                                                                                                               |
|-------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x, y</code>                         | variables to be plotted in the panel. Typically <code>y</code> is the ‘factor’                                                                                                                                                                                                                                |
| <code>horizontal</code>                   | logical. If <code>FALSE</code> , the plot is ‘transposed’ in the sense that the behaviours of <code>x</code> and <code>y</code> are switched. <code>x</code> is now the ‘factor’. Interpretation of other arguments change accordingly. See documentation of <a href="#">bwplot</a> for a fuller explanation. |
| <code>pch, col, lty, lwd, col.line</code> | graphical parameters                                                                                                                                                                                                                                                                                          |
| <code>levels.fos</code>                   | locations where reference lines will be drawn                                                                                                                                                                                                                                                                 |
| <code>groups</code>                       | grouping variable (affects graphical parameters)                                                                                                                                                                                                                                                              |
| <code>...</code>                          | extra parameters, passed to <code>panel.xyplot</code> which is responsible for drawing the foreground points ( <code>panel.dotplot</code> only draws the background reference lines).                                                                                                                         |
| <code>identifier</code>                   | A character string that is prepended to the names of grobs that are created by this panel function.                                                                                                                                                                                                           |

**Details**

Creates (possibly grouped) Dotplot of `x` against `y` or vice versa

F\_1\_panel.histogram

*Default Panel Function for histogram*

---

**Description**

This is the default panel function for histogram.

**Usage**

```
panel.histogram(x,
 breaks,
 equal.widths = TRUE,
 type = "density",
 nint = round(log2(length(x)) + 1),
 alpha, col, border, lty, lwd,
 ...,
 identifier = "histogram")
```

**Arguments**

|                                           |                                                                                                     |
|-------------------------------------------|-----------------------------------------------------------------------------------------------------|
| <code>x</code>                            | The data points for which the histogram is to be drawn                                              |
| <code>breaks</code>                       | The breakpoints for the histogram                                                                   |
| <code>equal.widths</code>                 | logical used when <code>breaks==NULL</code>                                                         |
| <code>type</code>                         | Type of histogram, possible values being "percent", "density" and "count"                           |
| <code>nint</code>                         | Number of bins for the histogram                                                                    |
| <code>alpha, col, border, lty, lwd</code> | graphical parameters for bars; defaults are obtained from the <code>plot.polygon</code> settings.   |
| <code>...</code>                          | other arguments, passed to <code>hist</code> when deemed appropriate                                |
| <code>identifier</code>                   | A character string that is prepended to the names of grobs that are created by this panel function. |

*Panel Functions for levelplot and contourplot*

---

**Description**

These are the default panel functions for [levelplot](#) and `contourplot`. Also documented is an alternative raster-based panel function for use with `levelplot`.

**Usage**

```
panel.levelplot(x, y, z,
 subscripts,
 at = pretty(z),
 shrink,
 labels,
 label.style = c("mixed", "flat", "align"),
 contour = FALSE,
 region = TRUE,
 col = add.line$col,
 lty = add.line$lty,
 lwd = add.line$lwd,
 border = "transparent",
 border.lty = 1,
 border.lwd = 0.1,
 ...,
 col.regions = regions$col,
```

```

 alpha.regions = regions$alpha,
 identifier = "levelplot")
panel.contourplot(...)

panel.levelplot.raster(x, y, z,
 subscripts,
 at = pretty(z),
 ...,
 col.regions = regions$col,
 alpha.regions = regions$alpha,
 interpolate = FALSE,
 identifier = "levelplot")

```

### Arguments

|                                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x, y, z</code>                | Variables defining the plot.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>subscripts</code>             | Integer vector indicating what subset of <code>x</code> , <code>y</code> and <code>z</code> to draw.                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <code>at</code>                     | Numeric vector giving breakpoints along the range of <code>z</code> . See <a href="#">levelplot</a> for details.                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <code>shrink</code>                 | Either a numeric vector of length 2 (meant to work as both <code>x</code> and <code>y</code> components), or a list with components <code>x</code> and <code>y</code> which are numeric vectors of length 2. This allows the rectangles to be scaled proportional to the <code>z</code> -value. The specification can be made separately for widths ( <code>x</code> ) and heights ( <code>y</code> ). The elements of the length 2 numeric vector gives the minimum and maximum proportion of shrinkage (corresponding to min and max of <code>z</code> ). |
| <code>labels</code>                 | Either a logical scalar indicating whether the labels are to be drawn, or a character or expression vector giving the labels associated with the <code>at</code> values. Alternatively, <code>labels</code> can be a list with the following components:<br><br><code>labels</code> : a character or expression vector giving the labels. This can be omitted, in which case the defaults will be used.<br><code>col, cex, alpha</code> : graphical parameters for label texts<br><code>fontfamily, fontface, font</code> : font used for the labels        |
| <code>label.style</code>            | Controls how label positions and rotation are determined. A value of <code>"flat"</code> causes the label to be positioned where the contour is flattest, and the label is not rotated. A value of <code>"align"</code> causes the label to be drawn as far from the boundaries as possible, and the label is rotated to align with the contour at that point. The default is to mix these approaches, preferring the flattest location unless it is too close to the boundaries.                                                                           |
| <code>contour</code>                | A logical flag, specifying whether contour lines should be drawn.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>region</code>                 | A logical flag, specifying whether inter-contour regions should be filled with appropriately colored rectangles.                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <code>col, lty, lwd</code>          | Graphical parameters for contour lines.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>border</code>                 | Border color for rectangles used when <code>region=TRUE</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <code>border.lty, border.lwd</code> | Graphical parameters for the border                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>...</code>                    | Extra parameters.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

`col.regions` A vector of colors, or a function to produce a vector of colors, to be used if `region=TRUE`. Each interval defined by `at` is assigned a color, so the number of colors actually used is one less than the length of `at`. See [level.colors](#) for details on how the color assignment is done.

`alpha.regions` numeric scalar controlling transparency of facets

`interpolate` logical, passed to [grid.raster](#).

`identifier` A character string that is prepended to the names of grobs that are created by this panel function.

## Details

The same panel function is used for both `levelplot` and `contourplot` (which differ only in default values of some arguments). `panel.contourplot` is a simple wrapper to `panel.levelplot`.

When `contour=TRUE`, the `contourLines` function is used to calculate the contour lines.

`panel.levelplot.raster` is an alternative panel function that uses the raster drawing abilities in R 2.11.0 and higher (through [grid.raster](#)). It has fewer options (e.g., can only render data on an equispaced grid), but can be more efficient. When using `panel.levelplot.raster`, it may be desirable to render the color key in the same way. This is possible, but must be done separately; see [levelplot](#) for details.

## Examples

```
require(grid)

levelplot(rnorm(10) ~ 1:10 + sort(runif(10)), panel = panel.levelplot)

suppressWarnings(plot(levelplot(rnorm(10) ~ 1:10 + sort(runif(10)),
 panel = panel.levelplot.raster,
 interpolate = TRUE)))

levelplot(volcano, panel = panel.levelplot.raster)

levelplot(volcano, panel = panel.levelplot.raster,
 col.regions = topo.colors, cuts = 30, interpolate = TRUE)
```

## Description

This is the default superpanel function for splom.

## Usage

```
panel.pairs(z,
 panel = lattice.getOption("panel.splom"),
 lower.panel = panel,
 upper.panel = panel,
 diag.panel = "diag.panel.splom",
 as.matrix = FALSE,
 groups = NULL,
 panel.subscripts,
 subscripts,
 pscales = 5,
 prepanel.limits = scale.limits,
 varnames = colnames(z),
 varname.col, varname.cex, varname.font,
 varname.fontfamily, varname.fontface,
 axis.text.col, axis.text.cex, axis.text.font,
 axis.text.fontfamily, axis.text.fontface,
 axis.text.lineheight,
 axis.line.col, axis.line.lty, axis.line.lwd,
 axis.line.alpha, axis.line.tck,
 ...)
diag.panel.splom(x = NULL,
 varname = NULL, limits, at = NULL, labels = NULL,
 draw = TRUE, tick.number = 5,
 varname.col, varname.cex,
 varname.lineheight, varname.font,
 varname.fontfamily, varname.fontface,
 axis.text.col, axis.text.alpha,
 axis.text.cex, axis.text.font,
 axis.text.fontfamily, axis.text.fontface,
 axis.text.lineheight,
 axis.line.col, axis.line.alpha,
 axis.line.lty, axis.line.lwd,
 axis.line.tck,
 ...)
```

## Arguments

**z** The data frame used for the plot.

**panel, lower.panel, upper.panel** The panel function used to display each pair of variables. If specified, lower.panel and upper.panel are used for panels below and above the diagonal respectively.

|                               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

|                               | In addition to extra arguments not recognized by <code>panel.pairs</code> , the list of arguments passed to the panel function also includes arguments named <code>i</code> and <code>j</code> , with values indicating the row and column of the scatterplot matrix being plotted.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <code>diag.panel</code>       | The panel function used for the diagonals. See arguments to <code>diag.panel.splom</code> to know what arguments this function is passed when called. Use <code>diag.panel=NULL</code> to suppress plotting on the diagonal panels.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <code>as.matrix</code>        | logical. If TRUE, the layout of the panels will have origin on the top left instead of bottom left (similar to <code>pairs</code> ). This is in essence the same functionality as provided by <code>as.table</code> for the panel layout                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <code>groups</code>           | Grouping variable, if any                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>panel.subscripts</code> | logical specifying whether the panel function accepts an argument named <code>subscripts</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <code>subscripts</code>       | The indices of the rows of <code>z</code> that are to be displayed in this (super)panel.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <code>pscales</code>          | Controls axis labels, passed down from <code>splom</code> . If <code>pscales</code> is a single number, it indicates the approximate number of equally-spaced ticks that should appear on each axis. If <code>pscales</code> is a list, it should have one component for each column in <code>z</code> , each of which itself a list with the following valid components:<br><code>at</code> : a numeric vector specifying tick locations<br><code>labels</code> : character vector labels to go with <code>at</code><br><code>limits</code> : numeric 2-vector specifying axis limits (should be made more flexible at some point to handle factors)<br>These are specifications on a per-variable basis, and used on all four sides in the diagonal cells used for labelling. Factor variables are labelled with the factor names. Use <code>pscales=0</code> to suppress the axes entirely. |
| <code>prepanel.limits</code>  | A function to calculate suitable axis limits given a single argument <code>x</code> containing a data vector. The return value of the function should be similar to the <code>xlim</code> or <code>ylim</code> argument documented in <code>xyplot</code> ; that is, it should be a numeric or <code>DateTime</code> vector of length 2 defining a range, or a character vector representing levels of a factor.<br>Most high-level lattice plots (such as <code>xyplot</code> ) use the <code>prepanel</code> function for deciding on axis limits from data. This function serves a similar function by calculating the per-variable limits. These limits can be overridden by the corresponding <code>limits</code> component in the <code>pscales</code> list.                                                                                                                             |
| <code>x</code>                | data vector corresponding to that row / column (which will be the same for diagonal 'panels').                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <code>varname</code>          | (scalar) character string or expression that is to be written centred within the panel                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>limits</code>           | numeric of length 2, or, vector of characters, specifying the scale for that panel (used to calculate tick locations when missing)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>at</code>               | locations of tick marks                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <code>labels</code>           | optional labels for tick marks                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <code>draw</code>             | A logical flag specifying whether to draw the tick marks and labels. If FALSE, variable names are shown but axis annotation is omitted.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <code>tick.number</code>      | A Numeric scalar giving the suggested number of tick marks.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

|                                                                                                   |                                                                                                                                                                                                                             |

| <code>axis.text.font</code> , <code>axis.text.fontfamily</code> , <code>axis.text.fontface</code> | Font specification for axis label text.                                                                                                                                                                                     |
| <code>axis.text.lineheight</code>                                                                 | Line height for axis label text.                                                                                                                                                                                            |
| <code>axis.text.alpha</code>                                                                      | Alpha-transparency for axis label text.                                                                                                                                                                                     |
| <code>axis.line.col</code>                                                                        | Color for the axes.                                                                                                                                                                                                         |
| <code>axis.line.lty</code>                                                                        | Line type for the axes.                                                                                                                                                                                                     |
| <code>axis.line.lwd</code>                                                                        | Line width for the axes.                                                                                                                                                                                                    |
| <code>axis.line.alpha</code>                                                                      | Alpha-transparency for the axes.                                                                                                                                                                                            |
| <code>axis.line.tck</code>                                                                        | A numeric multiplier for the length of tick marks in diagonal panels.                                                                                                                                                       |
| <code>...</code>                                                                                  | Further arguments, passed on to <code>panel</code> , <code>lower.panel</code> , <code>upper.panel</code> , and <code>diag.panel</code> from <code>panel.pairs</code> . Currently ignored by <code>diag.panel.splom</code> . |

## Details

`panel.pairs` is the function that is actually used as the panel function in a "trellis" object produced by `splom`.

## Author(s)

Deepayan Sarkar <Deepayan.Sarkar@R-project.org>

## Examples

```
Cmat <- outer(1:6,1:6,
 function(i,j) rainbow(11, start=.12, end=.5)[i+j-1])

splom(~diag(6), as.matrix = TRUE,
 panel = function(x, y, i, j, ...) {
 panel.fill(Cmat[i,j])
 panel.text(.5,.5, paste("(",i,",",j,")",sep=""))
 })
```

---

F\_1\_panel.parallel *Default Panel Function for parallel*

---

## Description

This is the default panel function for parallel.

## Usage

```
panel.parallel(x, y, z, subscripts,
 groups = NULL,
 col, lwd, lty, alpha,
 common.scale = FALSE,
 lower,
 upper,
 ...,
 horizontal.axis = TRUE,
 identifier = "parallel")
```

## Arguments

|                                   |                                                                                                                                                                                                                                                                                                                                                                                 |
|-----------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x, y</code>                 | dummy variables, ignored.                                                                                                                                                                                                                                                                                                                                                       |
| <code>z</code>                    | The data frame used for the plot. Each column will be coerced to numeric before being plotted, and an error will be issued if this fails.                                                                                                                                                                                                                                       |
| <code>subscripts</code>           | The indices of the rows of <code>z</code> that are to be displayed in this panel.                                                                                                                                                                                                                                                                                               |
| <code>groups</code>               | An optional grouping variable. If specified, different groups are distinguished by use of different graphical parameters (i.e., rows of <code>z</code> in the same group share parameters).                                                                                                                                                                                     |
| <code>col, lwd, lty, alpha</code> | graphical parameters (defaults to the settings for <code>superpose.line</code> ). If <code>groups</code> is non-null, these parameters used one for each group. Otherwise, they are recycled and used to distinguish between rows of the data frame <code>z</code> .                                                                                                            |
| <code>common.scale</code>         | logical, whether a common scale should be used columns of <code>z</code> . Defaults to <code>FALSE</code> , in which case the horizontal range for each column is different (as determined by <code>lower</code> and <code>upper</code> ).                                                                                                                                      |
| <code>lower, upper</code>         | numeric vectors replicated to be as long as the number of columns in <code>z</code> . Determines the lower and upper bounds to be used for scaling the corresponding columns of <code>z</code> after coercing them to numeric. Defaults to the minimum and maximum of each column. Alternatively, these could be functions (to be applied on each column) that return a scalar. |

|                 |                                                                                                            |
|-----------------|------------------------------------------------------------------------------------------------------------|
| ...             | other arguments (ignored)                                                                                  |
| horizontal.axis | logical indicating whether the parallel axes should be laid out horizontally (TRUE) or vertically (FALSE). |
| identifier      | A character string that is prepended to the names of grobs that are created by this panel function.        |

### Details

Produces parallel coordinate plots, which are easier to understand from an example than through a verbal description. See example for [parallel](#)

|------------------|------------------------------------------|
| F_1_panel.qqmath | <i>Default Panel Function for qqmath</i> |
|------------------|------------------------------------------|

---

### Description

This is the default panel function for qqmath.

### Usage

```
panel.qqmath(x, f.value = NULL,
 distribution = qnorm,
 qtype = 7,
 groups = NULL, ...,
 tails.n = 0,
 identifier = "qqmath")
```

### Arguments

|                       |                                                                                                                                                                         |
|-----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x                     | vector (typically numeric, coerced if not) of data values to be used in the panel.                                                                                      |
| f.value, distribution | Defines how quantiles are calculated. See <a href="#">qqmath</a> for details.                                                                                           |
| qtype                 | The type argument to be used in <a href="#">quantile</a>                                                                                                                |
| groups                | An optional grouping variable. Within each panel, one Q-Q plot is produced for every level of this grouping variable, differentiated by different graphical parameters. |

|                         |                                                                                                                                                                                                                                                                                                                                       |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ...                     | Further arguments, often graphical parameters, eventually passed on to <a href="#">panel.xyplot</a> . Arguments <code>grid</code> and <code>abline</code> of <code>panel.xyplot</code> may be particularly useful.                                                                                                                    |
| <code>tails.n</code>    | number of data points to represent exactly on each tail of the distribution. This reproduces the effect of <code>f.value = NULL</code> for the extreme data values, while approximating the remaining data. It has no effect if <code>f.value = NULL</code> . If <code>tails.n</code> is given, <code>qtype</code> is forced to be 1. |
| <code>identifier</code> | A character string that is prepended to the names of grobs that are created by this panel function.                                                                                                                                                                                                                                   |

### Details

Creates a Q-Q plot of the data and the theoretical distribution given by `distribution`. Note that most of the arguments controlling the display can be supplied directly to the high-level `qqmath` call.

### Examples

```
set.seed(0)
xx <- rt(10000, df = 10)
qqmath(~ xx, pch = "+", distribution = qnorm,
 grid = TRUE, abline = c(0, 1),
 xlab.top = c("raw", "ppoints(100)", "tails.n = 50"),
 panel = function(..., f.value) {
 switch(panel.number(),
 panel.qqmath(..., f.value = NULL),
 panel.qqmath(..., f.value = ppoints(100)),
 panel.qqmath(..., f.value = ppoints(100), tails.n = 50))
 }, layout = c(3, 1))[c(1,1,1)]
```

---

F\_1\_panel.stripplot

*Default Panel Function for stripplot*

---

### Description

This is the default panel function for `stripplot`. Also see `panel.superpose`

### Usage

```
panel.stripplot(x, y, jitter.data = FALSE,
 factor = 0.5, amount = NULL,
 horizontal = TRUE, groups = NULL,
 ...,
 identifier = "stripplot")
```

**Arguments**

|                             |                                                                                                                                                                                                                                                                                                            |
|-----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x, y</code>           | coordinates of points to be plotted                                                                                                                                                                                                                                                                        |
| <code>jitter.data</code>    | whether points should be jittered to avoid overplotting. The actual jittering is performed inside <code>panel.xyplot</code> , using its <code>jitter.x</code> or <code>jitter.y</code> argument (depending on the value of <code>horizontal</code> ).                                                      |
| <code>factor, amount</code> | amount of jittering, see <code>jitter</code>                                                                                                                                                                                                                                                               |
| <code>horizontal</code>     | logical. If <code>FALSE</code> , the plot is ‘transposed’ in the sense that the behaviours of <code>x</code> and <code>y</code> are switched. <code>x</code> is now the ‘factor’. Interpretation of other arguments change accordingly. See documentation of <code>bwplot</code> for a fuller explanation. |
| <code>groups</code>         | optional grouping variable                                                                                                                                                                                                                                                                                 |
| <code>...</code>            | additional arguments, passed on to <code>panel.xyplot</code>                                                                                                                                                                                                                                               |
| <code>identifier</code>     | A character string that is prepended to the names of grobs that are created by this panel function.                                                                                                                                                                                                        |

**Details**

Creates stripplot (one dimensional scatterplot) of `x` for each level of `y` (or vice versa, depending on the value of `horizontal`)

**Author(s)**

Deepayan Sarkar <Deepayan.Sarkar@R-project.org>

`F_1_panel.xyplot`      *Default Panel Function for xyplot*

---

**Description**

This is the default panel function for `xyplot`. Also see `panel.superpose`. The default panel functions for `splo`m and `qq` are essentially the same function.

**Usage**

```
panel.xyplot(x, y, type = "p",
 groups = NULL,
 pch, col, col.line, col.symbol,
 font, fontfamily, fontface,
 lty, cex, fill, lwd,
 horizontal = FALSE, ...,
 grid = FALSE, abline = NULL,
 jitter.x = FALSE, jitter.y = FALSE,
 factor = 0.5, amount = NULL,
 identifier = "xyplot")
panel.splo
```

**Arguments**

|                                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-----------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x, y</code>                       | variables to be plotted in the scatterplot                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <code>type</code>                       | <p>character vector consisting of one or more of the following: "p", "l", "h", "b", "o", "s", "S", "r", "a", "g", "smooth", and "spline". If <code>type</code> has more than one element, an attempt is made to combine the effect of each of the components.</p> <p>The behaviour if any of the first six are included in <code>type</code> is similar to the effect of <code>type</code> in <code>plot</code> (<code>type</code> "b" is actually the same as "o"). "r" adds a linear regression line (same as <code>panel.lmline</code>, except for default graphical parameters). "smooth" adds a loess fit (same as <code>panel.loess</code>). "spline" adds a cubic smoothing spline fit (same as <code>panel.spline</code>). "g" adds a reference grid using <code>panel.grid</code> in the background (but using the <code>grid</code> argument is now the preferred way to do so). "a" has the effect of calling <code>panel.average</code>, which can be useful for creating interaction plots. The effect of several of these specifications depend on the value of <code>horizontal</code>.</p> <p>Type "s" (and "S") sorts the values along one of the axes (depending on <code>horizontal</code>); this is unlike the behavior in <code>plot</code>. For the latter behavior, use <code>type = "s"</code> with <code>panel = panel.points</code>.</p> <p>See <code>example(xyplot)</code> and <code>demo(lattice)</code> for examples.</p> |
| <code>groups</code>                     | an optional grouping variable. If present, <code>panel.superpose</code> will be used instead to display each subgroup                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>col, col.line, col.symbol</code>  | default colours are obtained from <code>plot.symbol</code> and <code>plot.line</code> using <code>trellis.par.get</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| <code>pch, lty, cex, lwd, fill</code>   | other graphical parameters. <code>fill</code> serves the purpose of <code>bg</code> in <code>points</code> for certain values of <code>pch</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <code>horizontal</code>                 | A logical flag controlling the orientation for certain <code>type</code> 's, e.g., "h", "s", and "S".                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>...</code>                        | Extra arguments, if any, for <code>panel.xyplot</code> . In most cases <code>panel.xyplot</code> ignores these. For types "r" and "smooth", these are passed on to <code>panel.lmline</code> and <code>panel.loess</code> respectively.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <code>grid</code>                       | <p>A logical flag, character string, or list specifying whether and how a background grid should be drawn. This provides the same functionality as <code>type="g"</code>, but is the preferred alternative as the effect <code>type="g"</code> is conceptually different from that of other <code>type</code> values (which are all data-dependent). Using the <code>grid</code> argument also allows more flexibility.</p> <p>Most generally, <code>grid</code> can be a list of arguments to be supplied to <code>panel.grid</code>, which is called with those arguments. Three shortcuts are available:</p> <p>TRUE: roughly equivalent to <code>list(h = -1, v = -1)</code></p> <p>"h": roughly equivalent to <code>list(h = -1, v = 0)</code></p> <p>"v": roughly equivalent to <code>list(h = 0, v = -1)</code></p> <p>No grid is drawn if <code>grid = FALSE</code>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <code>abline</code>                     | A numeric vector or list, specifying arguments arguments for <code>panel.abline</code> , which is called with those arguments. If specified as a (possibly named) numeric vector, <code>abline</code> is coerced to a list. This allows arguments of the form                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

`abline = c(0, 1)`, which adds the diagonal line, or `abline = c(h = 0, v = 0)`, which adds the x- and y-axes to the plot. Use the list form for finer control; e.g., `abline = list(h = 0, v = 0, col = "grey")`.

For more flexibility, use `panel.abline` directly.

`jitter.x, jitter.y`  
logical, whether the data should be jittered before being plotted.

`factor, amount`  
controls amount of jittering.

`identifier` A character string that is prepended to the names of grobs that are created by this panel function.

## Details

Creates scatterplot of `x` and `y`, with various modifications possible via the `type` argument. `panel.qq` draws a 45 degree line before calling `panel.xyplot`.

Note that most of the arguments controlling the display can be supplied directly to the high-level (e.g. `xyplot`) call.

## Examples

```
types.plain <- c("p", "l", "o", "r", "g", "s", "S", "h", "a", "smooth")
types.horiz <- c("s", "S", "h", "a", "smooth")
horiz <- rep(c(FALSE, TRUE), c(length(types.plain), length(types.horiz)))

types <- c(types.plain, types.horiz)

x <- sample(seq(-10, 10, length.out = 15), 30, TRUE)
y <- x + 0.25 * (x + 1)^2 + rnorm(length(x), sd = 5)

xyplot(y ~ x | gl(1, length(types)),
 xlab = "type",
 ylab = list(c("horizontal=TRUE", "horizontal=FALSE"), y = c(1/6, 4/6)),
 as.table = TRUE, layout = c(5, 3),
 between = list(y = c(0, 1)),
 strip = function(...) {
 panel.fill(trellis.par.get("strip.background")$col[1])
 type <- types[panel.number()]
 grid::grid.text(label = sprintf('%s', type),
 x = 0.5, y = 0.5)
 grid::grid.rect()
 },
 scales = list(alternating = c(0, 2), tck = c(0, 0.7), draw = FALSE),
 par.settings =
 list(layout.widths = list(strip.left = c(1, 0, 0, 0, 0))),
 panel = function(...) {
 type <- types[panel.number()]
```

```

horizontal <- horiz[panel.number()]
panel.xyplot(...,
 type = type,
 horizontal = horizontal)
})[rep(1, length(types))]

```

F\_2\_llines

*Replacements of traditional graphics functions*

## Description

These functions are intended to replace common low level traditional graphics functions, primarily for use in panel functions. The originals can not be used (at least not easily) because lattice panel functions need to use grid graphics. Low level drawing functions in grid can be used directly as well, and is often more flexible. These functions are provided for convenience and portability.

## Usage

```

lplot.xy(xy, type, pch, lty, col, cex, lwd,
 font, fontfamily, fontface,
 col.line, col.symbol, alpha, fill,
 origin = 0, ..., identifier, name.type)

llines(x, ...)
lpoints(x, ...)
ltext(x, ...)

Default S3 method:
llines(x, y = NULL, type = "l",
 col, alpha, lty, lwd, ..., identifier, name.type)
Default S3 method:
lpoints(x, y = NULL, type = "p", col, pch, alpha, fill,
 font, fontfamily, fontface, cex, ..., identifier, name.type)
Default S3 method:
ltext(x, y = NULL, labels = seq_along(x),
 col, alpha, cex, srt = 0,
 lineheight, font, fontfamily, fontface,
 adj = c(0.5, 0.5), pos = NULL, offset = 0.5, ..., identifier, name.type)

lsegments(x0, y0, x1, y1, x2, y2,
 col, alpha, lty, lwd,
 font, fontface, ..., identifier, name.type)
lrect(xleft, ybottom, xright, ytop,
 x = (xleft + xright) / 2,
 y = (ybottom + ytop) / 2,
 width = xright - xleft,
 height = ytop - ybottom,
 col = "transparent",
 border = "black",
 lty = 1, lwd = 1, alpha = 1,

```

```

 just = "center",
 hjust = NULL, vjust = NULL,
 font, fontface,
 ..., identifier, name.type)
larrows(x0 = NULL, y0 = NULL, x1, y1, x2 = NULL, y2 = NULL,
 angle = 30, code = 2, length = 0.25, unit = "inches",
 ends = switch(code, "first", "last", "both"),
 type = "open",
 col = add.line$col,
 alpha = add.line$alpha,
 lty = add.line$lty,
 lwd = add.line$lwd,
 fill = NULL,
 font, fontface,
 ..., identifier, name.type)
lpolygon(x, y = NULL,
 border = "black", col = "transparent", fill = NULL,
 font, fontface, ..., identifier, name.type)

panel.lines(...)
panel.points(...)
panel.segments(...)
panel.text(...)
panel.rect(...)
panel.arrows(...)
panel.polygon(...)

```

### Arguments

`x, y, x0, y0, x1, y1, x2, y2, xy`  
 locations. `x2` and `y2` are available for for S compatibility.

`length, unit` determines extent of arrow head. `length` specifies the length in terms of `unit`, which can be any valid grid unit as long as it doesn't need a data argument. `unit` defaults to inches, which is the only option in the base version of the function, [arrows](#).

`angle, code, type, labels, srt, adj, pos, offset`  
 arguments controlling behaviour. See respective base functions for details. For `larrows` and `panel.larrows`, `type` is either "open" or "closed", indicating the type of arrowhead.

`ends`  
 serves the same function as `code`, using descriptive names rather than integer codes. If specified, this overrides `code`

`col, alpha, lty, lwd, fill, pch, cex, lineheight, font, fontfamily, fontface, col.line`  
 graphical parameters. `fill` applies to points when `pch` is in 21:25 and specifies the fill color, similar to the `bg` argument in the base graphics function [points](#). For devices that support alpha-transparency, a numeric argument `alpha` between 0 and 1 can controls transparency. Be careful with this, since for devices that do not support alpha-transparency, nothing will be drawn at all if this is set to anything other than 0.  
`fill, font` and `fontface` are included in `lrect`, `larrows`, `lpolygon`, and `lsegments` only to ensure that they are not passed down (as [gpar](#) does not like them).

`origin`  
 for `type="h"` or `type="H"`, the value to which lines drop down.

```

xleft, ybottom, xright, ytop
 see rect
width, height, just, hjust, vjust
 finer control over rectangles, see grid.rect
...
 extra arguments, passed on to lower level functions as appropriate.
identifier
 A character string that is prepended to the name of the grob that is created.
name.type
 A character value indicating whether the name of the grob should have panel
 or strip information added to it. Typically either "panel", "strip",
 "strip.left", or "" (for no extra information).

```

### Details

These functions are meant to be grid replacements of the corresponding base R graphics functions, to allow existing Trellis code to be used with minimal modification. The functions `panel.*` are essentially identical to the `l*` versions, are recommended for use in new code (as opposed to ported code) as they have more readable names.

See the documentation of the base functions for usage. Not all arguments are always supported. All these correspond to the default methods only.

### Note

There is a new `type="H"` option wherever appropriate, which is similar to `type="h"`, but with horizontal lines.

F\_2\_panel.functions

*Useful Panel Function Components*

---

### Description

These are predefined panel functions available in lattice for use in constructing new panel functions (often on-the-fly).

### Usage

```

panel.abline(a = NULL, b = 0,
 h = NULL, v = NULL,
 reg = NULL, coef = NULL,
 col, col.line, lty, lwd, alpha, type,
 ...,
 reference = FALSE,
 identifier = "abline")
panel.refline(...)

```

```

panel.curve(expr, from, to, n = 101,
 curve.type = "l",
 col, lty, lwd, type,
 ...,
 identifier = "curve")
panel.rug(x = NULL, y = NULL,
 regular = TRUE,
 start = if (regular) 0 else 0.97,
 end = if (regular) 0.03 else 1,
 x.units = rep("npc", 2),
 y.units = rep("npc", 2),
 col, col.line, lty, lwd, alpha,
 ...,
 identifier = "rug")
panel.average(x, y, fun = mean, horizontal = TRUE,
 lwd, lty, col, col.line, type,
 ...,
 identifier = "linejoin")
panel.linejoin(x, y, fun = mean, horizontal = TRUE,
 lwd, lty, col, col.line, type,
 ...,
 identifier = "linejoin")

panel.fill(col, border, ..., identifier = "fill")
panel.grid(h=3, v=3, col, col.line, lty, lwd, x, y, ..., identifier = "grid")
panel.lmline(x, y, ..., identifier = "lmline")
panel.mathdensity(dmath = dnorm, args = list(mean=0, sd=1),
 n = 50, col, col.line, lwd, lty, type,
 ..., identifier = "mathdensity")

```

## Arguments

|                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x, y</code> | Variables defining the contents of the panel. In <code>panel.grid</code> these are optional and are used only to choose an appropriate method of <code>pretty</code> .                                                                                                                                                                                                                                                                                                                          |
| <code>a, b</code> | Coefficients of the line to be added by <code>panel.abline</code> . <code>a</code> can be a vector of length 2, representing the coefficients of the line to be added, in which case <code>b</code> should be missing. <code>a</code> can also be an appropriate 'regression' object, i.e., an object which has a <code>coef</code> method that returns a length 2 numeric vector. The corresponding line will be plotted. The <code>reg</code> argument overrides <code>a</code> if specified. |
| <code>coef</code> | Coefficients of the line to be added as a vector of length 2.                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>reg</code>  | A (linear) regression object, with a <code>coef</code> method that gives the coefficients of the corresponding regression line.                                                                                                                                                                                                                                                                                                                                                                 |
| <code>h, v</code> | For <code>panel.abline</code> , these are numeric vectors giving locations respectively of horizontal and vertical lines to be added to the plot, in native coordinates.<br>For <code>panel.grid</code> , these usually specify the number of horizontal and vertical reference lines to be added to the plot. Alternatively, they can be negative                                                                                                                                              |

numbers. `h=-1` and `v=-1` are intended to make the grids aligned with the axis labels. This doesn't always work; all that actually happens is that the locations are chosen using `pretty`, which is also how the label positions are chosen in the most common cases (but not for factor variables, for instance). `h` and `v` can be negative numbers other than `-1`, in which case `-h` and `-v` (as appropriate) is supplied as the `n` argument to `pretty`.

If `x` and/or `y` are specified in `panel.grid`, they will be used to select an appropriate method for `pretty`. This is particularly useful while plotting date-time objects.

|                                                     |                                                                                                                                                                                                                                                                                                                                                                    |
|-----------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>reference</code>                              | A logical flag determining whether the default graphical parameters for <code>panel.abline</code> should be taken from the "reference.line" parameter settings. The default is to take them from the "add.line" settings. The <code>panel.refline</code> function is a wrapper around <code>panel.abline</code> that calls it with <code>reference = TRUE</code> . |
| <code>expr</code>                                   | An expression considered as a function of <code>x</code> , or a function, to be plotted as a curve.                                                                                                                                                                                                                                                                |
| <code>n</code>                                      | The number of points to use for drawing the curve.                                                                                                                                                                                                                                                                                                                 |
| <code>from, to</code>                               | optional lower and upper x-limits of curve. If missing, limits of current panel are used                                                                                                                                                                                                                                                                           |
| <code>curve.type</code>                             | Type of curve ("p" for points, etc), passed to <code>llines</code>                                                                                                                                                                                                                                                                                                 |
| <code>regular</code>                                | A logical flag indicating whether the 'rug' is to be drawn on the 'regular' side (left / bottom) or not (right / top).                                                                                                                                                                                                                                             |
| <code>start, end</code>                             | endpoints of rug segments, in normalized parent coordinates (between 0 and 1). Defaults depend on value of <code>regular</code> , and cover 3% of the panel width and height.                                                                                                                                                                                      |
| <code>x.units, y.units</code>                       | Character vectors, replicated to be of length two. Specifies the (grid) units associated with <code>start</code> and <code>end</code> above. <code>x.units</code> and <code>y.units</code> are for the rug on the x-axis and y-axis respectively (and thus are associated with <code>start</code> and <code>end</code> values on the y and x scales respectively). |
| <code>col, col.line, lty, lwd, alpha, border</code> | Graphical parameters.                                                                                                                                                                                                                                                                                                                                              |
| <code>type</code>                                   | Usually ignored by the panel functions documented here; the argument is present only to make sure an explicitly specified <code>type</code> argument (perhaps meant for another function) does not affect the display.                                                                                                                                             |
| <code>fun</code>                                    | The function that will be applied to the subset of <code>x</code> values (or <code>y</code> if <code>horizontal</code> is <code>FALSE</code> ) determined by the unique values of <code>y(x)</code> .                                                                                                                                                              |
| <code>horizontal</code>                             | A logical flag. If <code>FALSE</code> , the plot is 'transposed' in the sense that the roles of <code>x</code> and <code>y</code> are switched; <code>x</code> is now the 'factor'. Interpretation of other arguments change accordingly. See documentation of <code>bwplot</code> for a fuller explanation.                                                       |
| <code>dmath</code>                                  | A vectorized function that produces density values given a numeric vector named <code>x</code> , e.g., <code>dnorm</code> .                                                                                                                                                                                                                                        |
| <code>args</code>                                   | A list giving additional arguments to be passed to <code>dmath</code> .                                                                                                                                                                                                                                                                                            |
| <code>...</code>                                    | Further arguments, typically graphical parameters, passed on to other low-level functions as appropriate. Color can usually be specified by <code>col</code> , <code>col.line</code> , and <code>col.symbol</code> , the last two overriding the first for lines and points respectively.                                                                          |
| <code>identifier</code>                             | A character string that is prepended to the names of grobs that are created by this panel function.                                                                                                                                                                                                                                                                |

## Details

`panel.abline` adds a line of the form  $y = a + b * x$ , or vertical and/or horizontal lines. Graphical parameters are obtained from the “add.line” settings by default. `panel.refline` is similar, but uses the “reference.line” settings for the defaults.

`panel.grid` draws a reference grid.

`panel.curve` adds a curve, similar to what `curve` does with `add = TRUE`. Graphical parameters for the curve are obtained from the “add.line” setting.

`panel.average` treats one of `x` and `y` as a factor (according to the value of `horizontal`), calculates `fun` applied to the subsets of the other variable determined by each unique value of the factor, and joins them by a line. Can be used in conjunction with `panel.xyplot`, and more commonly with `panel.superpose` to produce interaction plots.

`panel.linejoin` is an alias for `panel.average`. It is retained for back-compatibility, and may go away in future.

`panel.mathdensity` plots a (usually theoretical) probability density function. This can be useful in conjunction with `histogram` and `densityplot` to visually assess goodness of fit (note, however, that `qqmath` is more suitable for this).

`panel.rug` adds a *rug* representation of the (marginal) data to the panel, much like `rug`.

`panel.lmline(x, y)` is equivalent to `panel.abline(lm(y ~ x))`.

## Examples

```
Interaction Plot

bwplot(yield ~ site, barley, groups = year,
 panel = function(x, y, groups, subscripts, ...) {
 panel.grid(h = -1, v = 0)
 panel.stripplot(x, y, ..., jitter.data = TRUE,
 groups = groups, subscripts = subscripts)
 panel.superpose(x, y, ..., panel.groups = panel.average,
 groups = groups, subscripts = subscripts)
 },
 auto.key =
 list(points = FALSE, lines = TRUE, columns = 2))

Superposing a fitted normal density on a Histogram

histogram(~ height | voice.part, data = singer, layout = c(2, 4),
 type = "density", border = "transparent", col.line = "grey60",
 xlab = "Height (inches)",
 ylab = "Density Histogram\n with Normal Fit",
 panel = function(x, ...) {
 panel.histogram(x, ...)
 panel.mathdensity(dmath = dnorm,
 args = list(mean=mean(x), sd=sd(x)), ...)
```

```
})
```

|-----------------|---------------------------------------------|
| F_2_panel.loess | <i>Panel Function to Add a LOESS Smooth</i> |
|-----------------|---------------------------------------------|

---

## Description

A predefined panel function that can be used to add a LOESS smooth based on the provided data.

## Usage

```
panel.loess(x, y, span = 2/3, degree = 1,
 family = c("symmetric", "gaussian"),
 evaluation = 50,
 lwd, lty, col, col.line, type,
 horizontal = FALSE,
 ..., identifier = "loess")
```

## Arguments

|                                               |                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-----------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x, y</code>                             | Variables defining the data to be used.                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>lwd, lty, col, col.line</code>          | Graphical parameters for the added line. <code>col.line</code> overrides <code>col</code> .                                                                                                                                                                                                                                                                                                                                           |
| <code>type</code>                             | Ignored. The argument is present only to make sure that an explicitly specified <code>type</code> argument (perhaps meant for another function) does not affect the display.                                                                                                                                                                                                                                                          |
| <code>span, degree, family, evaluation</code> | Arguments to <code>loess.smooth</code> , for which <code>panel.loess</code> is essentially a wrapper.                                                                                                                                                                                                                                                                                                                                 |
| <code>horizontal</code>                       | A logical flag controlling which variable is to be treated as the predictor (by default <code>x</code> ) and which as the response (by default <code>y</code> ). If <code>TRUE</code> , the plot is ‘transposed’ in the sense that <code>y</code> becomes the predictor and <code>x</code> the response. (The name ‘horizontal’ may seem an odd choice for this argument, and originates from similar usage in <code>bwplot</code> ). |
| <code>...</code>                              | Extra arguments, passed on to <code>panel.lines</code> .                                                                                                                                                                                                                                                                                                                                                                              |
| <code>identifier</code>                       | A character string that is prepended to the names of grobs that are created by this panel function.                                                                                                                                                                                                                                                                                                                                   |

## Value

The object returned by `loess.smooth`.

---

## Description

Useful panel function with qqmath. Draws a line passing through the points (usually) determined by the .25 and .75 quantiles of the sample and the theoretical distribution.

## Usage

```
panel.qqmathline(x, y = x,
 distribution = qnorm,
 probs = c(0.25, 0.75),
 qtype = 7,
 groups = NULL,
 ...,
 identifier = "qqmathline")
```

## Arguments

|                           |                                                                                                                                                 |
|---------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>            | The original sample, possibly reduced to a fewer number of quantiles, as determined by the <code>f.value</code> argument to <code>qqmath</code> |
| <code>y</code>            | an alias for <code>x</code> for backwards compatibility                                                                                         |
| <code>distribution</code> | quantile function for reference theoretical distribution.                                                                                       |
| <code>probs</code>        | numeric vector of length two, representing probabilities. Corresponding quantile pairs define the line drawn.                                   |
| <code>qtype</code>        | the type of quantile computation used in <a href="#">quantile</a>                                                                               |
| <code>groups</code>       | optional grouping variable. If non-null, a line will be drawn for each group.                                                                   |
| <code>...</code>          | other arguments.                                                                                                                                |
| <code>identifier</code>   | A character string that is prepended to the names of grobs that are created by this panel function.                                             |

F\_2\_panel.smoothScatter

*Lattice panel function analogous to smoothScatter*

---

## Description

This function allows the user to place `smoothScatter` plots in lattice graphics.

## Usage

```
panel.smoothScatter(x, y = NULL,
 nbin = 64, cuts = 255,
 bandwidth,
 colramp,
 nrpoints = 100,
 transformation = function(x) x^0.25,
 pch = ".",
 cex = 1, col="black",
 range.x,
 ...,
 raster = FALSE,
 subscripts,
 identifier = "smoothScatter")
```

## Arguments

|                             |                                                                                                                                                                                                                                                                                                                                              |
|-----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>              | Numeric vector containing x-values or n by 2 matrix containing x and y values.                                                                                                                                                                                                                                                               |
| <code>y</code>              | Numeric vector containing y-values (optional). The length of <code>x</code> must be the same as that of <code>y</code> .                                                                                                                                                                                                                     |
| <code>nbin</code>           | Numeric vector of length 1 (for both directions) or 2 (for x and y separately) containing the number of equally spaced grid points for the density estimation.                                                                                                                                                                               |
| <code>cuts</code>           | number of cuts defining the color gradient                                                                                                                                                                                                                                                                                                   |
| <code>bandwidth</code>      | Numeric vector: the smoothing bandwidth. If missing, these functions come up with a more or less useful guess. This parameter then gets passed on to the function <a href="#">bkde2D</a> .                                                                                                                                                   |
| <code>colramp</code>        | Function accepting an integer <code>n</code> as an argument and returning <code>n</code> colors.                                                                                                                                                                                                                                             |
| <code>nrpoints</code>       | Numeric vector of length 1 giving number of points to be superimposed on the density image. The first <code>nrpoints</code> points from those areas of lowest regional densities will be plotted. Adding points to the plot allows for the identification of outliers. If all points are to be plotted, choose <code>nrpoints = Inf</code> . |
| <code>transformation</code> | Function that maps the density scale to the color scale.                                                                                                                                                                                                                                                                                     |
| <code>pch, cex</code>       | graphical parameters for the <code>nrpoints</code> “outlying” points shown in the display                                                                                                                                                                                                                                                    |
| <code>range.x</code>        | see <a href="#">bkde2D</a> for details.                                                                                                                                                                                                                                                                                                      |
| <code>col</code>            | <a href="#">points</a> color parameter                                                                                                                                                                                                                                                                                                       |
| <code>...</code>            | Further arguments that are passed on to <a href="#">panel.levelplot</a> .                                                                                                                                                                                                                                                                    |
| <code>raster</code>         | logical; if TRUE, <a href="#">panel.levelplot.raster</a> is used, making potentially smaller output files.                                                                                                                                                                                                                                   |

|            |                                                                                                     |
|------------|-----------------------------------------------------------------------------------------------------|
| subscripts | ignored, but necessary for handling of ...in certain situations. Likely to be removed in future.    |
| identifier | A character string that is prepended to the names of grobs that are created by this panel function. |

### Details

This replicates the display part of the `smoothScatter` function by replacing standard graphics calls by grid-compatible ones.

### Value

The function is called for its side effects, namely the production of the appropriate plots on a graphics device.

### Author(s)

Deepayan Sarkar <deepayan.sarkar@r-project.org>

### Examples

```
ddf <- as.data.frame(matrix(rnorm(40000), ncol = 4) + 3 * rnorm(10000))
ddf[, c(2,4)] <- (-ddf[, c(2,4)])
xyplot(V1 ~ V2 + V3, ddf, outer = TRUE,
 panel = panel.smoothScatter, aspect = "iso")
splom(ddf, panel = panel.smoothScatter, nbin = 64, raster = TRUE)
```

---

F\_2\_panel.spline     *Panel Function to Add a Spline Smooth*

---

### Description

A predefined panel function that can be used to add a spline smooth based on the provided data.

### Usage

```
panel.spline(x, y, npoints = 101,
 lwd = plot.line$lwd,
 lty = plot.line$lty,
 col, col.line = plot.line$col,
 type,
 horizontal = FALSE, ...,
 keep.data = FALSE,
 identifier = "spline")
```

**Arguments**

|                                      |                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|--------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x, y</code>                    | Variables defining the data to be used.                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>npoints</code>                 | The number of equally spaced points within the range of the predictor at which the fitted model is evaluated for plotting.                                                                                                                                                                                                                                                                                                            |
| <code>lwd, lty, col, col.line</code> | Graphical parameters for the added line. <code>col.line</code> overrides <code>col</code> .                                                                                                                                                                                                                                                                                                                                           |
| <code>type</code>                    | Ignored. The argument is present only to make sure that an explicitly specified <code>type</code> argument (perhaps meant for another function) does not affect the display.                                                                                                                                                                                                                                                          |
| <code>horizontal</code>              | A logical flag controlling which variable is to be treated as the predictor (by default <code>x</code> ) and which as the response (by default <code>y</code> ). If <code>TRUE</code> , the plot is 'transposed' in the sense that <code>y</code> becomes the predictor and <code>x</code> the response. (The name 'horizontal' may seem an odd choice for this argument, and originates from similar usage in <code>bwplot</code> ). |
| <code>keep.data</code>               | Passed on to <code>smooth.spline</code> . The default here ( <code>FALSE</code> ) is different, and results in the original data not being retained in the fitted spline model. It may be useful to set this to <code>TRUE</code> if the return value of <code>panel.spline</code> , which is the fitted model as returned by <code>smooth.spline</code> , is to be used for subsequent computations.                                 |
| <code>...</code>                     | Extra arguments, passed on to <code>smooth.spline</code> and <code>panel.lines</code> as appropriate.                                                                                                                                                                                                                                                                                                                                 |
| <code>identifier</code>              | A character string that is prepended to the names of grobs that are created by this panel function.                                                                                                                                                                                                                                                                                                                                   |

**Value**

The fitted model as returned by `smooth.spline`.

*Panel Function for Display Marked by groups*

---

**Description**

These are panel functions for Trellis displays useful when a grouping variable is specified for use within panels. The `x` (and `y` where appropriate) variables are plotted with different graphical parameters for each distinct value of the grouping variable.

**Usage**

```

panel.superpose(x, y = NULL, subscripts, groups,
 panel.groups = "panel.xyplot",
 ...,
 col, col.line, col.symbol,
 pch, cex, fill, font,
 fontface, fontfamily,
 lty, lwd, alpha,
 type = "p", grid = FALSE,
 distribute.type = FALSE)
panel.superpose.2(..., distribute.type = TRUE)

panel.superpose.plain(...,
 col, col.line, col.symbol,
 pch, cex, fill, font,
 fontface, fontfamily,
 lty, lwd, alpha)

```

**Arguments**

- |                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|---------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x, y</code>         | Coordinates of the points to be displayed. Usually numeric.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <code>panel.groups</code> | <p>The panel function to be used for each subgroup of points. Defaults to <code>panel.xyplot</code>.</p> <p>To be able to distinguish between different levels of the originating group inside <code>panel.groups</code>, it will be supplied two special arguments called <code>group.number</code> and <code>group.value</code> which will hold the numeric code and factor level corresponding to the current level of <code>groups</code>. No special care needs to be taken when writing a <code>panel.groups</code> function if this feature is not used.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>subscripts</code>   | An integer vector of subscripts giving indices of the <code>x</code> and <code>y</code> values in the original data source. See the corresponding entry in <a href="#">xyplot</a> for details.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>groups</code>       | A grouping variable. Different graphical parameters will be used to plot the subsets of observations given by each distinct value of <code>groups</code> . The default graphical parameters are obtained from the <code>"superpose.symbol"</code> and <code>"superpose.line"</code> settings using <a href="#">trellis.par.get</a> wherever appropriate.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>type</code>         | <p>Usually a character vector specifying how each group should be drawn. Formally, it is passed on to the <code>panel.groups</code> function, which must know what to do with it. By default, <code>panel.groups</code> is <a href="#">panel.xyplot</a>, whose help page describes the admissible values.</p> <p>The functions <code>panel.superpose</code> and <code>panel.superpose.2</code> differ only in the default value of <code>distribute.type</code>, which controls the way the <code>type</code> argument is interpreted. If <code>distribute.type = FALSE</code>, then the interpretation is the same as for <code>panel.xyplot</code> for each of the unique groups. In other words, if <code>type</code> is a vector, all the individual components are honoured concurrently. If <code>distribute.type = TRUE</code>, <code>type</code> is replicated to be as long as the number of unique values in <code>groups</code>, and one component used for the points corresponding to the each different group. Even in this case, it is possible to request multiple types per group, specifying <code>type</code> as a list, each component being the desired <code>type</code> vector for the corresponding group.</p> |

|                                         |                                                                                                                                                                                                                           |
|-----------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                         | If <code>distribute.type = FALSE</code> , any occurrence of "g" in <code>type</code> causes a grid to be drawn, and all such occurrences are removed before <code>type</code> is passed on to <code>panel.groups</code> . |
| <code>grid</code>                       | Logical flag specifying whether a background reference grid should be drawn. See <a href="#">panel.xyplot</a> for details.                                                                                                |
| <code>col</code>                        | A vector color specification. See Details.                                                                                                                                                                                |
| <code>col.line</code>                   | A vector color specification. See Details.                                                                                                                                                                                |
| <code>col.symbol</code>                 | A vector color specification. See Details.                                                                                                                                                                                |
| <code>pch</code>                        | A vector plotting character specification. See Details.                                                                                                                                                                   |
| <code>cex</code>                        | A vector size factor specification. See Details.                                                                                                                                                                          |
| <code>fill</code>                       | A vector fill color specification. See Details.                                                                                                                                                                           |
| <code>font, fontface, fontfamily</code> | A vector color specification. See Details.                                                                                                                                                                                |
| <code>lty</code>                        | A vector color specification. See Details.                                                                                                                                                                                |
| <code>lwd</code>                        | A vector color specification. See Details.                                                                                                                                                                                |
| <code>alpha</code>                      | A vector alpha-transparency specification. See Details.                                                                                                                                                                   |
| <code>...</code>                        | Extra arguments. Passed down to <code>panel.superpose</code> from <code>panel.superpose.2</code> , and to <code>panel.groups</code> from <code>panel.superpose</code> .                                                   |
| <code>distribute.type</code>            | logical controlling interpretation of the <code>type</code> argument.                                                                                                                                                     |

## Details

`panel.superpose` divides up the `x` (and optionally `y`) variable(s) by the unique values of `groups[subscripts]`, and plots each subset with different graphical parameters. The graphical parameters (`col.symbol`, `pch`, etc.) are usually supplied as suitable atomic vectors, but can also be lists. When `panel.groups` is called for the *i*-th level of `groups`, the corresponding element of each graphical parameter is passed to it. In the list form, the individual components can themselves be vectors.

The actual plot for each subgroup is created by the `panel.groups` function. With the default `panel.groups`, the `col` argument is overridden by `col.line` and `col.symbol` for lines and points respectively, which default to the "superpose.line" and "superpose.symbol" settings. However, `col` will still be supplied as an argument to `panel.groups` functions that make use of it, with a default of "black". The defaults of other graphical parameters are also taken from the "superpose.line" and "superpose.symbol" settings as appropriate. The `alpha` parameter takes its default from the "superpose.line" setting.

`panel.superpose` and `panel.superpose.2` differ essentially in how `type` is interpreted by default. The default behaviour in `panel.superpose` is the opposite of that in `S`, which is the same as that of `panel.superpose.2`.

`panel.superpose.plain` is the same as `panel.superpose`, except that the default settings for the style arguments are the same for all groups and are taken from the default plot style. It is used in [xyplot.ts](#).

Different functions when used as `panel.groups` gives different types of plots, for example [panel.xyplot](#), [panel.dotplot](#) and [panel.average](#) (This can be used to produce interaction plots).

See [Lattice](#) for an overview of the package, and [xyplot](#) for common arguments (in particular, the discussion of the extended formula interface and the `groups` argument).

---

F\_2\_panel.violin      *Panel Function to create Violin Plots*

---

**Description**

This is a panel function that can create a violin plot. It is typically used in a high-level call to `bwplot`.

**Usage**

```
panel.violin(x, y, box.ratio = 1, box.width,
 horizontal = TRUE,
 alpha, border, lty, lwd, col,
 varwidth = FALSE,
 bw, adjust, kernel, window,
 width, n = 50, from, to, cut,
 na.rm, ...,
 identifier = "violin")
```

**Arguments**

|                                                                         |                                                                                                                                                                                                                                                                                                                |
|-------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x, y</code>                                                       | numeric vector or factor. Violin plots are drawn for each unique value of <code>y</code> ( <code>x</code> ) if <code>horizontal</code> is <code>TRUE</code> ( <code>FALSE</code> )                                                                                                                             |
| <code>box.ratio</code>                                                  | ratio of the thickness of each violin and inter violin space                                                                                                                                                                                                                                                   |
| <code>box.width</code>                                                  | thickness of the violins in absolute units; overrides <code>box.ratio</code> . Useful for specifying thickness when the categorical variable is not a factor, as use of <code>box.ratio</code> alone cannot achieve a thickness greater than 1.                                                                |
| <code>horizontal</code>                                                 | logical. If <code>FALSE</code> , the plot is ‘transposed’ in the sense that the behaviours of <code>x</code> and <code>y</code> are switched. <code>x</code> is now the ‘factor’. See documentation of <a href="#">bwplot</a> for a fuller explanation.                                                        |
| <code>alpha, border, lty, lwd, col</code>                               | graphical parameters controlling the violin. Defaults are taken from the “ <code>plot.polygon</code> ” settings.                                                                                                                                                                                               |
| <code>varwidth</code>                                                   | logical. If <code>FALSE</code> , the densities are scaled separately for each group, so that the maximum value of the density reaches the limit of the allocated space for each violin (as determined by <code>box.ratio</code> ). If <code>TRUE</code> , densities across violins will have comparable scale. |
| <code>bw, adjust, kernel, window, width, n, from, to, cut, na.rm</code> | arguments to <a href="#">density</a> , passed on as appropriate                                                                                                                                                                                                                                                |
| <code>...</code>                                                        | arguments passed on to <code>density</code> .                                                                                                                                                                                                                                                                  |
| <code>identifier</code>                                                 | A character string that is prepended to the names of grobs that are created by this panel function.                                                                                                                                                                                                            |

**Details**

Creates Violin plot of  $x$  for every level of  $y$ . Note that most arguments controlling the display can be supplied to the high-level (typically `bwplot`) call directly.

**Author(s)**

Deepayan Sarkar <Deepayan.Sarkar@R-project.org>

**See Also**

[bwplot](#), [density](#)

**Examples**

```
bwplot(voice.part ~ height, singer,
 panel = function(..., box.ratio) {
 panel.violin(..., col = "transparent",
 varwidth = FALSE, box.ratio = box.ratio)
 panel.bwplot(..., fill = NULL, box.ratio = .1)
 })
```

---

F\_3\_prepanel.default

*Default Prepanel Functions*

---

**Description**

These prepanel functions are used as fallback defaults in various high level plot functions in Lattice. These are rarely useful to normal users but may be helpful in developing new displays.

**Usage**

```
prepanel.default.bwplot(x, y, horizontal, nlevels, origin, stack, ...)
prepanel.default.histogram(x, breaks, equal.widths, type, nint, ...)
prepanel.default.qq(x, y, ...)
prepanel.default.xyplot(x, y, type, subscripts, groups, ...)
prepanel.default.cloud(perspective, distance,
 xlim, ylim, zlim,
 screen = list(z = 40, x = -60),
 R.mat = diag(4),
 aspect = c(1, 1), panel.aspect = 1,
 ..., zoom = 0.8)
prepanel.default.levelplot(x, y, subscripts, ...)
prepanel.default.qqmath(x, f.value, distribution, qtype,
 groups, subscripts, ..., tails.n = 0)
prepanel.default.densityplot(x, darg, groups, weights, subscripts, ...)
prepanel.default.parallel(x, y, z, ..., horizontal.axis)
prepanel.default.splom(z, ...)
```

**Arguments**

|                                                                                                 |                                                                                                                                                          |
|-------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x, y</code>                                                                               | x and y values, numeric or factor                                                                                                                        |
| <code>horizontal</code>                                                                         | logical, applicable when one of the variables is to be treated as categorical (factor or shingle).                                                       |
| <code>horizontal.axis</code>                                                                    | logical indicating whether the parallel axes should be laid out horizontally (TRUE) or vertically (FALSE).                                               |
| <code>nlevels</code>                                                                            | number of levels of such a categorical variable.                                                                                                         |
| <code>origin, stack</code>                                                                      | for barcharts or the <code>type="h"</code> plot type                                                                                                     |
| <code>breaks, equal.widths, type, nint</code>                                                   | details of histogram calculations. <code>type</code> has a different meaning in <code>prepanel.default.xyplot</code> (see <a href="#">panel.xyplot</a> ) |
| <code>groups, subscripts</code>                                                                 | See <a href="#">xyplot</a> . Whenever appropriate, calculations are done separately for each group and then combined.                                    |
| <code>weights</code>                                                                            | numeric vector of weights for the density calculations. If this is specified, it is subsetted by <code>subscripts</code> to match it to <code>x</code> . |
| <code>perspective, distance, xlim, ylim, zlim, screen, R.mat, aspect, panel.aspect, zoom</code> | see <a href="#">panel.cloud</a>                                                                                                                          |
| <code>f.value, distribution, tails.n</code>                                                     | see <code>panel.qqmath</code>                                                                                                                            |
| <code>darg</code>                                                                               | list of arguments passed to <a href="#">density</a>                                                                                                      |
| <code>z</code>                                                                                  | see <a href="#">panel.parallel</a> and <a href="#">panel.pairs</a>                                                                                       |
| <code>qtype</code>                                                                              | type of <a href="#">quantile</a>                                                                                                                         |
| <code>...</code>                                                                                | other arguments, usually ignored                                                                                                                         |

**Value**

A list with components `xlim`, `ylim`, `dx` and `dy`, and possibly `xat` and `yat`, the first two being used to calculate panel axes limits, the last two for banking computations. The form of these components are described in the help page for [xyplot](#).

---

F\_3\_prepanel.functions

*Useful Prepanel Function for Lattice*

---

## Description

These are predefined prepanel functions available in Lattice.

## Usage

```
prepanel.lmline(x, y, ...)
prepanel.qqmathline(x, y = x, distribution = qnorm,
 probs = c(0.25, 0.75), qtype = 7,
 groups, subscripts,
 ...)
prepanel.loess(x, y, span, degree, family, evaluation,
 horizontal = FALSE, ...)
prepanel.spline(x, y, npoints = 101,
 horizontal = FALSE, ...,
 keep.data = FALSE)
```

## Arguments

|                                               |                                                                                                                                                                                                                                         |
|-----------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x, y</code>                             | <code>x</code> and <code>y</code> values, numeric or factor                                                                                                                                                                             |
| <code>distribution</code>                     | quantile function for theoretical distribution. This is automatically passed in when this is used as a prepanel function in <code>qqmath</code> .                                                                                       |
| <code>qtype</code>                            | type of <a href="#">quantile</a>                                                                                                                                                                                                        |
| <code>probs</code>                            | numeric vector of length two, representing probabilities. If used with <code>aspect="xy"</code> , the aspect ratio will be chosen to make the line passing through the corresponding quantile pairs as close to 45 degrees as possible. |
| <code>span, degree, family, evaluation</code> | Arguments controlling the underlying <a href="#">loess</a> smooth.                                                                                                                                                                      |
| <code>horizontal, npoints</code>              | See documentation for corresponding panel function.                                                                                                                                                                                     |
| <code>keep.data</code>                        | Ignored. Present to capture argument of the same name in <a href="#">smooth.spline</a> .                                                                                                                                                |
| <code>groups, subscripts</code>               | See <a href="#">xyplot</a> . Whenever appropriate, calculations are done separately for each group and then combined.                                                                                                                   |
| <code>...</code>                              | Other arguments. These are passed on to other functions if appropriate (in particular, <a href="#">smooth.spline</a> ), and ignored otherwise.                                                                                          |

## Details

All these prepanel functions compute the limits to be large enough to contain all points as well as the relevant smooth.

In addition, `prepanel.lmline` computes the `dx` and `dy` such that it reflects the slope of the linear regression line; for `prepanel.qqmathline`, this is the slope of the line passing through the quantile pairs specified by `probs`. For `prepanel.loess` and `prepanel.spline`, `dx` and `dy` reflect the piecewise slopes of the nonlinear smooth.

**Value**

usually a list with components `xlim`, `ylim`, `dx` and `dy`, the first two being used to calculate panel axes limits, the last two for banking computations. The form of these components are described under `xyplot`. There are also several `prepanel` functions that serve as the default for high level functions, see `prepanel.default.xyplot`

---

G\_axis.default

*Default axis annotation utilities*

---

**Description**

Lattice functions provide control over how the plot axes are annotated through a common interface. There are two levels of control. The `xscale.components` and `yscale.components` arguments can be functions that determine tick mark locations and labels given a packet. For more direct control, the `axis` argument can be a function that actually draws the axes. The functions documented here are the defaults for these arguments. They can additionally be used as components of user written replacements.

**Usage**

```
xscale.components.default(lim,
 packet.number = 0,
 packet.list = NULL,
 top = TRUE,
 ...)
yscale.components.default(lim,
 packet.number = 0,
 packet.list = NULL,
 right = TRUE,
 ...)
axis.default(side = c("top", "bottom", "left", "right"),
 scales, components, as.table,
 labels = c("default", "yes", "no"),
 ticks = c("default", "yes", "no"),
 ..., prefix)
```

**Arguments**

`lim` the range of the data in that packet (data subset corresponding to a combination of levels of the conditioning variable). The range is not necessarily numeric; e.g. for factors, they could be character vectors representing levels, and for the various date-time representations, they could be vectors of length 2 with the corresponding class.

|                            |                                                                                                                                                                                                                                                                                                |
|----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>packet.number</code> | which packet (counted according to the packet order, described in <a href="#">print.trellis</a> ) is being processed. In cases where all panels have the same limits, this function is called only once (rather than once for each packet), in which case this argument will have the value 0. |
| <code>packet.list</code>   | list, as long as the number of packets, giving all the actual packets. Specifically, each component is the list of arguments given to the panel function when and if that packet is drawn in a panel. (This has not yet been implemented.)                                                     |
| <code>top, right</code>    | the value of the <code>top</code> and <code>right</code> components of the result, as appropriate. See below for interpretation.                                                                                                                                                               |
| <code>side</code>          | on which side the axis is to be drawn. The usual partial matching rules apply.                                                                                                                                                                                                                 |
| <code>scales</code>        | the appropriate component of the <code>scales</code> argument supplied to the high level function, suitably standardized.                                                                                                                                                                      |
| <code>components</code>    | list, similar to those produced by <code>xscale.components.default</code> and <code>yscale.components.default</code> .                                                                                                                                                                         |
| <code>as.table</code>      | the <code>as.table</code> argument in the high level function.                                                                                                                                                                                                                                 |
| <code>labels</code>        | whether labels are to be drawn. By default, the rules determined by <code>scales</code> are used.                                                                                                                                                                                              |
| <code>ticks</code>         | whether labels are to be drawn. By default, the rules determined by <code>scales</code> are used.                                                                                                                                                                                              |
| <code>...</code>           | many other arguments may be supplied, and are passed on to other internal functions.                                                                                                                                                                                                           |
| <code>prefix</code>        | A character string identifying the plot being drawn (see <a href="#">print.trellis</a> ). Used to retrieve location of current panel in the overall layout, so that axes can be drawn appropriately.                                                                                           |

## Details

These functions are part of a new API introduced in `lattice 0.14` to provide the user more control over how axis annotation is done. While the API has been designed in anticipation of use that was previously unsupported, the implementation has initially focused on reproducing existing capabilities, rather than test new features. At the time of writing, several features are unimplemented. If you require them, please contact the maintainer.

## Value

`xscale.components.default` and `yscale.components.default` return a list of the form suitable as the `components` argument of `axis.default`. Valid components in the return value of `xscale.components.default` are:

|                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>num.limit</code> | A numeric limit for the box.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <code>bottom</code>    | A list with two elements, <code>ticks</code> and <code>labels</code> . <code>ticks</code> must be a list with components <code>at</code> and <code>tck</code> which give the location and lengths of tick marks. <code>tck</code> can be a vector, and will be recycled to be as long as <code>at</code> . <code>labels</code> must be a list with components <code>at</code> , <code>labels</code> , and <code>check.overlap</code> . <code>at</code> and <code>labels</code> give the location and labels of the tick labels; this is usually the same as the location of the ticks, but is not required to be so. <code>check.overlap</code> is a logical flag indicating whether overlapping of labels should be avoided by omitting some of the labels while rendering. |

`top` This can be a logical flag; if `TRUE`, `top` is treated as being the same as `bottom`; if `FALSE`, axis annotation for the top axis is omitted. Alternatively, `top` can be a list like `bottom`.

Valid components in the return value of `yscale.components.default` are `left` and `right`. Their interpretations are analogous to (respectively) the `bottom` and `top` components described above.

### Examples

```
str(xscale.components.default(c(0, 1)))

set.seed(36872)
rln <- rlnorm(100)

densityplot(rln,
 scales = list(x = list(log = 2), alternating = 3),
 xlab = "Simulated lognormal variates",
 xscale.components = function(...) {
 ans <- xscale.components.default(...)
 ans$top <- ans$bottom
 ans$bottom$labels$labels <- parse(text = ans$bottom$labels$labels)
 anstoplabels$labels <-
 if (require(MASS))
 fractions(2^(anstoplabels$at))
 else
 2^(anstoplabels$at)
 ans
 })

Direct use of axis to show two temperature scales (Celcius and
Fahrenheit). This does not work for multi-row plots, and doesn't
do automatic allocation of space

F2C <- function(f) 5 * (f - 32) / 9
C2F <- function(c) 32 + 9 * c / 5

axis.CF <-
 function(side, ...)
 {
 ylim <- current.panel.limits()$ylim
 switch(side,
 left = {
 prettyF <- pretty(ylim)
 labF <- parse(text = sprintf("%s ~ degree * F", prettyF))
 panel.axis(side = side, outside = TRUE,
 at = prettyF, labels = labF)
 }
)
 }
```

```

 },
 right = {
 prettyC <- pretty(F2C(ylim))
 labC <- parse(text = sprintf("%s ~ degree * C", prettyC))
 panel.axis(side = side, outside = TRUE,
 at = C2F(prettyC), labels = labC)
 },
 axis.default(side = side, ...)
 }

xyplot(nhtemp ~ time(nhtemp), aspect = "xy", type = "o",
 scales = list(y = list(alternating = 3)),
 axis = axis.CF, xlab = "Year", ylab = "Temperature",
 main = "Yearly temperature in New Haven, CT")

version using yscale.components

yscale.components.CF <-
 function(...)
 {
 ans <- yscale.components.default(...)

G\_banking

*Banking*

---

### Description

Calculates banking slope

### Usage

```
banking(dx, dy)
```

### Arguments

dx, dy                      vector of consecutive x, y differences.

## Details

banking is the banking function used when `aspect = "xy"` in high level Trellis functions. It is usually not very meaningful except with `xyplot`. It considers the absolute slopes (based on `dx` and `dy`) and returns a value which when adjusted by the panel scale limits will make the median of the above absolute slopes correspond to a 45 degree line.

This function was inspired by the discussion of banking in the documentation for Trellis Graphics available at Bell Labs' website (see [Lattice](#)), but is most likely identical to an algorithm described by Cleveland et al (see below). It is not clear (to the author) whether this is the algorithm used in S-PLUS. Alternative banking rules, implemented as a similar function, can be used as a drop-in replacement by suitably modifying `lattice.options("banking")`.

G\_latticeParseFormula

*Parse Trellis formula*

---

## Description

this function is used by high level Lattice functions like `xyplot` to parse the formula argument and evaluate various components of the data.

**Usage**

```
latticeParseFormula(model, data, dimension = 2,
 subset = TRUE, groups = NULL,
 multiple, outer,
 subscripts,
 drop)
```

**Arguments**

|                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| model           | the model/formula to be parsed. This can be in either of two possible forms, one for 2d and one for 3d formulas, determined by the <code>dimension</code> argument. The 2d formulas are of the form <code>y ~ x   g1 * ... * gn</code> , and the 3d formulas are of the form <code>z ~ x * y   g1 * ... * gn</code> . In the first form, <code>y</code> may be omitted. The conditioning variables <code>g1, ..., gn</code> can be omitted in either case. |
| data            | the environment/dataset where the variables in the formula are evaluated.                                                                                                                                                                                                                                                                                                                                                                                  |
| dimension       | dimension of the model, see above                                                                                                                                                                                                                                                                                                                                                                                                                          |
| subset          | index for choosing a subset of the data frame                                                                                                                                                                                                                                                                                                                                                                                                              |
| groups          | the grouping variable, if present                                                                                                                                                                                                                                                                                                                                                                                                                          |
| multiple, outer | logicals, determining how a '+' in the y and x components of the formula are processed. See <a href="#">xyplot</a> for details                                                                                                                                                                                                                                                                                                                             |
| subscripts      | logical, whether subscripts are to be calculated                                                                                                                                                                                                                                                                                                                                                                                                           |
| drop            | logical or list, similar to the <code>drop.unused.levels</code> argument in <a href="#">xyplot</a> , indicating whether unused levels of conditioning factors and data variables that are factors are to be dropped.                                                                                                                                                                                                                                       |

**Value**

returns a list with several components, including `left`, `right`, `left.name`, `right.name`, `condition` for 2-D, and `left.x`, `right.x`, `right.y`, `left.name`, `right.x.name`, `right.y.name`, `condition` for 3-D. Other possible components are `groups`, `subscr`

## Description

When a "trellis" object is plotted, panels are always drawn in an order such that columns vary the fastest, then rows and then pages. An optional function can be specified that determines, given the column, row and page and other relevant information, the packet (if any) which should be used in that panel. The function documented here implements the default behaviour, which is to match panel order with packet order, determined by varying the first conditioning variable the fastest, then the second, and so on. This matching is performed after any reordering and/or permutation of the conditioning variables.

## Usage

```
packet.panel.default(layout, condlevels, page, row, column,
 skip, all.pages.skip = TRUE)
```

## Arguments

|                   |                                                                                                                                                                                            |
|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| layout            | the layout argument in high level functions, suitably standardized.                                                                                                                        |
| condlevels        | a list of levels of conditioning variables, after relevant permutations and/or re-ordering of levels                                                                                       |
| page, row, column | the location of the panel in the coordinate system of pages, rows and columns.                                                                                                             |
| skip              | the skip argument in high level functions                                                                                                                                                  |
| all.pages.skip    | whether skip should be replicated over all pages. If FALSE, skip will be replicated to be only as long as the number of positions on a page, and that template will be used for all pages. |

## Value

A suitable combination of levels of the conditioning variables in the form of a numeric vector as long as the number of conditioning variables, with each element an integer indexing the levels of the corresponding variable. Specifically, if the return value is *p*, then the *i*-th conditioning variable will have level `condlevels[[i]][p[i]]`.

G\_panel.axis

*Panel Function for Drawing Axis Ticks and Labels***Description**

`panel.axis` is the function used by `lattice` to draw axes. It is typically not used by users, except those wishing to create advanced annotation. Keep in mind issues of clipping when trying to use it as part of the panel function. `current.panel.limits` can be used to retrieve a panel's x and y limits.

**Usage**

```

panel.axis(side = c("bottom", "left", "top", "right"),
 at,
 labels = TRUE,
 draw.labels = TRUE,
 check.overlap = FALSE,
 outside = FALSE,
 ticks = TRUE,
 half = !outside,
 which.half,
 tck = as.numeric(ticks),
 rot = if (is.logical(labels)) 0 else c(90, 0),
 text.col, text.alpha, text.cex, text.font,
 text.fontfamily, text.fontface, text.lineheight,
 line.col, line.lty, line.lwd, line.alpha)

current.panel.limits(unit = "native")

```

**Arguments**

|                          |                                                                                                                                                                                                                                                          |
|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>side</code>        | A character string indicating which side axes are to be drawn on. Partial specification is allowed.                                                                                                                                                      |
| <code>at</code>          | Numeric vector giving location of labels.                                                                                                                                                                                                                |
| <code>labels</code>      | The labels to go along with <code>at</code> . The labels can be a character vector or a vector of expressions. Alternatively, <code>at</code> can be a logical flag: If TRUE, the labels are derived from <code>at</code> , otherwise, labels are empty. |
| <code>draw.labels</code> | A logical indicating whether labels are to be drawn.                                                                                                                                                                                                     |

|                                                        |                                                                                                                                                                                                          |
|--------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>check.overlap</code>                             | A logical, whether to check for overlapping of labels. This also has the effect of removing at values that are ‘too close’ to the limits.                                                                |
| <code>outside</code>                                   | A logical flag, indicating whether to draw the labels outside the panel or inside. Note that <code>outside=TRUE</code> will only have a visible effect if clipping is disabled for the viewport (panel). |
| <code>ticks</code>                                     | Logical flag, whether to draw the tickmarks.                                                                                                                                                             |
| <code>half</code>                                      | Logical flag, indicating whether only around half the scales will be drawn for each side. This is primarily used for axis labeling in <a href="#">splom</a> .                                            |
| <code>which.half</code>                                | Character string, either "lower" or "upper", indicating which half is to be used for tick locations if <code>half = TRUE</code> . Defaults to whichever is suitable for <a href="#">splom</a> .          |
| <code>tck</code>                                       | A numeric scalar multiplier for tick length. Can be negative, in which case the ticks point inwards.                                                                                                     |
| <code>rot</code>                                       | Rotation angle(s) for labels in degrees. Can be a vector of length 2 for x- and y-axes.                                                                                                                  |
| <code>text.col</code>                                  | Color for the axis label text. See <a href="#">gpar</a> for more details on this and the other graphical parameters listed below.                                                                        |
| <code>text.alpha</code>                                | Alpha-transparency value for the axis label text.                                                                                                                                                        |
| <code>text.cex</code>                                  | Size multiplier for the axis label text.                                                                                                                                                                 |
| <code>text.font, text.fontfamily, text.fontface</code> | Font for the axis label text.                                                                                                                                                                            |
| <code>text.lineheight</code>                           | Line height for the axis label text.                                                                                                                                                                     |
| <code>line.col</code>                                  | Color for the axis label text.                                                                                                                                                                           |
| <code>line.lty</code>                                  | Color for the axis.                                                                                                                                                                                      |
| <code>line.lwd</code>                                  | Color for the axis.                                                                                                                                                                                      |
| <code>line.alpha</code>                                | Alpha-transparency value for the axis.                                                                                                                                                                   |
| <code>unit</code>                                      | Which grid <a href="#">unit</a> the values should be in.                                                                                                                                                 |

### Details

`panel.axis` can draw axis tick marks inside or outside a panel (more precisely, a grid viewport). It honours the (native) axis scales. Used in [panel.pairs](#) for [splom](#), as well as for all the usual axis drawing by the print method for "trellis" objects. It can also be used to enhance plots ‘after the fact’ by adding axes.

### Value

`current.panel.limits` returns a list with components `xlim` and `ylim`, which are both numeric vectors of length 2, giving the scales of the current panel (viewport). The values correspond to the unit system specified by `unit`, by default "native".

G\_panel.number

*Accessing Auxiliary Information During Plotting***Description**

Control over lattice plots are provided through a collection of user specifiable functions that perform various tasks during the plotting. Not all information is available to all functions. The functions documented here attempt to provide a consistent interface to access relevant information from within these user specified functions, namely those specified as the `panel`, `strip` and `axis` functions. Note that this information is not available to the `prepanel` function, which is executed prior to the actual plotting.

**Usage**

```
current.row(prefix)
current.column(prefix)
panel.number(prefix)
packet.number(prefix)
which.packet(prefix)

trellis.currentLayout(which = c("packet", "panel"), prefix)
```

**Arguments**

|                     |                                                                                                                                                                                                                                                                        |
|---------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>which</code>  | whether return value (a matrix) should contain panel numbers or packet numbers, which are usually, but not necessarily, the same (see below for details).                                                                                                              |
| <code>prefix</code> | A character string acting as a prefix identifying the plot of a "trellis" object. Only relevant when a particular page is occupied by more than one plot. Defaults to the value appropriate for the last "trellis" object printed. See <a href="#">trellis.focus</a> . |

**Value**

`trellis.currentLayout` returns a matrix with as many rows and columns as in the layout of panels in the current plot. Entries in the matrix are integer indices indicating which packet (or panel; see below) occupies that position, with 0 indicating the absence of a panel. `current.row` and `current.column` return integer indices specifying which row and column in the layout are currently active. `panel.number` returns an integer counting which panel is being drawn (starting from 1 for the first panel, a.k.a. the panel order). `packet.number` gives the packet number according to the packet order, which is determined by varying the first conditioning variable the fastest, then the second, and so on. `which.packet` returns the combination of levels of the conditioning variables in the form of a numeric vector as long as the number of conditioning variables, with each element an integer indexing the levels of the corresponding variable.

**Note**

The availability of these functions make redundant some features available in earlier versions of lattice, namely optional arguments called `panel.number` and `packet.number` that were made available to `panel` and `strip`. If you have written such functions, it should be enough to replace instances of `panel.number` and `packet.number` by the corresponding function calls.

You should also remove `panel.number` and `packet.number` from the argument list of your function to avoid a warning.

If these accessor functions are not enough for your needs, feel free to contact the maintainer and ask for more.

G\_Rows

*Extract rows from a list*

---

**Description**

Convenience function to extract subset of a list. Usually used in creating keys.

**Usage**

```
Rows(x, which)
```

**Arguments**

|                    |                                                   |
|--------------------|---------------------------------------------------|
| <code>x</code>     | list with each member a vector of the same length |
| <code>which</code> | index for members of <code>x</code>               |

**Value**

A list similar to `x`, with each `x[[i]]` replaced by `x[[i]][which]`

## Description

These are (related to) the default panel functions for `cloud` and `wireframe`.

## Usage

```
ltransform3dMatrix(screen, R.mat)
ltransform3dto3d(x, R.mat, dist)
```

## Arguments

|                     |                                                                                      |
|---------------------|--------------------------------------------------------------------------------------|
| <code>x</code>      | <code>x</code> can be a numeric matrix with 3 rows for <code>ltransform3dto3d</code> |
| <code>screen</code> | list, as described in <a href="#">panel.cloud</a>                                    |
| <code>R.mat</code>  | 4x4 transformation matrix in homogeneous coordinates                                 |
| <code>dist</code>   | controls transformation to account for perspective viewing                           |

## Details

`ltransform3dMatrix` and `ltransform3dto3d` are utility functions to help in computation of projections. These functions are used inside the panel functions for `cloud` and `wireframe`. They may be useful in user-defined panel functions as well.

The first function takes a list of the form of the `screen` argument in `cloud` and `wireframe` and a `R.mat`, a 4x4 transformation matrix in homogeneous coordinates, to return a new 4x4 transformation matrix that is the result of applying `R.mat` followed by the rotations in `screen`. The second function applies a 4x4 transformation matrix in homogeneous coordinates to a 3xn matrix representing points in 3-D space, and optionally does some perspective computations. (There has been no testing with non-trivial transformation matrices, and my knowledge of the homogeneous coordinate system is very limited, so there may be bugs here.)

H\_barley

Yield data from a Minnesota barley trial

**Description**

Total yield in bushels per acre for 10 varieties at 6 sites in each of two years.

**Usage**

```
barley
```

**Format**

A data frame with 120 observations on the following 4 variables.

**yield** Yield (averaged across three blocks) in bushels/acre.

**variety** Factor with levels "Svansota", "No. 462", "Manchuria", "No. 475", "Velvet", "Peatland", "Glabron", "No. 457", "Wisconsin No. 38", "Trebi".

**year** Factor with levels 1932, 1931

**site** Factor with 6 levels: "Grand Rapids", "Duluth", "University Farm", "Morris", "Crookston", "Waseca"

**Details**

These data are yields in bushels per acre, of 10 varieties of barley grown in 1/40 acre plots at University Farm, St. Paul, and at the five branch experiment stations located at Waseca, Morris, Crookston, Grand Rapids, and Duluth (all in Minnesota). The varieties were grown in three randomized blocks at each of the six stations during 1931 and 1932, different land being used each year of the test.

Immer et al. (1934) present the data for each Year\*Site\*Variety\*Block. The data here is the average yield across the three blocks.

Immer et al. (1934) refer (once) to the experiment as being conducted in 1930 and 1931, then later refer to it (repeatedly) as being conducted in 1931 and 1932. Later authors have continued the confusion.

Cleveland (1993) suggests that the data for the Morris site may have had the years switched.

**Description**

Daily measurements of ozone concentration, wind speed, temperature and solar radiation in New York City from May to September of 1973.

**Usage**

```
environmental
```

**Format**

A data frame with 111 observations on the following 4 variables.

**ozone** Average ozone concentration (of hourly measurements) of in parts per billion.

**radiation** Solar radiation (from 08:00 to 12:00) in langleys.

**temperature** Maximum daily emperature in degrees Fahrenheit.

**wind** Average wind speed (at 07:00 and 10:00) in miles per hour.

**Author(s)**

Documentation contributed by Kevin Wright.

**Source**

**Examples**

```
Scatter plot matrix with loess lines
splom(~environmental,
 panel=function(x,y){
 panel.xyplot(x,y)
 panel.loess(x,y)
 }
)

Conditioned plot similar to figure 5.3 from Cleveland
attach(environmental)
Temperature <- equal.count(temperature, 4, 1/2)
Wind <- equal.count(wind, 4, 1/2)
xyplot((ozone^(1/3)) ~ radiation | Temperature * Wind,
 aspect=1,
 prepanel = function(x, y)
 prepanel.loess(x, y, span = 1),
 panel = function(x, y){
 panel.grid(h = 2, v = 2)
 panel.xyplot(x, y, cex = .5)
 panel.loess(x, y, span = 1)
 },
 xlab = "Solar radiation (langleys)",
 ylab = "Ozone (cube root ppb)")
detach()

Similar display using the coplot function
with(environmental,{
 coplot((ozone^.33) ~ radiation | temperature * wind,
 number=c(4,4),
 panel = function(x, y, ...) panel.smooth(x, y, span = .8, ...),
 xlab="Solar radiation (langleys)",
 ylab="Ozone (cube root ppb)")
})
```

H\_ethanol

*Engine exhaust fumes from burning ethanol***Description**

Ethanol fuel was burned in a single-cylinder engine. For various settings of the engine compression and equivalence ratio, the emissions of nitrogen oxides were recorded.

**Usage**

```
ethanol
```

**Format**

A data frame with 88 observations on the following 3 variables.

**NOx** Concentration of nitrogen oxides (NO and NO2) in micrograms/J.

**C** Compression ratio of the engine.

**E** Equivalence ratio—a measure of the richness of the air and ethanol fuel mixture.

**Author(s)**

Documentation contributed by Kevin Wright.

**Source**

Brinkman, N.D. (1981) Ethanol Fuel—A Single-Cylinder Engine Study of Efficiency and Exhaust Emissions. *SAE transactions*, **90**, 1410–1424.

**References**

Cleveland, William S. (1993) *Visualizing Data*. Hobart Press, Summit, New Jersey.

**Examples**

```
Constructing panel functions on the fly
EE <- equal.count(ethanol$E, number=9, overlap=1/4)
xyplot(NOx ~ C | EE, data = ethanol,
 prepanel = function(x, y) prepanel.loess(x, y, span = 1),
 xlab = "Compression ratio", ylab = "NOx (micrograms/J)",
 panel = function(x, y) {
 panel.grid(h=-1, v= 2)
 panel.xyplot(x, y)
 panel.loess(x,y, span=1)
 },
 aspect = "xy")

Wireframe loess surface fit. See Figure 4.61 from Cleveland.
require(stats)
with(ethanol, {
 eth.lo <- loess(NOx ~ C * E, span = 1/3, parametric = "C",
 drop.square = "C", family="symmetric")
 eth.marginal <- list(C = seq(min(C), max(C), length.out = 25),
 E = seq(min(E), max(E), length.out = 25))
 eth.grid <- expand.grid(eth.marginal)
 eth.fit <- predict(eth.lo, eth.grid)
 wireframe(eth.fit ~ eth.grid$C * eth.grid$E,
 shade=TRUE,
 screen = list(z = 40, x = -60, y=0),
 distance = .1,
 xlab = "C", ylab = "E", zlab = "NOx")

H\_melanoma

---

*Melanoma skin cancer incidence*

---

**Description**

These data from the Connecticut Tumor Registry present age-adjusted numbers of melanoma skin-cancer incidences per 100,000 people in Connecticut for the years from 1936 to 1972.

**Usage**

```
melanoma
```

**Format**

A data frame with 37 observations on the following 2 variables.

**year** Years 1936 to 1972.

**incidence** Rate of melanoma cancer per 100,000 population.

**Note**

This dataset is not related to the `melanoma` dataset in the `boot` package with the same name.

The S-PLUS 6.2 help for the melanoma data says that the incidence rate is per *million*, but this is not consistent with data found at the National Cancer Institute (<https://www.cancer.gov/>).

**Author(s)**

Documentation contributed by Kevin Wright.

**Examples**

```
Time-series plot. Figure 3.64 from Cleveland.
xyplot(incidence ~ year,
 data = melanoma,
 aspect = "xy",
 panel = function(x, y)
 panel.xyplot(x, y, type="o", pch = 16),
 ylim = c(0, 6),
 xlab = "Year",
 ylab = "Incidence")
```

---

H\_singer

*Heights of New York Choral Society singers*

---

**Description**

Heights in inches of the singers in the New York Choral Society in 1979. The data are grouped according to voice part. The vocal range for each voice part increases in pitch according to the following order: Bass 2, Bass 1, Tenor 2, Tenor 1, Alto 2, Alto 1, Soprano 2, Soprano 1.

**Usage**

```
singer
```

**Format**

A data frame with 235 observations on the following 2 variables.

**height** Height in inches of the singers.

**voice.part** (Unordered) factor with levels "Bass 2", "Bass 1", "Tenor 2", "Tenor 1", "Alto 2", "Alto 1", "Soprano 2", "Soprano 1".

**Author(s)**

Documentation contributed by Kevin Wright.

**Examples**

```
Separate histogram for each voice part (Figure 1.2 from Cleveland)
histogram(~ height | voice.part,
 data = singer,
 aspect=1,
 layout = c(2, 4),
 nint=15,
 xlab = "Height (inches)")

Quantile-Quantile plot (Figure 2.11 from Cleveland)
qqmath(~ height | voice.part,
 data=singer,
 aspect=1,
 layout=c(2,4),
 prepanel = prepanel.qqmathline,
 panel = function(x, ...) {
 panel.grid()
 panel.qqmathline(x, ...)
 panel.qqmath(x, ...)
 },
 xlab = "Unit Normal Quantile",
 ylab="Height (inches)")
```

**Description**

These datasets record mortality rates across all ages in the USA by cause of death, sex, and rural/urban status, 2011–2013. The two datasets represent the national aggregate rates and the region-wise rates for each administrative region under the Department of Health and Human Services (HHS).

**Usage**

```
USMortality
USRegionalMortality
```

**Format**

USRegionalMortality is a data frame with 400 observations on the following 6 variables.

Region A factor specifying HHS Region. See details.

Status A factor with levels Rural and Urban

Sex A factor with levels Female and Male

Cause Cause of death. A factor with levels Alzheimers, Cancer, Cerebrovascular diseases, Diabetes, Flu and pneumonia, Heart disease, Lower respiratory, Nephritis, Suicide, and Unintentional injuries

Rate Age-adjusted death rate per 100,000 population

SE Standard error for the rate

USMortality is a data frame with 40 observations, containing the same variables with the exception of Region.

**Details**

The region-wise data give estimated rates separately for each of 10 HHS regions. The location of the regional offices and their coverage area, available from <https://www.hhs.gov/about/agencies/iea/regional-offices/index.html>, is given below.

**HHS Region 01 - Boston:** Connecticut, Maine, Massachusetts, New Hampshire, Rhode Island, and Vermont

**HHS Region 02 - New York:** New Jersey, New York, Puerto Rico, and the Virgin Islands

**HHS Region 03 - Philadelphia:** Delaware, District of Columbia, Maryland, Pennsylvania, Virginia, and West Virginia

**HHS Region 04 - Atlanta:** Alabama, Florida, Georgia, Kentucky, Mississippi, North Carolina, South Carolina, and Tennessee

**HHS Region 05 - Chicago:** Illinois, Indiana, Michigan, Minnesota, Ohio, and Wisconsin

**HHS Region 06 - Dallas:** Arkansas, Louisiana, New Mexico, Oklahoma, and Texas

**HHS Region 07 - Kansas City:** Iowa, Kansas, Missouri, and Nebraska

**HHS Region 08 - Denver:** Colorado, Montana, North Dakota, South Dakota, Utah, and Wyoming

**HHS Region 09 - San Francisco:** Arizona, California, Hawaii, Nevada, American Samoa, Commonwealth of the Northern Mariana Islands, Federated States of Micronesia, Guam, Marshall Islands, and Republic of Palau

**HHS Region 10 - Seattle:** Alaska, Idaho, Oregon, and Washington

**References**

Rural Health Reform Policy Research Center. \_Exploring Rural and Urban Mortality Differences\_, August 2015 Bethesda, MD. <https://ruralhealth.und.edu/projects/health-reform-policy-research-center/rural-urban-mortality>

**Examples**

```
dotplot(reorder(Cause, Rate) ~ Rate | Status,
 data = USMortality, groups = Sex,
 par.settings = simpleTheme(pch = 16), auto.key = list(columns = 2),
 scales = list(x = list(log = TRUE, equispaced.log = FALSE)))
dotplot(reorder(Cause, Rate):Sex ~ Rate | Status,
 data = USRegionalMortality, groups = Sex,
 scales = list(x = list(log = TRUE, equispaced.log = FALSE)))
```

I\_lset

*Interface to modify Trellis Settings - Defunct***Description**

A (hopefully) simpler alternative to `trellis.par.get/set`. This is deprecated, and the same functionality is now available with `trellis.par.set`

**Usage**

```
lset(theme = col.whitebg())
```

**Arguments**

|       |                                                                                                                                                                                                                                                                                                                                                            |
|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| theme | a list describing how to change the settings of the current active device. Valid components are those in the list returned by <code>trellis.par.get()</code> . Each component must itself be a list, with one or more of the appropriate components (need not have all components). Changes are made to the settings for the currently active device only. |
|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## Chapter 24

# The mgcv package

---

`anova.gam`

*Approximate hypothesis tests related to GAM fits*

---

### Description

Performs hypothesis tests relating to one or more fitted `gam` objects. For a single fitted `gam` object, Wald tests of the significance of each parametric and smooth term are performed, so interpretation is analogous to [drop1](#) rather than `anova.lm` (i.e. it's like type III ANOVA, rather than a sequential type I ANOVA). Otherwise the fitted models are compared using an analysis of deviance table or GLRT test: this latter approach should not be use to test the significance of terms which can be penalized to zero. Models to be compared should be fitted to the same data using the same smoothing parameter selection method.

### Usage

```
S3 method for class 'gam'
anova(object, ..., dispersion = NULL, test = NULL,
 freq = FALSE)
S3 method for class 'anova.gam'
print(x, digits = max(3, getOption("digits") - 3), ...)
```

### Arguments

|                          |                                                                                                                                                   |
|--------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object, ...</code> | fitted model objects of class <code>gam</code> as produced by <code>gam()</code> .                                                                |
| <code>x</code>           | an <code>anova.gam</code> object produced by a single model call to <code>anova.gam()</code> .                                                    |
| <code>dispersion</code>  | a value for the dispersion parameter: not normally used.                                                                                          |
| <code>test</code>        | what sort of test to perform for a multi-model call. One of "Chisq", "F" or "Cp". Reset to "Chisq" for extended and general families unless NULL. |
| <code>freq</code>        | whether to use frequentist or Bayesian approximations for parametric term p-values. See <a href="#">summary.gam</a> for details.                  |
| <code>digits</code>      | number of digits to use when printing output.                                                                                                     |

## Details

If more than one fitted model is provided than `anova.glm` is used, with the difference in model degrees of freedom being taken as the difference in effective degrees of freedom (when possible this is a smoothing parameter uncertainty corrected version). For extended and general families this is set so that a GLRT test is used. The p-values resulting from the multi-model case are only approximate, and must be used with care. The approximation is most accurate when the comparison relates to unpenalized terms, or smoothers with a null space of dimension greater than zero. (Basically we require that the difference terms could be well approximated by unpenalized terms with degrees of freedom approximately the effective degrees of freedom). In simulations the p-values are usually slightly too low. For terms with a zero-dimensional null space (i.e. those which can be penalized to zero) the approximation is often very poor, and significance can be greatly overstated: i.e. p-values are often substantially too low. This case applies to random effect terms.

Note also that in the multi-model call to `anova.gam`, it is quite possible for a model with more terms to end up with lower effective degrees of freedom, but better fit, than the notionally null model with fewer terms. In such cases it is very rare that it makes sense to perform any sort of test, since there is then no basis on which to accept the notional null model.

If only one model is provided then the significance of each model term is assessed using Wald like tests, conditional on the smoothing parameter estimates: see `summary.gam` and Wood (2013a,b) for details. The p-values provided here are better justified than in the multi model case, and have close to the correct distribution under the null, unless smoothing parameters are poorly identified. ML or REML smoothing parameter selection leads to the best results in simulations as they tend to avoid occasional severe undersmoothing. In replication of the full simulation study of Scheipl et al. (2008) the tests give almost indistinguishable power to the method recommended there, but slightly too low p-values under the null in their section 3.1.8 test for a smooth interaction (the Scheipl et al. recommendation is not used directly, because it only applies in the Gaussian case, and requires model refits, but it is available in package `RLRsim`).

In the single model case `print.anova.gam` is used as the printing method.

By default the p-values for parametric model terms are also based on Wald tests using the Bayesian covariance matrix for the coefficients. This is appropriate when there are "re" terms present, and is otherwise rather similar to the results using the frequentist covariance matrix (`freq=TRUE`), since the parametric terms themselves are usually unpenalized. Default P-values for parameteric terms that are penalized using the `paraPen` argument will not be good.

## Value

In the multi-model case `anova.gam` produces output identical to `anova.glm`, which it in fact uses.

In the single model case an object of class `anova.gam` is produced, which is in fact an object returned from `summary.gam`.

`print.anova.gam` simply produces tabulated output.

## WARNING

If models 'a' and 'b' differ only in terms with no un-penalized components (such as random effects) then p values from `anova(a,b)` are unreliable, and usually much too low.

Default P-values will usually be wrong for parametric terms penalized using 'paraPen': use `freq=TRUE` to obtain better p-values when the penalties are full rank and represent conventional random effects.

For a single model, interpretation is similar to `drop1`, not `anova.lm`.

**Examples**

```
library(mgcv)
set.seed(0)
dat <- gamSim(5,n=200,scale=2)

b<-gam(y ~ x0 + s(x1) + s(x2) + s(x3),data=dat)
anova(b)
b1<-gam(y ~ x0 + s(x1) + s(x2),data=dat)
anova(b,b1,test="F")
```

**Description**

Fits a generalized additive model (GAM) to a very large data set, the term ‘GAM’ being taken to include any quadratically penalized GLM (the extended families listed in [family.mgcv](#) can also be used). The degree of smoothness of model terms is estimated as part of fitting. In use the function is much like [gam](#), except that the numerical methods are designed for datasets containing upwards of several tens of thousands of data (see Wood, Goude and Shaw, 2015). The advantage of [bam](#) is much lower memory footprint than [gam](#), but it can also be much faster, for large datasets. [bam](#) can also compute on a cluster set up by the [parallel](#) package.

An alternative fitting approach (Wood et al. 2017, Li and Wood, 2019) is provided by the `discrete==TRUE` method. In this case a method based on discretization of covariate values and C code level parallelization (controlled by the `nthreads` argument instead of the `cluster` argument) is used. This extends both the data set and model size that are practical.

## Usage

```
bam(formula, family=gaussian(), data=list(), weights=NULL, subset=NULL,
 na.action=na.omit, offset=NULL, method="fREML", control=list(),
 select=FALSE, scale=0, gamma=1, knots=NULL, sp=NULL, min.sp=NULL,
 paraPen=NULL, chunk.size=10000, rho=0, AR.start=NULL, discrete=FALSE,
 cluster=NULL, nthreads=1, gc.level=1, use.chol=FALSE, samfrac=1,
 coef=NULL, drop.unused.levels=TRUE, G=NULL, fit=TRUE, drop.intercept=NULL, ...)
```

## Arguments

|           |                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| formula   | A GAM formula (see <a href="#">formula.gam</a> and also <a href="#">gam.models</a> ). This is exactly like the formula for a GLM except that smooth terms, <code>s</code> and <code>te</code> can be added to the right hand side to specify that the linear predictor depends on smooth functions of predictors (or linear functionals of these).                                                                                                     |
| family    | This is a family object specifying the distribution and link to use in fitting etc. See <a href="#">glm</a> and <a href="#">family</a> for more details. The extended families listed in <a href="#">family.mgcv</a> can also be used.                                                                                                                                                                                                                 |
| data      | A data frame or list containing the model response variable and covariates required by the formula. By default the variables are taken from <code>environment(formula)</code> : typically the environment from which <code>gam</code> is called.                                                                                                                                                                                                       |
| weights   | prior weights on the contribution of the data to the log likelihood. Note that a weight of 2, for example, is equivalent to having made exactly the same observation twice. If you want to reweight the contributions of each datum without changing the overall magnitude of the log likelihood, then you should normalize the weights (e.g. <code>weights &lt;- weights/mean(weights)</code> ).                                                      |
| subset    | an optional vector specifying a subset of observations to be used in the fitting process.                                                                                                                                                                                                                                                                                                                                                              |
| na.action | a function which indicates what should happen when the data contain 'NA's. The default is set by the 'na.action' setting of 'options', and is 'na.fail' if that is unset. The "factory-fresh" default is 'na.omit'.                                                                                                                                                                                                                                    |
| offset    | Can be used to supply a model offset for use in fitting. Note that this offset will always be completely ignored when predicting, unlike an offset included in <code>formula</code> (this used to conform to the behaviour of <code>lm</code> and <code>glm</code> ).                                                                                                                                                                                  |
| method    | The smoothing parameter estimation method. "GCV.Cp" to use GCV for unknown scale parameter and Mallows' Cp/UBRE/AIC for known scale. "GACV.Cp" is equivalent, but using GACV in place of GCV. "REML" for REML estimation, including of unknown scale, "P-REML" for REML estimation, but using a Pearson estimate of the scale. "ML" and "P-ML" are similar, but using maximum likelihood in place of REML. Default "fREML" uses fast REML computation. |
| control   | A list of fit control parameters to replace defaults returned by <a href="#">gam.control</a> . Any control parameters not supplied stay at their default values.                                                                                                                                                                                                                                                                                       |
| select    | Should selection penalties be added to the smooth effects, so that they can in principle be penalized out of the model? See <code>gamma</code> to increase penalization. Has the side effect that smooths no longer have a fixed effect component (improper prior from a Bayesian perspective) allowing REML comparison of models with the same fixed effect structure.                                                                                |

|            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| scale      | If this is positive then it is taken as the known scale parameter. Negative signals that the scale parameter is unknown. 0 signals that the scale parameter is 1 for Poisson and binomial and unknown otherwise. Note that (RE)ML methods can only work with scale parameter 1 for the Poisson and binomial cases.                                                                                                                                                                 |
| gamma      | Increase above 1 to force smoother fits. <code>gamma</code> is used to multiply the effective degrees of freedom in the GCV/UBRE/AIC score (so $\log(n)/2$ is BIC like). $n/\text{gamma}$ can be viewed as an effective sample size, which allows it to play a similar role for RE/ML smoothing parameter estimation.                                                                                                                                                              |
| knots      | this is an optional list containing user specified knot values to be used for basis construction. For most bases the user simply supplies the knots to be used, which must match up with the <code>k</code> value supplied (note that the number of knots is not always just <code>k</code> ). See <a href="#">tprs</a> for what happens in the " <code>tp</code> " / " <code>ts</code> " case. Different terms can use different numbers of knots, unless they share a covariate. |
| sp         | A vector of smoothing parameters can be provided here. Smoothing parameters must be supplied in the order that the smooth terms appear in the model formula. Negative elements indicate that the parameter should be estimated, and hence a mixture of fixed and estimated parameters is possible. If smooths share smoothing parameters then <code>length(sp)</code> must correspond to the number of underlying smoothing parameters.                                            |
| min.sp     | Lower bounds can be supplied for the smoothing parameters. Note that if this option is used then the smoothing parameters <code>full.sp</code> , in the returned object, will need to be added to what is supplied here to get the smoothing parameters actually multiplying the penalties. <code>length(min.sp)</code> should always be the same as the total number of penalties (so it may be longer than <code>sp</code> , if smooths share smoothing parameters).             |
| paraPen    | optional list specifying any penalties to be applied to parametric model terms. <a href="#">gam.models</a> explains more.                                                                                                                                                                                                                                                                                                                                                          |
| chunk.size | The model matrix is created in chunks of this size, rather than ever being formed whole. Reset to $4 \times p$ if <code>chunk.size &lt; 4 \times p</code> where <code>p</code> is the number of coefficients.                                                                                                                                                                                                                                                                      |
| rho        | An AR1 error model can be used for the residuals (based on dataframe order), of Gaussian-identity link models. This is the AR1 correlation parameter. Standardized residuals (approximately uncorrelated under correct model) returned in <code>std.rsd</code> if non zero. Also usable with other models when <code>discrete=TRUE</code> , in which case the AR model is applied to the working residuals and corresponds to a GEE approximation.                                 |
| AR.start   | logical variable of same length as data, <code>TRUE</code> at first observation of an independent section of AR1 correlation. Very first observation in data frame does not need this. If <code>NULL</code> then there are no breaks in AR1 correlation.                                                                                                                                                                                                                           |
| discrete   | with <code>method="fREML"</code> it is possible to discretize covariates for storage and efficiency reasons. If <code>discrete</code> is <code>TRUE</code> , a number or a vector of numbers for each smoother term, then discretization happens. If numbers are supplied they give the number of discretization bins.                                                                                                                                                             |
| cluster    | <code>bam</code> can compute the computationally dominant QR decomposition in parallel using <a href="#">parLapply</a> from the <code>parallel</code> package, if it is supplied with a cluster on which to do this (a cluster here can be some cores of a single machine). See details and example code.                                                                                                                                                                          |
| nthreads   | Number of threads to use for non-cluster computation (e.g. combining results from cluster nodes). If <code>NA</code> set to <code>max(1, length(cluster))</code> . See details.                                                                                                                                                                                                                                                                                                    |

|                                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|---------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>gc.level</code>           | to keep the memory footprint down, it helps to call the garbage collector often, but this takes a substantial amount of time. Setting this to zero means that garbage collection only happens when R decides it should. Setting to 2 gives frequent garbage collection. 1 is in between.                                                                                                                                                               |
| <code>use.chol</code>           | By default <code>bam</code> uses a very stable QR update approach to obtaining the QR decomposition of the model matrix. For well conditioned models an alternative accumulates the crossproduct of the model matrix and then finds its Choleski decomposition, at the end. This is somewhat more efficient, computationally.                                                                                                                          |
| <code>samfrac</code>            | For very large sample size Generalized additive models the number of iterations needed for the model fit can be reduced by first fitting a model to a random sample of the data, and using the results to supply starting values. This initial fit is run with sloppy convergence tolerances, so is typically very low cost. <code>samfrac</code> is the sampling fraction to use. 0.1 is often reasonable.                                            |
| <code>coef</code>               | initial values for model coefficients                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <code>drop.unused.levels</code> | by default unused levels are dropped from factors before fitting. For some smooths involving factor variables you might want to turn this off. Only do so if you know what you are doing.                                                                                                                                                                                                                                                              |
| <code>G</code>                  | if not <code>NULL</code> then this should be the object returned by a previous call to <code>bam</code> with <code>fit=FALSE</code> . Causes all other arguments to be ignored except <code>sp</code> , <code>chunk.size</code> , <code>gamma</code> , <code>nthreads</code> , <code>cluster</code> , <code>rho</code> , <code>gc.level</code> , <code>samfrac</code> , <code>use.chol</code> , <code>method</code> and <code>scale</code> (if $>0$ ). |
| <code>fit</code>                | if <code>FALSE</code> then the model is set up for fitting but not estimated, and an object is returned, suitable for passing as the <code>G</code> argument to <code>bam</code> .                                                                                                                                                                                                                                                                     |
| <code>drop.intercept</code>     | Set to <code>TRUE</code> to force the model to really not have the a constant in the parametric model part, even with factor variables present.                                                                                                                                                                                                                                                                                                        |
| <code>...</code>                | further arguments for passing on e.g. to <code>gam.fit</code> (such as <code>mustart</code> ).                                                                                                                                                                                                                                                                                                                                                         |

## Details

When `discrete=FALSE`, `bam` operates by first setting up the basis characteristics for the smooths, using a representative subsample of the data. Then the model matrix is constructed in blocks using `predict.gam`. For each block the factor  $R$ , from the QR decomposition of the whole model matrix is updated, along with  $Q'y$ . and the sum of squares of  $y$ . At the end of block processing, fitting takes place, without the need to ever form the whole model matrix.

In the generalized case, the same trick is used with the weighted model matrix and weighted pseudodata, at each step of the PIRLS. Smoothness selection is performed on the working model at each stage (performance oriented iteration), to maintain the small memory footprint. This is trivial to justify in the case of GCV or Cp/UBRE/AIC based model selection, and for REML/ML is justified via the asymptotic multivariate normality of  $Q'z$  where  $z$  is the IRLS pseudodata.

For full method details see Wood, Goude and Shaw (2015).

Note that POI is not as stable as the default nested iteration used with `gam`, but that for very large, information rich, datasets, this is unlikely to matter much.

Note also that it is possible to spend most of the computational time on basis evaluation, if an expensive basis is used. In practice this means that the default `"tp"` basis should be avoided: almost any other basis (e.g. `"cr"` or `"ps"`) can be used in the 1D case, and tensor product smooths (`te`) are typically much less costly in the multi-dimensional case.

If `cluster` is provided as a cluster set up using `makeCluster` (or `makeForkCluster`) from the `parallel` package, then the rate limiting QR decomposition of the model matrix is performed

in parallel using this cluster. Note that the speed ups are often not that great. On a multi-core machine it is usually best to set the cluster size to the number of physical cores, which is often less than what is reported by `detectCores`. Using more than the number of physical cores can result in no speed up at all (or even a slow down). Note that a highly parallel BLAS may negate all advantage from using a cluster of cores. Computing in parallel of course requires more memory than computing in series. See examples.

When `discrete=TRUE` the covariate data are first discretized. Discretization takes place on a smooth by smooth basis, or in the case of tensor product smooths (or any smooth that can be represented as such, such as random effects), separately for each marginal smooth. The required spline bases are then evaluated at the discrete values, and stored, along with index vectors indicating which original observation they relate to. Fitting is by a version of performance oriented iteration/PQL using REML smoothing parameter selection on each iterative working model (as for the default method). The iteration is based on the derivatives of the REML score, without computing the score itself, allowing the expensive computations to be reduced to one parallel block Cholesky decomposition per iteration (plus two basic operations of equal cost, but easily parallelized). Unlike standard POI/PQL, only one step of the smoothing parameter update for the working model is taken at each step (rather than iterating to the optimal set of smoothing parameters for each working model). At each step a weighted model matrix crossproduct of the model matrix is required - this is efficiently computed from the pre-computed basis functions evaluated at the discretized covariate values. Efficient computation with tensor product terms means that some terms within a tensor product may be re-ordered for maximum efficiency. See Wood et al (2017) and Li and Wood (2019) for full details.

When `discrete=TRUE` parallel computation is controlled using the `nthreads` argument. For this method no cluster computation is used, and the `parallel` package is not required. Note that actual speed up from parallelization depends on the BLAS installed and your hardware. With the (R default) reference BLAS using several threads can make a substantial difference, but with a single threaded tuned BLAS, such as `openblas`, the effect is less marked (since cache use is typically optimized for one thread, and is then sub optimal for several). However the tuned BLAS is usually much faster than using the reference BLAS, however many threads you use. If you have a multi-threaded BLAS installed then you should leave `nthreads` at 1, since calling a multi-threaded BLAS from multiple threads usually slows things down: the only exception to this is that you might choose to form discrete matrix cross products (the main cost in the fitting routine) in a multi-threaded way, but use single threaded code for other computations: this can be achieved by e.g. `nthreads=c(2, 1)`, which would use 2 threads for discrete inner products, and 1 for most code calling BLAS. Not that the basic reason that multi-threaded performance is often disappointing is that most computers are heavily memory bandwidth limited, not flop rate limited. It is hard to get data to one core fast enough, let alone trying to get data simultaneously to several cores.

`discrete=TRUE` will often produce identical results to the methods without discretization, since covariates often only take a modest number of discrete values anyway, so no approximation at all is involved in the discretization process. Even when some approximation is involved, the differences are often very small as the algorithms discretize marginally whenever possible. For example each margin of a tensor product smooth is discretized separately, rather than discretizing onto a grid of covariate values (for an equivalent isotropic smooth we would have to discretize onto a grid). The marginal approach allows quite fine scale discretization and hence very low approximation error. Note that when using the `smooth.id` mechanism to link smoothing parameters, the discrete method cannot force the linked bases to be identical, so some differences to the none discrete methods will be noticeable.

The extended families given in `family.mgcv` can also be used. The extra parameters of these are estimated by maximizing the penalized likelihood, rather than the restricted marginal likelihood as in `gam`. So estimates may differ slightly from those returned by `gam`. Estimation is accomplished by a Newton iteration to find the extra parameters (e.g. the theta parameter of the negative binomial or the degrees of freedom and scale of the scaled t) maximizing the log likelihood given the model

coefficients at each iteration of the fitting procedure.

### Value

An object of class "gam" as described in [gamObject](#).

### WARNINGS

The routine may be slower than optimal if the default "tp" basis is used.

Unless discrete=TRUE, you must have more unique combinations of covariates than the model has total parameters. (Total parameters is sum of basis dimensions plus sum of non-spline terms less the number of spline terms).

This routine is less stable than 'gam' for the same dataset.

With discrete=TRUE, te terms are efficiently computed, but t2 are not.

### Examples

```
library(mgcv)
See help("mgcv-parallel") for using bam in parallel

Sample sizes are small for fast run times.

set.seed(3)
dat <- gamSim(1,n=25000,dist="normal",scale=20)
bs <- "cr";k <- 12
b <- bam(y ~ s(x0,bs=bs)+s(x1,bs=bs)+s(x2,bs=bs,k=k)+
 s(x3,bs=bs),data=dat)
summary(b)
plot(b,pages=1,rug=FALSE) ## plot smooths, but not rug
plot(b,pages=1,rug=FALSE,seWithMean=TRUE) ## `with intercept' CIs
```

```

ba <- bam(y ~ s(x0,bs=bs,k=k)+s(x1,bs=bs,k=k)+s(x2,bs=bs,k=k)+
 s(x3,bs=bs,k=k),data=dat,method="GCV.Cp") ## use GCV
summary(ba)

A Poisson example...

k <- 15
dat <- gamSim(1,n=21000,dist="poisson",scale=.1)

system.time(b1 <- bam(y ~ s(x0,bs=bs)+s(x1,bs=bs)+s(x2,bs=bs,k=k),
 data=dat,family=poisson()))
b1

Similar using faster discrete method...

system.time(b2 <- bam(y ~ s(x0,bs=bs,k=k)+s(x1,bs=bs,k=k)+s(x2,bs=bs,k=k)+
 s(x3,bs=bs,k=k),data=dat,family=poisson(),discrete=TRUE))
b2

```

bam.update

*Update a strictly additive bam model for new data.*

## Description

Gaussian with identity link models fitted by `bam` can be efficiently updated as new data becomes available, by simply updating the QR decomposition on which estimation is based, and re-optimizing the smoothing parameters, starting from the previous estimates. This routine implements this.

## Usage

```
bam.update(b, data, chunk.size=10000)
```

## Arguments

|                         |                                                                                                                                                                                                                                               |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>b</code>          | A gam object fitted by <code>bam</code> and representing a strictly additive model (i.e. gaussian errors, identity link).                                                                                                                     |
| <code>data</code>       | Extra data to augment the original data used to obtain <code>b</code> . Must include a <code>weights</code> column if the original fit was weighted and a <code>AR.start</code> column if <code>AR.start</code> was non NULL in original fit. |
| <code>chunk.size</code> | size of subsets of data to process in one go when getting fitted values.                                                                                                                                                                      |

## Details

`bam.update` updates the QR decomposition of the (weighted) model matrix of the GAM represented by `b` to take account of the new data. The orthogonal factor multiplied by the response vector is also updated. Given these updates the model and smoothing parameters can be re-estimated, as if the whole dataset (original and the new data) had been fitted in one go. The function will use the

same AR1 model for the residuals as that employed in the original model fit (see `rho` parameter of `bam`).

Note that there may be small numerical differences in fit between fitting the data all at once, and fitting in stages by updating, if the smoothing bases used have any of their details set with reference to the data (e.g. default knot locations).

### Value

An object of class "gam" as described in `gamObject`.

### WARNINGS

AIC computation does not currently take account of AR model, if used.

dat[c(50,13,3000,3005,3100),] <- NA
dat1 <- dat[(n-999):n,]
dat0 <- dat[1:(n-1000),]
bs <- "ps"; k <- 20
method <- "GCV.Cp"
b <- bam(y ~ s(x0,bs=bs,k=k)+s(x1,bs=bs,k=k)+s(x2,bs=bs,k=k)+
 s(x3,bs=bs,k=k),data=dat0,method=method)

b1 <- bam.update(b,dat1)

b2 <- bam.update(bam.update(b,dat1[1:500,]),dat1[501:1000,])

b3 <- bam(y ~ s(x0,bs=bs,k=k)+s(x1,bs=bs,k=k)+s(x2,bs=bs,k=k)+
 s(x3,bs=bs,k=k),data=dat,method=method)
b1;b2;b3

example with AR1 errors...

e <- rnorm(n)
for (i in 2:n) e[i] <- e[i-1]*.7 + e[i]
dat$y <- dat$f + e*3
dat[c(50,13,3000,3005,3100),] <- NA
dat1 <- dat[(n-999):n,]
```

```

dat0 <- dat[1:(n-1000),]

b <- bam(y ~ s(x0,bs=bs,k=k)+s(x1,bs=bs,k=k)+s(x2,bs=bs,k=k)+
 s(x3,bs=bs,k=k),data=dat0,rho=0.7)

b1 <- bam.update(b,dat1)

summary(b1);summary(b2);summary(b3)

```

bandchol

*Choleski decomposition of a band diagonal matrix***Description**

Computes Choleski decomposition of a (symmetric positive definite) band-diagonal matrix, A.

**Usage**

```
bandchol(B)
```

**Arguments**

**B** An n by k matrix containing the diagonals of the matrix A to be decomposed. First row is leading diagonal, next is first sub-diagonal, etc. sub-diagonals are zero padded at the end. Alternatively gives A directly, i.e. a square matrix with 2k-1 non zero diagonals (those from the lower triangle are not accessed).

**Details**

Calls `dpbtrf` from LAPACK. The point of this is that it has  $O(k^2n)$  computational cost, rather than the  $O(n^3)$  required by dense matrix methods.

**Value**

Let  $R$  be the factor such that  $t(R) \%*\%R = A$ .  $R$  is upper triangular and if the rows of  $B$  contained the diagonals of  $A$  on entry, then what is returned is an n by k matrix containing the diagonals of  $R$ , packed as  $B$  was packed on entry. If  $B$  was square on entry, then  $R$  is returned directly. See examples.

## Examples

```
require(mgcv)
simulate a banded diagonal matrix
n <- 7;set.seed(8)
A <- matrix(0,n,n)
sdiag(A) <- runif(n);sdiag(A,1) <- runif(n-1)
sdiag(A,2) <- runif(n-2)
A <- crossprod(A)

full matrix form...
bandchol(A)
chol(A) ## for comparison

compact storage form...
B <- matrix(0,3,n)
B[1,] <- sdiag(A);B[2,1:(n-1)] <- sdiag(A,1)
B[3,1:(n-2)] <- sdiag(A,2)
bandchol(B)
```

---

betar

---

*GAM beta regression family*

---

## Description

Family for use with [gam](#) or [bam](#), implementing regression for beta distributed data on (0,1). A linear predictor controls the mean,  $\mu$  of the beta distribution, while the variance is then  $\mu(1-\mu)/(1+\phi)$ , with parameter  $\phi$  being estimated during fitting, alongside the smoothing parameters.

## Usage

```
betar(theta = NULL, link = "logit", eps=.Machine$double.eps*100)
```

## Arguments

|       |                                                                                                                                                                                                                                                                                           |
|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| theta | the extra parameter ( $\phi$ above).                                                                                                                                                                                                                                                      |
| link  | The link function: one of "logit", "probit", "cloglog" and "cauchit".                                                                                                                                                                                                                     |
| eps   | the response variable will be truncated to the interval $[\text{eps}, 1-\text{eps}]$ if there are values outside this range. This truncation is not entirely benign, but too small a value of <code>eps</code> will cause stability problems if there are zeroes or ones in the response. |

## Details

These models are useful for proportions data which can not be modelled as binomial. Note the assumption that data are in (0,1), despite the fact that for some parameter values 0 and 1 are perfectly legitimate observations. The restriction is needed to keep the log likelihood bounded for all parameter values. Any data exactly at 0 or 1 are reset to be just above 0 or just below 1 using the `eps` argument (in fact any observation  $< \text{eps}$  is reset to `eps` and any observation  $> 1-\text{eps}$  is reset to  $1-\text{eps}$ ). Note the effect of this resetting. If  $\mu\phi > 1$  then impossible 0s are replaced with highly improbable `eps` values. If the inequality is reversed then 0s with infinite probability density are

replaced with `eps` values having high finite probability density. The equivalent condition for 1s is  $(1 - \mu)\phi > 1$ . Clearly all types of resetting are somewhat unsatisfactory, and care is needed if data contain 0s or 1s (often it makes sense to manually reset the 0s and 1s in a manner that somehow reflects the sampling setup).

### Value

An object of class `extended.family`.

### WARNINGS

Do read the details section if your data contain 0s and or 1s.

### Author(s)

Natalya Pya (nat.pya@gmail.com) and Simon Wood (s.wood@r-project.org)

### Examples

```
library(mgcv)
Simulate some beta data...
set.seed(3); n<-400
dat <- gamSim(1,n=n)
mu <- binomial()$linkinv(dat$f/4-2)
phi <- .5
a <- mu*phi;b <- phi - a;
dat$y <- rbeta(n,a,b)

bm <- gam(y~s(x0)+s(x1)+s(x2)+s(x3),family=betar(link="logit"),data=dat)

bm
plot(bm,pages=1)
```

---

`blas.thread.test`      *BLAS thread safety*

---

### Description

Most BLAS implementations are thread safe, but some versions of OpenBLAS, for example, are not. This routine is a diagnostic helper function, which you will never need if you don't set `nthreads>1`, and even then are unlikely to need.

### Usage

```
blas.thread.test(n=1000,nt=4)
```

### Arguments

|                 |                                                            |
|-----------------|------------------------------------------------------------|
| <code>n</code>  | Number of iterations to run of parallel BLAS calling code. |
| <code>nt</code> | Number of parallel threads to use                          |

## Details

While single threaded OpenBLAS 0.2.20 was thread safe, versions 0.3.0-0.3.6 are not, and from version 0.3.7 thread safety of the single threaded OpenBLAS requires making it with the option `USE_LOCKING=1`. The reference BLAS is thread safe, as are MKL and ATLAS. This routine repeatedly calls the BLAS from multi-threaded code and is sufficient to detect the problem in single threaded OpenBLAS 0.3.x.

A multi-threaded BLAS is often no faster than a single-threaded BLAS, while judicious use of threading in the code calling the BLAS can still deliver a modest speed improvement. For this reason it is often better to use a single threaded BLAS and the `codenthreads` options to [bam](#) or [gam](#). For `bam(..., discrete=TRUE)` using several threads can be a substantial benefit, especially with the reference BLAS.

The MKL BLAS is multithreaded by default. Under linux setting environment variable `MKL_NUM_THREADS=1` before starting R gives single threaded operation.

---

`bug.reports.mgcv`      *Reporting mgcv bugs.*

---

## Description

`mgcv` works largely because many people have reported bugs over the years. If you find something that looks like a bug, please report it, so that the package can be improved. `mgcv` does not have a large development budget, so it is a big help if bug reports follow the following guidelines.

The ideal report consists of an email to <[simon.wood@r-project.org](mailto:simon.wood@r-project.org)> with a subject line including `mgcv` somewhere, containing

1. The results of running `sessionInfo` in the R session where the problem occurs. This provides platform details, R and package version numbers, etc.
2. A brief description of the problem.
3. Short cut and paste-able code that produces the problem, including the code for loading/generating the data (using standard R functions like `load`, `read.table` etc).
4. Any required data files. If you send real data it will only be used for the purposes of debugging.

Of course if you have dug deeper and have an idea of what is causing the problem, that is also helpful to know, as is any suggested code fix. (Don't send a fixed package `.tar.gz` file, however - I can't use this).

choldrop

*Deletion and rank one Cholesky factor update***Description**

Given a Cholesky factor,  $R$ , of a matrix,  $A$ , `choldrop` finds the Cholesky factor of  $A[-k, -k]$ , where  $k$  is an integer. `cholup` finds the factor of  $A + uu^T$  (update) or  $A - uu^T$  (downdate).

**Usage**

```
choldrop(R, k)
cholup(R, u, up)
```

**Arguments**

|                 |                                             |
|-----------------|---------------------------------------------|
| $R$             | Cholesky factor of a matrix, $A$ .          |
| $k$             | row and column of $A$ to drop.              |
| $u$             | vector defining rank one update.            |
| <code>up</code> | if TRUE compute update, otherwise downdate. |

**Details**

First consider `choldrop`. If  $R$  is upper triangular then  $t(R[:, -k]) \%*\% R[:, -k] == A[-k, -k]$ , but  $R[:, -k]$  has elements on the first sub-diagonal, from its  $k$ th column onwards. To get from this to a triangular Cholesky factor of  $A[-k, -k]$  we can apply a sequence of Givens rotations from the left to eliminate the sub-diagonal elements. The routine does this. If  $R$  is a lower triangular factor then Givens rotations from the right are needed to remove the extra elements. If  $n$  is the dimension of  $R$  then the update has  $O(n^2)$  computational cost.

`cholup` (which assumes  $R$  is upper triangular) updates based on the observation that  $R^T R + uu^T = [u, R^T][u, R^T]^T = [u, R^T]Q^T Q[u, R^T]^T$ , and therefore we can construct  $Q$  so that  $Q[u, R^T]^T = [0, R_1^T]^T$ , where  $R_1$  is the modified factor.  $Q$  is constructed from a sequence of Givens rotations in order to zero the elements of  $u$ . Downdating is similar except that hyperbolic rotations have to be used in place of Givens rotations — see Golub and van Loan (2013, section 6.5.4) for details. Downdating only works if  $A - uu^T$  is positive definite. Again the computational cost is  $O(n^2)$ .

Note that the updates are vector oriented, and are hence not susceptible to speed up by use of an optimized BLAS. The updates are set up to be relatively Cache friendly, in that in the upper triangular case successive Givens rotations are stored for sequential application column-wise, rather than being applied row-wise as soon as they are computed. Even so, the upper triangular update is slightly slower than the lower triangular update.

**Author(s)**

Simon N. Wood <simon.wood@r-project.org>

**References**

Golub GH and CF Van Loan (2013) Matrix Computations (4th edition) Johns Hopkins

**Examples**

```

require(mgcv)
set.seed(0)
n <- 6
A <- crossprod(matrix(runif(n*n), n, n))
R0 <- chol(A)
k <- 3
Rd <- choldrop(R0, k)
range(Rd-chol(A[-k, -k]))
Rd;chol(A[-k, -k])

same but using lower triangular factor A = LL'
L <- t(R0)
Ld <- choldrop(L, k)
range(Ld-t(chol(A[-k, -k])))
Ld;t(chol(A[-k, -k]))

Rank one update example
u <- runif(n)
R <- cholup(R0, u, TRUE)
Ru <- chol(A+u %*% t(u)) ## direct for comparison
R;Ru
range(R-Ru)

Downdate - just going back from R to R0
Rd <- cholup(R, u, FALSE)
R0;Rd
range(R-Ru)

```

choose.k

*Basis dimension choice for smooths***Description**

Choosing the basis dimension, and checking the choice, when using penalized regression smoothers.

Penalized regression smoothers gain computational efficiency by virtue of being defined using a basis of relatively modest size,  $k$ . When setting up models in the `mgcv` package, using `s` or `te` terms in a model formula,  $k$  must be chosen: the defaults are essentially arbitrary.

In practice  $k-1$  (or  $k$ ) sets the upper limit on the degrees of freedom associated with an `s` smooth (1 degree of freedom is usually lost to the identifiability constraint on the smooth). For `te` smooths the upper limit of the degrees of freedom is given by the product of the  $k$  values provided for each marginal smooth less one, for the constraint. However the actual effective degrees of freedom are controlled by the degree of penalization selected during fitting, by GCV, AIC, REML or whatever is specified. The exception to this is if a smooth is specified using the `fx=TRUE` option, in which case it is unpenalized.

So, exact choice of  $k$  is not generally critical: it should be chosen to be large enough that you are reasonably sure of having enough degrees of freedom to represent the underlying ‘truth’ reasonably well, but small enough to maintain reasonable computational efficiency. Clearly ‘large’ and ‘small’ are dependent on the particular problem being addressed.

As with all model assumptions, it is useful to be able to check the choice of  $k$  informally. If the effective degrees of freedom for a model term are estimated to be much less than  $k-1$  then this is unlikely to be very worthwhile, but as the EDF approach  $k-1$ , checking can be important. A useful general purpose approach goes as follows: (i) fit your model and extract the deviance residuals; (ii) for each smooth term in your model, fit an equivalent, single, smooth to the residuals, using a substantially increased  $k$  to see if there is pattern in the residuals that could potentially be explained by increasing  $k$ . Examples are provided below.

The obvious, but more costly, alternative is simply to increase the suspect  $k$  and refit the original model. If there are no statistically important changes as a result of doing this, then  $k$  was large enough. (Change in the smoothness selection criterion, and/or the effective degrees of freedom, when  $k$  is increased, provide the obvious numerical measures for whether the fit has changed substantially.)

`gam.check` runs a simple simulation based check on the basis dimensions, which can help to flag up terms for which  $k$  is too low. Grossly too small  $k$  will also be visible from partial residuals available with `plot.gam`.

One scenario that can cause confusion is this: a model is fitted with  $k=10$  for a smooth term, and the EDF for the term is estimated as 7.6, some way below the maximum of 9. The model is then refitted with  $k=20$  and the EDF increases to 8.7 - what is happening - how come the EDF was not 8.7 the first time around? The explanation is that the function space with  $k=20$  contains a larger subspace of functions with EDF 8.7 than did the function space with  $k=10$ : one of the functions in this larger subspace fits the data a little better than did any function in the smaller subspace. These subtleties seldom have much impact on the statistical conclusions to be drawn from a model fit, however.

## References

Wood, S.N. (2017) Generalized Additive Models: An Introduction with R (2nd edition). CRC/Taylor & Francis.

<https://www.maths.ed.ac.uk/~swood34/>

## Examples

```
Simulate some data
library(mgcv)
set.seed(1)
dat <- gamSim(1,n=400,scale=2)

fit a GAM with quite low `k`
b<-gam(y~s(x0,k=6)+s(x1,k=6)+s(x2,k=6)+s(x3,k=6),data=dat)
plot(b,pages=1,residuals=TRUE) ## hint of a problem in s(x2)

the following suggests a problem with s(x2)
gam.check(b)

Another approach (see below for more obvious method)....
check for residual pattern, removeable by increasing `k`
typically `k`, below, should be substantially larger than
the original, `k` but certainly less than n/2.
Note use of cheap "cs" shrinkage smoothers, and gamma=1.4
```

```

to reduce chance of overfitting...
rsd <- residuals(b)
gam(rsd~s(x0,k=40,bs="cs"),gamma=1.4,data=dat) ## fine
gam(rsd~s(x1,k=40,bs="cs"),gamma=1.4,data=dat) ## fine
gam(rsd~s(x2,k=40,bs="cs"),gamma=1.4,data=dat) ## `k' too low
gam(rsd~s(x3,k=40,bs="cs"),gamma=1.4,data=dat) ## fine

refit...
b <- gam(y~s(x0,k=6)+s(x1,k=6)+s(x2,k=20)+s(x3,k=6),data=dat)
gam.check(b) ## better

similar example with multi-dimensional smooth
b1 <- gam(y~s(x0)+s(x1,x2,k=15)+s(x3),data=dat)
rsd <- residuals(b1)
gam(rsd~s(x0,k=40,bs="cs"),gamma=1.4,data=dat) ## fine
gam(rsd~s(x1,x2,k=100,bs="ts"),gamma=1.4,data=dat) ## `k' too low
gam(rsd~s(x3,k=40,bs="cs"),gamma=1.4,data=dat) ## fine

gam.check(b1) ## shows same problem

and a `te' example
b2 <- gam(y~s(x0)+te(x1,x2,k=4)+s(x3),data=dat)
rsd <- residuals(b2)
gam(rsd~s(x0,k=40,bs="cs"),gamma=1.4,data=dat) ## fine
gam(rsd~te(x1,x2,k=10,bs="cs"),gamma=1.4,data=dat) ## `k' too low
gam(rsd~s(x3,k=40,bs="cs"),gamma=1.4,data=dat) ## fine

gam.check(b2) ## shows same problem

same approach works with other families in the original model
dat <- gamSim(1,n=400,scale=.25,dist="poisson")
bp<-gam(y~s(x0,k=5)+s(x1,k=5)+s(x2,k=5)+s(x3,k=5),
 family=poisson,data=dat,method="ML")

gam.check(bp)

rsd <- residuals(bp)
gam(rsd~s(x0,k=40,bs="cs"),gamma=1.4,data=dat) ## fine
gam(rsd~s(x1,k=40,bs="cs"),gamma=1.4,data=dat) ## fine
gam(rsd~s(x2,k=40,bs="cs"),gamma=1.4,data=dat) ## `k' too low
gam(rsd~s(x3,k=40,bs="cs"),gamma=1.4,data=dat) ## fine

rm(dat)

More obvious, but more expensive tactic... Just increase
suspicious k until fit is stable.

set.seed(0)
dat <- gamSim(1,n=400,scale=2)
fit a GAM with quite low `k'
b <- gam(y~s(x0,k=6)+s(x1,k=6)+s(x2,k=6)+s(x3,k=6),
 data=dat,method="REML")
b
edf for 3rd smooth is highest as proportion of k -- increase k
b <- gam(y~s(x0,k=6)+s(x1,k=6)+s(x2,k=12)+s(x3,k=6),
 data=dat,method="REML")
b

```

```
edf substantially up, -ve REML substantially down
b <- gam(y~s(x0,k=6)+s(x1,k=6)+s(x2,k=24)+s(x3,k=6),
 data=dat,method="REML")
b
slight edf increase and -ve REML change
b <- gam(y~s(x0,k=6)+s(x1,k=6)+s(x2,k=40)+s(x3,k=6),
 data=dat,method="REML")
b
definitely stabilized (but really k around 20 would have been fine)
```

columb

*Reduced version of Columbus OH crime data*

## Description

By district crime data from Columbus OH, together with polygons describing district shape. Useful for illustrating use of simple Markov Random Field smoothers.

## Usage

```
data(columb)
data(columb.polys)
```

## Format

columb is a 49 row data frame with the following columns

**area** land area of district

**home.value** housing value in 1000USD.

**income** household income in 1000USD.

**crime** residential burglaries and auto thefts per 1000 households.

**open.space** measure of open space in district.

**district** code identifying district, and matching names(columb.polys).

columb.polys contains the polygons defining the areas in the format described below.

## Details

The data frame columb relates to the districts whose boundaries are coded in columb.polys. columb.polys[[i]] is a 2 column matrix, containing the vertices of the polygons defining the boundary of the ith district. columb.polys[[2]] has an artificial hole inserted to illustrate how holes in districts can be specified. Different polygons defining the boundary of a district are separated by NA rows in columb.polys[[1]], and a polygon enclosed within another is treated as a hole in that region (a hole should never come first). names(columb.polys) matches columb\$district (order unimportant).

## Source

The data are adapted from the columbus example in the spdep package, where the original source is given as:

Anselin, Luc. 1988. Spatial econometrics: methods and models. Dordrecht: Kluwer Academic, Table 12.1 p. 189.

## Examples

|            |                                |
|------------|--------------------------------|
| concurvity | <i>GAM concurvity measures</i> |
|------------|--------------------------------|

---

## Description

Produces summary measures of concurvity between [gam](#) components.

## Usage

```
concurvity(b, full=TRUE)
```

## Arguments

|             |                                                                                                                                                                                                                       |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>b</b>    | An object inheriting from class "gam".                                                                                                                                                                                |
| <b>full</b> | If TRUE then concurvity of each term with the whole of the rest of the model is considered. If FALSE then pairwise concurvity measures between each smooth term (as well as the parametric component) are considered. |

## Details

Concurvity occurs when some smooth term in a model could be approximated by one or more of the other smooth terms in the model. This is often the case when a smooth of space is included in a model, along with smooths of other covariates that also vary more or less smoothly in space. Similarly it tends to be an issue in models including a smooth of time, along with smooths of other time varying covariates.

Concurvity can be viewed as a generalization of co-linearity, and causes similar problems of interpretation. It can also make estimates somewhat unstable (so that they become sensitive to apparently innocuous modelling details, for example).

This routine computes three related indices of concurvity, all bounded between 0 and 1, with 0 indicating no problem, and 1 indicating total lack of identifiability. The three indices are all based on the idea that a smooth term,  $f$ , in the model can be decomposed into a part,  $g$ , that lies entirely in the space of one or more other terms in the model, and a remainder part that is completely within the term's own space. If  $g$  makes up a large part of  $f$  then there is a concurvity problem. The indices used are all based on the square of  $\|g\|/\|f\|$ , that is the ratio of the squared Euclidean norms of the vectors of  $f$  and  $g$  evaluated at the observed covariate values.

The three measures are as follows

**worst** This is the largest value that the square of  $\|g\|/\|f\|$  could take for any coefficient vector. This is a fairly pessimistic measure, as it looks at the worst case irrespective of data. This is the only measure that is symmetric.

**observed** This just returns the value of the square of  $\|g\|/\|f\|$  according to the estimated coefficients. This could be a bit over-optimistic about the potential for a problem in some cases.

**estimate** This is the squared F-norm of the basis for  $g$  divided by the F-norm of the basis for  $f$ . It is a measure of the extent to which the  $f$  basis can be explained by the  $g$  basis. It does not suffer from the pessimism or potential for over-optimism of the previous two measures, but is less easy to understand.

**Value**

If `full=TRUE` a matrix with one column for each term and one row for each of the 3 concurvity measures detailed below. If `full=FALSE` a list of 3 matrices, one for each of the three concurvity measures detailed below. Each row of the matrix relates to how the model terms depend on the model term supplying that rows name.

**Examples**

```
library(mgcv)
simulate data with concurvity...
set.seed(8); n<- 200
f2 <- function(x) 0.2 * x^11 * (10 * (1 - x))^6 + 10 *
 (10 * x)^3 * (1 - x)^10
t <- sort(runif(n)) ## first covariate
make covariate x a smooth function of t + noise...
x <- f2(t) + rnorm(n)*3
simulate response dependent on t and x...
y <- sin(4*pi*t) + exp(x/20) + rnorm(n)*.3

fit model...
b <- gam(y ~ s(t,k=15) + s(x,k=15),method="REML")

assess concurvity between each term and `rest of model'...
concurvity(b)

... and now look at pairwise concurvity between terms...
concurvity(b,full=FALSE)
```

**Description**

The `cox.ph` family implements the Cox Proportional Hazards model with Peto's correction for ties, optional stratification, and estimation by penalized partial likelihood maximization, for use with `gam`. In the model formula, event time is the response. Under stratification the response has two columns: time and a numeric index for stratum. The `weights` vector provides the censoring information (0 for censoring, 1 for event). `cox.ph` deals with the case in which each subject has one event/censoring time and one row of covariate values. When each subject has several time dependent covariates see `cox.pht`.

See example below for conditional logistic regression.

## Usage

```
cox.ph(link="identity")
```

## Arguments

`link` currently (and possibly for ever) only "identity" supported.

## Details

Used with `gam` to fit Cox Proportional Hazards models to survival data. The model formula will have event/censoring times on the left hand side and the linear predictor specification on the right hand side. Censoring information is provided by the `weights` argument to `gam`, with 1 indicating an event and 0 indicating censoring.

Stratification is possible, allowing for different baseline hazards in different strata. In that case the response has two columns: the first is event/censoring time and the second is a numeric stratum index. See below for an example.

Prediction from the fitted model object (using the `predict` method) with `type="response"` will predict on the survivor function scale. This requires evaluation times to be provided as well as covariates (see example). Also see example code below for extracting the cumulative baseline hazard/survival directly. The `fitted.values` stored in the model object are survival function estimates for each subject at their event/censoring time.

`deviance`, `martingale`, `score`, or `schoenfeld` residuals can be extracted. See Klein and Moeschberger (2003) for descriptions. The score residuals are returned as a matrix of the same dimension as the model matrix, with a "terms" attribute, which is a list indicating which model matrix columns belong to which model terms. The score residuals are scaled. For parametric terms this is by the standard deviation of associated model coefficient. For smooth terms the sub matrix of score residuals for the term is postmultiplied by the transposed Cholesky factor of the covariance matrix for the term's coefficients. This is a transformation that makes the coefficients approximately independent, as required to make plots of the score residuals against event time interpretable for checking the proportional hazards assumption (see Klein and Moeschberger, 2003, p376). Penalization causes drift in the score residuals, which is also removed, to allow the residuals to be approximately interpreted as unpenalized score residuals. Schoenfeld and score residuals are computed by strata. See the examples for simple PH assumption checks by plotting score residuals, and Klein and Moeschberger (2003, section 11.4) for details. Note that high correlation between terms can undermine these checks.

Estimation of model coefficients is by maximising the log-partial likelihood penalized by the smoothing penalties. See e.g. Hastie and Tibshirani, 1990, section 8.3. for the partial likelihood used (with Peto's approximation for ties), but note that optimization of the partial likelihood does not follow Hastie and Tibshirani. See Klein and Moeschberger (2003) for estimation of residuals, the cumulative baseline hazard, survival function and associated standard errors (the survival standard error expression has a typo).

The percentage deviance explained reported for Cox PH models is based on the sum of squares of the deviance residuals, as the model deviance, and the sum of squares of the deviance residuals when the covariate effects are set to zero, as the null deviance. The same baseline hazard estimate is used for both.

This family deals efficiently with the case in which each subject has one event/censoring time and one row of covariate values. For studies in which there are multiple time varying covariate measures for each subject then the equivalent Poisson model should be fitted to suitable pseudodata using `bam(..., discrete=TRUE)`. See [cox.ph](#).

**Value**

An object inheriting from class `general.family`.

plot(b,pages=1)
ph.resid(b) ## The checking plot picks up the problem in s(x2)

conditional logistic regression models are often estimated using the
cox proportional hazards partial likelihood with a strata for each
case-control group. A dummy vector of times is created (all equal).
The following compares to 'clogit' for a simple case. Note that
the gam log likelihood is not exact if there is more than one case
per stratum, corresponding to clogit's approximate method.
library(survival);library(mgcv)
infert$dumt <- rep(1,nrow(infert))
mg <- gam(cbind(dumt,stratum) ~ spontaneous + induced, data=infert,
 family=cox.ph,weights=case)
ms <- clogit(case ~ spontaneous + induced + strata(stratum), data=infert,
 method="approximate")
summary(mg)$p.table[1:2,]; ms

```

## Description

The `cox.ph` family only allows one set of covariate values per subject. If each subject has several time varying covariate measurements then it is still possible to fit a proportional hazards regression

model, via an equivalent Poisson model. The recipe is provided by Whitehead (1980) and is equally valid in the smooth additive case. Its drawback is that the equivalent Poisson dataset can be quite large.

The trick is to generate an artificial Poisson observation for each subject in the risk set at each non-censored event time. The corresponding covariate values for each subject are whatever they are at the event time, while the Poisson response is zero for all subjects except those experiencing the event at that time (this corresponds to Peto's correction for ties). The linear predictor for the model must include an intercept for each event time (the cumulative sum of the exponential of these is the Breslow estimate of the baseline hazard).

Below is some example code employing this trick for the `pbcsseq` data from the `survival` package. It uses `bam` for fitting with the `discrete=TRUE` option for efficiency: there is some approximation involved in doing this, and the exact equivalent to what is done in `cox.ph` is rather obtained by using `gam` with `method="REML"` (taking some 14 times the computational time for the example below).

The function `tdpois` in the example code uses crude piecewise constant interpolation for the covariates, in which the covariate value at an event time is taken to be whatever it was the previous time that it was measured. Obviously more sophisticated interpolation schemes might be preferable.

## Examples

```
require(mgcv);require(survival)

First define functions for producing Poisson model data frame

app <- function(x,t,to) {
 ## wrapper to approx for calling from apply...
 y <- if (sum(!is.na(x))<1) rep(NA,length(to)) else
 approx(t,x,to,method="constant",rule=2)$y
 if (is.factor(x)) factor(levels(x)[y],levels=levels(x)) else y
} ## app

tdpois <- function(dat,event="z",et="fuptime",t="day",status="status1",
 id="id") {
 ## dat is data frame. id is patient id; et is event time; t is
 ## observation time; status is 1 for death 0 otherwise;
 ## event is name for Poisson response.
 if (event %in% names(dat)) warning("event name in use")
 require(utils) ## for progress bar
 te <- sort(unique(dat[[et]][dat[[status]]==1])) ## event times
 sid <- unique(dat[[id]])
 inter <- interactive()
 if (inter) prg <- txtProgressBar(min = 0, max = length(sid), initial = 0,
 char = "=",width = NA, title="Progress", style = 3)
 ## create dataframe for poisson model data
 dat[[event]] <- 0; start <- 1
 dap <- dat[rep(1:length(sid),length(te)),]
 for (i in 1:length(sid)) { ## work through patients
 di <- dat[dat[[id]]==sid[i],] ## ith patient's data
 tr <- te[te <= di[[et]][1]] ## times required for this patient
```

```

Now do the interpolation of covariates to event times...
um <- data.frame(lapply(X=di,FUN=app,t=di[[t]],to=tr))
Mark the actual event...
if (um[[et]][1]==max(tr)&&um[[status]][1]==1) um[[event]][nrow(um)] <- 1
um[[et]] <- tr ## reset time to relevant event times
dap[start:(start-1+nrow(um)),] <- um ## copy to dap
start <- start + nrow(um)
if (inter) setTxtProgressBar(prg, i)
}
if (inter) close(prg)
dap[1:(start-1),]
} ## tdpois

The following typically takes a minute or less...

Convert pbcseq to equivalent Poisson form...
pbcseq$status1 <- as.numeric(pbcseq$status==2) ## death indicator
pb <- tdpois(pbcseq) ## conversion
pb$tf <- factor(pb$futime) ## add factor for event time

Fit Poisson model...
b <- bam(z ~ tf - 1 + sex + trt + s(sqrt(protime)) + s(platelet) + s(age) +
s(bili) + s(albumin), family=poisson, data=pb, discrete=TRUE, nthreads=2)

par(mfrow=c(2,3))
plot(b, scale=0)

compute residuals...
chaz <- tapply(fitted(b), pb$id, sum) ## cum haz by subject
d <- tapply(pbz, pbid, sum) ## censoring indicator
mrds <- d - chaz ## Martingale
drsd <- sign(mrds)*sqrt(-2*(mrds + d*log(chaz))) ## deviance

plot survivor function and s.e. band for subject 25
te <- sort(unique(pb$futime)) ## event times
di <- pbcseq[pbcseq$id==25,] ## data for subject 25
pd <- data.frame(lapply(X=di,FUN=app,t=di$day,to=te)) ## interpolate to te
pd$tf <- factor(te)
X <- predict(b, newdata=pd, type="lpmatrix")
eta <- drop(X%*%coef(b)); H <- cumsum(exp(eta))
J <- apply(exp(eta)*X, 2, cumsum)
se <- diag(J%*%vcov(b)%*%t(J))^0.5
plot(stepfun(te, c(1, exp(-H))), do.points=FALSE, ylim=c(0.7, 1),
 ylab="S(t)", xlab="t (days)", main="", lwd=2)
lines(stepfun(te, c(1, exp(-H+se))), do.points=FALSE)
lines(stepfun(te, c(1, exp(-H-se))), do.points=FALSE)

```

## Description

Uses splineDesign to set up the model matrix for a cyclic B-spline basis.

**Usage**

```
cSplineDes(x, knots, ord = 4, derivs=0)
```

**Arguments**

|                     |                                                                                                                          |
|---------------------|--------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>      | covariate values for smooth.                                                                                             |
| <code>knots</code>  | The knot locations: the range of these must include all the data.                                                        |
| <code>ord</code>    | order of the basis. 4 is a cubic spline basis. Must be >1.                                                               |
| <code>derivs</code> | order of derivative of the spline to evaluate, between 0 and <code>ord-1</code> . Recycled to length of <code>x</code> . |

**Details**

The routine is a wrapper that sets up a B-spline basis, where the basis functions wrap at the first and last knot locations.

**Value**

A matrix with `length(x)` rows and `length(knots)-1` columns.

**Author(s)**

**Examples**

```
require(mgcv)
create some x's and knots...
n <- 200
x <- 0:(n-1)/(n-1); k<- 0:5/5
X <- cSplineDes(x,k) ## cyclic spline design matrix
plot evaluated basis functions...
plot(x,X[,1],type="l"); for (i in 2:5) lines(x,X[,i],col=i)
check that the ends match up....
ee <- X[1,]-X[n,]; ee
tol <- .Machine$double.eps^.75
if (all.equal(ee,ee*0,tolerance=tol)!=TRUE)
 stop("cyclic spline ends don't match!")

similar with uneven data spacing...
x <- sort(runif(n)) + 1 ## sorting just makes end checking easy
k <- seq(min(x),max(x),length=8) ## create knots
X <- cSplineDes(x,k) ## get cyclic spline model matrix
plot(x,X[,1],type="l"); for (i in 2:ncol(X)) lines(x,X[,i],col=i)
ee <- X[1,]-X[n,]; ee ## do ends match??
tol <- .Machine$double.eps^.75
if (all.equal(ee,ee*0,tolerance=tol)!=TRUE)
 stop("cyclic spline ends don't match!")
```

dDeta

*Obtaining derivative w.r.t. linear predictor***Description**

INTERNAL function. Distribution families provide derivatives of the deviance and link w.r.t.  $\mu = \text{inv\_link}(\eta)$ . This routine converts these to the required derivatives of the deviance w.r.t.  $\eta$ , the linear predictor.

**Usage**

```
dDeta(y, mu, wt, theta, fam, deriv = 0)
```

**Arguments**

|                    |                                                                                                         |
|--------------------|---------------------------------------------------------------------------------------------------------|
| <code>y</code>     | vector of observations.                                                                                 |
| <code>mu</code>    | if $\eta$ is the linear predictor, $\mu = \text{inv\_link}(\eta)$ . In a traditional GAM $\mu = E(y)$ . |
| <code>wt</code>    | vector of weights.                                                                                      |
| <code>theta</code> | vector of family parameters that are not regression coefficients (e.g. scale parameters).               |
| <code>fam</code>   | the family object.                                                                                      |
| <code>deriv</code> | the order of derivative of the smoothing parameter score required.                                      |

**Value**

A list of derivatives.

**Author(s)**

Simon N. Wood <simon.wood@r-project.org>.

exclude.too.far

*Exclude prediction grid points too far from data***Description**

Takes two arrays defining the nodes of a grid over a 2D covariate space and two arrays defining the location of data in that space, and returns a logical vector with elements TRUE if the corresponding node is too far from data and FALSE otherwise. Basically a service routine for `vis.gam` and `plot.gam`.

**Usage**

```
exclude.too.far(g1, g2, d1, d2, dist)
```

**Arguments**

|                   |                                                                                                                                                                               |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>g1</code>   | co-ordinates of grid relative to first axis.                                                                                                                                  |
| <code>g2</code>   | co-ordinates of grid relative to second axis.                                                                                                                                 |
| <code>d1</code>   | co-ordinates of data relative to first axis.                                                                                                                                  |
| <code>d2</code>   | co-ordinates of data relative to second axis.                                                                                                                                 |
| <code>dist</code> | how far away counts as too far. Grid and data are first scaled so that the grid lies exactly in the unit square, and <code>dist</code> is a distance within this unit square. |

**Details**

Linear scalings of the axes are first determined so that the grid defined by the nodes in `g1` and `g2` lies exactly in the unit square (i.e. on  $[0,1]$  by  $[0,1]$ ). These scalings are applied to `g1`, `g2`, `d1` and `d2`. The minimum Euclidean distance from each node to a datum is then determined and if it is greater than `dist` the corresponding entry in the returned array is set to `TRUE` (otherwise to `FALSE`). The distance calculations are performed in compiled code for speed without storage overheads.

**Value**

A logical array with `TRUE` indicating a node in the grid defined by `g1`, `g2` that is ‘too far’ from any datum.

|                 |                                                              |
|-----------------|--------------------------------------------------------------|
| extract.lme.cov | <i>Extract the data covariance matrix from an lme object</i> |
|-----------------|--------------------------------------------------------------|

---

## Description

This is a service routine for [gamm](#). Extracts the estimated covariance matrix of the data from an `lme` object, allowing the user control about which levels of random effects to include in this calculation. `extract.lme.cov` forms the full matrix explicitly: `extract.lme.cov2` tries to be more economical than this.

## Usage

```
extract.lme.cov(b, data=NULL, start.level=1)
extract.lme.cov2(b, data=NULL, start.level=1)
```

## Arguments

|                          |                                                                                                                                                                                                                     |
|--------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>b</code>           | A fitted model object returned by a call to <a href="#">lme</a> .                                                                                                                                                   |
| <code>data</code>        | The data frame/ model frame that was supplied to <a href="#">lme</a> , but with any rows removed by the na action dropped. Uses the data stored in the model object if not supplied.                                |
| <code>start.level</code> | The level of nesting at which to start including random effects in the calculation. This is used to allow smooth terms to be estimated as random effects, but treated like fixed effects for variance calculations. |

## Details

The random effects, correlation structure and variance structure used for a linear mixed model combine to imply a covariance matrix for the response data being modelled. These routines extract that covariance matrix. The process is slightly complicated, because different components of the fitted model object are stored in different orders (see function code for details!).

The `extract.lme.cov` calculation is not optimally efficient, since it forms the full matrix, which may in fact be sparse. `extract.lme.cov2` is more efficient. If the covariance matrix is diagonal, then only the leading diagonal is returned; if it can be written as a block diagonal matrix (under some permutation of the original data) then a list of matrices defining the non-zero blocks is returned along with an index indicating which row of the original data each row/column of the block diagonal matrix relates to. The block sizes are defined by the coarsest level of grouping in the random effect structure.

[gamm](#) uses `extract.lme.cov2`.

`extract.lme.cov` does not currently deal with the situation in which the grouping factors for a correlation structure are finer than those for the random effects. `extract.lme.cov2` does deal with this situation.

## Value

For `extract.lme.cov` an estimated covariance matrix.

For `extract.lme.cov2` a list containing the estimated covariance matrix and an indexing array. The covariance matrix is stored as the elements on the leading diagonal, a list of the matrices defining a block diagonal matrix, or a full matrix if the previous two options are not possible.

family.mgcv

*Distribution families in mgcv*

---

**Description**

As well as the standard families documented in [family](#) (see also [glm](#)) which can be used with functions [gam](#), [bam](#) and [gamm](#), [mgcv](#) also supplies some extra families, most of which are currently only usable with [gam](#), although some can also be used with [bam](#). These are described here.

**Details**

The following families are in the exponential family given the value of a single parameter. They are usable with all modelling functions.

- [Tweedie](#) An exponential family distribution for which the variance of the response is given by the mean response to the power  $p$ .  $p$  is in (1,2) and must be supplied. Alternatively, see [tw](#) to estimate  $p$  ([gam](#) only).
- [negbin](#) The negative binomial. Alternatively see [nb](#) to estimate the  $\theta$  parameter of the negative binomial ([gam](#) only).

The following families are for regression type models dependent on a single linear predictor, and with a log likelihood which is a sum of independent terms, each corresponding to a single response observation. Usable with `gam`, with smoothing parameter estimation by "REML" or "ML" (the latter does not integrate the unpenalized and parametric effects out of the marginal likelihood optimized for the smoothing parameters). Also usable with `bam`.

- `ocat` for ordered categorical data.
- `tw` for Tweedie distributed data, when the power parameter relating the variance to the mean is to be estimated.
- `nb` for negative binomial data when the `theta` parameter is to be estimated.
- `betar` for proportions data on (0,1) when the binomial is not appropriate.
- `scat` scaled t for heavy tailed data that would otherwise be modelled as Gaussian.
- `zip` for zero inflated Poisson data, when the zero inflation rate depends simply on the Poisson mean.

The following families implement more general model classes. Usable only with `gam` and only with REML smoothing parameter estimation.

- `cox.ph` the Cox Proportional Hazards model for survival data.
- `gammals` a gamma location-scale model, where the mean and standard deviation are modelled with separate linear predictors.
- `gaulss` a Gaussian location-scale model where the mean and the standard deviation are both modelled using smooth linear predictors.
- `gevlss` a generalized extreme value (GEV) model where the location, scale and shape parameters are each modelled using a linear predictor.
- `gumb1s` a Gumbel location-scale model (2 linear predictors).
- `shash` Sinh-arcsinh location scale and shape model family (4 linear predictors).
- `zip1ss` a 'two-stage' zero inflated Poisson model, in which 'potential-presence' is modelled with one linear predictor, and Poisson mean abundance given potential presence is modelled with a second linear predictor.
- `mvn`: multivariate normal additive models.
- `multinom`: multinomial logistic regression, for unordered categorical responses.

FFdes(5,TRUE)
```

fix.family.link

*Modify families for use in GAM fitting and checking***Description**

Generalized Additive Model fitting by ‘outer’ iteration, requires extra derivatives of the variance and link functions to be added to family objects. The first 3 functions add what is needed. Model checking can be aided by adding quantile and random deviate generating functions to the family. The final two functions do this.

## Usage

```
fix.family.link(fam)
fix.family.var(fam)
fix.family.ls(fam)
fix.family.qf(fam)
fix.family.rd(fam)
```

## Arguments

fam                      A family.

## Details

Consider the first 3 function first.

Outer iteration GAM estimation requires derivatives of the GCV, UBRE/gAIC, GACV, REML or ML score, which are obtained by finding the derivatives of the model coefficients w.r.t. the log smoothing parameters, using the implicit function theorem. The expressions for the derivatives require the second and third derivatives of the link w.r.t. the mean (and the 4th derivatives if Fisher scoring is not used). Also required are the first and second derivatives of the variance function w.r.t. the mean (plus the third derivative if Fisher scoring is not used). Finally REML or ML estimation of smoothing parameters requires the log saturated likelihood and its first two derivatives w.r.t. the scale parameter. These functions add functions evaluating these quantities to a family.

If the family already has functions `dvar`, `d2var`, `d3var`, `d2link`, `d3link`, `d4link` and for RE/ML `ls`, then these functions simply return the family unmodified: this allows non-standard links to be used with `gam` when using outer iteration (performance iteration operates with unmodified families). Note that if you only need Fisher scoring then `d4link` and `d3var` can be dummy, as they are ignored. Similarly `ls` is only needed for RE/ML.

The `dvar` function is a function of a mean vector, `mu`, and returns a vector of corresponding first derivatives of the family variance function. The `d2link` function is also a function of a vector of mean values, `mu`: it returns a vector of second derivatives of the link, evaluated at `mu`. Higher derivatives are defined similarly.

If modifying your own family, note that you can often get away with supplying only a `dvar` and `d2var`, function if your family only requires links that occur in one of the standard families.

The second two functions are useful for investigating the distribution of residuals and are used by `qq.gam`. If possible the functions add quantile (`qf`) or random deviate (`rd`) generating functions to the family. If a family already has `qf` or `rd` functions then it is left unmodified. `qf` functions are only available for some families, and for quasi families neither type of function is available.

## Value

A family object with extra component functions `dvar`, `d2var`, `d2link`, `d3link`, `d4link`, `ls`, and possibly `qf` and `rd`, depending on which functions are called. `fix.family.var` also adds a variable `scale` set to negative to indicate that family has a free scale parameter.

fixDependence

---

*Detect linear dependencies of one matrix on another*

---

## Description

Identifies columns of a matrix `X2` which are linearly dependent on columns of a matrix `X1`. Primarily of use in setting up identifiability constraints for nested GAMs.

## Usage

```
fixDependence(X1, X2, tol=.Machine$double.eps^.5, rank.def=0, strict=FALSE)
```

## Arguments

|                       |                                                                                                                                                                                                                                                    |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>X1</code>       | A matrix.                                                                                                                                                                                                                                          |
| <code>X2</code>       | A matrix, the columns of which may be partially linearly dependent on the columns of <code>X1</code> .                                                                                                                                             |
| <code>tol</code>      | The tolerance to use when assessing linear dependence.                                                                                                                                                                                             |
| <code>rank.def</code> | If the degree of rank deficiency in <code>X2</code> , given <code>X1</code> , is known, then it can be supplied here, and <code>tol</code> is then ignored. Unused unless positive and not greater than the number of columns in <code>X2</code> . |
| <code>strict</code>   | if <code>TRUE</code> then only columns individually dependent on <code>X1</code> are detected, if <code>FALSE</code> then enough columns to make the reduced <code>X2</code> full rank and independent of <code>X1</code> are detected.            |

## Details

The algorithm uses a simple approach based on QR decomposition: see Wood (2017, section 5.6.3) for details.

## Value

A vector of the columns of `X2` which are linearly dependent on columns of `X1` (or which need to be deleted to achieve independence and full rank if `strict==FALSE`). `NULL` if the two matrices are independent.

## Description

Description of [gam](#) formula (see Details), and how to extract it from a fitted gam object.

## Usage

```
S3 method for class 'gam'
formula(x, ...)
```

## Arguments

|     |                                                                                                        |
|-----|--------------------------------------------------------------------------------------------------------|
| x   | fitted model objects of class gam (see <a href="#">gamObject</a> ) as produced by <code>gam()</code> . |
| ... | un-used in this case                                                                                   |

## Details

[gam](#) will accept a formula or, with some families, a list of formulae. Other `mgcv` modelling functions will not accept a list. The list form provides a mechanism for specifying several linear predictors, and allows these to share terms: see below.

The formulae supplied to [gam](#) are exactly like those supplied to [glm](#) except that smooth terms, [s](#), [te](#), [ti](#) and [t2](#) can be added to the right hand side (and [.](#) is not supported in gam formulae).

Smooth terms are specified by expressions of the form:

```
s(x1, x2, ..., k=12, fx=FALSE, bs="tp", by=z, id=1)
```

where `x1`, `x2`, etc. are the covariates which the smooth is a function of, and `k` is the dimension of the basis used to represent the smooth term. If `k` is not specified then basis specific defaults are used. Note that these defaults are essentially arbitrary, and it is important to check that they are not so small that they cause oversmoothing (too large just slows down computation). Sometimes the modelling context suggests sensible values for `k`, but if not informal checking is easy: see [choose.k](#) and [gam.check](#).

`fx` is used to indicate whether or not this term should be unpenalized, and therefore have a fixed number of degrees of freedom set by `k` (almost always `k-1`). `bs` indicates the basis to use for the smooth: the built in options are described in [smooth.terms](#), and user defined smooths can be added (see [user.defined.smooth](#)). If `bs` is not supplied then the default "tp" ([tprs](#)) basis is used. `by` can be used to specify a variable by which the smooth should be multiplied. For example `gam(y~s(x, by=z))` would specify a model  $E(y) = f(x)z$  where  $f(\cdot)$  is a smooth function. The `by` option is particularly useful for models in which different functions of the same variable are required for each level of a factor and for 'varying coefficient models': see [gam.models](#). `id`

is used to give smooths identities: smooths with the same identity have the same basis, penalty and smoothing parameter (but different coefficients, so they are different functions).

An alternative for specifying smooths of more than one covariate is e.g.:

```
te(x, z, bs=c("tp", "tp"), m=c(2, 3), k=c(5, 10))
```

which would specify a tensor product smooth of the two covariates  $x$  and  $z$  constructed from marginal t.p.r.s. bases of dimension 5 and 10 with marginal penalties of order 2 and 3. Any combination of basis types is possible, as is any number of covariates. `te` provides further information. `ti` terms are a variant designed to be used as interaction terms when the main effects (and any lower order interactions) are present. `t2` produces tensor product smooths that are the natural low rank analogue of smoothing spline anova models.

`s`, `te`, `ti` and `t2` terms accept an `sp` argument of supplied smoothing parameters: positive values are taken as fixed values to be used, negative to indicate that the parameter should be estimated. If `sp` is supplied then it over-rides whatever is in the `sp` argument to `gam`, if it is not supplied then it defaults to all negative, but does not over-ride the `sp` argument to `gam`.

Formulae can involve nested or “overlapping” terms such as

```
y~s(x)+s(z)+s(x, z) or y~s(x, z)+s(z, v)
```

but nested models should really be set up using `ti` terms: see `gam.side` for further details and examples.

Smooth terms in a `gam` formula will accept matrix arguments as covariates (and corresponding by variable), in which case a ‘summation convention’ is invoked. Consider the example of `s(X, Z, by=L)` where  $X$ ,  $Z$  and  $L$  are  $n$  by  $m$  matrices. Let  $F$  be the  $n$  by  $m$  matrix that results from evaluating the smooth at the values in  $X$  and  $Z$ . Then the contribution to the linear predictor from the term will be `rowSums(F*L)` (note the element-wise multiplication). This convention allows the linear predictor of the GAM to depend on (a discrete approximation to) any linear functional of a smooth: see `linear.functional.terms` for more information and examples (including functional linear models/signal regression).

Note that `gam` allows any term in the model formula to be penalized (possibly by multiple penalties), via the `paraPen` argument. See `gam.models` for details and example code.

When several formulae are provided in a list, then they can be used to specify multiple linear predictors for families for which this makes sense (e.g. `mvn`). The first formula in the list must include a response variable, but later formulae need not (depending on the requirements of the family). Let the linear predictors be indexed, 1 to  $d$  where  $d$  is the number of linear predictors, and the indexing is in the order in which the formulae appear in the list. It is possible to supply extra formulae specifying that several linear predictors should share some terms. To do this a formula is supplied in which the response is replaced by numbers specifying the indices of the linear predictors which will share the terms specified on the r.h.s. For example `1+3~s(x)+z-1` specifies that linear predictors 1 and 3 will share the terms `s(x)` and `z` (but we don’t want an extra intercept, as this would usually be unidentifiable). Note that it is possible that a linear predictor only includes shared terms: it must still have its own formula, but the r.h.s. would simply be `-1` (e.g. `y ~ -1` or `~ -1`).

## Value

Returns the model formula, `x$formula`. Provided so that `anova` methods print an appropriate description of the model.

## WARNING

A `gam` formula should not refer to variables using e.g. `dat[["x"]]`.

formXtViX

*Form component of GAMM covariance matrix***Description**

This is a service routine for [gamm](#). Given,  $V$ , an estimated covariance matrix obtained using [extract.lme.cov2](#) this routine forms a matrix square root of  $X^T V^{-1} X$  as efficiently as possible, given the structure of  $V$  (usually sparse).

**Usage**

```
formXtViX(V, X)
```

**Arguments**

|     |                                                                              |
|-----|------------------------------------------------------------------------------|
| $V$ | A data covariance matrix list returned from <a href="#">extract.lme.cov2</a> |
| $X$ | A model matrix.                                                              |

**Details**

The covariance matrix returned by [extract.lme.cov2](#) may be in a packed and re-ordered format, since it is usually sparse. Hence a special service routine is required to form the required products involving this matrix.

**Value**

A matrix,  $R$  such that `crossprod(R)` gives  $X^T V^{-1} X$ .

|---------|--------------------------------|
| fs.test | <i>FELSPLINE test function</i> |
|---------|--------------------------------|

---

## Description

Implements a finite area test function based on one proposed by Tim Ramsay (2002).

## Usage

```
fs.test(x, y, r0=.1, r=.5, l=3, b=1, exclude=TRUE)
fs.boundary(r0=.1, r=.5, l=3, n.theta=20)
```

## Arguments

|                      |                                                                                                                           |
|----------------------|---------------------------------------------------------------------------------------------------------------------------|
| <code>x, y</code>    | Points at which to evaluate the test function.                                                                            |
| <code>r0</code>      | The test domain is a sort of bent sausage. This is the radius of the inner bend                                           |
| <code>r</code>       | The radius of the curve at the centre of the sausage.                                                                     |
| <code>l</code>       | The length of an arm of the sausage.                                                                                      |
| <code>b</code>       | The rate at which the function increases per unit increase in distance along the centre line of the sausage.              |
| <code>exclude</code> | Should exterior points be set to NA?                                                                                      |
| <code>n.theta</code> | How many points to use in a piecewise linear representation of a quarter of a circle, when generating the boundary curve. |

## Details

The function details are not given in the source article: but this is pretty close. The function is modified from Ramsay (2002), in that it bulges, rather than being flat: this makes a better test of the smoother.

## Value

`fs.test` returns function evaluations, or NAs for points outside the boundary. `fs.boundary` returns a list of `x, y` points to be jointed up in order to define/draw the boundary.

## Examples

```
require(mgcv)
plot the function, and its boundary...
fsb <- fs.boundary()
m<-300;n<-150
xm <- seq(-1,4,length=m);yn<-seq(-1,1,length=n)
xx <- rep(xm,n);yy<-rep(yn,rep(m,n))
tru <- matrix(fs.test(xx,yy),m,n) ## truth
image(xm,yn,tru,col=heat.colors(100),xlab="x",ylab="y")
lines(fsbx,fsby,lwd=3)
contour(xm,yn,tru,levels=seq(-5,5,by=.25),add=TRUE)
```

---

full.score

*GCV/UBRE score for use within nlm*

---

## Description

Evaluates GCV/UBRE score for a GAM, given smoothing parameters. The routine calls `gam.fit` to fit the model, and is usually called by `nlm` to optimize the smoothing parameters.

This is basically a service routine for `gam`, and is not usually called directly by users. It is only used in this context for GAMs fitted by outer iteration (see `gam.outer`) when the the outer method is "nlm.fd" (see `gam` argument `optimizer`).

## Usage

```
full.score(sp,G,family,control,gamma,...)
```

## Arguments

|                      |                                                                     |
|----------------------|---------------------------------------------------------------------|
| <code>sp</code>      | The logs of the smoothing parameters                                |
| <code>G</code>       | a list returned by <code>mgcv:::gam.setup</code>                    |
| <code>family</code>  | The family object for the GAM.                                      |
| <code>control</code> | a list returned by <code>gam.control</code>                         |
| <code>gamma</code>   | the degrees of freedom inflation factor (usually 1).                |
| <code>...</code>     | other arguments, typically for passing on to <code>gam.fit</code> . |

## Value

The value of the GCV/UBRE score, with attribute "full.gam.object" which is the full object returned by `gam.fit`.

## Author(s)

Simon N. Wood <simon.wood@r-project.org>

## Description

Fits a generalized additive model (GAM) to data, the term ‘GAM’ being taken to include any quadratically penalized GLM and a variety of other models estimated by a quadratically penalised likelihood type approach (see [family.mgcv](#)). The degree of smoothness of model terms is estimated as part of fitting. `gam` can also fit any GLM subject to multiple quadratic penalties (including estimation of degree of penalization). Confidence/credible intervals are readily available for any quantity predicted using a fitted model.

Smooth terms are represented using penalized regression splines (or similar smoothers) with smoothing parameters selected by GCV/UBRE/AIC/REML or by regression splines with fixed degrees of freedom (mixtures of the two are permitted). Multi-dimensional smooths are available using penalized thin plate regression splines (isotropic) or tensor product splines (when an isotropic smooth is inappropriate), and users can add smooths. Linear functionals of smooths can also be included in models. For an overview of the smooths available see [smooth.terms](#). For more on specifying models see [gam.models](#), [random.effects](#) and [linear.functional.terms](#). For more on model selection see [gam.selection](#). Do read [gam.check](#) and [choose.k](#).

See package `gam`, for GAMs via the original Hastie and Tibshirani approach (see details for differences to this implementation).

For very large datasets see [bam](#), for mixed GAM see [gamm](#) and [random.effects](#).

## Usage

```
gam(formula, family=gaussian(), data=list(), weights=NULL, subset=NULL,
 na.action, offset=NULL, method="GCV.Cp",
 optimizer=c("outer", "newton"), control=list(), scale=0,
 select=FALSE, knots=NULL, sp=NULL, min.sp=NULL, H=NULL, gamma=1,
 fit=TRUE, paraPen=NULL, G=NULL, in.out, drop.unused.levels=TRUE,
 drop.intercept=NULL, discrete=FALSE, ...)
```

## Arguments

- |         |                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|---------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| formula | A GAM formula, or a list of formulae (see <a href="#">formula.gam</a> and also <a href="#">gam.models</a> ). These are exactly like the formula for a GLM except that smooth terms, <code>s</code> , <code>te</code> , <code>ti</code> and <code>t2</code> , can be added to the right hand side to specify that the linear predictor depends on smooth functions of predictors (or linear functionals of these).                           |
| family  | This is a family object specifying the distribution and link to use in fitting etc (see <a href="#">glm</a> and <a href="#">family</a> ). See <a href="#">family.mgcv</a> for a full list of what is available, which goes well beyond exponential family. Note that <code>quasi</code> families actually result in the use of extended quasi-likelihood if <code>method</code> is set to a RE/ML method (McCullagh and Nelder, 1989, 9.6). |
| data    | A data frame or list containing the model response variable and covariates required by the formula. By default the variables are taken from <code>environment(formula)</code> : typically the environment from which <code>gam</code> is called.                                                                                                                                                                                            |

|                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>weights</code>   | prior weights on the contribution of the data to the log likelihood. Note that a weight of 2, for example, is equivalent to having made exactly the same observation twice. If you want to re-weight the contributions of each datum without changing the overall magnitude of the log likelihood, then you should normalize the weights (e.g. <code>weights &lt;- weights/mean(weights)</code> ).                                                                                                                                                                                 |
| <code>subset</code>    | an optional vector specifying a subset of observations to be used in the fitting process.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <code>na.action</code> | a function which indicates what should happen when the data contain 'NA's. The default is set by the 'na.action' setting of 'options', and is 'na.fail' if that is unset. The "factory-fresh" default is 'na.omit'.                                                                                                                                                                                                                                                                                                                                                                |
| <code>offset</code>    | Can be used to supply a model offset for use in fitting. Note that this offset will always be completely ignored when predicting, unlike an offset included in <code>formula</code> (this used to conform to the behaviour of <code>lm</code> and <code>glm</code> ).                                                                                                                                                                                                                                                                                                              |
| <code>control</code>   | A list of fit control parameters to replace defaults returned by <code>gam.control</code> . Values not set assume default values.                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <code>method</code>    | The smoothing parameter estimation method. "GCV.Cp" to use GCV for unknown scale parameter and Mallows' Cp/UBRE/AIC for known scale. "GACV.Cp" is equivalent, but using GACV in place of GCV. "REML" for REML estimation, including of unknown scale, "P-REML" for REML estimation, but using a Pearson estimate of the scale. "ML" and "P-ML" are similar, but using maximum likelihood in place of REML. Beyond the exponential family "REML" is the default, and the only other option is "ML".                                                                                 |
| <code>optimizer</code> | An array specifying the numerical optimization method to use to optimize the smoothing parameter estimation criterion (given by <code>method</code> ). "perf" (deprecated) for performance iteration. "outer" for the more stable direct approach. "outer" can use several alternative optimizers, specified in the second element of <code>optimizer</code> : "newton" (default), "bfgs", "optim", "nlm" and "nlm.fd" (the latter is based entirely on finite differenced derivatives and is very slow). "efs" for the extended Fellner Schall method of Wood and Fasiolo (2017). |
| <code>scale</code>     | If this is positive then it is taken as the known scale parameter. Negative signals that the scale parameter is unknown. 0 signals that the scale parameter is 1 for Poisson and binomial and unknown otherwise. Note that (RE)ML methods can only work with scale parameter 1 for the Poisson and binomial cases.                                                                                                                                                                                                                                                                 |
| <code>select</code>    | If this is TRUE then <code>gam</code> can add an extra penalty to each term so that it can be penalized to zero. This means that the smoothing parameter estimation that is part of fitting can completely remove terms from the model. If the corresponding smoothing parameter is estimated as zero then the extra penalty has no effect. Use <code>gamma</code> to increase level of penalization.                                                                                                                                                                              |
| <code>knots</code>     | this is an optional list containing user specified knot values to be used for basis construction. For most bases the user simply supplies the knots to be used, which must match up with the <code>k</code> value supplied (note that the number of knots is not always just <code>k</code> ). See <code>tp<sub>rs</sub></code> for what happens in the "tp"/"ts" case. Different terms can use different numbers of knots, unless they share a covariate.                                                                                                                         |
| <code>sp</code>        | A vector of smoothing parameters can be provided here. Smoothing parameters must be supplied in the order that the smooth terms appear in the model formula. Negative elements indicate that the parameter should be estimated, and hence a mixture of fixed and estimated parameters is possible. If smooths share smoothing parameters then <code>length(sp)</code> must correspond to the number of underlying smoothing parameters.                                                                                                                                            |

|                                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|---------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>min.sp</code>             | Lower bounds can be supplied for the smoothing parameters. Note that if this option is used then the smoothing parameters <code>full.sp</code> , in the returned object, will need to be added to what is supplied here to get the smoothing parameters actually multiplying the penalties. <code>length(min.sp)</code> should always be the same as the total number of penalties (so it may be longer than <code>sp</code> , if smooths share smoothing parameters).                                            |
| <code>H</code>                  | A user supplied fixed quadratic penalty on the parameters of the GAM can be supplied, with this as its coefficient matrix. A common use of this term is to add a ridge penalty to the parameters of the GAM in circumstances in which the model is close to un-identifiable on the scale of the linear predictor, but perfectly well defined on the response scale.                                                                                                                                               |
| <code>gamma</code>              | Increase this beyond 1 to produce smoother models. <code>gamma</code> multiplies the effective degrees of freedom in the GCV or UBRE/AIC. <code>coden/gamma</code> can be viewed as an effective sample size in the GCV score, and this also enables it to be used with REML/ML. Ignored with P-RE/ML or the <code>efs</code> optimizer.                                                                                                                                                                          |
| <code>fit</code>                | If this argument is <code>TRUE</code> then <code>gam</code> sets up the model and fits it, but if it is <code>FALSE</code> then the model is set up and an object <code>G</code> containing what would be required to fit is returned. See argument <code>G</code> .                                                                                                                                                                                                                                              |
| <code>paraPen</code>            | optional list specifying any penalties to be applied to parametric model terms. <a href="#">gam.models</a> explains more.                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>G</code>                  | Usually <code>NULL</code> , but may contain the object returned by a previous call to <code>gam</code> with <code>fit=FALSE</code> , in which case all other arguments are ignored except for <code>sp</code> , <code>gamma</code> , <code>in.out</code> , <code>scale</code> , <code>control</code> , <code>method</code> <code>optimizer</code> and <code>fit</code> .                                                                                                                                          |
| <code>in.out</code>             | optional list for initializing outer iteration. If supplied then this must contain two elements: <code>sp</code> should be an array of initialization values for all smoothing parameters (there must be a value for all smoothing parameters, whether fixed or to be estimated, but those for fixed s.p.s are not used); <code>scale</code> is the typical scale of the GCV/UBRE function, for passing to the outer optimizer, or the initial value of the scale parameter, if this is to be estimated by RE/ML. |
| <code>drop.unused.levels</code> | by default unused levels are dropped from factors before fitting. For some smooths involving factor variables you might want to turn this off. Only do so if you know what you are doing.                                                                                                                                                                                                                                                                                                                         |
| <code>drop.intercept</code>     | Set to <code>TRUE</code> to force the model to really not have the a constant in the parametric model part, even with factor variables present. Can be vector when <code>formula</code> is a list.                                                                                                                                                                                                                                                                                                                |
| <code>discrete</code>           | experimental option for setting up models for use with discrete methods employed in <a href="#">bam</a> . Do not modify.                                                                                                                                                                                                                                                                                                                                                                                          |
| <code>...</code>                | further arguments for passing on e.g. to <code>gam.fit</code> (such as <code>mustart</code> ).                                                                                                                                                                                                                                                                                                                                                                                                                    |

## Details

A generalized additive model (GAM) is a generalized linear model (GLM) in which the linear predictor is given by a user specified sum of smooth functions of the covariates plus a conventional parametric component of the linear predictor. A simple example is:

$$\log(E(y_i)) = \alpha + f_1(x_{1i}) + f_2(x_{2i})$$

where the (independent) response variables  $y_i \sim \text{Poi}$ , and  $f_1$  and  $f_2$  are smooth functions of covariates  $x_1$  and  $x_2$ . The log is an example of a link function. Note that to be identifiable the model

requires constraints on the smooth functions. By default these are imposed automatically and require that the function sums to zero over the observed covariate values (the presence of a metric by variable is the only case which usually suppresses this).

If absolutely any smooth functions were allowed in model fitting then maximum likelihood estimation of such models would invariably result in complex over-fitting estimates of  $f_1$  and  $f_2$ . For this reason the models are usually fit by penalized likelihood maximization, in which the model (negative log) likelihood is modified by the addition of a penalty for each smooth function, penalizing its ‘wiggleness’. To control the trade-off between penalizing wiggleness and penalizing badness of fit each penalty is multiplied by an associated smoothing parameter: how to estimate these parameters, and how to practically represent the smooth functions are the main statistical questions introduced by moving from GLMs to GAMs.

The `mgcv` implementation of `gam` represents the smooth functions using penalized regression splines, and by default uses basis functions for these splines that are designed to be optimal, given the number basis functions used. The smooth terms can be functions of any number of covariates and the user has some control over how smoothness of the functions is measured.

`gam` in `mgcv` solves the smoothing parameter estimation problem by using the Generalized Cross Validation (GCV) criterion

$$nD/(n - DoF)^2$$

or an Un-Biased Risk Estimator (UBRE) criterion

$$D/n + 2sDoF/n - s$$

where  $D$  is the deviance,  $n$  the number of data,  $s$  the scale parameter and  $DoF$  the effective degrees of freedom of the model. Notice that UBRE is effectively just AIC rescaled, but is only used when  $s$  is known.

Alternatives are GACV, or a Laplace approximation to REML. There is some evidence that the latter may actually be the most effective choice. The main computational challenge solved by the `mgcv` package is to optimize the smoothness selection criteria efficiently and reliably.

Broadly `gam` works by first constructing basis functions and one or more quadratic penalty coefficient matrices for each smooth term in the model formula, obtaining a model matrix for the strictly parametric part of the model formula, and combining these to obtain a complete model matrix (design matrix) and a set of penalty matrices for the smooth terms. The linear identifiability constraints are also obtained at this point. The model is fit using `gam.fit`, `gam.fit3` or variants, which are modifications of `glm.fit`. The GAM penalized likelihood maximization problem is solved by Penalized Iteratively Re-weighted Least Squares (P-IRLS) (see e.g. Wood 2000). Smoothing parameter selection is possible in one of two ways. (i) ‘Performance iteration’ uses the fact that at each P-IRLS step a working penalized linear model is estimated, and the smoothing parameter estimation can be performed for each such working model. Eventually, in most cases, both model parameter estimates and smoothing parameter estimates converge. This option is available in `bam` and `gamm` but is deprecated for `gam` (ii) Alternatively the P-IRLS scheme is iterated to convergence for each trial set of smoothing parameters, and GCV, UBRE or REML scores are only evaluated on convergence - optimization is then ‘outer’ to the P-IRLS loop: in this case the P-IRLS iteration has to be differentiated, to facilitate optimization, and `gam.fit3` or one of its variants is used in place of `gam.fit`. `gam` uses the second method, outer iteration.

Several alternative basis-penalty types are built in for representing model smooths, but alternatives can easily be added (see `smooth.terms` for an overview and `smooth.construct` for how to add smooth classes). The choice of the basis dimension ( $k$  in the `s`, `te`, `ti` and `t2` terms) is something that should be considered carefully (the exact value is not critical, but it is important not to make it restrictively small, nor very large and computationally costly). The basis should be chosen to be larger than is believed to be necessary to approximate the smooth function concerned. The effective degrees of freedom for the smooth will then be controlled by the smoothing penalty

on the term, and (usually) selected automatically (with an upper limit set by  $k-1$  or occasionally  $k$ ). Of course the  $k$  should not be made too large, or computation will be slow (or in extreme cases there will be more coefficients to estimate than there are data).

Note that `gam` assumes a very inclusive definition of what counts as a GAM: basically any penalized GLM can be used: to this end `gam` allows the non smooth model components to be penalized via argument `paraPen` and allows the linear predictor to depend on general linear functionals of smooths, via the summation convention mechanism described in [linear.functional.terms](#). `link{family.mgcv}` details what is available beyond GLMs and the exponential family.

Details of the default underlying fitting methods are given in Wood (2011 and 2004). Some alternative methods are discussed in Wood (2000 and 2006).

`gam()` is not a clone of Trevor Hastie's original (as supplied in S-PLUS or package `gam`). The major differences are (i) that by default estimation of the degree of smoothness of model terms is part of model fitting, (ii) a Bayesian approach to variance estimation is employed that makes for easier confidence interval calculation (with good coverage probabilities), (iii) that the model can depend on any (bounded) linear functional of smooth terms, (iv) the parametric part of the model can be penalized, (v) simple random effects can be incorporated, and (vi) the facilities for incorporating smooths of more than one variable are different: specifically there are no `lo` smooths, but instead (a) `s` terms can have more than one argument, implying an isotropic smooth and (b) `te`, `ti` or `t2` smooths are provided as an effective means for modelling smooth interactions of any number of variables via scale invariant tensor product smooths. Splines on the sphere, Duchon splines and Gaussian Markov Random Fields are also available. (vii) Models beyond the exponential family are available. See package `gam`, for GAMs via the original Hastie and Tibshirani approach.

## Value

If `fit=FALSE` the function returns a list `G` of items needed to fit a GAM, but doesn't actually fit it. Otherwise the function returns an object of class `"gam"` as described in [gamObject](#).

## WARNINGS

The default basis dimensions used for smooth terms are essentially arbitrary, and it should be checked that they are not too small. See [choose.k](#) and [gam.check](#).

You must have more unique combinations of covariates than the model has total parameters. (Total parameters is sum of basis dimensions plus sum of non-spline terms less the number of spline terms).

Automatic smoothing parameter selection is not likely to work well when fitting models to very few response data.

For data with many zeroes clustered together in the covariate space it is quite easy to set up GAMs which suffer from identifiability problems, particularly when using Poisson or binomial families. The problem is that with e.g. log or logit links, mean value zero corresponds to an infinite range on the linear predictor scale.

## Author(s)

Simon N. Wood <[simon.wood@r-project.org](mailto:simon.wood@r-project.org)>

Front end design inspired by the `S` function of the same name based on the work of Hastie and Tibshirani (1990). Underlying methods owe much to the work of Wahba (e.g. 1990) and Gu (e.g. 2002).

gam.check

*Some diagnostics for a fitted gam model*

## Description

Takes a fitted `gam` object produced by `gam()` and produces some diagnostic information about the fitting procedure and results. The default is to produce 4 residual plots, some information about the convergence of the smoothness selection optimization, and to run diagnostic tests of whether the basis dimension choices are adequate. Care should be taken in interpreting the results when applied to `gam` objects returned by [gamm](#).

## Usage

```
gam.check(b, old.style=FALSE,
 type=c("deviance","pearson","response"),
 k.sample=5000,k.rep=200,
 rep=0, level=.9, rl.col=2, rep.col="gray80", ...)
```

## Arguments

|                        |                                                                           |
|------------------------|---------------------------------------------------------------------------|
| <code>b</code>         | a fitted <code>gam</code> object as produced by <a href="#">gam()</a> .   |
| <code>old.style</code> | If you want old fashioned plots, exactly as in Wood, 2006, set to TRUE.   |
| <code>type</code>      | type of residuals, see <a href="#">residuals.gam</a> , used in all plots. |
| <code>k.sample</code>  | Above this <code>k</code> testing uses a random sub-sample of data.       |

```

k.rep how many re-shuffles to do to get p-value for k testing.
rep, level, rl.col, rep.col
 arguments passed to qq.gam() when old.style is false, see there.
... extra graphics parameters to pass to plotting functions.

```

## Details

Checking a fitted `gam` is like checking a fitted `glm`, with two main differences. Firstly, the basis dimensions used for smooth terms need to be checked, to ensure that they are not so small that they force oversmoothing: the defaults are arbitrary. `choose.k` provides more detail, but the diagnostic tests described below and reported by this function may also help. Secondly, fitting may not always be as robust to violation of the distributional assumptions as would be the case for a regular GLM, so slightly more care may be needed here. In particular, the theory of quasi-likelihood implies that if the mean variance relationship is OK for a GLM, then other departures from the assumed distribution are not problematic: GAMs can sometimes be more sensitive. For example, un-modelled overdispersion will typically lead to overfit, as the smoothness selection criterion tries to reduce the scale parameter to the one specified. Similarly, it is not clear how sensitive REML and ML smoothness selection will be to deviations from the assumed response distribution. For these reasons this routine uses an enhanced residual QQ plot.

This function plots 4 standard diagnostic plots, some smoothing parameter estimation convergence information and the results of tests which may indicate if the smoothing basis dimension for a term is too low.

Usually the 4 plots are various residual plots. For the default optimization methods the convergence information is summarized in a readable way, but for other optimization methods, whatever is returned by way of convergence diagnostics is simply printed.

The test of whether the basis dimension for a smooth is adequate (Wood, 2017, section 5.9) is based on computing an estimate of the residual variance based on differencing residuals that are near neighbours according to the (numeric) covariates of the smooth. This estimate divided by the residual variance is the `k-index` reported. The further below 1 this is, the more likely it is that there is missed pattern left in the residuals. The `p-value` is computed by simulation: the residuals are randomly re-shuffled `k.rep` times to obtain the null distribution of the differencing variance estimator, if there is no pattern in the residuals. For models fitted to more than `k.sample` data, the tests are based on `k.sample` randomly sampled data. Low `p-values` may indicate that the basis dimension, `k`, has been set too low, especially if the reported `edf` is close to `k'`, the maximum possible EDF for the term. Note the disconcerting fact that if the test statistic itself is based on random resampling and the null is true, then the associated `p-values` will of course vary widely from one replicate to the next. Currently smooths of factor variables are not supported and will give an NA `p-value`.

Doubling a suspect `k` and re-fitting is sensible: if the reported `edf` increases substantially then you may have been missing something in the first fit. Of course `p-values` can be low for reasons other than a too low `k`. See `choose.k` for fuller discussion.

The QQ plot produced is usually created by a call to `qq.gam`, and plots deviance residuals against approximate theoretical quantiles of the deviance residual distribution, according to the fitted model. If this looks odd then investigate further using `qq.gam`. Note that residuals for models fitted to binary data contain very little information useful for model checking (it is necessary to find some way of aggregating them first), so the QQ plot is unlikely to be useful in this case.

Take care when interpreting results from applying this function to a model fitted using `gamm`. In this case the returned `gam` object is based on the working model used for estimation, and will treat all the random effects as part of the error. This means that the residuals extracted from the `gam` object are not standardized for the family used or for the random effects or correlation structure.

Usually it is necessary to produce your own residual checks based on consideration of the model structure you have used.

### Value

A vector of reference quantiles for the residual distribution, if these can be computed.

```

---

gam.control

*Setting GAM fitting defaults*

---

### Description

This is an internal function of package `mgcv` which allows control of the numerical options for fitting a GAM. Typically users will want to modify the defaults if model fitting fails to converge, or if the warnings are generated which suggest a loss of numerical stability during fitting. To change the default choice of fitting method, see [gam](#) arguments `method` and `optimizer`.

### Usage

```
gam.control(nthreads=1, irls.reg=0.0, epsilon = 1e-07, maxit = 200,
 mgcv.tol=1e-7, mgcv.half=15, trace = FALSE,
 rank.tol=.Machine$double.eps^0.5, nlm=list(),
 optim=list(), newton=list(), outerPIsteps=0,
 idLinksBases=TRUE, scalePenalty=TRUE, efs.lspmmax=15,
 efs.tol=.1, keepData=FALSE, scale.est="fletcher",
 edge.correct=FALSE)
```

**Arguments**

|                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|---------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>nthreads</code>     | Some parts of some smoothing parameter selection methods (e.g. REML) can use some parallelization in the C code if your R installation supports openMP, and <code>nthreads</code> is set to more than 1. Note that it is usually better to use the number of physical cores here, rather than the number of hyper-threading cores.                                                                                                                                                                                                                                                                                                                                                                                          |
| <code>irls.reg</code>     | For most models this should be 0. The iteratively re-weighted least squares method by which GAMs are fitted can fail to converge in some circumstances. For example, data with many zeroes can cause problems in a model with a log link, because a mean of zero corresponds to an infinite range of linear predictor values. Such convergence problems are caused by a fundamental lack of identifiability, but do not show up as lack of identifiability in the penalized linear model problems that have to be solved at each stage of iteration. In such circumstances it is possible to apply a ridge regression penalty to the model to impose identifiability, and <code>irls.reg</code> is the size of the penalty. |
| <code>epsilon</code>      | This is used for judging convergence of the GLM IRLS loop in <code>gam.fit</code> or <code>gam.fit3</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>maxit</code>        | Maximum number of IRLS iterations to perform.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>mgcv.tol</code>     | The convergence tolerance parameter to use in GCV/UBRE optimization.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <code>mgcv.half</code>    | If a step of the GCV/UBRE optimization method leads to a worse GCV/UBRE score, then the step length is halved. This is the number of halvings to try before giving up.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>trace</code>        | Set this to TRUE to turn on diagnostic output.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <code>rank.tol</code>     | The tolerance used to estimate the rank of the fitting problem.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>nlm</code>          | list of control parameters to pass to <code>nlm</code> if this is used for outer estimation of smoothing parameters (not default). See details.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>optim</code>        | list of control parameters to pass to <code>optim</code> if this is used for outer estimation of smoothing parameters (not default). See details.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>newton</code>       | list of control parameters to pass to default Newton optimizer used for outer estimation of log smoothing parameters. See details.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <code>outerPIsteps</code> | The number of performance iteration steps used to initialize outer iteration.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>idLinksBases</code> | If smooth terms have their smoothing parameters linked via the <code>id</code> mechanism (see <a href="#">s</a> ), should they also have the same bases. Set this to FALSE only if you are sure you know what you are doing (you should almost surely set <code>scalePenalty</code> to FALSE as well in this case).                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>scalePenalty</code> | <code>gamm</code> is somewhat sensitive to the absolute scaling of the penalty matrices of a smooth relative to its model matrix. This option rescales the penalty matrices to accomodate this problem. Probably should be set to FALSE if you are linking smoothing parameters but have set <code>idLinkBases</code> to FALSE.                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>efs.lspmax</code>   | maximum log smoothing parameters to allow under extended Fellner Schall smoothing parameter optimization.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>efs.tol</code>      | change in REML to count as negligible when testing for EFS convergence. If the step is small and the last 3 steps led to a REML change smaller than this, then stop.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <code>keepData</code>     | Should a copy of the original <code>data</code> argument be kept in the <code>gam</code> object? Strict compatibility with class <code>glm</code> would keep it, but it wastes space to do so.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <code>scale.est</code>    | How to estimate the scale parameter for exponential family models estimated by outer iteration. `edge.correct` With RE/ML smoothing parameter selection in `gam` using the default Newton RE/ML optimizer, it is possible to improve inference at the ‘completely smooth’ edge of the smoothing parameter space, by decreasing smoothing parameters until there is a small increase in the negative RE/ML (e.g. 0.02). Set to `TRUE` or to a number representing the target increase to use. Only changes the corrected smoothing parameter matrix, `Vc`.

## Details

Outer iteration using `newton` is controlled by the list `newton` with the following elements: `conv.tol` (default `1e-6`) is the relative convergence tolerance; `maxNstep` is the maximum length allowed for an element of the Newton search direction (default 5); `maxSstep` is the maximum length allowed for an element of the steepest descent direction (only used if Newton fails - default 2); `maxHalf` is the maximum number of step halvings to permit before giving up (default 30).

If outer iteration using `nlm` is used for fitting, then the control list `nlm` stores control arguments for calls to routine `nlm`. The list has the following named elements: (i) `ndigit` is the number of significant digits in the GCV/UBRE score - by default this is worked out from `epsilon`; (ii) `gradtol` is the tolerance used to judge convergence of the gradient of the GCV/UBRE score to zero - by default set to `10*epsilon`; (iii) `stepmax` is the maximum allowable log smoothing parameter step - defaults to 2; (iv) `steptol` is the minimum allowable step length - defaults to `1e-4`; (v) `iterlim` is the maximum number of optimization steps allowed - defaults to 200; (vi) `check.analyticals` indicates whether the built in exact derivative calculations should be checked numerically - defaults to `FALSE`. Any of these which are not supplied and named in the list are set to their default values.

Outer iteration using `optim` is controlled using list `optim`, which currently has one element: `factr` which takes default value `1e7`.

## Description

When fitting GAMs there is a tradeoff between speed of fitting and probability of fit convergence. The fitting methods used by `gam` opt for certainty of convergence over speed of fit. `bam` opts for speed.

`gam` uses a nested iteration method (see `gam.outer`), in which each trial set of smoothing parameters proposed by an outer Newton algorithm require an inner Newton algorithm (penalized iteratively re-weighted least squares, PIRLS) to find the corresponding best fit model coefficients. Implicit differentiation is used to find the derivatives of the coefficients with respect to log smoothing parameters, so that the derivatives of the smoothness selection criterion can be obtained, as required by the outer iteration. This approach is less expensive than it at first appears, since excellent starting values for the inner iteration are available as soon as the smoothing parameters start to converge. See Wood (2011) and Wood, Pya and Saeften (2016).

`bam` uses an alternative approach similar to ‘performance iteration’ or ‘PQL’. A single PIRLS iteration is run to find the model coefficients. At each step this requires the estimation of a working penalized linear model. Smoothing parameter selection is applied directly to this working model at each step (as if it were a Gaussian additive model). This approach is more straightforward to code and in principle less costly than the nested approach. However it is not guaranteed to converge, since the smoothness selection criterion is changing at each iteration. It is sometimes possible for the algorithm to cycle around a small set of smoothing parameter, coefficient combinations without ever converging. `bam` includes some checks to limit this behaviour, and the further checks in the algorithm used by `bam(..., discrete=TRUE)` actually guarantee convergence in some cases, but in general guarantees are not possible. See Wood, Goude and Shaw (2015) and Wood et al. (2017).

`gam` when used with ‘general’ families (such as `multinom` or `cox.ph`) can also use a potentially faster scheme based on the extended Fellner-Schall method (Wood and Fasiolo, 2017). This also operates with a single iteration and is not guaranteed to converge, theoretically.

There are three things that you can try to speed up GAM fitting. (i) if you have large numbers of smoothing parameters in the generalized case, then try the `"bfgs"` method option in `gam` argument `optimizer`: this can be faster than the default. (ii) Try using `bam` (iii) For large datasets it may be worth changing the smoothing basis to use `bs="cr"` (see `s` for details) for 1-d smooths, and to use `te` smooths in place of `s` smooths for smooths of more than one variable. This is because the default thin plate regression spline basis `"tp"` is costly to set up for large datasets.

If you have convergence problems, it’s worth noting that a GAM is just a (penalized) GLM and the IRLS scheme used to estimate GLMs is not guaranteed to converge. Hence non convergence of a GAM may relate to a lack of stability in the basic IRLS scheme. Therefore it is worth trying to establish whether the IRLS iterations are capable of converging. To do this fit the problematic GAM with all smooth terms specified with `fx=TRUE` so that the smoothing parameters are all fixed at zero. If this ‘largest’ model can converge then, then the maintainer would quite like to know about your problem! If it doesn’t converge, then its likely that your model is just too flexible for the IRLS process itself. Having tried increasing `maxit` in `gam.control`, there are several other possibilities for stabilizing the iteration. It is possible to try (i) setting lower bounds on the smoothing parameters using the `min.sp` argument of `gam`: this may or may not change the model being fitted; (ii) reducing the flexibility of the model by reducing the basis dimensions `k` in the specification of `s` and `te` model terms: this obviously changes the model being fitted somewhat.

Usually, a major contributor to fitting difficulties is that the model is a very poor description of the data.

Please report convergence problems, especially if you there is no obvious pathology in the data/model that suggests convergence should fail.

*GAM P-IRLS estimation with GCV/UBRE smoothness estimation*

---

**Description**

This is an internal function of package `mgcv`. It is a modification of the function `glm.fit`, designed to be called from `gam` when performance iteration is selected (not the default). The major modification is that rather than solving a weighted least squares problem at each IRLS step, a weighted, penalized least squares problem is solved at each IRLS step with smoothing parameters associated with each penalty chosen by GCV or UBRE, using routine `magic`. For further information on usage see code for `gam`. Some regularization of the IRLS weights is also permitted as a way of addressing identifiability related problems (see `gam.control`). Negative binomial parameter estimation is supported.

The basic idea of estimating smoothing parameters at each step of the P-IRLS is due to Gu (1992), and is termed ‘performance iteration’ or ‘performance oriented iteration’.

**Usage**

```
gam.fit(G, start = NULL, etastart = NULL,
 mustart = NULL, family = gaussian(),
 control = gam.control(), gamma=1,
 fixedSteps=(control$maxit+1), ...)
```

**Arguments**

|                         |                                                                                                                       |

`gam.fit3`

*P-IRLS GAM estimation with GCV\& UBRE/AIC or RE/ML derivative calculation*

---

**Description**

Estimation of GAM smoothing parameters is most stable if optimization of the UBRE/AIC, GCV, GACV, REML or ML score is outer to the penalized iteratively re-weighted least squares scheme used to estimate the model given smoothing parameters.

This routine estimates a GAM (any quadratically penalized GLM) given log smoothing parameters, and evaluates derivatives of the smoothness selection scores of the model with respect to the log smoothing parameters. Calculation of exact derivatives is generally faster than approximating them

by finite differencing, as well as generally improving the reliability of GCV/UBRE/AIC/REML score minimization.

The approach is to run the P-IRLS to convergence, and only then to iterate for first and second derivatives.

Not normally called directly, but rather service routines for [gam](#).

## Usage

```
gam.fit3(x, y, sp, Eb, UrS=list(),
 weights = rep(1, nobs), start = NULL, etastart = NULL,
 mustart = NULL, offset = rep(0, nobs), U1 = diag(ncol(x)),
 Mp = -1, family = gaussian(), control = gam.control(),
 intercept = TRUE, deriv=2, gamma=1, scale=1,
 printWarn=TRUE, scoreType="REML", null.coef=rep(0, ncol(x)),
 pearson.extra=0, dev.extra=0, n.true=-1, Sl=NULL, ...)
```

## Arguments

|           |                                                                                                                                                                                                  |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x         | The model matrix for the GAM (or any penalized GLM).                                                                                                                                             |
| y         | The response variable.                                                                                                                                                                           |
| sp        | The log smoothing parameters.                                                                                                                                                                    |
| Eb        | A balanced version of the total penalty matrix: used for numerical rank determination.                                                                                                           |
| UrS       | List of square root penalties premultiplied by transpose of orthogonal basis for the total penalty.                                                                                              |
| weights   | prior weights for fitting.                                                                                                                                                                       |
| start     | optional starting parameter guesses.                                                                                                                                                             |
| etastart  | optional starting values for the linear predictor.                                                                                                                                               |
| mustart   | optional starting values for the mean.                                                                                                                                                           |
| offset    | the model offset                                                                                                                                                                                 |
| U1        | An orthogonal basis for the range space of the penalty — required for ML smoothness estimation only.                                                                                             |
| Mp        | The dimension of the total penalty null space — required for ML smoothness estimation only.                                                                                                      |
| family    | the family - actually this routine would never be called with <code>gaussian()</code>                                                                                                            |
| control   | control list as returned from <a href="#">glm.control</a>                                                                                                                                        |
| intercept | does the model have an intercept, TRUE or FALSE                                                                                                                                                  |
| deriv     | Should derivatives of the GCV and UBRE/AIC scores be calculated? 0, 1 or 2, indicating the maximum order of differentiation to apply.                                                            |
| gamma     | The weight given to each degree of freedom in the GCV and UBRE scores can be varied (usually increased) using this parameter.                                                                    |
| scale     | The scale parameter - needed for the UBRE/AIC score.                                                                                                                                             |
| printWarn | Set to FALSE to suppress some warnings. Useful in order to ensure that some warnings are only printed if they apply to the final fitted model, rather than an intermediate used in optimization. |
| scoreType | specifies smoothing parameter selection criterion to use.                                                                                                                                        |

|                            |                                                                                                                                        |
|----------------------------|----------------------------------------------------------------------------------------------------------------------------------------|
| <code>null.coef</code>     | coefficients for a model which gives some sort of upper bound on deviance. This allows immediate divergence problems to be controlled. |
| <code>pearson.extra</code> | Extra component to add to numerator of pearson statistic in P-REML/P-ML smoothness selection criteria.                                 |
| <code>dev.extra</code>     | Extra component to add to deviance for REML/ML type smoothness selection criteria.                                                     |
| <code>n.true</code>        | Number of data to assume in smoothness selection criteria. $\leq 0$ indicates that it should be the number of rows of $X$ .            |
| <code>s1</code>            | A smooth list suitable for passing to <code>gam.fit5</code> .                                                                          |
| <code>...</code>           | Other arguments: ignored.                                                                                                              |

### Details

This routine is basically `glm.fit` with some modifications to allow (i) for quadratic penalties on the log likelihood; (ii) derivatives of the model coefficients with respect to log smoothing parameters to be obtained by use of the implicit function theorem and (iii) derivatives of the GAM GCV, UBRE/AIC, REML or ML scores to be evaluated at convergence.

In addition the routines apply step halving to any step that increases the penalized deviance substantially.

The most costly parts of the calculations are performed by calls to compiled C code (which in turn calls LAPACK routines) in place of the compiled code that would usually perform least squares estimation on the working model in the IRLS iteration.

Estimation of smoothing parameters by optimizing GCV scores obtained at convergence of the P-IRLS iteration was proposed by O'Sullivan et al. (1986), and is here termed 'outer' iteration.

Note that use of non-standard families with this routine requires modification of the families as described in [fix.family.link](#).

---

## Description

INTERNAL function for post-processing the output of `gam.fit5`.

## Usage

```
gam.fit5.post.proc(object, Sl, L, lsp0, S, off)
```

## Arguments

|                     |                                                   |
|---------------------|---------------------------------------------------|
| <code>object</code> | output of <code>gam.fit5</code> .                 |
| <code>Sl</code>     | penalty object, output of <code>Sl.setup</code> . |
| <code>L</code>      | matrix mapping the working smoothing parameters.  |
| <code>lsp0</code>   | log smoothing parameters.                         |
| <code>S</code>      | penalty matrix.                                   |
| <code>off</code>    | vector of offsets.                                |

## Value

A list containing:

- `R`: unpivoted Choleski of estimated expected hessian of log-likelihood.
- `Vb`: the Bayesian covariance matrix of the model parameters.
- `Ve`: "frequentist" alternative to `Vb`.
- `Vc`: corrected covariance matrix.
- `F`: matrix of effective degrees of freedom (EDF).
- `edf`: `diag(F)`.
- `edf2`: `diag(2F-FF)`.

gam.mh

*Simple posterior simulation with gam fits***Description**

GAM coefficients can be simulated directly from the Gaussian approximation to the posterior for the coefficients, or using a simple Metropolis Hastings sampler. See also [ginla](#).

**Usage**

```
gam.mh(b, ns=10000, burn=1000, t.df=40, rw.scale=.25, thin=1)
```

**Arguments**

|                       |                                                                                                                                                  |
|-----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>b</code>        | a fitted model object from <a href="#">gam</a> . <a href="#">bam</a> fits are not supported.                                                     |
| <code>ns</code>       | the number of samples to generate.                                                                                                               |
| <code>burn</code>     | the length of any initial burn in period to discard (in addition to codens).                                                                     |
| <code>t.df</code>     | degrees of freedom for static multivariate t proposal. Lower for heavier tailed proposals.                                                       |
| <code>rw.scale</code> | Factor by which to scale posterior covariance matrix when generating random walk proposals. Negative or non finite to skip the random walk step. |
| <code>thin</code>     | retain only every <code>thin</code> samples.                                                                                                     |

**Details**

Posterior simulation is particularly useful for making inferences about non-linear functions of the model coefficients. Simulate random draws from the posterior, compute the function for each draw, and you have a draw from the posterior for the function. In many cases the Gaussian approximation to the posterior of the model coefficients is accurate, and samples generated from it can be treated as samples from the posterior for the coefficients. See example code below. This approach is computationally very efficient.

In other cases the Gaussian approximation can become poor. A typical example is in a spatial model with a log or logit link when there is a large area of observations containing only zeroes. In this case the linear predictor is poorly identified and the Gaussian approximation can become useless (an example is provided below). In that case it can sometimes be useful to simulate from the posterior using a Metropolis Hastings sampler. A simple approach alternates fixed proposals, based on the Gaussian approximation to the posterior, with random walk proposals, based on a shrunk version of the approximate posterior covariance matrix. `gam.mh` implements this. The fixed proposal often promotes rapid mixing, while the random walk component ensures that the chain does not become stuck in regions for which the fixed Gaussian proposal density is much lower than the posterior density.

The function reports the acceptance rate of the two types of step. If the random walk acceptance probability is higher than a quarter then `rw.step` should probably be increased. Similarly if the acceptance rate is too low, it should be decreased. The random walk steps can be turned off altogether (see above), but it is important to check the chains for stuck sections if this is done.

**Value**

A list containing the retained simulated coefficients in matrix `bs` and two entries for the acceptance probabilities.

gam.models

*Specifying generalized additive models*

## Description

This page is intended to provide some more information on how to specify GAMs. A GAM is a GLM in which the linear predictor depends, in part, on a sum of smooth functions of predictors and (possibly) linear functionals of smooth functions of (possibly dummy) predictors.

Specifically let  $y_i$  denote an independent random variable with mean  $\mu_i$  and an exponential family distribution, or failing that a known mean variance relationship suitable for use of quasi-likelihood methods. Then the the linear predictor of a GAM has a structure something like

$$g(\mu_i) = \mathbf{X}_i\beta + f_1(x_{1i}, x_{2i}) + f_2(x_{3i}) + L_i f_3(x_4) + \dots$$

where  $g$  is a known smooth monotonic ‘link’ function,  $\mathbf{X}_i\beta$  is the parametric part of the linear predictor, the  $x_j$  are predictor variables, the  $f_j$  are smooth functions and  $L_i$  is some linear functional of  $f_3$ . There may of course be multiple linear functional terms, or none.

The key idea here is that the dependence of the response on the predictors can be represented as a parametric sub-model plus the sum of some (functionals of) smooth functions of one or more of the predictor variables. Thus the model is quite flexible relative to strictly parametric linear or generalized linear models, but still has much more structure than the completely general model that says that the response is just some smooth function of all the covariates.

Note one important point. In order for the model to be identifiable the smooth functions usually have to be constrained to have zero mean (usually taken over the set of covariate values). The constraint is needed if the term involving the smooth includes a constant function in its span. `gam` always applies such constraints unless there is a `by` variable present, in which case an assessment is made of whether the constraint is needed or not (see below).

The following sections discuss specifying model structures for `gam`. Specification of the distribution and link function is done using the `family` argument to `gam` and works in the same way as for `glm`. This page therefore concentrates on the model formula for `gam`.

## Models with simple smooth terms

Consider the example model.

$$g(\mu_i) = \beta_0 + \beta_1 x_{1i} + \beta_2 x_{2i} + f_1(x_{3i}) + f_2(x_{4i}, x_{5i})$$

where the response variables  $y_i$  has expectation  $\mu_i$  and  $g$  is a link function.

The gam formula for this would be

`y ~ x1 + x2 + s(x3) + s(x4, x5)`.

This would use the default basis for the smooths (a thin plate regression spline basis for each), with automatic selection of the effective degrees of freedom for both smooths. The dimension of the smoothing basis is given a default value as well (the dimension of the basis sets an upper limit on the maximum possible degrees of freedom for the basis - the limit is typically one less than basis dimension). Full details of how to control smooths are given in [s](#) and [te](#), and further discussion of basis dimension choice can be found in [choose.k](#). For the moment suppose that we would like to change the basis of the first smooth to a cubic regression spline basis with a dimension of 20, while fixing the second term at 25 degrees of freedom. The appropriate formula would be:

`y ~ x1 + x2 + s(x3, bs="cr", k=20) + s(x4, x5, k=26, fx=TRUE)`.

The above assumes that  $x_4$  and  $x_5$  are naturally on similar scales (e.g. they might be co-ordinates), so that isotropic smoothing is appropriate. If this assumption is false then tensor product smoothing might be better (see [te](#)).

`y ~ x1 + x2 + s(x3) + te(x4, x5)`

would generate a tensor product smooth of  $x_4$  and  $x_5$ . By default this smooth would have basis dimension 25 and use cubic regression spline marginals. Varying the defaults is easy. For example

`y ~ x1 + x2 + s(x3) + te(x4, x5, bs=c("cr", "ps"), k=c(6, 7))`

specifies that the tensor product should use a rank 6 cubic regression spline marginal and a rank 7 P-spline marginal to create a smooth with basis dimension 42.

## Nested terms/functional ANOVA

Sometimes it is interesting to specify smooth models with a main effects + interaction structure such as

$$E(y_i) = f_1(x_i) + f_2(z_i) + f_3(x_i, z_i)$$

or

$$E(y_i) = f_1(x_i) + f_2(z_i) + f_3(v_i) + f_4(x_i, z_i) + f_5(z_i, v_i) + f_6(z_i, v_i) + f_7(x_i, z_i, v_i)$$

for example. Such models should be set up using [ti](#) terms in the model formula. For example:

`y ~ ti(x) + ti(z) + ti(x, z)`, or

`y ~ ti(x) + ti(z) + ti(v) + ti(x, z) + ti(x, v) + ti(z, v) + ti(x, z, v)`.

The [ti](#) terms produce interactions with the component main effects excluded appropriately. (There is in fact no need to use [ti](#) terms for the main effects here, [s](#) terms could also be used.)

gam allows nesting (or ‘overlap’) of [te](#) and [s](#) smooths, and automatically generates side conditions to make such models identifiable, but the resulting models are much less stable and interpretable than those constructed using [ti](#) terms.

## ‘by’ variables

[by](#) variables are the means for constructing ‘varying-coefficient models’ (geographic regression models) and for letting smooths ‘interact’ with factors or parametric terms. They are also the key to specifying general linear functionals of smooths.

The [s](#) and [te](#) terms used to specify smooths accept an argument [by](#), which is a numeric or factor variable of the same dimension as the covariates of the smooth. If a [by](#) variable is numeric, then its  $i^{th}$  element multiplies the  $i^{th}$  row of the model matrix corresponding to the smooth term concerned.

Factor smooth interactions (see also `factor.smooth.interaction`). If a `by` variable is a `factor` then it generates an indicator vector for each level of the factor, unless it is an `ordered` factor. In the non-ordered case, the model matrix for the smooth term is then replicated for each factor level, and each copy has its rows multiplied by the corresponding rows of its indicator variable. The smoothness penalties are also duplicated for each factor level. In short a different smooth is generated for each factor level (the `id` argument to `s` and `te` can be used to force all such smooths to have the same smoothing parameter). `ordered` `by` variables are handled in the same way, except that no smooth is generated for the first level of the ordered factor (see `b3` example below). This is useful for setting up identifiable models when the same smooth occurs more than once in a model, with different factor `by` variables.

As an example, consider the model

$$E(y_i) = \beta_0 + f(x_i)z_i$$

where  $f$  is a smooth function, and  $z_i$  is a numeric variable. The appropriate formula is:

```
y ~ s(x, by=z)
```

- the `by` argument ensures that the smooth function gets multiplied by covariate  $z$ . Note that when using factor `by` variables, centering constraints are applied to the smooths, which usually means that the `by` variable should be included as a parametric term, as well.

The example code below also illustrates the use of factor `by` variables.

`by` variables may be supplied as numeric matrices as part of specifying general linear functional terms.

If a `by` variable is present and numeric (rather than a factor) then the corresponding smooth is only subjected to an identifiability constraint if (i) the `by` variable is a constant vector, or, (ii) for a matrix `by` variable, `L`, if `L%%rep(1, ncol(L))` is constant or (iii) if a user defined smooth constructor supplies an identifiability constraint explicitly, and that constraint has an attribute `"always.apply"`.

### Linking smooths with 'id'

It is sometimes desirable to insist that different smooth terms have the same degree of smoothness. This can be done by using the `id` argument to `s` or `te` terms. Smooths which share an `id` will have the same smoothing parameter. Really this only makes sense if the smooths use the same basis functions, and the default behaviour is to force this to happen: all smooths sharing an `id` have the same basis functions as the first smooth occurring with that `id`. Note that if you want exactly the same function for each smooth, then this is best achieved by making use of the summation convention covered under 'linear functional terms'.

As an example suppose that  $E(y_i) \equiv \mu_i$  and

$$g(\mu_i) = f_1(x_{1i}) + f_2(x_{2i}, x_{3i}) + f_3(x_{4i})$$

but that  $f_1$  and  $f_3$  should have the same smoothing parameters (and  $x_2$  and  $x_3$  are on different scales). Then the `gam` formula

```
y ~ s(x1, id=1) + te(x_2, x3) + s(x4, id=1)
```

would achieve the desired result. `id` can be numbers or character strings. Giving an `id` to a term with a factor `by` variable causes the smooths at each level of the factor to have the same smoothing parameter.

Smooth term `ids` are not supported by `gamm`.

### Linear functional terms

General linear functional terms have a long history in the spline literature including in the penalized GLM context (see e.g. Wahba 1990). Such terms encompass varying coefficient models/ geographic

regression, functional GLMs (i.e. GLMs with functional predictors), GLASS models, etc, and allow smoothing with respect to aggregated covariate values, for example.

Such terms are implemented in `mgcv` using a simple ‘summation convention’ for smooth terms: If the covariates of a smooth are supplied as matrices, then summation of the evaluated smooth over the columns of the matrices is implied. Each covariate matrix and any `by` variable matrix must be of the same dimension. Consider, for example the term

`s(X, Z, by=L)`

where  $X$ ,  $Z$  and  $L$  are  $n \times p$  matrices. Let  $f$  denote the thin plate regression spline specified. The resulting contribution to the  $i^{\text{th}}$  element of the linear predictor is

$$\sum_{j=1}^p L_{ij} f(X_{ij}, Z_{ij})$$

If no  $L$  is supplied then all its elements are taken as 1. In R code terms, let  $F$  denote the  $n \times p$  matrix obtained by evaluating the smooth at the values in  $X$  and  $Z$ . Then the contribution of the term to the linear predictor is `rowSums(L * F)` (note that it’s element by element multiplication here!).

The summation convention applies to `te` terms as well as `s` terms. More details and examples are provided in [linear.functional.terms](#).

## Random effects

Random effects can be added to `gam` models using `s(..., bs="re")` terms (see [smooth.construct.re.smooth.spec](#)), or the `paraPen` argument to `gam` covered below. See [gam.vcomp](#), [random.effects](#) and [smooth.construct.re.smooth.spec](#) for further details. An alternative is to use the approach of [gamm](#).

## Penalizing the parametric terms

In case the ability to add smooth classes, smooth identities, `by` variables and the summation convention are still not sufficient to implement exactly the penalized GLM that you require, `gam` also allows you to penalize the parametric terms in the model formula. This is mostly useful in allowing one or more matrix terms to be included in the formula, along with a sequence of quadratic penalty matrices for each.

Suppose that you have set up a model matrix  $X$ , and want to penalize the corresponding coefficients,  $\beta$  with two penalties  $\beta^T S_1 \beta$  and  $\beta^T S_2 \beta$ . Then something like the following would be appropriate:

```
gam(y ~ X-1, paraPen=list(X=list(S1, S2)))
```

The `paraPen` argument should be a list with elements having names corresponding to the terms being penalized. Each element of `paraPen` is itself a list, with optional elements `L`, `rank` and `sp`: all other elements must be penalty matrices. If present, `rank` is a vector giving the rank of each penalty matrix (if absent this is determined numerically). `L` is a matrix that maps underlying log smoothing parameters to the log smoothing parameters that actually multiply the individual quadratic penalties: taken as the identity if not supplied. `sp` is a vector of (underlying) smoothing parameter values: positive values are taken as fixed, negative to signal that the smoothing parameter should be estimated. Taken as all negative if not supplied.

An obvious application of `paraPen` is to incorporate random effects, and an example of this is provided below. In this case the supplied penalty matrices will be (generalized) inverse covariance matrices for the random effects — i.e. precision matrices. The final estimate of the covariance matrix corresponding to one of these penalties is given by the (generalized) inverse of the penalty matrix multiplied by the estimated scale parameter and divided by the estimated smoothing parameter for the penalty. For example, if you use an identity matrix to penalize some coefficients that are to be viewed as i.i.d. Gaussian random effects, then their estimated variance will be the estimated

scale parameter divided by the estimate of the smoothing parameter, for this penalty. See the 'rail' example below.

P-values for penalized parametric terms should be treated with caution. If you must have them, then use the option `freq=TRUE` in `anova.gam` and `summary.gam`, which will tend to give reasonable results for random effects implemented this way, but not for terms with a rank deficient penalty (or penalties with a wide eigen-spectrum).

### Examples

```
require(mgcv)
set.seed(10)
simulate data from $y = f(x_2) * x_1 + \text{error}$
dat <- gamSim(3, n=400)

b <- gam(y ~ s(x2, by=x1), data=dat)
plot(b, pages=1)
summary(b)

Factor 'by' variable example (with a spurious covariate x0)
simulate data...

dat <- gamSim(4)

fit model...
b <- gam(y ~ fac + s(x2, by=fac) + s(x0), data=dat)
plot(b, pages=1)
summary(b)

note that the preceding fit is the same as...
b1 <- gam(y ~ s(x2, by=as.numeric(fac==1)) + s(x2, by=as.numeric(fac==2)) +
 s(x2, by=as.numeric(fac==3)) + s(x0) - 1, data=dat)
... the '-1' is because the intercept is confounded with the
uncentred smooths here.
plot(b1, pages=1)
summary(b1)

repeat forcing all s(x2) terms to have the same smoothing param
(not a very good idea for these data!)
b2 <- gam(y ~ fac + s(x2, by=fac, id=1) + s(x0), data=dat)
plot(b2, pages=1)
summary(b2)

now repeat with a single reference level smooth, and
two 'difference' smooths...
dat$fac <- ordered(dat$fac)
b3 <- gam(y ~ fac + s(x2) + s(x2, by=fac) + s(x0), data=dat, method="REML")
```

```

plot(b3,pages=1)
summary(b3)

rm(dat)

An example of a simple random effects term implemented via
penalization of the parametric part of the model...

dat <- gamSim(1,n=400,scale=2) ## simulate 4 term additive truth
Now add some random effects to the simulation. Response is
grouped into one of 20 groups by `fac' and each groups has a
random effect added....
fac <- as.factor(sample(1:20,400,replace=TRUE))
dat$X <- model.matrix(~fac-1)
b <- rnorm(20)*.5
dat$y <- dat$y + dat$X%*%b

now fit appropriate random effect model...
PP <- list(X=list(rank=20,diag(20)))
rm <- gam(y~ X+s(x0)+s(x1)+s(x2)+s(x3),data=dat,paraPen=PP)
plot(rm,pages=1)
Get estimated random effects standard deviation...
sig.b <- sqrt(rm$sig2/rm$sp[1]);sig.b

a much simpler approach uses "re" terms...

rml <- gam(y ~ s(fac,bs="re")+s(x0)+s(x1)+s(x2)+s(x3),data=dat,method="ML")
gam.vcomp(rml)

Simple comparison with lme, using Rail data.
See ?random.effects for a simpler method
require(nlme)
b0 <- lme(travel~1,data=Rail,~1|Rail,method="ML")

gam.outer

*Minimize GCV or UBRE score of a GAM using 'outer' iteration*

## Description

Estimation of GAM smoothing parameters is most stable if optimization of the smoothness selection score (GCV, GACV, UBRE/AIC, REML, ML etc) is outer to the penalized iteratively re-weighted least squares scheme used to estimate the model given smoothing parameters.

This routine optimizes a smoothness selection score in this way. Basically the score is evaluated for each trial set of smoothing parameters by estimating the GAM for those smoothing parameters. The score is minimized w.r.t. the parameters numerically, using `newton` (default), `bfgs`, `optim` or `nlm`. Exact (first and second) derivatives of the score can be used by fitting with `gam.fit3`. This improves efficiency and reliability relative to relying on finite difference derivatives.

Not normally called directly, but rather a service routine for `gam`.

**Usage**

```
gam.outer(lsp, fscale, family, control, method, optimizer,
 criterion, scale, gamma, G, start=NULL, ...)
```

**Arguments**

|                        |                                                                                                                             |
|------------------------|-----------------------------------------------------------------------------------------------------------------------------|
| <code>lsp</code>       | The log smoothing parameters.                                                                                               |
| <code>fscale</code>    | Typical scale of the GCV or UBRE/AIC score.                                                                                 |
| <code>family</code>    | the model family.                                                                                                           |
| <code>control</code>   | control argument to pass to <code>gam.fit</code> if pure finite differencing is being used.                                 |
| <code>method</code>    | method argument to <code>gam</code> defining the smoothness criterion to use (but depending on whether or not scale known). |
| <code>optimizer</code> | The argument to <code>gam</code> defining the numerical optimization method to use.                                         |
| <code>criterion</code> | Which smoothness selection criterion to use. One of "UBRE", "GCV", "GACV", "REML" or "P-REML".                              |
| <code>scale</code>     | Supplied scale parameter. Positive indicates known.                                                                         |
| <code>gamma</code>     | The degree of freedom inflation factor for the GCV/UBRE/AIC score.                                                          |
| <code>G</code>         | List produced by <code>mgcv:::gam.setup</code> , containing most of what's needed to actually fit a GAM.                    |
| <code>start</code>     | starting parameter values.                                                                                                  |
| <code>...</code>       | other arguments, typically for passing on to <code>gam.fit3</code> (ultimately).                                            |

**Details**

|-------------|----------------------------------------------------------------------------------|

---

## Description

INTERNAL function for finding an orthogonal re-parameterization which avoids "dominant machine zero leakage" between components of the square root penalty.

## Usage

```
gam.reparam(rS, lsp, deriv)
```

## Arguments

|       |                                                                                                                                                                                                                                                                                                                                 |
|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| rS    | list of the square root penalties: last entry is root of fixed penalty, if <code>fixed.penalty==TRUE</code> (i.e. <code>length(rS)&gt;length(sp)</code> ). The assumption here is that <code>rS[[i]]</code> are in a null space of total penalty already; see e.g. <code>totalPenaltySpace</code> and <code>mini.roots</code> . |
| lsp   | vector of log smoothing parameters.                                                                                                                                                                                                                                                                                             |
| deriv | if <code>deriv==1</code> also the first derivative of the log-determinant of the penalty matrix is returned, if <code>deriv&gt;1</code> also the second derivative is returned.                                                                                                                                                 |

## Value

A list containing

- S: the total penalty matrix similarity transformed for stability.
- rS: the component square roots, transformed in the same way.
- Qs: the orthogonal transformation matrix  $S = t(Qs) \%*\%S0\%*\%Qs$ , where S0 is the untransformed total penalty implied by sp and rS on input.
- det: log|S|.
- det1: dlog|S|/dlog(sp) if `deriv>0`.
- det2: hessian of log|S| wrt log(sp) if `deriv>1`.

## Author(s)

Simon N. Wood <simon.wood@r-project.org>.

**Description**

Scale parameter estimation in `gam` depends on the type of `family`. For extended families then the RE/ML estimate is used. For conventional exponential families, estimated by the default outer iteration, the scale estimator can be controlled using argument `scale.est` in `gam.control`. The options are "fletcher" (default), "pearson" or "deviance". The Pearson estimator is the (weighted) sum of squares of the pearson residuals, divided by the effective residual degrees of freedom. The Fletcher (2012) estimator is an improved version of the Pearson estimator. The deviance estimator simply substitutes deviance residuals for Pearson residuals.

Usually the Pearson estimator is recommended for GLMs, since it is asymptotically unbiased. However, it can also be unstable at finite sample sizes, if a few Pearson residuals are very large. For example, a very low Poisson mean with a non zero count can give a huge Pearson residual, even though the deviance residual is much more modest. The Fletcher (2012) estimator is designed to reduce these problems.

For performance iteration the Pearson estimator is always used.

`gamm` uses the estimate of the scale parameter from the underlying call to `lme`. `bam` uses the REML estimator if the method is "fREML". Otherwise the estimator is a Pearson estimator.

`gam.control`

**Description**

This page is intended to provide some more information on how to select GAMs. In particular, it gives a brief overview of smoothness selection, and then discusses how this can be extended to select inclusion/exclusion of terms. Hypothesis testing approaches to the latter problem are also discussed.

### Smoothness selection criteria

Given a model structure specified by a gam model formula, `gam()` attempts to find the appropriate smoothness for each applicable model term using prediction error criteria or likelihood based methods. The prediction error criteria used are Generalized (Approximate) Cross Validation (GCV or GACV) when the scale parameter is unknown or an Un-Biased Risk Estimator (UBRE) when it is known. UBRE is essentially scaled AIC (Generalized case) or Mallows' Cp (additive model case). GCV and UBRE are covered in Craven and Wahba (1979) and Wahba (1990). Alternatively REML of maximum likelihood (ML) may be used for smoothness selection, by viewing the smooth components as random effects (in this case the variance component for each smooth random effect will be given by the scale parameter divided by the smoothing parameter — for smooths with multiple penalties, there will be multiple variance components). The `method` argument to `gam` selects the smoothness selection criterion.

Automatic smoothness selection is unlikely to be successful with few data, particularly with multiple terms to be selected. In addition GCV and UBRE/AIC score can occasionally display local minima that can trap the minimisation algorithms. GCV/UBRE/AIC scores become constant with changing smoothing parameters at very low or very high smoothing parameters, and on occasion these 'flat' regions can be separated from regions of lower score by a small 'lip'. This seems to be the most common form of local minimum, but is usually avoidable by avoiding extreme smoothing parameters as starting values in optimization, and by avoiding big jumps in smoothing parameters while optimizing. Never the less, if you are suspicious of smoothing parameter estimates, try changing fit method (see `gam` arguments `method` and `optimizer`) and see if the estimates change, or try changing some or all of the smoothing parameters 'manually' (argument `sp` of `gam`, or `sp` arguments to `s` or `te`).

REML and ML are less prone to local minima than the other criteria, and may therefore be preferable.

### Automatic term selection

Unmodified smoothness selection by GCV, AIC, REML etc. will not usually remove a smooth from a model. This is because most smoothing penalties view some space of (non-zero) functions as 'completely smooth' and once a term is penalized heavily enough that it is in this space, further penalization does not change it.

However it is straightforward to modify smooths so that under heavy penalization they are penalized to the zero function and thereby 'selected out' of the model. There are two approaches.

The first approach is to modify the smoothing penalty with an additional shrinkage term. Smooth classes `cs.smooth` and `tp.rs.smooth` (specified by "`cs`" and "`ts`" respectively) have smoothness penalties which include a small shrinkage component, so that for large enough smoothing parameters the smooth becomes identically zero. This allows automatic smoothing parameter selection methods to effectively remove the term from the model altogether. The shrinkage component of the penalty is set at a level that usually makes negligible contribution to the penalization of the model, only becoming effective when the term is effectively 'completely smooth' according to the conventional penalty.

The second approach leaves the original smoothing penalty unchanged, but constructs an additional penalty for each smooth, which penalizes only functions in the null space of the original penalty (the 'completely smooth' functions). Hence, if all the smoothing parameters for a term tend to infinity, the term will be selected out of the model. This latter approach is more expensive computationally, but has the advantage that it can be applied automatically to any smooth term. The `select` argument to `gam` turns on this method.

In fact, as implemented, both approaches operate by eigen-decomposing the original penalty matrix. A new penalty is created on the null space: it is the matrix with the same eigenvectors as

the original penalty, but with the originally positive eigenvalues set to zero, and the originally zero eigenvalues set to something positive. The first approach just adds a multiple of this penalty to the original penalty, where the multiple is chosen so that the new penalty can not dominate the original. The second approach treats the new penalty as an extra penalty, with its own smoothing parameter.

Of course, as with all model selection methods, some care must be taken to ensure that the automatic selection is sensible, and a decision about the effective degrees of freedom at which to declare a term ‘negligible’ has to be made.

### Interactive term selection

In general the most logically consistent method to use for deciding which terms to include in the model is to compare GCV/UBRE/ML scores for models with and without the term (REML scores should not be used to compare models with different fixed effects structures). When UBRE is the smoothness selection method this will give the same result as comparing by AIC (the AIC in this case uses the model EDF in place of the usual model DF). Similarly, comparison via GCV score and via AIC seldom yields different answers. Note that the negative binomial with estimated `theta` parameter is a special case: the GCV score is not informative, because of the `theta` estimation scheme used. More generally the score for the model with a smooth term can be compared to the score for the model with the smooth term replaced by appropriate parametric terms. Candidates for replacement by parametric terms are smooth terms with estimated degrees of freedom close to their minimum possible.

Candidates for removal can also be identified by reference to the approximate p-values provided by `summary.gam`, and by looking at the extent to which the confidence band for an estimated term includes the zero function. It is perfectly possible to perform backwards selection using p-values in the usual way: that is by sequentially dropping the single term with the highest non-significant p-value from the model and re-fitting, until all terms are significant. This suffers from the same problems as stepwise procedures for any GLM/LM, with the additional caveat that the p-values are only approximate. If adopting this approach, it is probably best to use ML smoothness selection.

Note that GCV and UBRE are not appropriate for comparing models using different families: in that case AIC should be used.

### Caveats/platitudes

Formal model selection methods are only appropriate for selecting between reasonable models. If formal model selection is attempted starting from a model that simply doesn’t fit the data, then it is unlikely to provide meaningful results.

The more thought is given to appropriate model structure up front, the more successful model selection is likely to be. Simply starting with a hugely flexible model with ‘everything in’ and hoping that automatic selection will find the right structure is not often successful.

gam.side

*Identifiability side conditions for a GAM*

---

## Description

GAM formulae with repeated variables may only correspond to identifiable models given some side conditions. This routine works out appropriate side conditions, based on zeroing redundant parameters. It is called from `mgcv:::gam.setup` and is not intended to be called by users.

The method identifies nested and repeated variables by their names, but numerically evaluates which constraints need to be imposed. Constraints are always applied to smooths of more variables in preference to smooths of fewer variables. The numerical approach allows appropriate constraints to be applied to models constructed using any smooths, including user defined smooths.

## Usage

```
gam.side(sm, Xp, tol=.Machine$double.eps^.5, with.pen=FALSE)
```

## Arguments

|                       |                                                                                                              |
|-----------------------|--------------------------------------------------------------------------------------------------------------|
| <code>sm</code>       | A list of smooth objects as returned by <a href="#">smooth.construct</a> .                                   |
| <code>Xp</code>       | The model matrix for the strictly parametric model components.                                               |
| <code>tol</code>      | The tolerance to use when assessing linear dependence of smooths.                                            |
| <code>with.pen</code> | Should the computation of dependence consider the penalties or not. Doing so will lead to fewer constraints. |

## Details

Models such as  $y \sim s(x) + s(z) + s(x, z)$  can be estimated by `gam`, but require identifiability constraints to be applied, to make them identifiable. This routine does this, effectively setting redundant parameters to zero. When the redundancy is between smooths of lower and higher numbers of variables, the constraint is always applied to the smooth of the higher number of variables.

Dependent smooths are identified symbolically, but which constraints are needed to ensure identifiability of these smooths is determined numerically, using `fixDependence`. This makes the routine rather general, and not dependent on any particular basis.

`Xp` is used to check whether there is a constant term in the model (or columns that can be linearly combined to give a constant). This is because centred smooths can appear independent, when they would be dependent if there is a constant in the model, so dependence testing needs to take account of this.

## Value

A list of smooths, with model matrices and penalty matrices adjusted to automatically impose the required constraints. Any smooth that has been modified will have an attribute `"del.index"`, listing the columns of its model matrix that were deleted. This index is used in the creation of prediction matrices for the term.

## WARNINGS

Much better statistical stability will be obtained by using models like  $y \sim s(x) + s(z) + ti(x, z)$  or  $y \sim ti(x) + ti(z) + ti(x, z)$  rather than  $y \sim s(x) + s(z) + s(x, z)$ , since the former are designed not to require further constraint.

## Examples

```
The first two examples here illustrate models that cause
gam.side to impose constraints, but both are a bad way
of estimating such models. The 3rd example is the right
way....
set.seed(7)
require(mgcv)
dat <- gamSim(n=400, scale=2) ## simulate data
estimate model with redundant smooth interaction (bad idea).
b<-gam(y~s(x0)+s(x1)+s(x0,x1)+s(x2), data=dat)
plot(b, pages=1)

Simulate data with real interaction...
dat <- gamSim(2, n=500, scale=.1)
old.par<-par(mfrow=c(2,2))

a fully nested tensor product example (bad idea)
b <- gam(y~s(x, bs="cr", k=6)+s(z, bs="cr", k=6)+te(x, z, k=6),
 data=dat$data)
```

```

plot(b)

old.par<-par(mfrow=c(2,2))
A fully nested tensor product example, done properly,
so that gam.side is not needed to ensure identifiability.
ti terms are designed to produce interaction smooths
suitable for adding to main effects (we could also have
used s(x) and s(z) without a problem, but not s(z,x)
or te(z,x)).
b <- gam(y ~ ti(x,k=6) + ti(z,k=6) + ti(x,z,k=6),
 data=dat$data)
plot(b)

par(old.par)
rm(dat)

```

gam.vcomp

*Report gam smoothness estimates as variance components***Description**

GAMs can be viewed as mixed models, where the smoothing parameters are related to variance components. This routine extracts the estimated variance components associated with each smooth term, and if possible returns confidence intervals on the standard deviation scale.

**Usage**

```
gam.vcomp(x, rescale=TRUE, conf.lev=.95)
```

**Arguments**

|                       |                                                                                                                                                                                                                    |
|-----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>        | a fitted model object of class <code>gam</code> as produced by <code>gam()</code> .                                                                                                                                |
| <code>rescale</code>  | the penalty matrices for smooths are rescaled before fitting, for numerical stability reasons, if <code>TRUE</code> this rescaling is reversed, so that the variance components are on the original scale.         |
| <code>conf.lev</code> | when the smoothing parameters are estimated by REML or ML, then confidence intervals for the variance components can be obtained from large sample likelihood results. This gives the confidence level to work at. |

**Details**

The (pseudo) inverse of the penalty matrix penalizing a term is proportional to the covariance matrix of the term's coefficients, when these are viewed as random. For single penalty smooths, it is possible to compute the variance component for the smooth (which multiplies the inverse penalty matrix to obtain the covariance matrix of the smooth's coefficients). This variance component is given by the scale parameter divided by the smoothing parameter.

This routine computes such variance components, for `gam` models, and associated confidence intervals, if smoothing parameter estimation was likelihood based. Note that variance components are also returned for tensor product smooths, but that their interpretation is not so straightforward.

The routine is particularly useful for model fitted by `gam` in which random effects have been incorporated.

**Value**

Either a vector of variance components for each smooth term (as standard deviations), or a matrix. The first column of the matrix gives standard deviations for each term, while the subsequent columns give lower and upper confidence bounds, on the same scale.

For models in which there are more smoothing parameters than actually estimated (e.g. if some were fixed, or smoothing parameters are linked) then a list is returned. The `vc` element is as above, the `all` element is a vector of variance components for all the smoothing parameters (estimated + fixed or replicated).

The routine prints a table of estimated standard deviations and confidence limits, if these can be computed, and reports the numerical rank of the covariance matrix.

**Examples**

```
set.seed(3)
require(mgcv)
simulate some data, consisting of a smooth truth + random effects

dat <- gamSim(1,n=400,dist="normal",scale=2)
a <- factor(sample(1:10,400,replace=TRUE))
b <- factor(sample(1:7,400,replace=TRUE))
Xa <- model.matrix(~a-1) ## random main effects
Xb <- model.matrix(~b-1)
Xab <- model.matrix(~a:b-1) ## random interaction
dat$y <- dat$y + Xa%*%rnorm(10)*.5 +
 Xb%*%rnorm(7)*.3 + Xab%*%rnorm(70)*.7
dat$a <- a; dat$b <- b

Fit the model using "re" terms, and smoother linkage

mod <- gam(y~s(a,bs="re")+s(b,bs="re")+s(a,b,bs="re")+s(x0,id=1)+s(x1,id=1)+
 s(x2,k=15)+s(x3),data=dat,method="ML")

gam.vcomp(mod)
```

gam2objective

*Objective functions for GAM smoothing parameter estimation***Description**

Estimation of GAM smoothing parameters is most stable if optimization of the UBRE/AIC or GCV score is outer to the penalized iteratively re-weighted least squares scheme used to estimate the model given smoothing parameters. These functions evaluate the GCV/UBRE/AIC score of a GAM model, given smoothing parameters, in a manner suitable for use by `optim` or `nlm`. Not normally called directly, but rather service routines for `gam.outer`.

**Usage**

```
gam2objective(lsp, args, ...)
gam2derivative(lsp, args, ...)
```

**Arguments**

|                   |                                                            |
|-------------------|------------------------------------------------------------|
| <code>lsp</code>  | The log smoothing parameters.                              |
| <code>args</code> | List of arguments required to call <code>gam.fit3</code> . |
| <code>...</code>  | Other arguments for passing to <code>gam.fit3</code> .     |

**Details**

`gam2objective` and `gam2derivative` are functions suitable for calling by `optim`, to evaluate the GCV/UBRE/AIC score and its derivatives w.r.t. log smoothing parameters.

`gam4objective` is an equivalent to `gam2objective`, suitable for optimization by `nlm` - derivatives of the GCV/UBRE/AIC function are calculated and returned as attributes.

The basic idea of optimizing smoothing parameters ‘outer’ to the P-IRLS loop was first proposed in O’Sullivan et al. (1986).

gamlss.etamu

*Transform derivatives wrt mu to derivatives wrt linear predictor***Description**

Mainly intended for internal use in specifying location scale models. Let  $g(\mu) = \eta$ , where  $\eta$  is the linear predictor, and  $g$  is the link function. Assume that we have calculated the derivatives of the log-likelihood wrt  $\mu$ . This function uses the chain rule to calculate the derivatives of the log-likelihood wrt  $\eta$ . See [trind.generator](#) for array packing conventions.

**Usage**

```
gamlss.etamu(l1, l2, l3 = NULL, l4 = NULL, ig1, g2, g3 = NULL,
 g4 = NULL, i2, i3 = NULL, i4 = NULL, deriv = 0)
```

**Arguments**

|                    |                                                                                                                                                                                                                         |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>l1</code>    | array of 1st order derivatives of log-likelihood wrt $\mu$ .                                                                                                                                                            |
| <code>l2</code>    | array of 2nd order derivatives of log-likelihood wrt $\mu$ .                                                                                                                                                            |
| <code>l3</code>    | array of 3rd order derivatives of log-likelihood wrt $\mu$ .                                                                                                                                                            |
| <code>l4</code>    | array of 4th order derivatives of log-likelihood wrt $\mu$ .                                                                                                                                                            |
| <code>ig1</code>   | reciprocal of the first derivative of the link function wrt the linear predictor.                                                                                                                                       |
| <code>g2</code>    | array containing the 2nd order derivative of the link function wrt the linear predictor.                                                                                                                                |
| <code>g3</code>    | array containing the 3rd order derivative of the link function wrt the linear predictor.                                                                                                                                |
| <code>g4</code>    | array containing the 4th order derivative of the link function wrt the linear predictor.                                                                                                                                |
| <code>i2</code>    | two-dimensional index array, such that <code>l2[, i2[i, j]]</code> contains the partial w.r.t. params indexed by $i, j$ with no restriction on the index values (except that they are in $1, \dots, \text{ncol}(l1)$ ). |
| <code>i3</code>    | third-dimensional index array, such that <code>l3[, i3[i, j, k]]</code> contains the partial w.r.t. params indexed by $i, j, k$ .                                                                                       |
| <code>i4</code>    | third-dimensional index array, such that <code>l4[, i4[i, j, k, l]]</code> contains the partial w.r.t. params indexed by $i, j, k, l$ .                                                                                 |
| <code>deriv</code> | if <code>deriv==0</code> only first and second order derivatives will be calculated. If <code>deriv==1</code> the function goes up to 3rd order, and if <code>deriv==2</code> it provides also 4th order derivatives.   |

**Value**

A list where the arrays `l1`, `l2`, `l3`, `l4` contain the derivatives (up to order four) of the log-likelihood wrt the linear predictor.

**Author(s)**

Simon N. Wood <[simon.wood@r-project.org](mailto:simon.wood@r-project.org)>.

gamlss.gH

*Calculating derivatives of log-likelihood wrt regression coefficients***Description**

Mainly intended for internal use with location scale model families. Given the derivatives of the log-likelihood wrt the linear predictor, this function obtains the derivatives and Hessian wrt the regression coefficients and derivatives of the Hessian w.r.t. the smoothing parameters. For input derivative array packing conventions see [trind.generator](#).

**Usage**

```
gamlss.gH(X, jj, l1, l2, i2, l3 = 0, i3 = 0, l4 = 0, i4 = 0, d1b = 0,
 d2b = 0, deriv = 0, fh = NULL, D = NULL)
```

**Arguments**

|       |                                                                                                                                                                                                                                                                                                                                   |
|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| X     | matrix containing the model matrices of all the linear predictors.                                                                                                                                                                                                                                                                |
| jj    | list of index vectors such that <code>X[,jj[[i]]]</code> is the model matrix of the i-th linear predictor.                                                                                                                                                                                                                        |
| l1    | array of 1st order derivatives of each element of the log-likelihood wrt each parameter.                                                                                                                                                                                                                                          |
| l2    | array of 2nd order derivatives of each element of the log-likelihood wrt each parameter.                                                                                                                                                                                                                                          |
| i2    | two-dimensional index array, such that <code>l2[,i2[i,j]]</code> contains the partial w.r.t. params indexed by i,j with no restriction on the index values (except that they are in 1,...,ncol(l1)).                                                                                                                              |
| l3    | array of 3rd order derivatives of each element of the log-likelihood wrt each parameter.                                                                                                                                                                                                                                          |
| i3    | third-dimensional index array, such that <code>l3[,i3[i,j,k]]</code> contains the partial w.r.t. params indexed by i,j,k.                                                                                                                                                                                                         |
| l4    | array of 4th order derivatives of each element of the log-likelihood wrt each parameter.                                                                                                                                                                                                                                          |
| i4    | third-dimensional index array, such that <code>l4[,i4[i,j,k,l]]</code> contains the partial w.r.t. params indexed by i,j,k,l.                                                                                                                                                                                                     |
| d1b   | first derivatives of the regression coefficients wrt the smoothing parameters.                                                                                                                                                                                                                                                    |
| d2b   | second derivatives of the regression coefficients wrt the smoothing parameters.                                                                                                                                                                                                                                                   |
| deriv | if <code>deriv==0</code> only first and second order derivatives will be calculated. If <code>deriv==1</code> the function return also the diagonal of the first derivative of the Hessian, if <code>deriv==2</code> it return the full 3rd order derivative and if <code>deriv==3</code> it provides also 4th order derivatives. |
| fh    | eigen-decomposition or Cholesky factor of the penalized Hessian.                                                                                                                                                                                                                                                                  |
| D     | diagonal matrix, used to provide some scaling.                                                                                                                                                                                                                                                                                    |

## Value

A list containing `lb` - the grad vector w.r.t. `coefs`; `lbb` - the Hessian matrix w.r.t. `coefs`; `d1H` - either a list of the derivatives of the Hessian w.r.t. the smoothing parameters, or a single matrix whose columns are the leading diagonals of these dervative matrices; `trHid2H` - the trace of the inverse Hessian multiplied by the second derivative of the Hessian w.r.t. all combinations of smoothing parameters.

*Generalized Additive Mixed Models*

---

## Description

Fits the specified generalized additive mixed model (GAMM) to data, by a call to `lme` in the normal errors identity link case, or by a call to `gammPQL` (a modification of `glmPQL` from the MASS library) otherwise. In the latter case estimates are only approximately MLEs. The routine is typically slower than `gam`, and not quite as numerically robust.

To use `lme4` in place of `nlme` as the underlying fitting engine, see `gamm4` from package `gamm4`.

Smooths are specified as in a call to [gam](#) as part of the fixed effects model formula, but the wiggly components of the smooth are treated as random effects. The random effects structures and correlation structures available for `lme` are used to specify other random effects and correlations.

It is assumed that the random effects and correlation structures are employed primarily to model residual correlation in the data and that the prime interest is in inference about the terms in the fixed effects model formula including the smooths. For this reason the routine calculates a posterior covariance matrix for the coefficients of all the terms in the fixed effects formula, including the smooths.

To use this function effectively it helps to be quite familiar with the use of [gam](#) and [lme](#).

## Usage

```
gamm(formula, random=NULL, correlation=NULL, family=gaussian(),
data=list(), weights=NULL, subset=NULL, na.action, knots=NULL,
control=list(niterEM=0, optimMethod="L-BFGS-B", returnObject=TRUE),
niterPQL=20, verbosePQL=TRUE, method="ML", drop.unused.levels=TRUE,
mustart=NULL, etastart=NULL, ...)
```

## Arguments

|                      |                                                                                                                                                                                                                                                                                                                                                                                                     |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>formula</code> | A GAM formula (see also <a href="#">formula.gam</a> and <a href="#">gam.models</a> ). This is like the formula for a <code>glm</code> except that smooth terms ( <code>s</code> , <code>te</code> etc.) can be added to the right hand side of the formula. Note that <code>ids</code> for smooths and fixed smoothing parameters are not supported. Any offset should be specified in the formula. |

|                                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|---------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>random</code>             | The (optional) random effects structure as specified in a call to <code>lme</code> : only the <code>list</code> form is allowed, to facilitate manipulation of the random effects structure within <code>gamm</code> in order to deal with smooth terms. See example below.                                                                                                                                                                                                                                                                                                                                                                                                        |
| <code>correlation</code>        | An optional <code>corStruct</code> object (see <code>corClasses</code> ) as used to define correlation structures in <code>lme</code> . Any grouping factors in the formula for this object are assumed to be nested within any random effect grouping factors, without the need to make this explicit in the formula (this is slightly different to the behaviour of <code>lme</code> ). This is a GEE approach to correlation in the generalized case. See examples below.                                                                                                                                                                                                       |
| <code>family</code>             | A family as used in a call to <code>glm</code> or <code>gam</code> . The default <code>gaussian</code> with identity link causes <code>gamm</code> to fit by a direct call to <code>lme</code> provided there is no offset term, otherwise <code>gammPQL</code> is used.                                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>data</code>               | A data frame or list containing the model response variable and covariates required by the formula. By default the variables are taken from <code>environment(formula)</code> , typically the environment from which <code>gamm</code> is called.                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <code>weights</code>            | In the generalized case, weights with the same meaning as <code>glm</code> weights. An <code>lme</code> type weights argument may only be used in the identity link gaussian case, with no offset (see documentation for <code>lme</code> for details of how to use such an argument).                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>subset</code>             | an optional vector specifying a subset of observations to be used in the fitting process.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <code>na.action</code>          | a function which indicates what should happen when the data contain 'NA's. The default is set by the 'na.action' setting of 'options', and is 'na.fail' if that is unset. The "factory-fresh" default is 'na.omit'.                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>knots</code>              | this is an optional list containing user specified knot values to be used for basis construction. Different terms can use different numbers of knots, unless they share a covariate.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>control</code>            | A list of fit control parameters for <code>lme</code> to replace the defaults returned by <code>lmeControl</code> . Note the setting for the number of EM iterations used by <code>lme</code> : smooths are set up using custom <code>pdMat</code> classes, which are currently not supported by the EM iteration code. If you supply a list of control values, it is advisable to include <code>niterEM=0</code> , as well, and only increase from 0 if you want to perturb the starting values used in model fitting (usually to worse values!). The <code>optimMethod</code> option is only used if your version of R does not have the <code>nlminb</code> optimizer function. |
| <code>niterPQL</code>           | Maximum number of PQL iterations (if any).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>verbosePQL</code>         | Should PQL report its progress as it goes along?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>method</code>             | Which of "ML" or "REML" to use in the Gaussian additive mixed model case when <code>lme</code> is called directly. Ignored in the generalized case (or if the model has an offset), in which case <code>gammPQL</code> is used.                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>drop.unused.levels</code> | by default unused levels are dropped from factors before fitting. For some smooths involving factor variables you might want to turn this off. Only do so if you know what you are doing.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <code>mustart</code>            | starting values for mean if PQL used.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <code>etastart</code>           | starting values for linear predictor if PQL used (over-rides <code>mustart</code> if supplied).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>...</code>                | further arguments for passing on e.g. to <code>lme</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

## Details

The Bayesian model of spline smoothing introduced by Wahba (1983) and Silverman (1985) opens up the possibility of estimating the degree of smoothness of terms in a generalized additive model as variances of the wiggly components of the smooth terms treated as random effects. Several authors have recognised this (see Wang 1998; Ruppert, Wand and Carroll, 2003) and in the normal errors, identity link case estimation can be performed using general linear mixed effects modelling software such as `lme`. In the generalized case only approximate inference is so far available, for example using the Penalized Quasi-Likelihood approach of Breslow and Clayton (1993) as implemented in `glmmPQL` by Venables and Ripley (2002). One advantage of this approach is that it allows correlated errors to be dealt with via random effects or the correlation structures available in the `nlme` library (using correlation structures beyond the strictly additive case amounts to using a GEE approach to fitting).

Some details of how GAMs are represented as mixed models and estimated using `lme` or `gammPQL` in `gamm` can be found in Wood (2004, 2006a,b). In addition `gamm` obtains a posterior covariance matrix for the parameters of all the fixed effects and the smooth terms. The approach is similar to that described in Lin & Zhang (1999) - the covariance matrix of the data (or pseudodata in the generalized case) implied by the weights, correlation and random effects structure is obtained, based on the estimates of the parameters of these terms and this is used to obtain the posterior covariance matrix of the fixed and smooth effects.

The bases used to represent smooth terms are the same as those used in `gam`, although adaptive smoothing bases are not available. Prediction from the returned `gam` object is straightforward using `predict.gam`, but this will set the random effects to zero. If you want to predict with random effects set to their predicted values then you can adapt the prediction code given in the examples below.

In the event of `lme` convergence failures, consider modifying `options(mgcv.vc.logrange):` reducing it helps to remove indefiniteness in the likelihood, if that is the problem, but too large a reduction can force over or undersmoothing. See [notExp2](#) for more information on this option. Failing that, you can try increasing the `niterEM` option in `control`: this will perturb the starting values used in fitting, but usually to values with lower likelihood! Note that this version of `gamm` works best with R 2.2.0 or above and `nlme`, 3.1-62 and above, since these use an improved optimizer.

## Value

Returns a list with two items:

|                  |                                                                                                                                                                                                                                                                                                                                                                                                          |
|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>gam</code> | an object of class <code>gam</code> , less information relating to GCV/UBRE model selection. At present this contains enough information to use <code>predict</code> , <code>summary</code> and <code>print</code> methods and <code>vis.gam</code> , but not to use e.g. the <code>anova</code> method function to compare models. This is based on the working model when using <code>gammPQL</code> . |
| <code>lme</code> | the fitted model object returned by <code>lme</code> or <code>gammPQL</code> . Note that the model formulae and grouping structures may appear to be rather bizarre, because of the manner in which the GAMM is split up and the calls to <code>lme</code> and <code>gammPQL</code> are constructed.                                                                                                     |

## WARNINGS

`gamm` has a somewhat different argument list to `gam`, `gam` arguments such as `gamma` supplied to `gamm` will just be ignored.

`gamm` performs poorly with binary data, since it uses PQL. It is better to use `gam` with `s(..., bs="re")` terms, or `gamm4`.

`gamm` assumes that you know what you are doing! For example, unlike `glmPQL` from MASS it will return the complete `lme` object from the working model at convergence of the PQL iteration, including the ‘log likelihood’, even though this is not the likelihood of the fitted GAMM.

The routine will be very slow and memory intensive if correlation structures are used for the very large groups of data. e.g. attempting to run the spatial example in the examples section with many 1000’s of data is definitely not recommended: often the correlations should only apply within clusters that can be defined by a grouping factor, and provided these clusters do not get too huge then fitting is usually possible.

Models must contain at least one random effect: either a smooth with non-zero smoothing parameter, or a random effect specified in argument `random`.

`gamm` is not as numerically stable as `gam`: an `lme` call will occasionally fail. See details section for suggestions, or try the ‘`gamm4`’ package.

`gamm` is usually much slower than `gam`, and on some platforms you may need to increase the memory available to R in order to use it with large data sets (see `memory.limit`).

Note that the weights returned in the fitted GAM object are dummy, and not those used by the PQL iteration: this makes partial residual plots look odd.

Note that the `gam` object part of the returned object is not complete in the sense of having all the elements defined in `gamObject` and does not inherit from `glm`: hence e.g. multi-model `anova` calls will not work. It is also based on the working model when PQL is used.

The parameterization used for the smoothing parameters in `gamm`, bounds them above and below by an effective infinity and effective zero. See `notExp2` for details of how to change this.

Linked smoothing parameters and adaptive smoothing are not supported.

### Examples

```
library(mgcv)
simple examples using gamm as alternative to gam
set.seed(0)
dat <- gamSim(1,n=200,scale=2)
b <- gamm(y~s(x0)+s(x1)+s(x2)+s(x3),data=dat)
plot(b$gam,pages=1)
summary(b$lme) # details of underlying lme fit
summary(b$gam) # gam style summary of fitted model
anova(b$gam)
gam.check(b$gam) # simple checking plots

b <- gamm(y~te(x0,x1)+s(x2)+s(x3),data=dat)
op <- par(mfrow=c(2,2))
plot(b$gam)
par(op)
rm(dat)

Add a factor to the linear predictor, to be modelled as random
dat <- gamSim(6,n=200,scale=.2,dist="poisson")
b2 <- gamm(y~s(x0)+s(x1)+s(x2),family=poisson,
 data=dat,random=list(fac=~1))
plot(b2$gam,pages=1)
fac <- dat$fac
rm(dat)
vis.gam(b2$gam)

In the generalized case the 'gam' object is based on the working
model used in the PQL fitting. Residuals for this are not
that useful on their own as the following illustrates...

gam.check(b2$gam)

But more useful residuals are easy to produce on a model
by model basis. For example...

fv <- exp(fitted(b2$lme)) ## predicted values (including re)
rsd <- (b2gamy - fv)/sqrt(fv) ## Pearson residuals (Poisson case)
op <- par(mfrow=c(1,2))
qqnorm(rsd);plot(fv^.5,rsd)
par(op)
```

```

now an example with autocorrelated errors....
n <- 200; sig <- 2
x <- 0:(n-1)/(n-1)
f <- 0.2*x^11*(10*(1-x))^6+10*(10*x)^3*(1-x)^10
e <- rnorm(n,0,sig)
for (i in 2:n) e[i] <- 0.6*e[i-1] + e[i]
y <- f + e
op <- par(mfrow=c(2,2))
Fit model with AR1 residuals
b <- gamm(y~s(x,k=20),correlation=corAR1())
plot(b$gam); lines(x,f-mean(f),col=2)
Raw residuals still show correlation, of course...
acf(residuals(b$gam),main="raw residual ACF")
But standardized are now fine...
acf(residuals(b$lme,type="normalized"),main="standardized residual ACF")
compare with model without AR component...
b <- gam(y~s(x,k=20))
plot(b); lines(x,f-mean(f),col=2)

more complicated autocorrelation example - AR errors
only within groups defined by `fac`
e <- rnorm(n,0,sig)
for (i in 2:n) e[i] <- 0.6*e[i-1]*(fac[i-1]==fac[i]) + e[i]
y <- f + e
b <- gamm(y~s(x,k=20),correlation=corAR1(form=~1|fac))
plot(b$gam); lines(x,f-mean(f),col=2)
par(op)

more complex situation with nested random effects and within
group correlation

set.seed(0)

gammals

*Gamma location-scale model family***Description**

The `gammals` family implements gamma location scale additive models in which the log of the mean and the log of the scale parameter (see details) can depend on additive smooth predictors. Useable only with `gam`, the linear predictors are specified via a list of formulae.

**Usage**

```
gammals(link=list("identity", "log"), b=-7)
```

## Arguments

- `link` two item list specifying the link for the mean and the standard deviation. See details for meaning which may not be intuitive.
- `b` The minimum log scale parameter.

## Details

Used with `gam` to fit gamma location - scale models parameterized in terms of the log mean and the log scale parameter (the response variance is the mean multiplied by the scale parameter). Note that `identity` links mean that the linear predictors give the log mean and scale directly. By default the `log` link for the scale parameter simply forces the log scale parameter to have a lower limit given by argument `b`: if  $\eta$  is the linear predictor for the log scale parameter,  $\phi$ , then  $\log \phi = b + \log(1 + e^\eta)$ .

`gam` is called with a list containing 2 formulae, the first specifies the response on the left hand side and the structure of the linear predictor for the log mean on the right hand side. The second is one sided, specifying the linear predictor for the log scale on the right hand side.

The fitted values for this family will be a two column matrix. The first column is the mean (on original, not log, scale), and the second column is the log scale. Predictions using `predict.gam` will also produce 2 column matrices for `type="link"` and `"response"`. The first column is on the original data scale when `type="response"` and on the log mean scale of the linear predictor when `type="link"`. The second column when `type="response"` is again the log scale parameter, but is on the linear predictor when `type="link"`.

The null deviance reported for this family computed by setting the fitted values to the mean response, but using the model estimated scale.

## Value

An object inheriting from class `general.family`.

## Examples

```
library(mgcv)
simulate some data
f0 <- function(x) 2 * sin(pi * x)
f1 <- function(x) exp(2 * x)
f2 <- function(x) 0.2 * x^11 * (10 * (1 - x))^6 + 10 *
 (10 * x)^3 * (1 - x)^10
f3 <- function(x) 0 * x
n <- 400; set.seed(9)
x0 <- runif(n); x1 <- runif(n);
x2 <- runif(n); x3 <- runif(n);
mu <- exp((f0(x0) + f2(x2)) / 5)
th <- exp(f1(x1) / 2 - 2)
y <- rgamma(n, shape=1/th, scale=mu*th)

b1 <- gam(list(y~s(x0)+s(x2), ~s(x1)+s(x3)), family=gammals)
plot(b1, pages=1)
summary(b1)
```

```
gam.check(b1)
plot(mu, fitted(b1)[,1]); abline(0,1,col=2)
plot(log(th), fitted(b1)[,2]); abline(0,1,col=2)
```

gamObject

*Fitted gam object*

## Description

A fitted GAM object returned by function `gam` and of class "gam" inheriting from classes "glm" and "lm". Method functions `anova`, `logLik`, `influence`, `plot`, `predict`, `print`, `residuals` and `summary` exist for this class.

All compulsory elements of "glm" and "lm" objects are present, but the fitting method for a GAM is different to a linear model or GLM, so that the elements relating to the QR decomposition of the model matrix are absent.

## Value

A gam object has the following elements:

|                           |                                                                                                                                                                                                                                                       |
|---------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>aic</code>          | AIC of the fitted model: bear in mind that the degrees of freedom used to calculate this are the effective degrees of freedom of the model, and the likelihood is evaluated at the maximum of the penalized likelihood in most cases, not at the MLE. |
| <code>assign</code>       | Array whose elements indicate which model term (listed in <code>pterm</code> s) each parameter relates to: applies only to non-smooth terms.                                                                                                          |
| <code>boundary</code>     | did parameters end up at boundary of parameter space?                                                                                                                                                                                                 |
| <code>call</code>         | the matched call (allows <code>update</code> to be used with <code>gam</code> objects, for example).                                                                                                                                                  |
| <code>cmX</code>          | column means of the model matrix (with elements corresponding to smooths set to zero) — useful for componentwise CI calculation.                                                                                                                      |
| <code>coefficients</code> | the coefficients of the fitted model. Parametric coefficients are first, followed by coefficients for each spline term in turn.                                                                                                                       |
| <code>control</code>      | the <code>gam</code> control list used in the fit.                                                                                                                                                                                                    |
| <code>converged</code>    | indicates whether or not the iterative fitting method converged.                                                                                                                                                                                      |
| <code>data</code>         | the original supplied data argument (for class "glm" compatibility). Only included if <code>gam</code> control argument element <code>keepData</code> is set to <code>TRUE</code> (default is <code>FALSE</code> ).                                   |
| <code>db.drho</code>      | matrix of first derivatives of model coefficients w.r.t. log smoothing parameters.                                                                                                                                                                    |
| <code>deviance</code>     | model deviance (not penalized deviance).                                                                                                                                                                                                              |
| <code>df.null</code>      | null degrees of freedom.                                                                                                                                                                                                                              |
| <code>df.residual</code>  | effective residual degrees of freedom of the model.                                                                                                                                                                                                   |
| <code>edf</code>          | estimated degrees of freedom for each model parameter. Penalization means that many of these are less than 1.                                                                                                                                         |
| <code>edf1</code>         | similar, but using alternative estimate of EDF. Useful for testing.                                                                                                                                                                                   |

|                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| edf2              | if estimation is by ML or REML then an edf that accounts for smoothing parameter uncertainty can be computed, this is it. edf1 is a heuristic upper bound for edf2.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| family            | family object specifying distribution and link used.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| formula           | the model formula.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| full.sp           | full array of smoothing parameters multiplying penalties (excluding any contribution from min.sp argument to gam). May be larger than sp if some terms share smoothing parameters, and/or some smoothing parameter values were supplied in the sp argument of gam.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| F                 | Degrees of freedom matrix. This may be removed at some point, and should probably not be used.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| gcv.ubre          | The minimized smoothing parameter selection score: GCV, UBRE(AIC), GACV, negative log marginal likelihood or negative log restricted likelihood.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| hat               | array of elements from the leading diagonal of the ‘hat’ (or ‘influence’) matrix. Same length as response data vector.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| iter              | number of iterations of P-IRLS taken to get convergence.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| linear.predictors | fitted model prediction of link function of expected value for each datum.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| method            | One of "GCV" or "UBRE", "REML", "P-REML", "ML", "P-ML", "PQL", "lme.ML" or "lme.REML", depending on the fitting criterion used.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| mgcv.conv         | A list of convergence diagnostics relating to the "magic" parts of smoothing parameter estimation - this will not be very meaningful for pure "outer" estimation of smoothing parameters. The items are: full.rank, The apparent rank of the problem given the model matrix and constraints; rank, The numerical rank of the problem; fully.converged, TRUE is multiple GCV/UBRE converged by meeting convergence criteria and FALSE if method stopped with a steepest descent step failure; hess.pos.def Was the hessian of the GCV/UBRE score positive definite at smoothing parameter estimation convergence?; iter How many iterations were required to find the smoothing parameters? score.calls, and how many times did the GCV/UBRE score have to be evaluated?; rms.grad, root mean square of the gradient of the GCV/UBRE score at convergence. |
| min.edf           | Minimum possible degrees of freedom for whole model.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| model             | model frame containing all variables needed in original model fit.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| na.action         | The na.action used in fitting.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| nsdf              | number of parametric, non-smooth, model terms including the intercept.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| null.deviance     | deviance for single parameter model.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| offset            | model offset.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| optimizer         | optimizer argument to gam, or "magic" if it's a pure additive model.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| outer.info        | If ‘outer’ iteration has been used to fit the model (see gam argument optimizer) then this is present and contains whatever was returned by the optimization routine used (currently nlm or optim).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| paraPen           | If the paraPen argument to gam was used then this provides information on the parametric penalties. NULL otherwise.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| <code>pred.formula</code>    | one sided formula containing variables needed for prediction, used by <code>predict.gam</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>prior.weights</code>   | prior weights on observations.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>pterm</code>           | terms object for strictly parametric part of model.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <code>R</code>               | Factor R from QR decomposition of weighted model matrix, unpivoted to be in same column order as model matrix (so need not be upper triangular).                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>rank</code>            | apparent rank of fitted model.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>reml.scale</code>      | The scale (RE)ML scale parameter estimate, if (P-)(RE)ML used for smoothness estimation.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>residuals</code>       | the working residuals for the fitted model.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>rV</code>              | If present, <code>rV%*%t(rV)*sig2</code> gives the estimated Bayesian covariance matrix.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>scale</code>           | when present, the scale (as <code>sig2</code> )                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <code>scale.estimated</code> | TRUE if the scale parameter was estimated, FALSE otherwise.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>sig2</code>            | estimated or supplied variance/scale parameter.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <code>smooth</code>          | list of smooth objects, containing the basis information for each term in the model formula in the order in which they appear. These smooth objects are what gets returned by the <code>smooth.construct</code> objects.                                                                                                                                                                                                                                                                                                                                                   |
| <code>sp</code>              | estimated smoothing parameters for the model. These are the underlying smoothing parameters, subject to optimization. For the full set of smoothing parameters multiplying the penalties see <code>full.sp</code> . Divide the scale parameter by the smoothing parameters to get, variance components, but note that this is not valid for smooths that have used rescaling to improve conditioning.                                                                                                                                                                      |
| <code>terms</code>           | terms object of model model frame.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>var.summary</code>     | A named list of summary information on the predictor variables. If a parametric variable is a matrix, then the summary is a one row matrix, containing the observed data value closest to the column median, for each matrix column. If the variable is a factor the then summary is the modal factor level, returned as a factor, with levels corresponding to those of the data. For numerics and matrix arguments of smooths, the summary is the mean, nearest observed value to median and maximum, as a numeric vector. Used by <code>vis.gam</code> , in particular. |
| <code>Ve</code>              | frequentist estimated covariance matrix for the parameter estimators. Particularly useful for testing whether terms are zero. Not so useful for CI's as smooths are usually biased.                                                                                                                                                                                                                                                                                                                                                                                        |
| <code>Vp</code>              | estimated covariance matrix for the parameters. This is a Bayesian posterior covariance matrix that results from adopting a particular Bayesian model of the smoothing process. Particularly useful for creating credible/confidence intervals.                                                                                                                                                                                                                                                                                                                            |
| <code>Vc</code>              | Under ML or REML smoothing parameter estimation it is possible to correct the covariance matrix <code>Vp</code> for smoothing parameter uncertainty. This is the corrected version.                                                                                                                                                                                                                                                                                                                                                                                        |
| <code>weights</code>         | final weights used in IRLS iteration.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>y</code>               | response data.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

## WARNINGS

This model object is different to that described in Chambers and Hastie (1993) in order to allow smoothing parameter estimation etc.

*Simulate example data for GAMs*

---

**Description**

Function used to simulate data sets to illustrate the use of [gam](#) and [gamm](#). Mostly used in help files to keep down the length of the example code sections.

**Usage**

```
gamSim(eg=1, n=400, dist="normal", scale=2, verbose=TRUE)
```

**Arguments**

|         |                                                                                 |
|---------|---------------------------------------------------------------------------------|
| eg      | numeric value specifying the example required.                                  |
| n       | number of data to simulate.                                                     |
| dist    | character string which may be used to specify the distribution of the response. |
| scale   | Used to set noise level.                                                        |
| verbose | Should information about simulation type be printed?                            |

**Details**

See the source code for exactly what is simulated in each case.

1. Gu and Wahba 4 univariate term example.
2. A smooth function of 2 variables.
3. Example with continuous by variable.
4. Example with factor by variable.
5. An additive example plus a factor variable.
6. Additive + random effect.
7. As 1 but with correlated covariates.

## Value

Depends on `eg`, but usually a dataframe, which may also contain some information on the underlying truth. Sometimes a list with more items, including a data frame for model fitting. See source code or helpfile examples where the function is used for further information.

|--------|---------------------------------------------|
| gaulss | <i>Gaussian location-scale model family</i> |
|--------|---------------------------------------------|

---

## Description

The `gaulss` family implements Gaussian location scale additive models in which the mean and the `logb` of the standard deviation (see details) can depend on additive smooth predictors. Useable only with [gam](#), the linear predictors are specified via a list of formulae.

## Usage

```
gaulss(link=list("identity", "logb"), b=0.01)
```

## Arguments

- |                   |                                                                                         |
|-------------------|-----------------------------------------------------------------------------------------|
| <code>link</code> | two item list specifying the link for the mean and the standard deviation. See details. |
| <code>b</code>    | The minumum standard deviation, for the "logb" link.                                    |

## Details

Used with [gam](#) to fit Gaussian location - scale models. `gam` is called with a list containing 2 formulae, the first specifies the response on the left hand side and the structure of the linear predictor for the mean on the right hand side. The second is one sided, specifying the linear predictor for the standard deviation on the right hand side.

Link functions "identity", "inverse", "log" and "sqrt" are available for the mean. For the standard deviation only the "logb" link is implemented:  $\eta = \log(\sigma - b)$  and  $\sigma = b + \exp(\eta)$ . This link is designed to avoid singularities in the likelihood caused by the standard deviation tending to zero. Note that internally the family is parameterized in terms of the  $\tau = \sigma^{-1}$ , i.e. the standard deviation of the precision, so the link and inverse link are coded to reflect this, however the relationships between the linear predictor and the standard deviation are as given above.

The fitted values for this family will be a two column matrix. The first column is the mean, and the second column is the inverse of the standard deviation. Predictions using [predict.gam](#) will also produce 2 column matrices for type "link" and "response". The second column

when `type="response"` is again on the reciprocal standard deviation scale (i.e. the square root precision scale). The second column when `type="link"` is  $\log(\sigma - b)$ . Also `plot.gam` will plot smooths relating to  $\sigma$  on the  $\log(\sigma - b)$  scale (so high values correspond to high standard deviation and low values to low standard deviation). Similarly the smoothing penalties are applied on the (log) standard deviation scale, not the log precision scale.

The null deviance reported for this family is the sum of squares of the difference between the response and the mean response divided by the standard deviation of the response according to the model. The deviance is the sum of squares of residuals divided by model standard deviations.

Value

An object inheriting from class `general.family`.

Examples

```
library(mgcv); library(MASS)
b <- gam(list(accel~s(times,k=20,bs="ad"),~s(times)),
 data=mcycle,family=gaulss())
summary(b)
plot(b,pages=1,scale=0)
```

---

|         |                                                                   |
|---------|-------------------------------------------------------------------|
| get.var | Get named variable or evaluate expression from list or data.frame |
|---------|-------------------------------------------------------------------|

---

Description

This routine takes a text string and a data frame or list. It first sees if the string is the name of a variable in the data frame/ list. If it is then the value of this variable is returned. Otherwise the routine tries to evaluate the expression within the data.frame/list (but nowhere else) and if successful returns the result. If neither step works then NULL is returned. The routine is useful for processing gam formulae. If the variable is a matrix then it is coerced to a numeric vector, by default.

Usage

```
get.var(txt,data,vecMat=TRUE)
```

Arguments

- |        |                                                                                                                                                                                             |
|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| txt    | a text string which is either the name of a variable in data or when parsed is an expression that can be evaluated in data. It can also be neither in which case the function returns NULL. |
| data   | A data frame or list.                                                                                                                                                                       |
| vecMat | Should matrices be coerced to numeric vectors?                                                                                                                                              |

**Value**

The evaluated variable or NULL. May be coerced to a numeric vector if it's a matrix.

gevlss

*Generalized Extreme Value location-scale model family*

---

**Description**

The `gevlss` family implements Generalized Extreme Value location scale additive models in which the location, scale and shape parameters depend on additive smooth predictors. Usable only with [gam](#), the linear predictors are specified via a list of formulae.

**Usage**

```
gevlss(link=list("identity", "identity", "logit"))
```

**Arguments**

|      |                                                                                               |
|------|-----------------------------------------------------------------------------------------------|
| link | three item list specifying the link for the location scale and shape parameters. See details. |
|------|-----------------------------------------------------------------------------------------------|

**Details**

Used with [gam](#) to fit Generalized Extreme Value location scale and shape models. `gam` is called with a list containing 3 formulae: the first specifies the response on the left hand side and the structure of the linear predictor for the location parameter on the right hand side. The second is one sided, specifying the linear predictor for the log scale parameter on the right hand side. The third is one sided specifying the linear predictor for the shape parameter.

Link functions "identity" and "log" are available for the location ( $\mu$ ) parameter. There is no choice of link for the log scale parameter ( $\rho = \log \sigma$ ). The shape parameter ( $\xi$ ) defaults to a

modified logit link restricting its range to  $(-1, 5)$ , the upper limit is required to ensure finite variance, while the lower limit ensures consistency of the MLE (Smith, 1985).

The fitted values for this family will be a three column matrix. The first column is the location parameter, the second column is the log scale parameter, the third column is the shape parameter.

This family does not produce a null deviance. Note that the distribution for  $\xi = 0$  is approximated by setting  $\xi$  to a small number.

The derivative system code for this family is mostly auto-generated, and the family is still somewhat experimental.

The GEV distribution is rather challenging numerically, and for small datasets or poorly fitting models improved numerical robustness may be obtained by using the extended Fellner-Schall method of Wood and Fasiolo (2017) for smoothing parameter estimation. See examples.

## Value

An object inheriting from class `general.family`.

ginla

*GAM Integrated Nested Laplace Approximation Newton Enhanced***Description**

Apply Integrated Nested Laplace Approximation (INLA, Rue et al. 2009) to models estimable by [gam](#) or [bam](#), using the INLA variant described in Wood (2019). Produces marginal posterior densities for each coefficient, selected coefficients or linear transformations of the coefficient vector.

**Usage**

```
ginla(G,A=NULL,nk=16,nb=100,J=1,interactive=FALSE,int=0,approx=0)
```

**Arguments**

|             |                                                                                                                                                                                                                                                                                                 |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| G           | A pre-fit gam object, as produced by <code>gam(...,fit=FALSE)</code> or <code>bam(...,discrete=TRUE,fit=FALSE)</code> .                                                                                                                                                                         |
| A           | Either a matrix of transforms of the coefficients that are of interest, or an array of indices of the parameters of interest. If <code>NULL</code> then distributions are produced for all coefficients.                                                                                        |
| nk          | Number of values of each coefficient at which to evaluate its log marginal posterior density. These points are then spline interpolated.                                                                                                                                                        |
| nb          | Number of points at which to evaluate posterior density of coefficients for returning as a gridded function.                                                                                                                                                                                    |
| J           | How many determinant updating steps to take in the log determinant approximation step. Not recommended to increase this.                                                                                                                                                                        |
| interactive | If this is <code>&gt;0</code> or <code>TRUE</code> then every approximate posterior is plotted in red, overlaid on the simple Gaussian approximate posterior. If 2 then waits for user to press return between each plot. Useful for judging whether anything is gained by using INLA approach. |

|                     |                                                                                                                                                      |
|---------------------|------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>int</code>    | 0 to skip integration and just use the posterior modal smoothing parameter. >0 for integration using the CCD approach proposed in Rue et al. (2009). |
| <code>approx</code> | 0 for full approximation; 1 to update Hessian, but use approximate modes; 2 as 1 and assume constant Hessian. See details.                           |

## Details

Let  $\beta$ ,  $\theta$  and  $y$  denote the model coefficients, hyperparameters/smoothing parameters and response data, respectively. In principle, INLA employs Laplace approximations for  $\pi(\beta_i|\theta, y)$  and  $\pi(\theta|y)$  and then obtains the marginal posterior distribution  $\pi(\beta_i|y)$  by integrating the approximations to  $\pi(\beta_i|\theta, y)\pi(\theta|y)$  w.r.t  $\theta$  (marginals for the hyperparameters can also be produced). In practice the Laplace approximation for  $\pi(\beta_i|\theta, y)$  is too expensive to compute for each  $\beta_i$  and must itself be approximated. To this end, there are two quantities that have to be computed: the posterior mode  $\beta^*|\beta_i$  and the determinant of the Hessian of the joint log density  $\log \pi(\beta, \theta, y)$  w.r.t.  $\beta$  at the mode. Rue et al. (2009) originally approximated the posterior conditional mode by the conditional mode implied by a simple Gaussian approximation to the posterior  $\pi(\beta|y)$ . They then approximated the log determinant of the Hessian as a function of  $\beta_i$  using a first order Taylor expansion, which is cheap to compute for the sparse model representation that they use, but not when using the dense low rank basis expansions used by `gam`. They also offer a more expensive alternative approximation based on computing the log determinant with respect only to those elements of  $\beta$  with sufficiently high correlation with  $\beta_i$  according to the simple Gaussian posterior approximation: efficiency again seems to rest on sparsity. Wood (2018) suggests computing the required posterior modes exactly, and basing the log determinant approximation on a BFGS update of the Hessian at the unconditional model. The latter is efficient with or without sparsity, whereas the former is a ‘for free’ improvement. Both steps are efficient because it is cheap to obtain the Cholesky factor of  $H[-i, -i]$  from that of  $H$  - see `choldrop`. This is the approach taken by this routine.

The `approx` argument allows two further approximations to speed up computations. For `approx==1` the exact posterior conditional modes are not used, but instead the conditional modes implied by the simple Gaussian posterior approximation. For `approx==2` the same approximation is used for the modes and the Hessian is assumed constant. The latter is quite fast as no log joint density gradient evaluations are required.

Note that for many models the INLA estimates are very close to the usual Gaussian approximation to the posterior, the `interactive` argument is useful for investigating this issue.

`bam` models are only supported with the `discrete=TRUE` option. The `discrete=FALSE` approach would be too inefficient. AR1 models are not supported (related arguments are simply ignored).

## Value

A list with elements `beta` and `density`, both of which are matrices. Each row relates to one coefficient (or linear coefficient combination) of interest. Both matrices have `nb` columns. If `int != 0` then a further element `reml` gives the integration weights used in the CCD integration, with the central point weight given first.

## WARNINGS

This routine is still somewhat experimental, so details are liable to change. Also currently not all steps are optimally efficient.

The routine is written for relatively expert users.

`ginla` is not designed to deal with rank deficient models.

**Examples**

```
require(mgcv); require(MASS)

example using a scale location model for the motorcycle data. A simple plotting
routine is produced first...

plot.inla <- function(x,inla,k=1,levels=c(.025,.1,.5,.9,.975),
 lcol = c(2,4,4,4,2),lwd = c(1,1,2,1,1),lty=c(1,1,1,1,1),
 xlab="x",ylab="y",cex.lab=1.5) {
 ## a simple effect plotter, when distributions of function values of
 ## 1D smooths have been computed
 require(splines)
 p <- length(x)
 betaq <- matrix(0,length(levels),p) ## storage for beta quantiles
 for (i in 1:p) { ## work through x and betas
 j <- i + k - 1
 p <- cumsum(inla$density[j,])*(inla$beta[j,2]-inla$beta[j,1])
 ## getting quantiles of function values...
 betaq[i,] <- approx(p,y=inla$beta[j,],levels)$y
 }
 xg <- seq(min(x),max(x),length=200)
 ylim <- range(betaq)
 ylim <- 1.1*(ylim-mean(ylim))+mean(ylim)
 for (j in 1:length(levels)) { ## plot the quantiles
 din <- interpSpline(x,betaq[j,])
 if (j==1) {
 plot(xg,predict(din,xg)$y,ylim=ylim,type="l",col=lcol[j],
 xlab=xlab,ylab=ylab,lwd=lwd[j],cex.lab=1.5,lty=lty[j])
 } else lines(xg,predict(din,xg)$y,col=lcol[j],lwd=lwd[j],lty=lty[j])
 }
} ## plot.inla

set up the model with a `gam' call...

G <- gam(list(accel~s(times,k=20,bs="ad"),~s(times)),
 data=mcycle,family=gauss(),fit=FALSE)
b <- gam(G,method="REML") ## regular GAM fit for comparison

Now use ginla to get posteriors of estimated effect values
at evenly spaced times. Create A matrix for this...

rat <- range(mcycle$times)
pd0 <- data.frame(times=seq(rat[1],rat[2],length=20))
X0 <- predict(b,newdata=pd0,type="lpmatrix")
X0[,21:30] <- 0
```

```

pd1 <- data.frame(times=seq(rat[1],rat[2],length=10))
X1 <- predict(b,newdata=pd1,type="lpmatrix")
X1[,1:20] <- 0
A <- rbind(X0,X1) ## A maps coefs to required function values

call ginla. Set int to 1 for integrated version.
Set interactive = 1 or 2 to plot marginal posterior distributions
(red) and simple Gaussian approximation (black).

inla <- ginla(G,A,int=0)

par(mfrow=c(1,2),mar=c(5,5,1,1))
fv <- predict(b,se=TRUE) ## usual Gaussian approximation, for comparison

plot inla mean smooth effect...
plot.inla(pd0$times,inla,k=1,xlab="time",ylab=expression(f[1](time)))

overlay simple Gaussian equivalent (in grey) ...
points(mcycle$times,mcycle$accel,col="grey")
lines(mcycle$times,fv$fit[,1],col="grey",lwd=2)
lines(mcycle$times,fv$fit[,1]+2*fv$se.fit[,1],lty=2,col="grey",lwd=2)
lines(mcycle$times,fv$fit[,1]-2*fv$se.fit[,1],lty=2,col="grey",lwd=2)

same for log sd smooth...
plot.inla(pd1$times,inla,k=21,xlab="time",ylab=expression(f[2](time)))
lines(mcycle$times,fv$fit[,2],col="grey",lwd=2)
lines(mcycle$times,fv$fit[,2]+2*fv$se.fit[,2],col="grey",lty=2,lwd=2)
lines(mcycle$times,fv$fit[,2]-2*fv$se.fit[,2],col="grey",lty=2,lwd=2)

... notice some real differences for the log sd smooth, especially
at the lower and upper ends of the time interval.

```

gumbls

*Gumbel location-scale model family*

## Description

The `gumbls` family implements Gumbel location scale additive models in which the location and scale parameters (see details) can depend on additive smooth predictors. Useable only with [gam](#), the linear predictors are specified via a list of formulae.

## Usage

```
gumbls(link=list("identity", "log"), b=-7)
```

## Arguments

|                   |                                                                                                                                                 |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>link</code> | two item list specifying the link for the location $\mu$ and log scale parameter $\beta$ . See details for meaning, which may not be intuitive. |
| <code>b</code>    | The minimum log scale parameter.                                                                                                                |

## Details

Let  $z = (y - \mu)e^{-\beta}$ , then the log Gumbel density is  $l = -\beta - z - e^{-z}$ . The expected value of a Gumbel r.v. is  $\mu + \gamma e^{\beta}$  where  $\gamma$  is Eulers constant (about 0.57721566). The corresponding variance is  $\pi^2 e^{2\beta} / 6$ .

`gumb1s` is used with `gam` to fit Gumbel location - scale models parameterized in terms of scale parameter  $\mu$  and the log scale parameter  $\beta$ . Note that `identity` link for the scale parameter means that the corresponding linear predictor gives  $\beta$  directly. By default the `log` link for the scale parameter simply forces the log scale parameter to have a lower limit given by argument `b`: if  $\eta$  is the linear predictor for the log scale parameter,  $\beta$ , then  $\beta = b + \log(1 + e^{\eta})$ .

`gam` is called with a list containing 2 formulae, the first specifies the response on the left hand side and the structure of the linear predictor for location parameter,  $\mu$ , on the right hand side. The second is one sided, specifying the linear predictor for the lg scale,  $\beta$ , on the right hand side.

The fitted values for this family will be a two column matrix. The first column is the mean, and the second column is the log scale parameter,  $\beta$ . Predictions using `predict.gam` will also produce 2 column matrices for `type="link"` and `"response"`. The first column is on the original data scale when `type="response"` and on the log mean scale of the linear predictor when `type="link"`. The second column when `type="response"` is again the log scale parameter, but is on the linear predictor when `type="link"`.

## Value

An object inheriting from class `general.family`.

## Examples

```
library(mgcv)
simulate some data
f0 <- function(x) 2 * sin(pi * x)
f1 <- function(x) exp(2 * x)
f2 <- function(x) 0.2 * x^11 * (10 * (1 - x))^6 + 10 *
 (10 * x)^3 * (1 - x)^10
n <- 400; set.seed(9)
x0 <- runif(n); x1 <- runif(n);
x2 <- runif(n); x3 <- runif(n);
mu <- f0(x0) + f1(x1)
beta <- exp(f2(x2) / 5)
y <- mu - beta * log(-log(runif(n))) ## Gumbel quantile function

b <- gam(list(y~s(x0)+s(x1), ~s(x2)+s(x3)), family=gumb1s)
plot(b, pages=1, scale=0)
summary(b)
gam.check(b)
```

## Description

Smooth terms are generally only identifiable up to an additive constant. In consequence sum-to-zero identifiability constraints are imposed on most smooth terms. The exceptions are terms with `by` variables which cause the smooth to be identifiable without constraint (that doesn't include factor `by` variables), and random effect terms. Alternatively smooths can be set up to pass through zero at a user specified point.

## Details

By default each smooth term is subject to the sum-to-zero constraint

$$\sum_i f(x_i) = 0.$$

The constraint is imposed by reparameterization. The sum-to-zero constraint causes the term to be orthogonal to the intercept: alternative constraints lead to wider confidence bands for the constrained smooth terms.

No constraint is used for random effect terms, since the penalty (random effect covariance matrix) anyway ensures identifiability in this case. Also if a `by` variable means that the smooth is anyway identifiable, then no extra constraint is imposed. Constraints are imposed for factor `by` variables, so that the main effect of the factor must usually be explicitly added to the model (the example below is an exception).

Occasionally it is desirable to substitute the constraint that a particular smooth curve should pass through zero at a particular point: the `pc` argument to `s`, `te`, `ti` and `t2` allows this: if specified then such constraints are always applied.

## Examples

```
Example of three groups, each with a different smooth dependence on x
but each starting at the same value...
require(mgcv)
set.seed(53)
n <- 100; x <- runif(3*n); z <- runif(3*n)
fac <- factor(rep(c("a", "b", "c"), each=100))
y <- c(sin(x[1:100]*4), exp(3*x[101:200])/10-.1, exp(-10*(x[201:300]-.5)) /
 (1+exp(-10*(x[201:300]-.5))))-0.9933071 + z*(1-z)*5 + rnorm(100)*.4

'pc' used to constrain smooths to 0 at x=0...
b <- gam(y~s(x,by=fac,pc=0)+s(z))
plot(b,pages=1)
```

in.out

*Which of a set of points lie within a polygon defined region***Description**

Tests whether each of a set of points lie within a region defined by one or more (possibly nested) polygons. Points count as ‘inside’ if they are interior to an odd number of polygons.

**Usage**

```
in.out(bnd, x)
```

**Arguments**

|     |                                                                                                                                                                                                                                                                                                                                       |
|-----|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| bnd | A two column matrix, the rows of which define the vertices of polygons defining the boundary of a region. Different polygons should be separated by an NA row, and the polygons are assumed closed. Alternatively can be a lists where <code>bnd[[i]][[1]]</code> , <code>bnd[[i]][[2]]</code> defines the <i>i</i> th boundary loop. |
| x   | A two column matrix. Each row is a point to test for inclusion in the region defined by bnd. Can also be a 2-vector, defining a single point.                                                                                                                                                                                         |

**Details**

The algorithm works by counting boundary crossings (using compiled C code).

**Value**

A logical vector of length `nrow(x)`. TRUE if the corresponding row of `x` is inside the boundary and FALSE otherwise.

**Author(s)**

Simon N. Wood <[simon.wood@r-project.org](mailto:simon.wood@r-project.org)>

**References**

<https://www.maths.ed.ac.uk/~swood34/>

**Examples**

```
library(mgcv)
data(columb.polys)
bnd <- columb.polys[[2]]
plot(bnd, type="n")
polygon(bnd)
x <- seq(7.9, 8.7, length=20)
y <- seq(13.7, 14.3, length=20)
gr <- as.matrix(expand.grid(x, y))
inside <- in.out(bnd, gr)
points(gr, col=as.numeric(inside)+1)
```

---

`influence.gam`*Extract the diagonal of the influence/hat matrix for a GAM*

---

**Description**

Extracts the leading diagonal of the influence matrix (hat matrix) of a fitted `gam` object.

**Usage**

```
S3 method for class 'gam'
influence(model, ...)
```

**Arguments**

|                    |                                                                                    |
|--------------------|------------------------------------------------------------------------------------|
| <code>model</code> | fitted model objects of class <code>gam</code> as produced by <code>gam()</code> . |
| <code>...</code>   | un-used in this case                                                               |

**Details**

Simply extracts `hat` array from fitted model. (More may follow!)

**Value**

An array (see above).

---

`initial.sp`*Starting values for multiple smoothing parameter estimation*

---

**Description**

Finds initial smoothing parameter guesses for multiple smoothing parameter estimation. The idea is to find values such that the estimated degrees of freedom per penalized parameter should be well away from 0 and 1 for each penalized parameter, thus ensuring that the values are in a region of parameter space where the smoothing parameter estimation criterion is varying substantially with smoothing parameter value.

**Usage**

```
initial.sp(X, S, off, expensive=FALSE, XX=FALSE)
```

**Arguments**

|                        |                                                                                                                                                                                                                                                                                                                                                                                                                           |
|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>X</code>         | is the model matrix.                                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>S</code>         | is a list of of penalty matrices. <code>S[[i]]</code> is the <i>i</i> th penalty matrix, but note that it is not stored as a full matrix, but rather as the smallest square matrix including all the non-zero elements of the penalty matrix. Element 1,1 of <code>S[[i]]</code> occupies element <code>off[i], off[i]</code> of the <i>i</i> th penalty matrix. Each <code>S[[i]]</code> must be positive semi-definite. |
| <code>off</code>       | is an array indicating the first parameter in the parameter vector that is penalized by the penalty involving <code>S[[i]]</code> .                                                                                                                                                                                                                                                                                       |
| <code>expensive</code> | if <code>TRUE</code> then the overall amount of smoothing is adjusted so that the average degrees of freedom per penalized parameter is exactly 0.5: this is numerically costly.                                                                                                                                                                                                                                          |
| <code>XX</code>        | if <code>TRUE</code> then <code>X</code> contains $X^T X$ , rather than $X$ .                                                                                                                                                                                                                                                                                                                                             |

**Details**

Basically uses a crude approximation to the estimated degrees of freedom per model coefficient, to try and find smoothing parameters which bound these e.d.f.'s away from 0 and 1.

Usually only called by `magic` and `gam`.

**Value**

An array of initial smoothing parameter estimates.

**Author(s)**

Simon N. Wood <simon.wood@r-project.org>

|                     |                                    |
|---------------------|------------------------------------|
| <code>inSide</code> | <i>Are points inside boundary?</i> |
|---------------------|------------------------------------|

---

**Description**

Assesses whether points are inside a boundary. The boundary must enclose the domain, but may include islands.

**Usage**

```
inSide(bnd, x, y)
```

**Arguments**

|                  |                                                                                                                                                                                                                                                                                                                                      |
|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>bnd</code> | This should have two equal length columns with names matching whatever is supplied in <code>x</code> and <code>y</code> . This may contain several sections of boundary separated by <code>NA</code> . Alternatively <code>bnd</code> may be a list, each element of which contains 2 columns named as above. See below for details. |
| <code>x</code>   | <code>x</code> co-ordinates of points to be tested.                                                                                                                                                                                                                                                                                  |
| <code>y</code>   | <code>y</code> co-ordinates of points to be tested.                                                                                                                                                                                                                                                                                  |

### Details

Segments of boundary are separated by NAs, or are in separate list elements. The boundary coordinates are taken to define nodes which are joined by straight line segments in order to create the boundary. Each segment is assumed to define a closed loop, and the last point in a segment will be assumed to be joined to the first. Loops must not intersect (no test is made for this).

The method used is to count how many times a line, in the y-direction from a point, crosses a boundary segment. An odd number of crossings defines an interior point. Hence in geographic applications it would be usual to have an outer boundary loop, possibly with some inner 'islands' completely enclosed in the outer loop.

The routine calls compiled C code and operates by an exhaustive search for each point in  $x, y$ .

### Value

The function returns a logical array of the same dimension as  $x$  and  $y$ . TRUE indicates that the corresponding  $x, y$  point lies inside the boundary.

### Author(s)

Simon N. Wood <simon.wood@r-project.org>

### References

<https://www.maths.ed.ac.uk/~swood34/>

### Examples

```
require(mgcv)
m <- 300; n <- 150
xm <- seq(-1, 4, length=m); yn <- seq(-1, 1, length=n)
x <- rep(xm, n); y <- rep(yn, rep(m, n))
er <- matrix(fs.test(x, y), m, n)
bnd <- fs.boundary()
in.bnd <- inSide(bnd, x, y)
plot(x, y, col=as.numeric(in.bnd)+1, pch=".")
lines(bndx, bndy, col=3)
points(x, y, col=as.numeric(in.bnd)+1, pch=".")
check boundary details ...
plot(x, y, col=as.numeric(in.bnd)+1, pch=".", ylim=c(-1, 0), xlim=c(3, 3.5))
lines(bndx, bndy, col=3)
points(x, y, col=as.numeric(in.bnd)+1, pch=".")
```

### Description

This is an internal function of package `mgcv`. It is a service routine for `gam` which splits off the strictly parametric part of the model formula, returning it as a formula, and interprets the smooth parts of the model formula.

Not normally called directly.

**Usage**

```
interpret.gam(gf, extra.special = NULL)
```

**Arguments**

`gf` A GAM formula as supplied to `gam` or `gamm`, or a list of such formulae, as supplied for some `gam` families.

`extra.special` Name of any extra special in formula in addition to `s`, `te`, `ti` and `t2`.

**Value**

An object of class `split.gam.formula` with the following items:

`pf` A model formula for the strictly parametric part of the model.

`pfok` TRUE if there is a `pf` formula.

`smooth.spec` A list of class `xx.smooth.spec` objects where `xx` depends on the basis specified for the term. (These can be passed to smooth constructor method functions to actually set up penalties and bases.)

`full.formula` An expanded version of the model formula in which the options are fully expanded, and the options do not depend on variables which might not be available later.

`fake.formula` A formula suitable for use in evaluating a model frame.

`response` Name of the response variable.

---

jagam

*Just Another Gibbs Additive Modeller: JAGS support for mgcv.*

---

**Description**

Facilities to auto-generate model specification code and associated data to simulate with GAMs in JAGS (or BUGS). This is useful for inference about models with complex random effects structure best coded in JAGS. It is a very inefficient approach to making inferences about standard GAMs. The idea is that `jagam` generates template JAGS code, and associated data, for the smooth part of the model. This template is then directly edited to include other stochastic components. After simulation with the resulting model, facilities are provided for plotting and prediction with the model smooth components.

## Usage

```
jagam(formula, family=gaussian, data=list(), file, weights=NULL, na.action,
 offset=NULL, knots=NULL, sp=NULL, drop.unused.levels=TRUE,
 control=gam.control(), centred=TRUE, sp.prior = "gamma", diagonalize=FALSE)

sim2jam(sam, pregam, edf.type=2, burnin=0)
```

## Arguments

|                                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|---------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>formula</code>            | A GAM formula (see <a href="#">formula.gam</a> and also <a href="#">gam.models</a> ). This is exactly like the formula for a GLM except that smooth terms, <code>s</code> , <code>te</code> , <code>ti</code> and <code>t2</code> can be added to the right hand side to specify that the linear predictor depends on smooth functions of predictors (or linear functionals of these).                                                                                             |
| <code>family</code>             | This is a family object specifying the distribution and link function to use. See <a href="#">glm</a> and <a href="#">family</a> for more details. Currently only gaussian, poisson, binomial and Gamma families are supported, but the user can easily modify the assumed distribution in the JAGS code.                                                                                                                                                                          |
| <code>data</code>               | A data frame or list containing the model response variable and covariates required by the formula. By default the variables are taken from <code>environment(formula)</code> : typically the environment from which <code>jagam</code> is called.                                                                                                                                                                                                                                 |
| <code>file</code>               | Name of the file to which JAGS model specification code should be written. See <a href="#">setwd</a> for setting and querying the current working directory.                                                                                                                                                                                                                                                                                                                       |
| <code>weights</code>            | prior weights on the data.                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>na.action</code>          | a function which indicates what should happen when the data contain 'NA's. The default is set by the 'na.action' setting of 'options', and is 'na.fail' if that is unset. The "factory-fresh" default is 'na.omit'.                                                                                                                                                                                                                                                                |
| <code>offset</code>             | Can be used to supply a model offset for use in fitting. Note that this offset will always be completely ignored when predicting, unlike an offset included in <code>formula</code> : this conforms to the behaviour of <code>lm</code> and <code>glm</code> .                                                                                                                                                                                                                     |
| <code>control</code>            | A list of fit control parameters to replace defaults returned by <a href="#">gam.control</a> . Any control parameters not supplied stay at their default values. little effect on <code>jagam</code> .                                                                                                                                                                                                                                                                             |
| <code>knots</code>              | this is an optional list containing user specified knot values to be used for basis construction. For most bases the user simply supplies the knots to be used, which must match up with the <code>k</code> value supplied (note that the number of knots is not always just <code>k</code> ). See <a href="#">tprs</a> for what happens in the " <code>tp</code> " / " <code>ts</code> " case. Different terms can use different numbers of knots, unless they share a covariate. |
| <code>sp</code>                 | A vector of smoothing parameters can be provided here. Smoothing parameters must be supplied in the order that the smooth terms appear in the model formula (without forgetting null space penalties). Negative elements indicate that the parameter should be estimated, and hence a mixture of fixed and estimated parameters is possible. If smooths share smoothing parameters then <code>length(sp)</code> must correspond to the number of underlying smoothing parameters.  |
| <code>drop.unused.levels</code> | by default unused levels are dropped from factors before fitting. For some smooths involving factor variables you might want to turn this off. Only do so if you know what you are doing.                                                                                                                                                                                                                                                                                          |

|                          |                                                                                                                                                                                                                                                                                                                     |
|--------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>centred</code>     | Should centring constraints be applied to the smooths, as is usual with GAMS? Only set this to <code>FALSE</code> if you know exactly what you are doing. If <code>FALSE</code> there is a (usually global) intercept for each smooth.                                                                              |
| <code>sp.prior</code>    | "gamma" or "log.uniform" prior for the smoothing parameters? Do check that the default parameters are appropriate for your model in the JAGS code.                                                                                                                                                                  |
| <code>diagonalize</code> | Should smooths be re-parameterized to have i.i.d. Gaussian priors (where possible)? For Gaussian data this allows efficient conjugate samplers to be used, and it can also work well with GLMs if the JAGS "glm" module is loaded, but otherwise it is often better to update smoothers blockwise, and not do this. |
| <code>sam</code>         | jags sample object, containing at least fields <code>b</code> (coefficients) and <code>rho</code> (log smoothing parameters). May also contain field <code>mu</code> containing monitored expected response.                                                                                                        |
| <code>pregam</code>      | standard <code>mgcv</code> GAM setup data, as returned in <code>jagam</code> return list.                                                                                                                                                                                                                           |
| <code>edf.type</code>    | Since EDF is not uniquely defined and may be affected by the stochastic structure added to the JAGS model file, 3 options are offered. See details.                                                                                                                                                                 |
| <code>burnin</code>      | the amount of burn in to discard from the simulation chains. Limited to .9 of the chain length.                                                                                                                                                                                                                     |

## Details

Smooths are easily incorporated into JAGS models using multivariate normal priors on the smooth coefficients. The smoothing parameters and smoothing penalty matrices directly specify the prior multivariate normal precision matrix. Normally a smoothing penalty does not correspond to a full rank precision matrix, implying an improper prior inappropriate for Gibbs sampling. To rectify this problem the null space penalties suggested in Marra and Wood (2011) are added to the usual penalties.

In an additive modelling context it is usual to centre the smooths, to avoid the identifiability issues associated with having an intercept for each smooth term (in addition to a global intercept). Under Gibbs sampling with JAGS it is technically possible to omit this centring, since we anyway force propriety on the priors, and this propriety implies formal model identifiability. However, in most situations this formal identifiability is rather artificial and does not imply statistically meaningful identifiability. Rather it serves only to massively inflate confidence intervals, since the multiple intercept terms are not identifiable from the data, but only from the prior. By default then, `jagam` imposes standard GAM identifiability constraints on all smooths. The `centred` argument does allow you to turn this off, but it is not recommended. If you do set `centred=FALSE` then chain convergence and mixing checks should be particularly stringent.

The final technical issue for model setup is the setting of initial conditions for the coefficients and smoothing parameters. The approach taken is to take the default initial smoothing parameter values used elsewhere by `mgcv`, and to take a single PIRLS fitting step with these smoothing parameters in order to obtain starting values for the smooth coefficients. In the setting of fully conjugate updating the initial values of the coefficients are not critical, and good results are obtained without supplying them. But in the usual setting in which slice sampling is required for at least some of the updates then very poor results can sometimes be obtained without initial values, as the sampler simply fails to find the region of the posterior mode.

The `sim2jam` function takes the partial gam object (`pregam`) from `jagam` along with simulation output in standard `rjags` form and creates a reduced version of a gam object, suitable for plotting and prediction of the model's smooth components. `sim2gam` computes effective degrees of freedom for each smooth, but it should be noted that there are several possibilities for doing this in the context of a model with a complex random effects structure. The simplest approach (`edf.type=0`) is to compute the degrees of freedom that the smooth would have had if it had

been part of an unweighted Gaussian additive model. One might choose to use this option if the model has been modified so that the response distribution and/or link are not those that were specified to `jagam`. The second option is (`edf.type=1`) uses the edf that would have been computed by `gam` had it produced these estimates - in the context in which the JAGS model modifications have all been about modifying the random effects structure, this is equivalent to simply setting all the random effects to zero for the effective degrees of freedom calculation. The default option (`edf.type=2`) is to base the EDF on the sample covariance matrix,  $V_p$ , of the model coefficients. If the simulation output (`sim`) includes a `mu` field, then this will be used to form the weight matrix  $W$  in  $XWX = t(X) \%*\%W\%*\%X$ , where the EDF is computed from `rowSums(Vp*XWX)*scale`. If `mu` is not supplied then it is estimated from the the model matrix  $X$  and the mean of the simulated coefficients, but the resulting  $W$  may not be strictly compatible with the  $V_p$  matrix in this case. In the situation in which the fitted model is very different in structure from the regression model of the template produced by `jagam` then the default option may make no sense, and indeed it may be best to use option 0.

### Value

For `jagam` a three item list containing

|                        |                                                                                                    |
|------------------------|----------------------------------------------------------------------------------------------------|
| <code>pregam</code>    | standard <code>mgcv</code> GAM setup data.                                                         |
| <code>jags.data</code> | list of arguments to be supplied to JAGS containing information referenced in model specification. |
| <code>jags.ini</code>  | initialization data for smooth coefficients and smoothing parameters.                              |

For `sim2jam` an object of class "jam": a partial version of an `mgcv gamObject`, suitable for plotting and predicting.

### WARNINGS

Gibb's sampling is a very slow inferential method for standard GAMs. It is only likely to be worthwhile when complex random effects structures are required above what is possible with direct GAMM methods.

Check that the parameters of the priors on the parameters are fit for your purpose.

## Examples

```
the following illustrates a typical workflow. To run the
'Not run' code you need rjags (and JAGS) to be installed.
require(mgcv)

set.seed(2) ## simulate some data...
n <- 400
dat <- gamSim(1,n=n,dist="normal",scale=2)
regular gam fit for comparison...
b0 <- gam(y~s(x0)+s(x1) + s(x2)+s(x3),data=dat,method="REML")

Set directory and file name for file containing jags code.
In real use you would *never* use tempdir() for this. It is
only done here to keep CRAN happy, and avoid any chance of
an accidental overwrite. Instead you would use
setwd() to set an appropriate working directory in which
to write the file, and just set the file name to what you
want to call it (e.g. "test.jags" here).

jags.file <- paste(tempdir(), "/test.jags", sep="")

Set up JAGS code and data. In this one might want to diagonalize
to use conjugate samplers. Usually call 'setwd' first, to set
directory in which model file ("test.jags") will be written.

jd <- jagam(y~s(x0)+s(x1)+s(x2)+s(x3),data=dat,file=jags.file,
 sp.prior="gamma",diagonalize=TRUE)

In normal use the model in "test.jags" would now be edited to add
the non-standard stochastic elements that require use of JAGS....

Not run:
require(rjags)
load.module("glm") ## improved samplers for GLMs often worth loading
jm <- jags.model(jags.file,data=jd$jags.data,inits=jd$jags.ini,n.chains=1)
list.samplers(jm)
sam <- jags.samples(jm,c("b","rho","scale"),n.iter=10000,thin=10)
jam <- sim2jag(sam,jd$pregam)
plot(jam,pages=1)
jam
pd <- data.frame(x0=c(.5,.6),x1=c(.4,.2),x2=c(.8,.4),x3=c(.1,.1))
fv <- predict(jam,newdata=pd)
and some minimal checking...
require(coda)
effectiveSize(as.mcmc.list(sam$b))

End(Not run)

a gamma example...
set.seed(1); n <- 400
dat <- gamSim(1,n=n,dist="normal",scale=2)
scale <- .5; Ey <- exp(dat$f/2)
dat$y <- rgamma(n,shape=1/scale,scale=Ey*scale)
jd <- jagam(y~s(x0)+te(x1,x2)+s(x3),data=dat,family=Gamma(link=log),
 file=jags.file,sp.prior="log.uniform")
```

```
In normal use the model in "test.jags" would now be edited to add
the non-standard stochastic elements that require use of JAGS....

Not run:
require(rjags)
following sets random seed, but note that under JAGS 3.4 many
models are still not fully repeatable (JAGS 4 should fix this)
jd$jags.ini$.RNG.name <- "base::Mersenne-Twister" ## setting RNG
jd$jags.ini$.RNG.seed <- 6 ## how to set RNG seed
jm <- jags.model(jags.file, data=jd$jags.data, inits=jd$jags.ini, n.chains=1)
list.samplers(jm)
sam <- jags.samples(jm, c("b", "rho", "scale", "mu"), n.iter=10000, thin=10)
jam <- sim2jam(sam, jd$pregam)
plot(jam, pages=1)
jam
pd <- data.frame(x0=c(.5, .6), x1=c(.4, .2), x2=c(.8, .4), x3=c(.1, .1))
fv <- predict(jam, newdata=pd)

End(Not run)
```

---

k.check

---

*Checking smooth basis dimension*

---

## Description

Takes a fitted `gam` object produced by `gam()` and runs diagnostic tests of whether the basis dimension choices are adequate.

## Usage

```
k.check(b, subsample=5000, n.rep=400)
```

## Arguments

|                        |                                                                                   |
|------------------------|-----------------------------------------------------------------------------------|
| <code>b</code>         | a fitted <code>gam</code> object as produced by <code>gam()</code> .              |
| <code>subsample</code> | above this number of data, testing uses a random sub-sample of data of this size. |
| <code>n.rep</code>     | how many re-shuffles to do to get p-value for k testing.                          |

## Details

The test of whether the basis dimension for a smooth is adequate (Wood, 2017, section 5.9) is based on computing an estimate of the residual variance based on differencing residuals that are near neighbours according to the (numeric) covariates of the smooth. This estimate divided by the residual variance is the `k-index` reported. The further below 1 this is, the more likely it is that there is missed pattern left in the residuals. The `p-value` is computed by simulation: the residuals are randomly re-shuffled `n.rep` times to obtain the null distribution of the differencing variance estimator, if there is no pattern in the residuals. For models fitted to more than `subsample` data, the tests are based of `subsample` randomly sampled data. Low `p-values` may indicate that the basis dimension, `k`, has been set too low, especially if the reported `edf` is close to `k\`, the maximum possible EDF for the term. Note the disconcerting fact that if the test statistic itself is based on random resampling and the null is true, then the associated `p-values` will of course vary widely

from one replicate to the next. Currently smooths of factor variables are not supported and will give an NA p-value.

Doubling a suspect `k` and re-fitting is sensible: if the reported `edf` increases substantially then you may have been missing something in the first fit. Of course p-values can be low for reasons other than a too low `k`. See [choose.k](#) for fuller discussion.

### Value

A matrix containing the output of the tests described above.

### Examples

```
library(mgcv)
set.seed(0)
dat <- gamSim(1,n=200)
b<-gam(y~s(x0)+s(x1)+s(x2)+s(x3),data=dat)
plot(b,pages=1)
k.check(b)
```

---

ldetS

---

*Getting log generalized determinant of penalty matrices*

---

### Description

INTERNAL function calculating the log generalized determinant of penalty matrix `S` stored block-wise in an `Sl` list (which is the output of `Sl.setup`).

### Usage

```
ldetS(Sl, rho, fixed, np, root = FALSE, repara = TRUE,
 nt = 1,deriv=2,sparse=FALSE)
```

**Arguments**

|                     |                                                                                                                                                       |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>Sl</code>     | the output of <code>Sl.setup</code> .                                                                                                                 |
| <code>rho</code>    | the log smoothing parameters.                                                                                                                         |
| <code>fixed</code>  | an array indicating whether the smoothing parameters are fixed (or free).                                                                             |
| <code>np</code>     | number of coefficients.                                                                                                                               |
| <code>root</code>   | indicates whether or not to return the matrix square root, $E$ , of the total penalty $S_{tot}$ .                                                     |
| <code>repara</code> | if TRUE multi-term blocks will be re-parameterized using <code>gam.reparam</code> , and a re-parameterization object supplied in the returned object. |
| <code>nt</code>     | number of parallel threads to use.                                                                                                                    |
| <code>deriv</code>  | order of derivative to use                                                                                                                            |
| <code>sparse</code> | should $E$ be sparse?                                                                                                                                 |

**Value**

A list containing:

- `ldetS`: the log-determinant of  $S$ .
- `ldetS1`: the gradient of the log-determinant of  $S$ .
- `ldetS2`: the Hessian of the log-determinant of  $S$ .
- `S1`: with modified  $rS$  terms, if needed and  $\rho$  added to each block
- `rp`: a re-parameterization list.
- `rp`:  $E$  a total penalty square root such that  $t(E) \%*\% E = S_{tot}$  (if `root==TRUE`).

ldTweedie

---

*Log Tweedie density evaluation*

---

**Description**

A function to evaluate the log of the Tweedie density for variance powers between 1 and 2, inclusive. Also evaluates first and second derivatives of log density w.r.t. its scale parameter,  $\phi$ , and  $p$ , or w.r.t.  $\rho = \log(\phi)$  and  $\theta$  where  $p = (a + b \exp(\theta)) / (1 + \exp(\theta))$ .

**Usage**

```
ldTweedie(y, mu=y, p=1.5, phi=1, rho=NA, theta=NA, a=1.001, b=1.999, all.derivs=FALSE)
```

**Arguments**

|                         |                                                                                                                                                                                                          |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>y</code>          | values at which to evaluate density.                                                                                                                                                                     |
| <code>mu</code>         | corresponding means (either of same length as <code>y</code> or a single value).                                                                                                                         |
| <code>p</code>          | the variance of <code>y</code> is proportional to its mean to the power <code>p</code> . <code>p</code> must be between 1 and 2. 1 is Poisson like (exactly Poisson if <code>phi</code> =1), 2 is gamma. |
| <code>phi</code>        | The scale parameter. Variance of <code>y</code> is $\phi \cdot \mu^p$ .                                                                                                                                  |
| <code>rho</code>        | optional log scale parameter. Over-rides <code>phi</code> if <code>theta</code> also supplied.                                                                                                           |
| <code>theta</code>      | parameter such that $p = (a + b \cdot \exp(\theta)) / (1 + \exp(\theta))$ . Over-rides <code>p</code> if <code>rho</code> also supplied.                                                                 |
| <code>a</code>          | lower limit parameter ( $>1$ ) used in definition of <code>p</code> from <code>theta</code> .                                                                                                            |
| <code>b</code>          | upper limit parameter ( $<2$ ) used in definition of <code>p</code> from <code>theta</code> .                                                                                                            |
| <code>all.derivs</code> | if TRUE then derivatives w.r.t. <code>mu</code> are also returned. Only available with <code>rho</code> and <code>phi</code> parameterization.                                                           |

**Details**

A Tweedie random variable with  $1 < p < 2$  is a sum of  $N$  gamma random variables where  $N$  has a Poisson distribution. The  $p=1$  case is a generalization of a Poisson distribution and is a discrete distribution supported on integer multiples of the scale parameter. For  $1 < p < 2$  the distribution is supported on the positive reals with a point mass at zero.  $p=2$  is a gamma distribution. As  $p$  gets very close to 1 the continuous distribution begins to converge on the discretely supported limit at  $p=1$ .

`ldTweedie` is based on the series evaluation method of Dunn and Smyth (2005). Without the restriction on `p` the calculation of Tweedie densities is less straightforward. If you really need this case then the `tweedie` package is the place to start.

The `rho`, `theta` parameterization is useful for optimization of `p` and `phi`, in order to keep `p` bounded well away from 1 and 2, and `phi` positive. The derivatives near  $p=1$  tend to infinity.

Note that if `p` and `phi` (or `theta` and `rho`) both contain only a single unique value, then the underlying code is able to use buffering to avoid repeated calls to expensive log gamma, di-gamma and tri-gamma functions (`mu` can still be a vector of different values). This is much faster than is possible when these parameters are vectors with different values.

**Value**

A matrix with 6 columns, or 10 if `all.derivs=TRUE`. The first is the log density of `y` (log probability if  $p=1$ ). The second and third are the first and second derivatives of the log density w.r.t. `phi`. 4th and 5th columns are first and second derivative w.r.t. `p`, final column is second derivative w.r.t. `phi` and `p`.

If `rho` and `theta` were supplied then derivatives are w.r.t. these. In this case, and if `all.derivs=TRUE` then the 7th column is the derivative w.r.t. `mu`, the 8th is the 2nd derivative w.r.t. `mu`, the 9th is the mixed derivative w.r.t. `theta` and `mu` and the 10th is the mixed derivative w.r.t. `rho` and `mu`.

linear.functional.terms

*Linear functionals of a smooth in GAMs*

---

## Description

`gam` allows the response variable to depend on linear functionals of smooth terms. Specifically dependencies of the form

$$g(\mu_i) = \dots + \sum_j L_{ij} f(x_{ij}) + \dots$$

are allowed, where the  $x_{ij}$  are covariate values and the  $L_{ij}$  are fixed weights. i.e. the response can depend on the weighted sum of the same smooth evaluated at different covariate values. This allows, for example, for the response to depend on the derivatives or integrals of a smooth (approximated by finite differencing or quadrature, respectively). It also allows dependence on predictor functions (sometimes called ‘signal regression’).

The mechanism by which this is achieved is to supply matrices of covariate values to the model smooth terms specified by `s` or `te` terms in the model formula. Each column of the covariate matrix gives rise to a corresponding column of predictions from the smooth. Let the resulting matrix of evaluated smooth values be  $F$  ( $F$  will have the same dimension as the covariate matrices). In the absence of a `by` variable then these columns are simply summed and added to the linear predictor. i.e. the contribution of the term to the linear predictor is `rowSums(F)`. If a `by` variable is present then it must be a matrix,  $L$ , say, of the same dimension as  $F$  (and the covariate matrices), and it contains the weights  $L_{ij}$  in the summation given above. So in this case the contribution to the linear predictor is `rowSums(L*F)`.

Note that if a **L1** (i.e. `rowSums(L)`) is a constant vector, or there is no `by` variable then the smooth will automatically be centred in order to ensure identifiability. Otherwise it will not be.

Note also that for centred smooths it can be worth replacing the constant term in the model with `rowSums(L)` in order to ensure that predictions are automatically on the right scale.

`predict.gam` can accept matrix predictors for prediction with such terms, in which case its `newdata` argument will need to be a list. However when predicting from the model it is not necessary to provide matrix covariate and `by` variable values. For example to simply examine the underlying smooth function one would use vectors of covariate values and vector `by` variables, with the `by` variable and equivalent of `L1`, above, set to vectors of ones.

The mechanism is usable with random effect smooths which take factor arguments, by using a trick to create a 2D array of factors. Simply create a factor vector containing the columns of the factor matrix stacked end to end (column major order). Then reset the dimensions of this vector to create the appropriate 2D array: the first dimension should be the number of response data and the second the number of columns of the required factor matrix. You can not use `matrix` or `data.matrix` to set up the required matrix of factor levels. See example below.

example of prediction using matrices...
dat <- list(L=L[1:20,],fac=fac[1:20,],x=x[1:20],y=y[1:20])
predict(mod,newdata=dat)

#####
multivariate integral example. Function `test1' will be integrated#
(by midpoint quadrature) over 100 equal area sub-squares covering
the unit square. Noise is added to the resulting simulated data.
`test1' is estimated from the resulting data using two alternative#
smooths.
#####

test1 <- function(x,z,sx=0.3,sz=0.4)
{ (pi*sx*sz)*(1.2*exp(-(x-0.2)^2/sx^2-(z-0.3)^2/sz^2)+
 0.8*exp(-(x-0.7)^2/sx^2-(z-0.8)^2/sz^2))
}

create quadrature (integration) grid, in useful order
ig <- 5 ## integration grid within square
mx <- mz <- (1:ig-.5)/ig
ix <- rep(mx,ig);iz <- rep(mz,rep(ig,ig))

og <- 10 ## observation grid
mx <- mz <- (1:og-1)/og
ox <- rep(mx,og);ox <- rep(ox,rep(ig^2,og^2))
oz <- rep(mz,rep(og,og));oz <- rep(oz,rep(ig^2,og^2))

x <- ox + ix/og;z <- oz + iz/og ## full grid, subsquare by subsquare

create matrix covariates...
X <- matrix(x,og^2,ig^2,byrow=TRUE)
Z <- matrix(z,og^2,ig^2,byrow=TRUE)

create simulated test data...
dA <- 1/(og*ig)^2 ## quadrature square area
F <- test1(X,Z) ## evaluate on grid
f <- rowSums(F)*dA ## integrate by midpoint quadrature

```

```

y <- f + rnorm(og^2)*5e-4 ## add noise
... so each y is a noisy observation of the integral of `test1'
over a 0.1 by 0.1 sub-square from the unit square

Now fit model to simulated data...

L <- X*0 + dA

... let F be the matrix of the smooth evaluated at the x,z values
in matrices X and Z. rowSums(L*F) gives the model predicted
integrals of `test1' corresponding to the observed `y'

L1 <- rowSums(L) ## smooths are centred --- need to add in L%*%1

fit models to reconstruct `test1'....

b <- gam(y~s(X,Z,by=L)+L1-1) ## (L1 and const are confounded here)
b1 <- gam(y~te(X,Z,by=L)+L1-1) ## tensor product alternative

plot results...

old.par<-par(mfrow=c(2,2))
x<-runif(n);z<-runif(n);
xs<-seq(0,1,length=30);zs<-seq(0,1,length=30)
pr<-data.frame(x=rep(xs,30),z=rep(zs,rep(30,30)))
truth<-matrix(test1(prx,prz),30,30)
contour(xs,zs,truth)
plot(b)
vis.gam(b,view=c("X","Z"),cond=list(L1=1,L=1),plot.type="contour")
vis.gam(b1,view=c("X","Z"),cond=list(L1=1,L=1),plot.type="contour")

#####
A "signal" regression example...#
#####

rf <- function(x=seq(0,1,length=100)) {
generates random functions...
 m <- ceiling(runif(1)*5) ## number of components
 f <- x*0;
 mu <- runif(m,min(x),max(x));sig <- (runif(m)+.5)*(max(x)-min(x))/10
 for (i in 1:m) f <- f+ dnorm(x,mu[i],sig[i])
 f
}

x <- seq(0,1,length=100) ## evaluation points

example functional predictors...
par(mfrow=c(3,3));for (i in 1:9) plot(x,rf(x),type="l",xlab="x")

simulate 200 functions and store in rows of L...
L <- matrix(NA,200,100)
for (i in 1:200) L[i,] <- rf() ## simulate the functional predictors

f2 <- function(x) { ## the coefficient function
 (0.2*x^11*(10*(1-x))^6+10*(10*x)^3*(1-x)^10)/10
}

```

```
f <- f2(x) ## the true coefficient function

y <- L%*%f + rnorm(200)*20 ## simulated response data

Now fit the model E(y) = L%*%f(x) where f is a smooth function.
The summation convention is used to evaluate smooth at each value
in matrix X to get matrix F, say. Then rowSum(L*F) gives E(y).

create matrix of eval points for each function. Note that
'smoothCon' is smart and will recognize the duplication...
X <- matrix(x,200,100,byrow=TRUE)

b <- gam(y~s(X,by=L,k=20))
par(mfrow=c(1,1))
plot(b,shade=TRUE);lines(x,f,col=2)
```

logLik.gam

*AIC and Log likelihood for a fitted GAM*

### Description

Function to extract the log-likelihood for a fitted `gam` model (note that the models are usually fitted by penalized likelihood maximization). Used by [AIC](#). See details for more information on AIC computation.

### Usage

```
S3 method for class 'gam'
logLik(object, ...)
```

### Arguments

|                     |                                                                                    |
|---------------------|------------------------------------------------------------------------------------|
| <code>object</code> | fitted model objects of class <code>gam</code> as produced by <code>gam()</code> . |
| <code>...</code>    | un-used in this case                                                               |

### Details

Modification of `logLik.glm` which corrects the degrees of freedom for use with `gam` objects.

The function is provided so that [AIC](#) functions correctly with `gam` objects, and uses the appropriate degrees of freedom (accounting for penalization). See e.g. Wood, Pya and Saefken (2016) for a derivation of an appropriate AIC.

There are two possible AIC's that might be considered for use with GAMs. Marginal AIC is based on the marginal likelihood of the GAM, that is the likelihood based on treating penalized (e.g. spline) coefficients as random and integrating them out. The degrees of freedom is then the number of smoothing/variance parameters + the number of fixed effects. The problem with Marginal AIC is that marginal likelihood underestimates variance components/oversmooths, so that the approach favours simpler models excessively (substituting REML does not work, because REML is not comparable between models with different unpenalized/fixed components). Conditional AIC uses the likelihood of all the model coefficients, evaluated at the penalized MLE. The degrees of freedom to use then is the effective degrees of freedom for the model. However, Greven and Kneib (2010) show that the neglect of smoothing parameter uncertainty can lead to this conditional AIC being

excessively likely to select larger models. Wood, Pya and Saecken (2016) propose a simple correction to the effective degrees of freedom to fix this problem. `mgcv` applies this correction whenever possible: that is when using ML or REML smoothing parameter selection with `gam` or `bam`. The correction is not computable when using the Extended Fellner Schall or BFGS optimizer (since the correction requires an estimate of the covariance matrix of the log smoothing parameters).

**Value**

Standard `logLik` object: see [logLik](#).

**Author(s)**

Simon N. Wood <[simon.wood@r-project.org](mailto:simon.wood@r-project.org)> based directly on `logLik.glm`

---

`ls.size`*Size of list elements*

---

**Description**

Produces a named array giving the size, in bytes, of the elements of a list.

**Usage**

```
ls.size(x)
```

**Arguments**

`x`                      A list.

**Value**

A numeric vector giving the size in bytes of each element of the list `x`. The elements of the array have the same names as the elements of the list. If `x` is not a list then its size in bytes is returned, un-named.

*Stable Multiple Smoothing Parameter Estimation by GCV or UBRE*

---

## Description

Function to efficiently estimate smoothing parameters in generalized ridge regression problems with multiple (quadratic) penalties, by GCV or UBRE. The function uses Newton's method in multi-dimensions, backed up by steepest descent to iteratively adjust the smoothing parameters for each penalty (one penalty may have a smoothing parameter fixed at 1).

For maximal numerical stability the method is based on orthogonal decomposition methods, and attempts to deal with numerical rank deficiency gracefully using a truncated singular value decomposition approach.

## Usage

```
magic(y,X,sp,S,off,L=NULL,lsp0=NULL,rank=NULL,H=NULL,C=NULL,
w=NULL,gamma=1,scale=1,gcv=TRUE,ridge.parameter=NULL,
control=list(tol=1e-6,step.half=25,rank.tol=
.Machine$double.eps^0.5),extra.rss=0,n.score=length(y),nthreads=1)
```

## Arguments

- |     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-----|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| y   | is the response data vector.                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| X   | is the model matrix (more columns than rows are allowed).                                                                                                                                                                                                                                                                                                                                                                                                                         |
| sp  | is the array of smoothing parameters. The vector $L \times \log(sp) + lsp0$ contains the logs of the smoothing parameters that actually multiply the penalty matrices stored in S (L is taken as the identity if NULL). Any sp values that are negative are autoinitialized, otherwise they are taken as supplying starting values. A supplied starting value will be reset to a default starting value if the gradient of the GCV/UBRE score is too small at the supplied value. |
| S   | is a list of of penalty matrices. $S[[i]]$ is the ith penalty matrix, but note that it is not stored as a full matrix, but rather as the smallest square matrix including all the non-zero elements of the penalty matrix. Element 1,1 of $S[[i]]$ occupies element $off[i], off[i]$ of the ith penalty matrix. Each $S[[i]]$ must be positive semi-definite. Set to <code>list()</code> if there are no smoothing parameters to be estimated.                                    |
| off | is an array indicating the first parameter in the parameter vector that is penalized by the penalty involving $S[[i]]$ .                                                                                                                                                                                                                                                                                                                                                          |

|                              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>L</code>               | is a matrix mapping $\log(sp)$ to the log smoothing parameters that actually multiply the penalties defined by the elements of $S$ . Taken as the identity, if <code>NULL</code> . See above under <code>sp</code> .                                                                                                                                                                                                                                                                          |
| <code>lsp0</code>            | If <code>L</code> is not <code>NULL</code> this is a vector of constants in the linear transformation from $\log(sp)$ to the actual log smoothing parameters. So the logs of the smoothing parameters multiplying the $S[[i]]$ are given by $L[i] * \log(sp) + lsp0$ . Taken as 0 if <code>NULL</code> .                                                                                                                                                                                      |
| <code>rank</code>            | is an array specifying the ranks of the penalties. This is useful, but not essential, for forming square roots of the penalty matrices.                                                                                                                                                                                                                                                                                                                                                       |
| <code>H</code>               | is the optional offset penalty - i.e. a penalty with a smoothing parameter fixed at 1. This is useful for allowing regularization of the estimation process, fixed smoothing penalties etc.                                                                                                                                                                                                                                                                                                   |
| <code>C</code>               | is the optional matrix specifying any linear equality constraints on the fitting problem. If <code>b</code> is the parameter vector then the parameters are forced to satisfy $Cb = 0$ .                                                                                                                                                                                                                                                                                                      |
| <code>w</code>               | the regression weights. If this is a matrix then it is taken as being the square root of the inverse of the covariance matrix of $y$ , specifically $V_y^{-1} = w'w$ . If <code>w</code> is an array then it is taken as the diagonal of this matrix, or simply the weight for each element of $y$ . See below for an example using this.                                                                                                                                                     |
| <code>gamma</code>           | is an inflation factor for the model degrees of freedom in the GCV or UBRE score.                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>scale</code>           | is the scale parameter for use with UBRE.                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>gcv</code>             | should be set to <code>TRUE</code> if GCV is to be used, <code>FALSE</code> for UBRE.                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>ridge.parameter</code> | It is sometimes useful to apply a ridge penalty to the fitting problem, penalizing the parameters in the constrained space directly. Setting this parameter to a value greater than zero will cause such a penalty to be used, with the magnitude given by the parameter value.                                                                                                                                                                                                               |
| <code>control</code>         | is a list of iteration control constants with the following elements:<br><b>tol</b> The tolerance to use in judging convergence.<br><b>step.half</b> If a trial step fails then the method tries halving it up to a maximum of <code>step.half</code> times.<br><b>rank.tol</b> is a constant used to test for numerical rank deficiency of the problem. Basically any singular value less than <code>rank_tol</code> multiplied by the largest singular value of the problem is set to zero. |
| <code>extra.rss</code>       | is a constant to be added to the residual sum of squares (squared norm) term in the calculation of the GCV, UBRE and scale parameter estimate. In conjunction with <code>n.score</code> , this is useful for certain methods for dealing with very large data sets.                                                                                                                                                                                                                           |
| <code>n.score</code>         | number to use as the number of data in GCV/UBRE score calculation: usually the actual number of data, but there are methods for dealing with very large datasets that change this.                                                                                                                                                                                                                                                                                                            |
| <code>nthreads</code>        | <code>magic</code> can make use of multiple threads if this is set to $>1$ .                                                                                                                                                                                                                                                                                                                                                                                                                  |

## Details

The method is a computationally efficient means of applying GCV or UBRE (often approximately AIC) to the problem of smoothing parameter selection in generalized ridge regression problems of

the form:

$$\text{minimise } \|\mathbf{W}(\mathbf{X}\mathbf{b} - \mathbf{y})\|^2 + \mathbf{b}'\mathbf{H}\mathbf{b} + \sum_{i=1}^m \theta_i \mathbf{b}'\mathbf{S}_i\mathbf{b}$$

possibly subject to constraints  $\mathbf{C}\mathbf{b} = \mathbf{0}$ .  $\mathbf{X}$  is a design matrix,  $\mathbf{b}$  a parameter vector,  $\mathbf{y}$  a data vector,  $\mathbf{W}$  a weight matrix,  $\mathbf{S}_i$  a positive semi-definite matrix of coefficients defining the  $i$ th penalty with associated smoothing parameter  $\theta_i$ ,  $\mathbf{H}$  is the positive semi-definite offset penalty matrix and  $\mathbf{C}$  a matrix of coefficients defining any linear equality constraints on the problem.  $\mathbf{X}$  need not be of full column rank.

The  $\theta_i$  are chosen to minimize either the GCV score:

$$V_g = \frac{n\|\mathbf{W}(\mathbf{y} - \mathbf{A}\mathbf{y})\|^2}{[tr(\mathbf{I} - \gamma\mathbf{A})]^2}$$

or the UBRE score:

$$V_u = \|\mathbf{W}(\mathbf{y} - \mathbf{A}\mathbf{y})\|^2/n - 2\phi tr(\mathbf{I} - \gamma\mathbf{A})/n + \phi$$

where  $\gamma$  is gamma the inflation factor for degrees of freedom (usually set to 1) and  $\phi$  is scale, the scale parameter.  $\mathbf{A}$  is the hat matrix (influence matrix) for the fitting problem (i.e the matrix mapping data to fitted values). Dependence of the scores on the smoothing parameters is through  $\mathbf{A}$ .

The method operates by Newton or steepest descent updates of the logs of the  $\theta_i$ . A key aspect of the method is stable and economical calculation of the first and second derivatives of the scores w.r.t. the log smoothing parameters. Because the GCV/UBRE scores are flat w.r.t. very large or very small  $\theta_i$ , it's important to get good starting parameters, and to be careful not to step into a flat region of the smoothing parameter space. For this reason the algorithm rescales any Newton step that would result in a  $\log(\theta_i)$  change of more than 5. Newton steps are only used if the Hessian of the GCV/UBRE is positive definite, otherwise steepest descent is used. Similarly steepest descent is used if the Newton step has to be contracted too far (indicating that the quadratic model underlying Newton is poor). All initial steepest descent steps are scaled so that their largest component is 1. However a step is calculated, it is never expanded if it is successful (to avoid flat portions of the objective), but steps are successively halved if they do not decrease the GCV/UBRE score, until they do, or the direction is deemed to have failed. (Given the smoothing parameters the optimal  $\mathbf{b}$  parameters are easily found.)

The method is coded in C with matrix factorizations performed using LINPACK and LAPACK routines.

## Value

The function returns a list with the following items:

|                      |                                                                                                                                                                                                       |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>b</code>       | The best fit parameters given the estimated smoothing parameters.                                                                                                                                     |
| <code>scale</code>   | the estimated (GCV) or supplied (UBRE) scale parameter.                                                                                                                                               |
| <code>score</code>   | the minimized GCV or UBRE score.                                                                                                                                                                      |
| <code>sp</code>      | an array of the estimated smoothing parameters.                                                                                                                                                       |
| <code>sp.full</code> | an array of the smoothing parameters that actually multiply the elements of <code>S</code> (same as <code>sp</code> if <code>L</code> was <code>NULL</code> ). This is <code>exp(L**log(sp))</code> . |
| <code>rV</code>      | a factored form of the parameter covariance matrix. The (Bayesian) covariance matrix of the parameters <code>b</code> is given by <code>rV**t(rV)*scale</code> .                                      |

`gcv.info` is a list of information about the performance of the method with the following elements:

- full.rank** The apparent rank of the problem: number of parameters less number of equality constraints.
- rank** The estimated actual rank of the problem (at the final iteration of the method).
- fully.converged** is TRUE if the method converged by satisfying the convergence criteria, and FALSE if it covered by failing to decrease the score along the search direction.
- hess.pos.def** is TRUE if the hessian of the UBRE or GCV score was positive definite at convergence.
- iter** is the number of Newton/Steepest descent iterations taken.
- score.calls** is the number of times that the GCV/UBRE score had to be evaluated.
- rms.grad** is the root mean square of the gradient of the UBRE/GCV score w.r.t. the smoothing parameters.
- R** The factor R from the QR decomposition of the weighted model matrix. This is un-pivoted so that column order corresponds to X. So it may not be upper triangular.

Note that some further useful quantities can be obtained using `magic.post.proc`.

#### Examples

```
Use 'magic' for a standard additive model fit ...
library(mgcv)
set.seed(1); n <- 200; sig <- 1
dat <- gamSim(1, n=n, scale=sig)
k <- 30
set up additive model
G <- gam(y~s(x0, k=k)+s(x1, k=k)+s(x2, k=k)+s(x3, k=k), fit=FALSE, data=dat)
fit using magic (and gam default tolerance)
mgfit <- magic(Gy, GX, Gsp, GS, G$off, rank=G$rank,
 control=list(tol=1e-7, step.half=15))
and fit using gam as consistency check
b <- gam(G=G)
mgfit$sp; b$sp # compare smoothing parameter estimates
edf <- magic.post.proc(G$X, mgfit, G$w)$edf # get e.d.f. per param
range(edf-b$edf) # compare
```

```
p>n example... fit model to first 100 data only, so more
params than data...

mgfit <- magic(G$y[1:100],G$X[1:100,],Gsp,GS,G$off,rank=G$rank)
edf <- magic.post.proc(G$X[1:100,],mgfit,G$w[1:100])$edf

constrain first two smooths to have identical smoothing parameters
L <- diag(3);L <- rbind(L[1,],L)
mgfit <- magic(Gy,GX,rep(-1,3),GS,Goff,L=L,rank=G$rank,C=G$C)

Now a correlated data example ...
library(nlme)
simulate truth
set.seed(1);n<-400;sig<-2
x <- 0:(n-1)/(n-1)
f <- 0.2*x^11*(10*(1-x))^6+10*(10*x)^3*(1-x)^10
produce scaled covariance matrix for AR1 errors...
V <- corMatrix(Initialize(corAR1(.6),data.frame(x=x)))
Cv <- chol(V) # t(Cv)%*%Cv=V
Simulate AR1 errors ...
e <- t(Cv)%*%rnorm(n,0,sig) # so cov(e) = V * sig^2
Observe truth + AR1 errors
y <- f + e
GAM ignoring correlation
par(mfrow=c(1,2))
b <- gam(y~s(x,k=20))
plot(b);lines(x,f-mean(f),col=2);title("Ignoring correlation")
Fit smooth, taking account of *known* correlation...
w <- solve(t(Cv)) # V^{-1} = w'w
Use `gam` to set up model for fitting...
G <- gam(y~s(x,k=20),fit=FALSE)
fit using magic, with weight *matrix*
mgfit <- magic(Gy,GX,Gsp,GS,G$off,rank=G$rank,C=G$C,w=w)
Modify previous gam object using new fit, for plotting...
mg.stuff <- magic.post.proc(G$X,mgfit,w)
b$edf <- mg.stuff$edf;b$Vp <- mg.stuff$Vb
b$coefficients <- mgfit$b
plot(b);lines(x,f-mean(f),col=2);title("Known correlation")
```

---

magic.post.proc

*Auxilliary information from magic fit*

---

## Description

Obtains Bayesian parameter covariance matrix, frequentist parameter estimator covariance matrix, estimated degrees of freedom for each parameter and leading diagonal of influence/hat matrix, for a penalized regression estimated by magic.

## Usage

```
magic.post.proc(X,object,w=NULL)
```

**Arguments**

|                     |                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>X</code>      | is the model matrix.                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>object</code> | is the list returned by <code>magic</code> after fitting the model with model matrix <code>X</code> .                                                                                                                                                                                                                                                                                                                                        |
| <code>w</code>      | is the weight vector used in fitting, or the weight matrix used in fitting (i.e. supplied to <code>magic</code> , if one was.). If <code>w</code> is a vector then its elements are typically proportional to reciprocal variances (but could even be negative). If <code>w</code> is a matrix then <code>t(w) %*% w</code> should typically give the inverse of the covariance matrix of the response data supplied to <code>magic</code> . |

**Details**

`object` contains `rV(V, say)`, and `scale(phi, say)` which can be used to obtain the require quantities as follows. The Bayesian covariance matrix of the parameters is  $\mathbf{V}\mathbf{V}'\phi$ . The vector of estimated degrees of freedom for each parameter is the leading diagonal of  $\mathbf{V}\mathbf{V}'\mathbf{X}'\mathbf{W}'\mathbf{W}\mathbf{X}$  where  $\mathbf{W}$  is either the weight matrix `w` or the matrix `diag(w)`. The hat/influence matrix is given by  $\mathbf{W}\mathbf{X}\mathbf{V}\mathbf{V}'\mathbf{X}'\mathbf{W}'$ .

The frequentist parameter estimator covariance matrix is  $\mathbf{V}\mathbf{V}'\mathbf{X}'\mathbf{W}'\mathbf{W}\mathbf{X}\mathbf{V}\mathbf{V}'\phi$ : it is sometimes useful for testing terms for equality to zero.

**Value**

A list with three items:

|                  |                                                                                   |
|------------------|-----------------------------------------------------------------------------------|
| <code>Vb</code>  | the Bayesian covariance matrix of the model parameters.                           |
| <code>Ve</code>  | the frequentist covariance matrix for the parameter estimators.                   |
| <code>hat</code> | the leading diagonal of the hat (influence) matrix.                               |
| <code>edf</code> | the array giving the estimated degrees of freedom associated with each parameter. |

**Description**

This page provides answers to some of the questions that get asked most often about mgcv

## FAQ list

1. **How can I compare gamm models?** In the identity link normal errors case, then AIC and hypothesis testing based methods are fine. Otherwise it is best to work out a strategy based on the [summary.gam](#). Alternatively, simple random effects can be fitted with [gam](#), which makes comparison straightforward. Package [gamm4](#) is an alternative, which allows AIC type model selection for generalized models.
