ppr

*Projection Pursuit Regression***Description**

Fit a projection pursuit regression model.

**Usage**

```
ppr(x, ...)

S3 method for class 'formula'
ppr(formula, data, weights, subset, na.action,
 contrasts = NULL, ..., model = FALSE)

Default S3 method:
ppr(x, y, weights = rep(1, n),
 ww = rep(1, q), nterms, max.terms = nterms, optlevel = 2,
 sm.method = c("supsmu", "spline", "gcv spline"),
 bass = 0, span = 0, df = 5, gcvpen = 1, trace = FALSE, ...)
```

**Arguments**

|           |                                                                                                                                                                                        |
|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| formula   | a formula specifying one or more numeric response variables and the explanatory variables.                                                                                             |
| x         | numeric matrix of explanatory variables. Rows represent observations, and columns represent variables. Missing values are not accepted.                                                |
| y         | numeric matrix of response variables. Rows represent observations, and columns represent variables. Missing values are not accepted.                                                   |
| nterms    | number of terms to include in the final model.                                                                                                                                         |
| data      | a data frame (or similar: see <a href="#">model.frame</a> ) from which variables specified in formula are preferentially to be taken.                                                  |
| weights   | a vector of weights $w_i$ for each case.                                                                                                                                               |
| ww        | a vector of weights for each <i>response</i> , so the fit criterion is the sum over case $i$ and responses $j$ of $w_i w_j (y_{ij} - \text{fit}_{ij})^2$ divided by the sum of $w_i$ . |
| subset    | an index vector specifying the cases to be used in the training sample. (NOTE: If given, this argument must be named.)                                                                 |
| na.action | a function to specify the action to be taken if NAs are found. The default action is given by <code>getOption("na.action")</code> . (NOTE: If given, this argument must be named.)     |
| contrasts | the contrasts to be used when any factor explanatory variables are coded.                                                                                                              |
| max.terms | maximum number of terms to choose from when building the model.                                                                                                                        |
| optlevel  | integer from 0 to 3 which determines the thoroughness of an optimization routine in the SMART program. See the ‘Details’ section.                                                      |

|                        |                                                                                                                                                                                                                                                                                                                                                                                 |
|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>sm.method</code> | the method used for smoothing the ridge functions. The default is to use Friedman's super smoother <code>supsmu</code> . The alternatives are to use the smoothing spline code underlying <code>smooth.spline</code> , either with a specified (equivalent) degrees of freedom for each ridge functions, or to allow the smoothness to be chosen by GCV.<br>Can be abbreviated. |
| <code>bass</code>      | super smoother bass tone control used with automatic span selection (see <code>supsmu</code> ); the range of values is 0 to 10, with larger values resulting in increased smoothing.                                                                                                                                                                                            |
| <code>span</code>      | super smoother span control (see <code>supsmu</code> ). The default, 0, results in automatic span selection by local cross validation. <code>span</code> can also take a value in $(0, 1]$ .                                                                                                                                                                                    |
| <code>df</code>        | if <code>sm.method</code> is "spline" specifies the smoothness of each ridge term via the requested equivalent degrees of freedom.                                                                                                                                                                                                                                              |
| <code>gcvpen</code>    | if <code>sm.method</code> is "gcv spline" this is the penalty used in the GCV selection for each degree of freedom used.                                                                                                                                                                                                                                                        |
| <code>trace</code>     | logical indicating if each spline fit should produce diagnostic output (about <code>lambda</code> and <code>df</code> ), and the <code>supsmu</code> fit about its steps.                                                                                                                                                                                                       |
| <code>...</code>       | arguments to be passed to or from other methods.                                                                                                                                                                                                                                                                                                                                |
| <code>model</code>     | logical. If true, the model frame is returned.                                                                                                                                                                                                                                                                                                                                  |

### Details

The basic method is given by Friedman (1984), and is essentially the same code used by S-PLUS's `ppreg`. This code is extremely sensitive to the compiler used.

The algorithm first adds up to `max.terms` ridge terms one at a time; it will use less if it is unable to find a term to add that makes sufficient difference. It then removes the least important term at each step until `nterms` terms are left.

The levels of optimization (argument `optlevel`) differ in how thoroughly the models are refitted during this process. At level 0 the existing ridge terms are not refitted. At level 1 the projection directions are not refitted, but the ridge functions and the regression coefficients are.

Levels 2 and 3 refit all the terms and are equivalent for one response; level 3 is more careful to re-balance the contributions from each regressor at each step and so is a little less likely to converge to a saddle point of the sum of squares criterion.

### Value

A list with the following components, many of which are for use by the method functions.

|                   |                                                                                                                                                                           |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>call</code> | the matched call                                                                                                                                                          |
| <code>p</code>    | the number of explanatory variables (after any coding)                                                                                                                    |
| <code>q</code>    | the number of response variables                                                                                                                                          |
| <code>mu</code>   | the argument <code>nterms</code>                                                                                                                                          |
| <code>ml</code>   | the argument <code>max.terms</code>                                                                                                                                       |
| <code>gof</code>  | the overall residual (weighted) sum of squares for the selected model                                                                                                     |
| <code>gofn</code> | the overall residual (weighted) sum of squares against the number of terms, up to <code>max.terms</code> . Will be invalid (and zero) for less than <code>nterms</code> . |
| <code>df</code>   | the argument <code>df</code>                                                                                                                                              |

|               |                                                                                                                                       |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------|
| edf           | if <code>sm.method</code> is "spline" or "gcv.spline" the equivalent number of degrees of freedom for each ridge term used.           |
| xnames        | the names of the explanatory variables                                                                                                |
| yname         | the names of the response variables                                                                                                   |
| alpha         | a matrix of the projection directions, with a column for each ridge term                                                              |
| beta          | a matrix of the coefficients applied for each response to the ridge terms: the rows are the responses and the columns the ridge terms |
| yb            | the weighted means of each response                                                                                                   |
| ys            | the overall scale factor used: internally the responses are divided by <code>ys</code> to have unit total weighted sum of squares.    |
| fitted.values | the fitted values, as a matrix if <code>q &gt; 1</code> .                                                                             |
| residuals     | the residuals, as a matrix if <code>q &gt; 1</code> .                                                                                 |
| smod          | internal work array, which includes the ridge functions evaluated at the training set points.                                         |
| model         | (only if <code>model = TRUE</code> ) the model frame.                                                                                 |

prcomp

*Principal Components Analysis***Description**

Performs a principal components analysis on the given data matrix and returns the results as an object of class `prcomp`.

**Usage**

```
prcomp(x, ...)

S3 method for class 'formula'
prcomp(formula, data = NULL, subset, na.action, ...)

Default S3 method:
prcomp(x, retx = TRUE, center = TRUE, scale. = FALSE,
 tol = NULL, rank. = NULL, ...)

S3 method for class 'prcomp'
predict(object, newdata, ...)
```

**Arguments**

|                      |                                                                                                                                                                                                                  |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>formula</code> | a formula with no response variable, referring only to numeric variables.                                                                                                                                        |
| <code>data</code>    | an optional data frame (or similar: see <a href="#">model.frame</a> ) containing the variables in the formula <code>formula</code> . By default the variables are taken from <code>environment(formula)</code> . |
| <code>subset</code>  | an optional vector used to select rows (observations) of the data matrix <code>x</code> .                                                                                                                        |

|                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>na.action</code> | a function which indicates what should happen when the data contain NAs. The default is set by the <code>na.action</code> setting of <code>options</code> , and is <code>na.fail</code> if that is unset. The ‘factory-fresh’ default is <code>na.omit</code> .                                                                                                                                                                                                                                                                                |
| <code>...</code>       | arguments passed to or from other methods. If <code>x</code> is a formula one might specify <code>scale.</code> or <code>tol</code> .                                                                                                                                                                                                                                                                                                                                                                                                          |
| <code>x</code>         | a numeric or complex matrix (or data frame) which provides the data for the principal components analysis.                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>retx</code>      | a logical value indicating whether the rotated variables should be returned.                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>center</code>    | a logical value indicating whether the variables should be shifted to be zero centered. Alternately, a vector of length equal the number of columns of <code>x</code> can be supplied. The value is passed to <code>scale</code> .                                                                                                                                                                                                                                                                                                             |
| <code>scale.</code>    | a logical value indicating whether the variables should be scaled to have unit variance before the analysis takes place. The default is <code>FALSE</code> for consistency with <code>S</code> , but in general scaling is advisable. Alternatively, a vector of length equal the number of columns of <code>x</code> can be supplied. The value is passed to <code>scale</code> .                                                                                                                                                             |
| <code>tol</code>       | a value indicating the magnitude below which components should be omitted. (Components are omitted if their standard deviations are less than or equal to <code>tol</code> times the standard deviation of the first component.) With the default null setting, no components are omitted (unless <code>rank.</code> is specified less than <code>min(dim(x))</code> ). Other settings for <code>tol</code> could be <code>tol = 0</code> or <code>tol = sqrt(.Machine\$double.eps)</code> , which would omit essentially constant components. |
| <code>rank.</code>     | optionally, a number specifying the maximal rank, i.e., maximal number of principal components to be used. Can be set as alternative or in addition to <code>tol</code> , useful notably when the desired rank is considerably smaller than the dimensions of the matrix.                                                                                                                                                                                                                                                                      |
| <code>object</code>    | object of class inheriting from <code>"prcomp"</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <code>newdata</code>   | An optional data frame or matrix in which to look for variables with which to predict. If omitted, the scores are used. If the original fit used a formula or a data frame or a matrix with column names, <code>newdata</code> must contain columns with the same names. Otherwise it must contain the same number of columns, to be used in the same order.                                                                                                                                                                                   |

## Details

The calculation is done by a singular value decomposition of the (centered and possibly scaled) data matrix, not by using `eigen` on the covariance matrix. This is generally the preferred method for numerical accuracy. The `print` method for these objects prints the results in a nice format and the `plot` method produces a scree plot.

Unlike `princomp`, variances are computed with the usual divisor  $N - 1$ .

Note that `scale = TRUE` cannot be used if there are zero or constant (for `center = TRUE`) variables.

## Value

`prcomp` returns a list with class `"prcomp"` containing the following components:

|                   |                                                                                                                                                                                                                            |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>sdev</code> | the standard deviations of the principal components (i.e., the square roots of the eigenvalues of the covariance/correlation matrix, though the calculation is actually done with the singular values of the data matrix). |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

|               |                                                                                                                                                                                                                                                                                                                                                                                         |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| rotation      | the matrix of variable loadings (i.e., a matrix whose columns contain the eigenvectors). The function <code>princomp</code> returns this in the element <code>loadings</code> .                                                                                                                                                                                                         |
| x             | if <code>retx</code> is true the value of the rotated data (the centred (and scaled if requested) data multiplied by the <code>rotation</code> matrix) is returned. Hence, <code>cov(x)</code> is the diagonal matrix <code>diag(sdev^2)</code> . For the formula method, <code>napredict()</code> is applied to handle the treatment of values omitted by the <code>na.action</code> . |
| center, scale | the centering and scaling used, or <code>FALSE</code> .                                                                                                                                                                                                                                                                                                                                 |

### Note

The signs of the columns of the rotation matrix are arbitrary, and so may differ between different programs for PCA, and even between different builds of R.

|---------|--------------------------|
| predict | <i>Model Predictions</i> |
|---------|--------------------------|

---

## Description

`predict` is a generic function for predictions from the results of various model fitting functions. The function invokes particular *methods* which depend on the `class` of the first argument.

## Usage

```
predict (object, ...)
```

## Arguments

|                     |                                                          |
|---------------------|----------------------------------------------------------|
| <code>object</code> | a model object for which prediction is desired.          |
| <code>...</code>    | additional arguments affecting the predictions produced. |

## Details

Most prediction methods which are similar to those for linear models have an argument `newdata` specifying the first place to look for explanatory variables to be used for prediction. Some considerable attempts are made to match up the columns in `newdata` to those used for fitting, for example that they are of comparable types and that any factors have the same level set in the same order (or can be transformed to be so).

Time series prediction methods in package **stats** have an argument `n.ahead` specifying how many time steps ahead to predict.

Many methods have a logical argument `se.fit` saying if standard errors are to returned.

## Value

The form of the value returned by `predict` depends on the class of its argument. See the documentation of the particular methods for details of what is produced by that method.

|---------------|---------------------------------|
| predict.Arima | <i>Forecast from ARIMA fits</i> |
|---------------|---------------------------------|

---

## Description

Forecast from models fitted by [arima](#).

## Usage

```
S3 method for class 'Arima'
predict(object, n.ahead = 1, newxreg = NULL,
 se.fit = TRUE, ...)
```

## Arguments

|         |                                                                                                          |
|---------|----------------------------------------------------------------------------------------------------------|
| object  | The result of an <code>arima</code> fit.                                                                 |
| n.ahead | The number of steps ahead for which prediction is required.                                              |
| newxreg | New values of <code>xreg</code> to be used for prediction. Must have at least <code>n.ahead</code> rows. |
| se.fit  | Logical: should standard errors of prediction be returned?                                               |
| ...     | arguments passed to or from other methods.                                                               |

## Details

Finite-history prediction is used, via [KalmanForecast](#). This is only statistically efficient if the MA part of the fit is invertible, so `predict.Arima` will give a warning for non-invertible MA models.

The standard errors of prediction exclude the uncertainty in the estimation of the ARMA model and the regression coefficients. According to Harvey (1993, pp. 58–9) the effect is small.

## Value

A time series of predictions, or if `se.fit = TRUE`, a list with components `pred`, the predictions, and `se`, the estimated standard errors. Both components are time series.

predict.glm

*Predict Method for GLM Fits*

---

## Description

Obtains predictions and optionally estimates standard errors of those predictions from a fitted generalized linear model object.

## Usage

```
S3 method for class 'glm'
predict(object, newdata = NULL,
 type = c("link", "response", "terms"),
 se.fit = FALSE, dispersion = NULL, terms = NULL,
 na.action = na.pass, ...)
```

## Arguments

- |         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|---------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object  | a fitted object of class inheriting from "glm".                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| newdata | optionally, a data frame in which to look for variables with which to predict. If omitted, the fitted linear predictors are used.                                                                                                                                                                                                                                                                                                                                                                             |
| type    | the type of prediction required. The default is on the scale of the linear predictors; the alternative "response" is on the scale of the response variable. Thus for a default binomial model the default predictions are of log-odds (probabilities on logit scale) and type = "response" gives the predicted probabilities. The "terms" option returns a matrix giving the fitted values of each term in the model formula on the linear predictor scale.<br>The value of this argument can be abbreviated. |

|                         |                                                                                                                                                                |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>se.fit</code>     | logical switch indicating if standard errors are required.                                                                                                     |
| <code>dispersion</code> | the dispersion of the GLM fit to be assumed in computing the standard errors. If omitted, that returned by <code>summary</code> applied to the object is used. |
| <code>terms</code>      | with <code>type = "terms"</code> by default all terms are returned. A character vector specifies which terms are to be returned                                |
| <code>na.action</code>  | function determining what should be done with missing values in <code>newdata</code> . The default is to predict NA.                                           |
| <code>...</code>        | further arguments passed to or from other methods.                                                                                                             |

### Details

If `newdata` is omitted the predictions are based on the data used for the fit. In that case how cases with missing values in the original fit is determined by the `na.action` argument of that fit. If `na.action = na.omit` omitted cases will not appear in the residuals, whereas if `na.action = na.exclude` they will appear (in predictions and standard errors), with residual value NA. See also [napredict](#).

### Value

If `se.fit = FALSE`, a vector or matrix of predictions. For `type = "terms"` this is a matrix with a column per term, and may have an attribute `"constant"`.

If `se.fit = TRUE`, a list with components

|                             |                                                                                          |
|-----------------------------|------------------------------------------------------------------------------------------|
| <code>fit</code>            | Predictions, as for <code>se.fit = FALSE</code> .                                        |
| <code>se.fit</code>         | Estimated standard errors.                                                               |
| <code>residual.scale</code> | A scalar giving the square root of the dispersion used in computing the standard errors. |

### Note

Variables are first looked for in `newdata` and then searched for in the usual way (which will include the environment of the formula used in the fit). A warning will be given if the variables found are not of the same length as those in `newdata` if it was supplied.

 sex = factor(rep("F", length(ld)), levels = levels(sex))),
 type = "response"))

```

---

predict.HoltWinters

*Prediction Function for Fitted Holt-Winters Models*

---

## Description

Computes predictions and prediction intervals for models fitted by the Holt-Winters method.

## Usage

```

S3 method for class 'HoltWinters'
predict(object, n.ahead = 1, prediction.interval = FALSE,
 level = 0.95, ...)

```

## Arguments

|                     |                                                                                                      |
|---------------------|------------------------------------------------------------------------------------------------------|
| object              | An object of class HoltWinters.                                                                      |
| n.ahead             | Number of future periods to predict.                                                                 |
| prediction.interval | logical. If TRUE, the lower and upper bounds of the corresponding prediction intervals are computed. |
| level               | Confidence level for the prediction interval.                                                        |
| ...                 | arguments passed to or from other methods.                                                           |

## Value

A time series of the predicted values. If prediction intervals are requested, a multiple time series is returned with columns `fit`, `lwr` and `upr` for the predicted values and the lower and upper bounds respectively.

*Predict method for Linear Model Fits***Description**

Predicted values based on linear model object.

**Usage**

```
S3 method for class 'lm'
predict(object, newdata, se.fit = FALSE, scale = NULL, df = Inf,
 interval = c("none", "confidence", "prediction"),
 level = 0.95, type = c("response", "terms"),
 terms = NULL, na.action = na.pass,
 pred.var = res.var/weights, weights = 1, ...)
```

**Arguments**

|           |                                                                                                                                                                          |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object    | Object of class inheriting from "lm"                                                                                                                                     |
| newdata   | An optional data frame in which to look for variables with which to predict. If omitted, the fitted values are used.                                                     |
| se.fit    | A switch indicating if standard errors are required.                                                                                                                     |
| scale     | Scale parameter for std.err. calculation.                                                                                                                                |
| df        | Degrees of freedom for scale.                                                                                                                                            |
| interval  | Type of interval calculation. Can be abbreviated.                                                                                                                        |
| level     | Tolerance/confidence level.                                                                                                                                              |
| type      | Type of prediction (response or model term). Can be abbreviated.                                                                                                         |
| terms     | If type = "terms", which terms (default is all terms), a <a href="#">character</a> vector.                                                                               |
| na.action | function determining what should be done with missing values in newdata. The default is to predict NA.                                                                   |
| pred.var  | the variance(s) for future observations to be assumed for prediction intervals. See 'Details'.                                                                           |
| weights   | variance weights for prediction. This can be a numeric vector or a one-sided model formula. In the latter case, it is interpreted as an expression evaluated in newdata. |
| ...       | further arguments passed to or from other methods.                                                                                                                       |

## Details

`predict.lm` produces predicted values, obtained by evaluating the regression function in the frame `newdata` (which defaults to `model.frame(object)`). If the logical `se.fit` is `TRUE`, standard errors of the predictions are calculated. If the numeric argument `scale` is set (with optional `df`), it is used as the residual standard deviation in the computation of the standard errors, otherwise this is extracted from the model fit. Setting `intervals` specifies computation of confidence or prediction (tolerance) intervals at the specified `level`, sometimes referred to as narrow vs. wide intervals.

If the fit is rank-deficient, some of the columns of the design matrix will have been dropped. Prediction from such a fit only makes sense if `newdata` is contained in the same subspace as the original data. That cannot be checked accurately, so a warning is issued.

If `newdata` is omitted the predictions are based on the data used for the fit. In that case how cases with missing values in the original fit are handled is determined by the `na.action` argument of that fit. If `na.action = na.omit` omitted cases will not appear in the predictions, whereas if `na.action = na.exclude` they will appear (in predictions, standard errors or interval limits), with value `NA`. See also [napredict](#).

The prediction intervals are for a single observation at each case in `newdata` (or by default, the data used for the fit) with error variance(s) `pred.var`. This can be a multiple of `res.var`, the estimated value of  $\sigma^2$ : the default is to assume that future observations have the same error variance as those used for fitting. If `weights` is supplied, the inverse of this is used as a scale factor. For a weighted fit, if the prediction is for the original data frame, `weights` defaults to the weights used for the model fit, with a warning since it might not be the intended result. If the fit was weighted and `newdata` is given, the default is to assume constant prediction variance, with a warning.

## Value

`predict.lm` produces a vector of predictions or a matrix of predictions and bounds with column names `fit`, `lwr`, and `upr` if `interval` is set. For `type = "terms"` this is a matrix with a column per term and may have an attribute `"constant"`.

If `se.fit` is `TRUE`, a list with the following components is returned:

|                             |                                   |
|-----------------------------|-----------------------------------|
| <code>fit</code>            | vector or matrix as above         |
| <code>se.fit</code>         | standard error of predicted means |
| <code>residual.scale</code> | residual standard deviations      |
| <code>df</code>             | degrees of freedom for residual   |

## Note

Variables are first looked for in `newdata` and then searched for in the usual way (which will include the environment of the formula used in the fit). A warning will be given if the variables found are not of the same length as those in `newdata` if it was supplied.

Notice that prediction variances and prediction intervals always refer to *future* observations, possibly corresponding to the same predictors as used for the fit. The variance of the *residuals* will be smaller.

Strictly speaking, the formula used for prediction limits assumes that the degrees of freedom for the fit are the same as those for the residual variance. This may not be the case if `res.var` is not obtained from the fit.

---

**Description**

Predictions from a loess fit, optionally with standard errors.

**Usage**

```
S3 method for class 'loess'
predict(object, newdata = NULL, se = FALSE,
 na.action = na.pass, ...)
```

**Arguments**

|                        |                                                                                                                                                                                                           |
|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code>    | an object fitted by <code>loess</code> .                                                                                                                                                                  |
| <code>newdata</code>   | an optional data frame in which to look for variables with which to predict, or a matrix or vector containing exactly the variables needed for prediction. If missing, the original data points are used. |
| <code>se</code>        | should standard errors be computed?                                                                                                                                                                       |
| <code>na.action</code> | function determining what should be done with missing values in data frame <code>newdata</code> . The default is to predict NA.                                                                           |
| <code>...</code>       | arguments passed to or from other methods.                                                                                                                                                                |

**Details**

The standard errors calculation `se = TRUE` is slower than prediction, notably as it needs a relatively large workspace (memory), notably matrices of dimension  $N \times Nf$  where  $f = \text{span}$ , i.e., `se = TRUE` is  $O(N^2)$  and hence stops when the sample size  $N$  is larger than about 40'600 (for default `span = 0.75`).

When the fit was made using `surface = "interpolate"` (the default), `predict.loess` will not extrapolate – so points outside an axis-aligned hypercube enclosing the original data will have missing (NA) predictions and standard errors.

**Value**

If `se = FALSE`, a vector giving the prediction for each row of `newdata` (or the original data). If `se = TRUE`, a list containing components

|                             |                                                                                                                                            |
|-----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------|
| <code>fit</code>            | the predicted values.                                                                                                                      |
| <code>se</code>             | an estimated standard error for each predicted value.                                                                                      |
| <code>residual.scale</code> | the estimated scale of the residuals used in computing the standard errors.                                                                |
| <code>df</code>             | an estimate of the effective degrees of freedom used in estimating the residual scale, intended for use with t-based confidence intervals. |

If `newdata` was the result of a call to `expand.grid`, the predictions (and s.e.'s if requested) will be an array of the appropriate dimensions.

Predictions from infinite inputs will be NA since `loess` does not support extrapolation.

**Note**

Variables are first looked for in `newdata` and then searched for in the usual way (which will include the environment of the formula used in the fit). A warning will be given if the variables found are not of the same length as those in `newdata` if it was supplied.

**Author(s)**

B. D. Ripley, based on the `cloess` package of Cleveland, Grosse and Shyu.

## Examples

```
cars.lo <- loess(dist ~ speed, cars)
predict(cars.lo, data.frame(speed = seq(5, 30, 1)), se = TRUE)
to get extrapolation
cars.lo2 <- loess(dist ~ speed, cars,
 control = loess.control(surface = "direct"))
predict(cars.lo2, data.frame(speed = seq(5, 30, 1)), se = TRUE)
```

---

predict.nls

*Predicting from Nonlinear Least Squares Fits*

---

## Description

`predict.nls` produces predicted values, obtained by evaluating the regression function in the frame `newdata`. If the logical `se.fit` is `TRUE`, standard errors of the predictions are calculated. If the numeric argument `scale` is set (with optional `df`), it is used as the residual standard deviation in the computation of the standard errors, otherwise this is extracted from the model fit. Setting `interval` specifies computation of confidence or prediction (tolerance) intervals at the specified level.

At present `se.fit` and `interval` are ignored.

## Usage

```
S3 method for class 'nls'
predict(object, newdata, se.fit = FALSE, scale = NULL, df = Inf,
 interval = c("none", "confidence", "prediction"),
 level = 0.95, ...)
```

## Arguments

|                       |                                                                                                                                                                                                                                                            |
|-----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code>   | An object that inherits from class <code>nls</code> .                                                                                                                                                                                                      |
| <code>newdata</code>  | A named list or data frame in which to look for variables with which to predict. If <code>newdata</code> is missing the fitted values at the original data points are returned.                                                                            |
| <code>se.fit</code>   | A logical value indicating if the standard errors of the predictions should be calculated. Defaults to <code>FALSE</code> . At present this argument is ignored.                                                                                           |
| <code>scale</code>    | A numeric scalar. If it is set (with optional <code>df</code> ), it is used as the residual standard deviation in the computation of the standard errors, otherwise this information is extracted from the model fit. At present this argument is ignored. |
| <code>df</code>       | A positive numeric scalar giving the number of degrees of freedom for the scale estimate. At present this argument is ignored.                                                                                                                             |
| <code>interval</code> | A character string indicating if prediction intervals or a confidence interval on the mean responses are to be calculated. At present this argument is ignored.                                                                                            |
| <code>level</code>    | A numeric scalar between 0 and 1 giving the confidence level for the intervals (if any) to be calculated. At present this argument is ignored.                                                                                                             |
| <code>...</code>      | Additional optional arguments. At present no optional arguments are used.                                                                                                                                                                                  |

**Value**

`predict.nls` produces a vector of predictions. When implemented, `interval` will produce a matrix of predictions and bounds with column names `fit`, `lwr`, and `upr`. When implemented, if `se.fit` is `TRUE`, a list with the following components will be returned:

|                             |                                 |
|-----------------------------|---------------------------------|
| <code>fit</code>            | vector or matrix as above       |
| <code>se.fit</code>         | standard error of predictions   |
| <code>residual.scale</code> | residual standard deviations    |
| <code>df</code>             | degrees of freedom for residual |

**Note**

Variables are first looked for in `newdata` and then searched for in the usual way (which will include the environment of the formula used in the fit). A warning will be given if the variables found are not of the same length as those in `newdata` if it was supplied.

**Examples**

```
require(graphics)

fm <- nls(demand ~ SSasymOrig(Time, A, lrc), data = BOD)
predict(fm) # fitted values at observed times
Form data plot and smooth line for the predictions
opar <- par(las = 1)
plot(demand ~ Time, data = BOD, col = 4,
 main = "BOD data and fitted first-order curve",
 xlim = c(0,7), ylim = c(0, 20))
tt <- seq(0, 8, length = 101)
lines(tt, predict(fm, list(Time = tt)))
par(opar)
```

---

`predict.smooth.spline`

*Predict from Smoothing Spline Fit*

---

**Description**

Predict a smoothing spline fit at new points, return the derivative if desired. The predicted fit is linear beyond the original data.

**Usage**

```
S3 method for class 'smooth.spline'
predict(object, x, deriv = 0, ...)
```

**Arguments**

|        |                                                    |
|--------|----------------------------------------------------|
| object | a fit from smooth.spline.                          |
| x      | the new values of x.                               |
| deriv  | integer; the order of the derivative required.     |
| ...    | further arguments passed to or from other methods. |

**Value**

A list with components

|   |                                        |
|---|----------------------------------------|
| x | The input x.                           |
| y | The fitted values or derivatives at x. |

**See Also**

**Examples**

```
require(graphics)

attach(cars)
cars.spl <- smooth.spline(speed, dist, df = 6.4)

"Proof" that the derivatives are okay, by comparing with approximation
diff.quot <- function(x, y) {
 ## Difference quotient (central differences where available)
 n <- length(x); i1 <- 1:2; i2 <- (n-1):n
 c(diff(y[i1]) / diff(x[i1]), (y[-i1] - y[-i2]) / (x[-i1] - x[-i2]),
 diff(y[i2]) / diff(x[i2]))
}

xx <- unique(sort(c(seq(0, 30, by = .2), kn <- unique(speed))))
i.kn <- match(kn, xx) # indices of knots within xx
op <- par(mfrow = c(2,2))
plot(speed, dist, xlim = range(xx), main = "Smooth.spline & derivatives")
lines(pp <- predict(cars.spl, xx), col = "red")
points(kn, pp$y[i.kn], pch = 3, col = "dark red")
mtext("s(x)", col = "red")
for(d in 1:3){
 n <- length(pp$x)
 plot(pp$x, diff.quot(pp$x,pp$y), type = "l", xlab = "x", ylab = "",
 col = "blue", col.main = "red",
 main = paste0("s", paste(rep("'", d), collapse = ""), "(x)"))
 mtext("Difference quotient approx.(last)", col = "blue")
 lines(pp <- predict(cars.spl, xx, deriv = d), col = "red")

 points(kn, pp$y[i.kn], pch = 3, col = "dark red")
 abline(h = 0, lty = 3, col = "gray")
}
detach(); par(op)
```

preplot

*Pre-computations for a Plotting Object***Description**

Compute an object to be used for plots relating to the given model object.

**Usage**

```
preplot(object, ...)
```

**Arguments**

`object` a fitted model object.  
`...` additional arguments for specific methods.

**Details**

Only the generic function is currently provided in base R, but some add-on packages have methods. Principally here for S compatibility.

**Value**

An object set up to make a plot that describes `object`.

princomp

*Principal Components Analysis***Description**

`princomp` performs a principal components analysis on the given numeric data matrix and returns the results as an object of class `princomp`.

**Usage**

```
princomp(x, ...)

S3 method for class 'formula'
princomp(formula, data = NULL, subset, na.action, ...)

Default S3 method:
princomp(x, cor = FALSE, scores = TRUE, covmat = NULL,
 subset = rep_len(TRUE, nrow(as.matrix(x))), fix_sign = TRUE, ...)

S3 method for class 'princomp'
predict(object, newdata, ...)
```

## Arguments

|                        |                                                                                                                                                                                                                                                                                                                                                              |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>formula</code>   | a formula with no response variable, referring only to numeric variables.                                                                                                                                                                                                                                                                                    |
| <code>data</code>      | an optional data frame (or similar: see <code>model.frame</code> ) containing the variables in the formula <code>formula</code> . By default the variables are taken from <code>environment(formula)</code> .                                                                                                                                                |
| <code>subset</code>    | an optional vector used to select rows (observations) of the data matrix <code>x</code> .                                                                                                                                                                                                                                                                    |
| <code>na.action</code> | a function which indicates what should happen when the data contain NAs. The default is set by the <code>na.action</code> setting of <code>options</code> , and is <code>na.fail</code> if that is unset. The ‘factory-fresh’ default is <code>na.omit</code> .                                                                                              |
| <code>x</code>         | a numeric matrix or data frame which provides the data for the principal components analysis.                                                                                                                                                                                                                                                                |
| <code>cor</code>       | a logical value indicating whether the calculation should use the correlation matrix or the covariance matrix. (The correlation matrix can only be used if there are no constant variables.)                                                                                                                                                                 |
| <code>scores</code>    | a logical value indicating whether the score on each principal component should be calculated.                                                                                                                                                                                                                                                               |
| <code>covmat</code>    | a covariance matrix, or a covariance list as returned by <code>cov.wt</code> (and <code>cov.mve</code> or <code>cov.mcd</code> from package <b>MASS</b> ). If supplied, this is used rather than the covariance matrix of <code>x</code> .                                                                                                                   |
| <code>fix_sign</code>  | Should the signs of the loadings and scores be chosen so that the first element of each loading is non-negative?                                                                                                                                                                                                                                             |
| <code>...</code>       | arguments passed to or from other methods. If <code>x</code> is a formula one might specify <code>cor</code> or <code>scores</code> .                                                                                                                                                                                                                        |
| <code>object</code>    | Object of class inheriting from <code>"princomp"</code> .                                                                                                                                                                                                                                                                                                    |
| <code>newdata</code>   | An optional data frame or matrix in which to look for variables with which to predict. If omitted, the scores are used. If the original fit used a formula or a data frame or a matrix with column names, <code>newdata</code> must contain columns with the same names. Otherwise it must contain the same number of columns, to be used in the same order. |

## Details

`princomp` is a generic function with `"formula"` and `"default"` methods.

The calculation is done using `eigen` on the correlation or covariance matrix, as determined by `cor`. This is done for compatibility with the S-PLUS result. A preferred method of calculation is to use `svd` on `x`, as is done in `prcomp`.

Note that the default calculation uses divisor `N` for the covariance matrix.

The `print` method for these objects prints the results in a nice format and the `plot` method produces a scree plot (`screeplot`). There is also a `biplot` method.

If `x` is a formula then the standard NA-handling is applied to the scores (if requested): see `napredict`.

`princomp` only handles so-called R-mode PCA, that is feature extraction of variables. If a data matrix is supplied (possibly via a formula) it is required that there are at least as many units as variables. For Q-mode PCA use `prcomp`.

**Value**

princomp returns a list with class "princomp" containing the following components:

|           |                                                                                                                                                                                                                                                                                                                   |
|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| sdev      | the standard deviations of the principal components.                                                                                                                                                                                                                                                              |
| loadings  | the matrix of variable loadings (i.e., a matrix whose columns contain the eigenvectors). This is of class "loadings": see <a href="#">loadings</a> for its print method.                                                                                                                                          |
| center    | the means that were subtracted.                                                                                                                                                                                                                                                                                   |
| scale     | the scalings applied to each variable.                                                                                                                                                                                                                                                                            |
| n.obs     | the number of observations.                                                                                                                                                                                                                                                                                       |
| scores    | if scores = TRUE, the scores of the supplied data on the principal components. These are non-null only if x was supplied, and if covmat was also supplied if it was a covariance list. For the formula method, <a href="#">napredict()</a> is applied to handle the treatment of values omitted by the na.action. |
| call      | the matched call.                                                                                                                                                                                                                                                                                                 |
| na.action | If relevant.                                                                                                                                                                                                                                                                                                      |

**Note**

The signs of the columns of the loadings and scores are arbitrary, and so may differ between different programs for PCA, and even between different builds of R: `fix_sign = TRUE` alleviates that.

**Examples**

```
require(graphics)

The variances of the variables in the
USArrests data vary by orders of magnitude, so scaling is appropriate
(pc.cr <- princomp(USArrests)) # inappropriate
princomp(USArrests, cor = TRUE) # ^= prcomp(USArrests, scale=TRUE)
Similar, but different:
The standard deviations differ by a factor of sqrt(49/50)

summary(pc.cr <- princomp(USArrests, cor = TRUE))
loadings(pc.cr) # note that blank entries are small but not zero
The signs of the columns of the loadings are arbitrary
plot(pc.cr) # shows a screeplot.
biplot(pc.cr)

Formula interface
princomp(~ ., data = USArrests, cor = TRUE)

NA-handling
```

```

USArrests[1, 2] <- NA
pc.cr <- princomp(~ Murder + Assault + UrbanPop,
 data = USArrests, na.action = na.exclude, cor = TRUE)
pc.cr$scores[1:5,]

(Simple) Robust PCA:
Classical:
(pc.cl <- princomp(stackloss))
Robust:
(pc.rob <- princomp(stackloss, covmat = MASS::cov.rob(stackloss)))

```

---

print.power.htest    *Print Methods for Hypothesis Tests and Power Calculation Objects*

---

## Description

Printing objects of class "htest" or "power.htest", respectively, by simple `print` methods.

## Usage

```

S3 method for class 'htest'
print(x, digits = getOption("digits"), prefix = "\t", ...)

S3 method for class 'power.htest'
print(x, digits = getOption("digits"), ...)

```

## Arguments

|                     |                                                                                                 |
|---------------------|-------------------------------------------------------------------------------------------------|
| <code>x</code>      | object of class "htest" or "power.htest".                                                       |
| <code>digits</code> | number of significant digits to be used.                                                        |
| <code>prefix</code> | string, passed to <code>strwrap</code> for displaying the method component of the htest object. |
| <code>...</code>    | further arguments to be passed to or from methods.                                              |

## Details

Both `print` methods traditionally have not obeyed the `digits` argument properly. They now do, the `htest` method mostly in expressions like `max(1, digits - 2)`.

A `power.htest` object is just a named list of numbers and character strings, supplemented with `method` and `note` elements. The `method` is displayed as a title, the `note` as a footnote, and the remaining elements are given in an aligned 'name = value' format.

## Value

the argument `x`, invisibly, as for all `print` methods.

print.ts

---

*Printing and Formatting of Time-Series Objects*

---

**Description**

Notably for calendar related time series objects, [format](#) and [print](#) methods showing years, months and or quarters respectively.

**Usage**

```
S3 method for class 'ts'
print(x, calendar, ...)
.preformat.ts(x, calendar, ...)
```

**Arguments**

|          |                                                                                                                                                                    |
|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x        | a time series object.                                                                                                                                              |
| calendar | enable/disable the display of information about month names, quarter names or year when printing. The default is TRUE for a frequency of 4 or 12, FALSE otherwise. |
| ...      | additional arguments to <a href="#">print</a> (or <a href="#">format</a> methods).                                                                                 |

**Details**

The [print](#) method for "ts" objects prints a header (basically of [tsp](#)(x)), if `calendar` is false, and then prints the result of `.preformat.ts(x, *)`, which is typically a [matrix](#) with [rownames](#) built from the calendar times where applicable.

**See Also**

[print](#), [ts](#).

**Examples**

```
print(ts(1:10, frequency = 7, start = c(12, 2)), calendar = TRUE)

print(sunsp.1 <- window(sunspot.month, end=c(1756, 12)))
m <- .preformat.ts(sunsp.1) # a character matrix
```

---

|              |                                   |
|--------------|-----------------------------------|
| printCoefmat | <i>Print Coefficient Matrices</i> |
|--------------|-----------------------------------|

---

## Description

Utility function to be used in higher-level `print` methods, such as those for `summary.lm`, `summary.glm` and `anova`. The goal is to provide a flexible interface with smart defaults such that often, only `x` needs to be specified.

## Usage

```
printCoefmat(x, digits = max(3, getOption("digits") - 2),
 signif.stars = getOption("show.signif.stars"),
 signif.legend = signif.stars,
 dig.tst = max(1, min(5, digits - 1)),
 cs.ind = 1L:k, tst.ind = k + 1L,
 zap.ind = integer(), P.values = NULL,
 has.Pvalue = nc >= 4L && length(cn <- colnames(x)) &&
 substr(cn[nc], 1L, 3L) %in% c("Pr(", "p-v"),
 eps.Pvalue = .Machine$double.eps,
 na.print = "NA", quote = FALSE, right = TRUE, ...)
```

## Arguments

|                                |                                                                                                                                                                                                                                                                                                                                                                    |
|--------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>                 | a numeric matrix like object, to be printed.                                                                                                                                                                                                                                                                                                                       |
| <code>digits</code>            | minimum number of significant digits to be used for most numbers.                                                                                                                                                                                                                                                                                                  |
| <code>signif.stars</code>      | logical; if TRUE, P-values are additionally encoded visually as ‘significance stars’ in order to help scanning of long coefficient tables. It defaults to the <code>show.signif.stars</code> slot of <code>options</code> .                                                                                                                                        |
| <code>signif.legend</code>     | logical; if TRUE, a legend for the ‘significance stars’ is printed provided <code>signif.stars = TRUE</code> .                                                                                                                                                                                                                                                     |
| <code>dig.tst</code>           | minimum number of significant digits for the test statistics, see <code>tst.ind</code> .                                                                                                                                                                                                                                                                           |
| <code>cs.ind</code>            | indices (integer) of column numbers which are (like) coefficients and standard errors to be formatted together.                                                                                                                                                                                                                                                    |
| <code>tst.ind</code>           | indices (integer) of column numbers for test statistics.                                                                                                                                                                                                                                                                                                           |
| <code>zap.ind</code>           | indices (integer) of column numbers which should be formatted by <code>zapsmall</code> , i.e., by ‘zapping’ values close to 0.                                                                                                                                                                                                                                     |
| <code>P.values</code>          | logical or NULL; if TRUE, the last column of <code>x</code> is formatted by <code>format.pval</code> as P values. If <code>P.values = NULL</code> , the default, it is set to TRUE only if <code>options("show.coef.Pvalue")</code> is TRUE and <code>x</code> has at least 4 columns and the last column name of <code>x</code> starts with <code>"Pr ("</code> . |
| <code>has.Pvalue</code>        | logical; if TRUE, the last column of <code>x</code> contains P values; in that case, it is printed if and only if <code>P.values</code> (above) is true.                                                                                                                                                                                                           |
| <code>eps.Pvalue</code>        | number, ..                                                                                                                                                                                                                                                                                                                                                         |
| <code>na.print</code>          | a character string to code NA values in printed output.                                                                                                                                                                                                                                                                                                            |
| <code>quote, right, ...</code> | further arguments passed to <code>print.default</code> .                                                                                                                                                                                                                                                                                                           |

**Value**

Invisibly returns its argument, `x`.

profile

*Generic Function for Profiling Models*

---

**Description**

Investigates behavior of objective function near the solution represented by `fitted`.

See documentation on method functions for further details.

**Usage**

```
profile(fitted, ...)
```

**Arguments**

`fitted`            the original fitted model object.

`...`            additional parameters. See documentation on individual methods.

**Value**

A list with an element for each parameter being profiled. See the individual methods for further details.

**See Also**

`profile.nls`, `profile.glm` in package **MASS**, ...

For profiling R code, see `Rprof`.

profile.nls

*Method for Profiling nls Objects***Description**

Investigates the profile log-likelihood function for a fitted model of class "nls".

**Usage**

```
S3 method for class 'nls'
profile(fitted, which = 1:npar, maxpts = 100, alphamax = 0.01,
 delta.t = cutoff/5, ...)
```

**Arguments**

|          |                                                                                                                                                        |
|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| fitted   | the original fitted model object.                                                                                                                      |
| which    | the original model parameters which should be profiled. This can be a numeric or character vector. By default, all non-linear parameters are profiled. |
| maxpts   | maximum number of points to be used for profiling each parameter.                                                                                      |
| alphamax | highest significance level allowed for the profile t-statistics.                                                                                       |
| delta.t  | suggested change on the scale of the profile t-statistics. Default value chosen to allow profiling at about 10 parameter values.                       |
| ...      | further arguments passed to or from other methods.                                                                                                     |

**Details**

The profile t-statistics is defined as the square root of change in sum-of-squares divided by residual standard error with an appropriate sign.

**Value**

A list with an element for each parameter being profiled. The elements are data-frames with two variables

|          |                                                     |
|----------|-----------------------------------------------------|
| par.vals | a matrix of parameter values for each fitted model. |
| tau      | the profile t-statistics.                           |

---

|      |                              |
|------|------------------------------|
| proj | <i>Projections of Models</i> |
|------|------------------------------|

---

## Description

`proj` returns a matrix or list of matrices giving the projections of the data onto the terms of a linear model. It is most frequently used for [aov](#) models.

## Usage

```
proj(object, ...)
```

```
S3 method for class 'aov'
proj(object, onedf = FALSE, unweighted.scale = FALSE, ...)
```

```
S3 method for class 'aovlist'
proj(object, onedf = FALSE, unweighted.scale = FALSE, ...)
```

```
Default S3 method:
proj(object, onedf = TRUE, ...)
```

```
S3 method for class 'lm'
proj(object, onedf = FALSE, unweighted.scale = FALSE, ...)
```

## Arguments

|                               |                                                                                                                                                                                                                                                        |
|-------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code>           | An object of class <code>"lm"</code> or a class inheriting from it, or an object with a similar structure including in particular components <code>qr</code> and <code>effects</code> .                                                                |
| <code>onedf</code>            | A logical flag. If <code>TRUE</code> , a projection is returned for all the columns of the model matrix. If <code>FALSE</code> , the single-column projections are collapsed by terms of the model (as represented in the analysis of variance table). |
| <code>unweighted.scale</code> | If the fit producing <code>object</code> used weights, this determines if the projections correspond to weighted or unweighted observations.                                                                                                           |
| <code>...</code>              | Swallow and ignore any other arguments.                                                                                                                                                                                                                |

## Details

A projection is given for each stratum of the object, so for `aov` models with an `Error` term the result is a list of projections.

## Value

A projection matrix or (for multi-stratum objects) a list of projection matrices.

Each projection is a matrix with a row for each observations and either a column for each term (`onedf = FALSE`) or for each coefficient (`onedf = TRUE`). Projection matrices from the default method have orthogonal columns representing the projection of the response onto the column space of the `Q` matrix from the QR decomposition. The fitted values are the sum of the projections, and the sum of squares for each column is the reduction in sum of squares from fitting that column (after those to the left of it).

The methods for `lm` and `aov` models add a column to the projection matrix giving the residuals (the projection of the data onto the orthogonal complement of the model space).

Strictly, when `onedf = FALSE` the result is not a projection, but the columns represent sums of projections onto the columns of the model matrix corresponding to that term. In this case the matrix does not depend on the coding used.

## Author(s)

The design was inspired by the `S` function of the same name described in Chambers *et al* (1992).

---

|           |                                           |
|-----------|-------------------------------------------|
| prop.test | <i>Test of Equal or Given Proportions</i> |
|-----------|-------------------------------------------|

---

**Description**

`prop.test` can be used for testing the null that the proportions (probabilities of success) in several groups are the same, or that they equal certain given values.

**Usage**

```
prop.test(x, n, p = NULL,
 alternative = c("two.sided", "less", "greater"),
 conf.level = 0.95, correct = TRUE)
```

**Arguments**

|                          |                                                                                                                                                                                                                                                                                                   |
|--------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>           | a vector of counts of successes, a one-dimensional table with two entries, or a two-dimensional table (or matrix) with 2 columns, giving the counts of successes and failures, respectively.                                                                                                      |
| <code>n</code>           | a vector of counts of trials; ignored if <code>x</code> is a matrix or a table.                                                                                                                                                                                                                   |
| <code>p</code>           | a vector of probabilities of success. The length of <code>p</code> must be the same as the number of groups specified by <code>x</code> , and its elements must be greater than 0 and less than 1.                                                                                                |
| <code>alternative</code> | a character string specifying the alternative hypothesis, must be one of "two.sided" (default), "greater" or "less". You can specify just the initial letter. Only used for testing the null that a single proportion equals a given value, or that two proportions are equal; ignored otherwise. |
| <code>conf.level</code>  | confidence level of the returned confidence interval. Must be a single number between 0 and 1. Only used when testing the null that a single proportion equals a given value, or that two proportions are equal; ignored otherwise.                                                               |
| <code>correct</code>     | a logical indicating whether Yates' continuity correction should be applied where possible.                                                                                                                                                                                                       |

**Details**

Only groups with finite numbers of successes and failures are used. Counts of successes and failures must be nonnegative and hence not greater than the corresponding numbers of trials which must be positive. All finite counts should be integers.

If `p` is `NULL` and there is more than one group, the null tested is that the proportions in each group are the same. If there are two groups, the alternatives are that the probability of success in the first group is less than, not equal to, or greater than the probability of success in the second group, as specified by `alternative`. A confidence interval for the difference of proportions with confidence level as specified by `conf.level` and clipped to  $[-1, 1]$  is returned. Continuity correction is used only if it does not exceed the difference of the sample proportions in absolute value. Otherwise, if there are more than 2 groups, the alternative is always "two.sided", the returned confidence interval is `NULL`, and continuity correction is never used.

If there is only one group, then the null tested is that the underlying probability of success is `p`, or .5 if `p` is not given. The alternative is that the probability of success is less than, not equal to, or greater than `p` or 0.5, respectively, as specified by `alternative`. A confidence interval for the

underlying proportion with confidence level as specified by `conf.level` and clipped to  $[0, 1]$  is returned. Continuity correction is used only if it does not exceed the difference between sample and null proportions in absolute value. The confidence interval is computed by inverting the score test.

Finally, if `p` is given and there are more than 2 groups, the null tested is that the underlying probabilities of success are those given by `p`. The alternative is always `"two.sided"`, the returned confidence interval is `NULL`, and continuity correction is never used.

## Value

A list with class `"htest"` containing the following components:

|                          |                                                                                                                                                                                                                                                                                                                                                                                                                             |
|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>statistic</code>   | the value of Pearson's chi-squared test statistic.                                                                                                                                                                                                                                                                                                                                                                          |
| <code>parameter</code>   | the degrees of freedom of the approximate chi-squared distribution of the test statistic.                                                                                                                                                                                                                                                                                                                                   |
| <code>p.value</code>     | the p-value of the test.                                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>estimate</code>    | a vector with the sample proportions $x/n$ .                                                                                                                                                                                                                                                                                                                                                                                |
| <code>conf.int</code>    | a confidence interval for the true proportion if there is one group, or for the difference in proportions if there are 2 groups and <code>p</code> is not given, or <code>NULL</code> otherwise. In the cases where it is not <code>NULL</code> , the returned confidence interval has an asymptotic confidence level as specified by <code>conf.level</code> , and is appropriate to the specified alternative hypothesis. |
| <code>null.value</code>  | the value of <code>p</code> if specified by the null, or <code>NULL</code> otherwise.                                                                                                                                                                                                                                                                                                                                       |
| <code>alternative</code> | a character string describing the alternative.                                                                                                                                                                                                                                                                                                                                                                              |
| <code>method</code>      | a character string indicating the method used, and whether Yates' continuity correction was applied.                                                                                                                                                                                                                                                                                                                        |
| <code>data.name</code>   | a character string giving the names of the data.                                                                                                                                                                                                                                                                                                                                                                            |

## See Also

[binom.test](#) for an *exact* test of a binomial hypothesis.

## Examples

```
heads <- rbinom(1, size = 100, prob = .5)
prop.test(heads, 100) # continuity correction TRUE by default
prop.test(heads, 100, correct = FALSE)

Data from Fleiss (1981), p. 139.
H0: The null hypothesis is that the four populations from which
the patients were drawn have the same true proportion of smokers.
```

```
A: The alternative is that this proportion is different in at
least one of the populations.

smokers <- c(83, 90, 129, 70)
patients <- c(86, 93, 136, 82)
prop.test(smokers, patients)
```

---

|                 |                                      |
|-----------------|--------------------------------------|
| prop.trend.test | <i>Test for trend in proportions</i> |
|-----------------|--------------------------------------|

---

### Description

Performs chi-squared test for trend in proportions, i.e., a test asymptotically optimal for local alternatives where the log odds vary in proportion with `score`. By default, `score` is chosen as the group numbers.

### Usage

```
prop.trend.test(x, n, score = seq_along(x))
```

### Arguments

|                    |                  |
|--------------------|------------------|
| <code>x</code>     | Number of events |
| <code>n</code>     | Number of trials |
| <code>score</code> | Group score      |

### Value

An object of class "htest" with title, test statistic, p-value, etc.

### Note

This really should get integrated with `prop.test`

### Author(s)

Peter Dalgaard

[prop.test](#)

### Examples

```
smokers <- c(83, 90, 129, 70)
patients <- c(86, 93, 136, 82)
prop.test(smokers, patients)
prop.trend.test(smokers, patients)
prop.trend.test(smokers, patients, c(0,0,0,1))
```

qqnorm

*Quantile-Quantile Plots***Description**

qqnorm is a generic function the default method of which produces a normal QQ plot of the values in `y`. qqline adds a line to a “theoretical”, by default normal, quantile-quantile plot which passes through the `probs` quantiles, by default the first and third quartiles.

qqplot produces a QQ plot of two datasets.

Graphical parameters may be given as arguments to qqnorm, qqplot and qqline.

**Usage**

```
qqnorm(y, ...)
Default S3 method:
qqnorm(y, ylim, main = "Normal Q-Q Plot",
 xlab = "Theoretical Quantiles", ylab = "Sample Quantiles",
 plot.it = TRUE, datax = FALSE, ...)

qqline(y, datax = FALSE, distribution = qnorm,
 probs = c(0.25, 0.75), qtype = 7, ...)

qqplot(x, y, plot.it = TRUE,
 xlab = deparse1(substitute(x)),
 ylab = deparse1(substitute(y)), ...)
```

**Arguments**

|                               |                                                                                                                               |
|-------------------------------|-------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>                | The first sample for qqplot.                                                                                                  |
| <code>y</code>                | The second or only data sample.                                                                                               |
| <code>xlab, ylab, main</code> | plot labels. The <code>xlab</code> and <code>ylab</code> refer to the y and x axes respectively if <code>datax</code> = TRUE. |
| <code>plot.it</code>          | logical. Should the result be plotted?                                                                                        |
| <code>datax</code>            | logical. Should data values be on the x-axis?                                                                                 |
| <code>distribution</code>     | quantile function for reference theoretical distribution.                                                                     |
| <code>probs</code>            | numeric vector of length two, representing probabilities. Corresponding quantile pairs define the line drawn.                 |
| <code>qtype</code>            | the type of quantile computation used in <a href="#">quantile</a> .                                                           |
| <code>ylim, ...</code>        | graphical parameters.                                                                                                         |

**Value**

For qqnorm and qqplot, a list with components

|                |                                                                                                                  |
|----------------|------------------------------------------------------------------------------------------------------------------|
| <code>x</code> | The x coordinates of the points that were/would be plotted                                                       |
| <code>y</code> | The original <code>y</code> vector, i.e., the corresponding y coordinates <i>including</i> <a href="#">NAs</a> . |

## See Also

[ppoints](#), used by qqnorm to generate approximations to expected order statistics for a normal distribution.

## Examples

```
require(graphics)

y <- rt(200, df = 5)
qqnorm(y); qqline(y, col = 2)
qqplot(y, rt(300, df = 5))

qqnorm(precip, ylab = "Precipitation [in/yr] for 70 US cities")

"QQ-Chisquare" : -----
y <- rchisq(500, df = 3)
Q-Q plot for Chi^2 data against true theoretical distribution:
qqplot(qchisq(ppoints(500), df = 3), y,
 main = expression("Q-Q plot for" ~~ {chi^2}[nu == 3]))
qqline(y, distribution = function(p) qchisq(p, df = 3),
 probs = c(0.1, 0.6), col = 2)
mtext("qqline(*, dist = qchisq(., df=3), prob = c(0.1, 0.6))")
(Note that the above uses ppoints() with a = 1/2, giving the
probability points for quantile type 5: so theoretically, using
qqline(qtype = 5) might be preferable.)
```

---

quade.test

*Quade Test*

---

## Description

Performs a Quade test with unreplicated blocked data.

## Usage

```
quade.test(y, ...)

Default S3 method:
quade.test(y, groups, blocks, ...)

S3 method for class 'formula'
quade.test(formula, data, subset, na.action, ...)
```

### Arguments

|                        |                                                                                                                                                                                                                            |
|------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>y</code>         | either a numeric vector of data values, or a data matrix.                                                                                                                                                                  |
| <code>groups</code>    | a vector giving the group for the corresponding elements of <code>y</code> if this is a vector; ignored if <code>y</code> is a matrix. If not a factor object, it is coerced to one.                                       |
| <code>blocks</code>    | a vector giving the block for the corresponding elements of <code>y</code> if this is a vector; ignored if <code>y</code> is a matrix. If not a factor object, it is coerced to one.                                       |
| <code>formula</code>   | a formula of the form $a \sim b \mid c$ , where <code>a</code> , <code>b</code> and <code>c</code> give the data values and corresponding groups and blocks, respectively.                                                 |
| <code>data</code>      | an optional matrix or data frame (or similar: see <a href="#">model.frame</a> ) containing the variables in the formula <code>formula</code> . By default the variables are taken from <code>environment(formula)</code> . |
| <code>subset</code>    | an optional vector specifying a subset of observations to be used.                                                                                                                                                         |
| <code>na.action</code> | a function which indicates what should happen when the data contain NAs. Defaults to <code>getOption("na.action")</code> .                                                                                                 |
| <code>...</code>       | further arguments to be passed to or from methods.                                                                                                                                                                         |

### Details

`quade.test` can be used for analyzing unreplicated complete block designs (i.e., there is exactly one observation in `y` for each combination of levels of `groups` and `blocks`) where the normality assumption may be violated.

The null hypothesis is that apart from an effect of `blocks`, the location parameter of `y` is the same in each of the `groups`.

If `y` is a matrix, `groups` and `blocks` are obtained from the column and row indices, respectively. NA's are not allowed in `groups` or `blocks`; if `y` contains NA's, corresponding blocks are removed.

### Value

A list with class `"htest"` containing the following components:

|                        |                                                                                                                         |
|------------------------|-------------------------------------------------------------------------------------------------------------------------|
| <code>statistic</code> | the value of Quade's F statistic.                                                                                       |
| <code>parameter</code> | a vector with the numerator and denominator degrees of freedom of the approximate F distribution of the test statistic. |
| <code>p.value</code>   | the p-value of the test.                                                                                                |
| <code>method</code>    | the character string <code>"Quade test"</code> .                                                                        |
| <code>data.name</code> | a character string giving the names of the data.                                                                        |

qT.$data.name <- qTst$data.name
stopifnot(all.equal(qTst, qT., tolerance = 1e-15))
dys <- dy[order(dy[, "Freq"]),]
qTs <- quade.test(Freq ~ Brand|Store, data = dys)
qTs$data.name <- qTst$data.name
stopifnot(all.equal(qTst, qTs, tolerance = 1e-15))
```

quantile

*Sample Quantiles***Description**

The generic function `quantile` produces sample quantiles corresponding to the given probabilities. The smallest observation corresponds to a probability of 0 and the largest to a probability of 1.

**Usage**

```
quantile(x, ...)

Default S3 method:
quantile(x, probs = seq(0, 1, 0.25), na.rm = FALSE,
 names = TRUE, type = 7, ...)
```

**Arguments**

|                    |                                                                                                                                                                                                                                                           |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>     | numeric vector whose sample quantiles are wanted, or an object of a class for which a method has been defined (see also ‘details’). <a href="#">NA</a> and NaN values are not allowed in numeric vectors unless <code>na.rm</code> is <code>TRUE</code> . |
| <code>probs</code> | numeric vector of probabilities with values in $[0, 1]$ . (Values up to ‘2e-14’ outside that range are accepted and moved to the nearby endpoint.)                                                                                                        |

|                    |                                                                                                            |
|--------------------|------------------------------------------------------------------------------------------------------------|
| <code>na.rm</code> | logical; if true, any NA and NaN's are removed from <code>x</code> before the quantiles are computed.      |
| <code>names</code> | logical; if true, the result has a <code>names</code> attribute. Set to FALSE for speedup with many probs. |
| <code>type</code>  | an integer between 1 and 9 selecting one of the nine quantile algorithms detailed below to be used.        |
| <code>...</code>   | further arguments passed to or from other methods.                                                         |

### Details

A vector of length `length(probs)` is returned; if `names = TRUE`, it has a `names` attribute.

NA and NaN values in `probs` are propagated to the result.

The default method works with classed objects sufficiently like numeric vectors that `sort` and (not needed by types 1 and 3) addition of elements and multiplication by a number work correctly. Note that as this is in a namespace, the copy of `sort` in **base** will be used, not some S4 generic of that name. Also note that that is no check on the 'correctly', and so e.g. `quantile` can be applied to complex vectors which (apart from ties) will be ordered on their real parts.

There is a method for the date-time classes (see "`POSIXt`"). Types 1 and 3 can be used for class "`Date`" and for ordered factors.

### Types

`quantile` returns estimates of underlying distribution quantiles based on one or two order statistics from the supplied elements in `x` at probabilities in `probs`. One of the nine quantile algorithms discussed in Hyndman and Fan (1996), selected by `type`, is employed.

All sample quantiles are defined as weighted averages of consecutive order statistics. Sample quantiles of type  $i$  are defined by:

$$Q_i(p) = (1 - \gamma)x_j + \gamma x_{j+1}$$

where  $1 \leq i \leq 9$ ,  $\frac{j-m}{n} \leq p < \frac{j-m+1}{n}$ ,  $x_j$  is the  $j$ th order statistic,  $n$  is the sample size, the value of  $\gamma$  is a function of  $j = \lfloor np + m \rfloor$  and  $g = np + m - j$ , and  $m$  is a constant determined by the sample quantile type.

#### Discontinuous sample quantile types 1, 2, and 3

For types 1, 2 and 3,  $Q_i(p)$  is a discontinuous function of  $p$ , with  $m = 0$  when  $i = 1$  and  $i = 2$ , and  $m = -1/2$  when  $i = 3$ .

**Type 1** Inverse of empirical distribution function.  $\gamma = 0$  if  $g = 0$ , and 1 otherwise.

**Type 2** Similar to type 1 but with averaging at discontinuities.  $\gamma = 0.5$  if  $g = 0$ , and 1 otherwise (SAS default, see Wicklin(2017)).

**Type 3** Nearest even order statistic (SAS default till ca. 2010).  $\gamma = 0$  if  $g = 0$  and  $j$  is even, and 1 otherwise.

#### Continuous sample quantile types 4 through 9

For types 4 through 9,  $Q_i(p)$  is a continuous function of  $p$ , with  $\gamma = g$  and  $m$  given below. The sample quantiles can be obtained equivalently by linear interpolation between the points  $(p_k, x_k)$  where  $x_k$  is the  $k$ th order statistic. Specific expressions for  $p_k$  are given below.

**Type 4**  $m = 0$ .  $p_k = \frac{k}{n}$ . That is, linear interpolation of the empirical cdf.

**Type 5**  $m = 1/2$ .  $p_k = \frac{k-0.5}{n}$ . That is a piecewise linear function where the knots are the values midway through the steps of the empirical cdf. This is popular amongst hydrologists.

**Type 6**  $m = p$ .  $p_k = \frac{k}{n+1}$ . Thus  $p_k = E[F(x_k)]$ . This is used by Minitab and by SPSS.

**Type 7**  $m = 1 - p$ .  $p_k = \frac{k-1}{n-1}$ . In this case,  $p_k = \text{mode}[F(x_k)]$ . This is used by S.

**Type 8**  $m = (p+1)/3$ .  $p_k = \frac{k-1/3}{n+1/3}$ . Then  $p_k \approx \text{median}[F(x_k)]$ . The resulting quantile estimates are approximately median-unbiased regardless of the distribution of  $x$ .

**Type 9**  $m = p/4 + 3/8$ .  $p_k = \frac{k-3/8}{n+1/4}$ . The resulting quantile estimates are approximately unbiased for the expected order statistics if  $x$  is normally distributed.

Further details are provided in Hyndman and Fan (1996) who recommended type 8. The default method is type 7, as used by S and by R < 2.0.0. Makkonen argues for type 6, also as already proposed by Weibull in 1939. The Wikipedia page contains further information about availability of these 9 types in software.

[ecdf](#) for empirical distributions of which quantile is an inverse; [boxplot.stats](#) and [fivenum](#) for computing other versions of quartiles, etc.

### Examples

```
quantile(x <- rnorm(1001)) # Extremes & Quartiles by default
quantile(x, probs = c(0.1, 0.5, 1, 2, 5, 10, 50, NA)/100)

Compare different types
quantAll <- function(x, prob, ...)
 t(vapply(1:9, function(typ) quantile(x, prob=prob, type = typ, ...),
 quantile(x, prob, type=1, ...)))
p <- c(0.1, 0.5, 1, 2, 5, 10, 50)/100
signif(quantAll(x, p), 4)

0% and 100% are equal to min(), max() for all types:
stopifnot(t(quantAll(x, prob=0:1)) == range(x))

for complex numbers:
z <- complex(re=x, im = -10*x)
signif(quantAll(z, p), 4)
```

r2dtable

*Random 2-way Tables with Given Marginals***Description**

Generate random 2-way tables with given marginals using Patefield's algorithm.

**Usage**

```
r2dtable(n, r, c)
```

**Arguments**

**n** a non-negative numeric giving the number of tables to be drawn.

**r** a non-negative vector of length at least 2 giving the row totals, to be coerced to integer. Must sum to the same as **c**.

**c** a non-negative vector of length at least 2 giving the column totals, to be coerced to integer.

**Value**

A list of length **n** containing the generated tables as its components.

**References**

Patefield, W. M. (1981). Algorithm AS 159: An efficient method of generating  $r \times c$  tables with given row and column totals. *Applied Statistics*, **30**, 91–97. doi: [10.2307/2346669](https://doi.org/10.2307/2346669).

**Examples**

```
Fisher's Tea Drinker data.
TeaTasting <-
matrix(c(3, 1, 1, 3),
 nrow = 2,
 dimnames = list(Guess = c("Milk", "Tea"),
 Truth = c("Milk", "Tea")))
Simulate permutation test for independence based on the maximum
Pearson residuals (rather than their sum).
rowTotals <- rowSums(TeaTasting)
colTotals <- colSums(TeaTasting)
nOfCases <- sum(rowTotals)
expected <- outer(rowTotals, colTotals, "*") / nOfCases
maxSqResid <- function(x) max((x - expected) ^ 2 / expected)
simMaxSqResid <-
 sapply(r2dtable(1000, rowTotals, colTotals), maxSqResid)
sum(simMaxSqResid >= maxSqResid(TeaTasting)) / 1000
Fisher's exact test gives p = 0.4857 ...
```

|-------------|-------------------------------------------|
| read.ftable | <i>Manipulate Flat Contingency Tables</i> |
|-------------|-------------------------------------------|

---

## Description

Read, write and coerce 'flat' contingency tables.

## Usage

```
read.ftable(file, sep = "", quote = "\"",
 row.var.names, col.vars, skip = 0)

write.ftable(x, file = "", quote = TRUE, append = FALSE,
 digits = getOption("digits"), ...)

S3 method for class 'ftable'
format(x, quote = TRUE, digits = getOption("digits"),
 method = c("non.compact", "row.compact",
 "col.compact", "compact"),
 lsep = " | ", ...)

S3 method for class 'ftable'
print(x, digits = getOption("digits"), ...)
```

## Arguments

|                            |                                                                                                                                                                                                                                                                        |
|----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>file</code>          | either a character string naming a file or a connection which the data are to be read from or written to. "" indicates input from the console for reading and output to the console for writing.                                                                       |
| <code>sep</code>           | the field separator string. Values on each line of the file are separated by this string.                                                                                                                                                                              |
| <code>quote</code>         | a character string giving the set of quoting characters for <code>read.ftable</code> ; to disable quoting altogether, use <code>quote=""</code> . For <code>write.table</code> , a logical indicating whether strings in the data will be surrounded by double quotes. |
| <code>row.var.names</code> | a character vector with the names of the row variables, in case these cannot be determined automatically.                                                                                                                                                              |
| <code>col.vars</code>      | a list giving the names and levels of the column variables, in case these cannot be determined automatically.                                                                                                                                                          |
| <code>skip</code>          | the number of lines of the data file to skip before beginning to read data.                                                                                                                                                                                            |
| <code>x</code>             | an object of class "ftable".                                                                                                                                                                                                                                           |
| <code>append</code>        | logical. If TRUE and <code>file</code> is the name of a file (and not a connection or " cmd"), the output from <code>write.ftable</code> is appended to the file. If FALSE, the contents of <code>file</code> will be overwritten.                                     |
| <code>digits</code>        | an integer giving the number of significant digits to use for (the cell entries of) <code>x</code> .                                                                                                                                                                   |
| <code>method</code>        | string specifying how the "ftable" object is formatted (and printed if used as in <code>write.ftable()</code> or the <code>print</code> method). Can be abbreviated. Available methods are (see the examples):                                                         |

**"non.compact"** the default representation of an "ftable" object.

**"row.compact"** a row-compact version without empty cells below the column labels.

**"col.compact"** a column-compact version without empty cells to the right of the row labels.

**"compact"** a row- and column-compact version. This may imply a row and a column label sharing the same cell. They are then separated by the string `lsep`.

`lsep` only for `method = "compact"`, the separation string for row and column labels.

`...` further arguments to be passed to or from methods; for `write()` and `print()`, notably arguments such as `method`, passed to `format()`.

## Details

`read.ftable` reads in a flat-like contingency table from a file. If the file contains the written representation of a flat table (more precisely, a header with all information on names and levels of column variables, followed by a line with the names of the row variables), no further arguments are needed. Similarly, flat tables with only one column variable the name of which is the only entry in the first line are handled automatically. Other variants can be dealt with by skipping all header information using `skip`, and providing the names of the row variables and the names and levels of the column variable using `row.var.names` and `col.vars`, respectively. See the examples below.

Note that flat tables are characterized by their ‘ragged’ display of row (and maybe also column) labels. If the full grid of levels of the row variables is given, one should instead use `read.table` to read in the data, and create the contingency table from this using `xtabs`.

`write.ftable` writes a flat table to a file, which is useful for generating ‘pretty’ ASCII representations of contingency tables. Different versions are available via the `method` argument, which may be useful, for example, for constructing LaTeX tables.

---

rect.hclust
*Draw Rectangles Around Hierarchical Clusters*

### Description

Draws rectangles around the branches of a dendrogram highlighting the corresponding clusters. First the dendrogram is cut at a certain level, then a rectangle is drawn around selected branches.

## Usage

```
rect.hclust(tree, k = NULL, which = NULL, x = NULL, h = NULL,
 border = 2, cluster = NULL)
```

## Arguments

|                       |                                                                                                                                                                                                                                                                                   |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>tree</code>     | an object of the type produced by <code>hclust</code> .                                                                                                                                                                                                                           |
| <code>k, h</code>     | Scalar. Cut the dendrogram such that either exactly <code>k</code> clusters are produced or by cutting at height <code>h</code> .                                                                                                                                                 |
| <code>which, x</code> | A vector selecting the clusters around which a rectangle should be drawn. <code>which</code> selects clusters by number (from left to right in the tree), <code>x</code> selects clusters containing the respective horizontal coordinates. Default is <code>which = 1:k</code> . |
| <code>border</code>   | Vector with border colors for the rectangles.                                                                                                                                                                                                                                     |
| <code>cluster</code>  | Optional vector with cluster memberships as returned by <code>cutree(hclust.obj, k = k)</code> , can be specified for efficiency if already computed.                                                                                                                             |

**Value**

(Invisibly) returns a list where each element contains a vector of data points contained in the respective cluster.

**See Also**

`hclust`, `identify.hclust`.

**Examples**

```
require(graphics)

hca <- hclust(dist(USArrests))
plot(hca)
rect.hclust(hca, k = 3, border = "red")
x <- rect.hclust(hca, h = 50, which = c(2,7), border = 3:4)
x
```

---

relevel

---

*Reorder Levels of Factor*

---

**Description**

The levels of a factor are re-ordered so that the level specified by `ref` is first and the others are moved down. This is useful for `contr.treatment` contrasts which take the first level as the reference.

**Usage**

```
relevel(x, ref, ...)
```

**Arguments**

|                  |                                          |
|------------------|------------------------------------------|
| <code>x</code>   | an unordered factor.                     |
| <code>ref</code> | the reference level, typically a string. |
| <code>...</code> | additional arguments for future methods. |

**Details**

This, as `reorder()`, is a special case of simply calling `factor(x, levels = levels(x)[...])`.

**Value**

A factor of the same length as `x`.

**See Also**

`factor`, `contr.treatment`, `levels`, `reorder`.

**Examples**

```
warpbreaks$tension <- relevel(warpbreaks$tension, ref = "M")
summary(lm(breaks ~ wool + tension, data = warpbreaks))
```

---

reorder.default      *Reorder Levels of a Factor*

---

**Description**

`reorder` is a generic function. The "default" method treats its first argument as a categorical variable, and reorders its levels based on the values of a second variable, usually numeric.

**Usage**

```
reorder(x, ...)

Default S3 method:
reorder(x, X, FUN = mean, ...,
 order = is.ordered(x))
```

**Arguments**

|                    |                                                                                                                                                                                                                                                  |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>     | an atomic vector, usually a <a href="#">factor</a> (possibly ordered). The vector is treated as a categorical variable whose levels will be reordered. If <code>x</code> is not a factor, its unique values will be used as the implicit levels. |
| <code>X</code>     | a vector of the same length as <code>x</code> , whose subset of values for each unique level of <code>x</code> determines the eventual order of that level.                                                                                      |
| <code>FUN</code>   | a <a href="#">function</a> whose first argument is a vector and returns a scalar, to be applied to each subset of <code>X</code> determined by the levels of <code>x</code> .                                                                    |
| <code>...</code>   | optional: extra arguments supplied to <code>FUN</code>                                                                                                                                                                                           |
| <code>order</code> | logical, whether return value will be an ordered factor rather than a factor.                                                                                                                                                                    |

**Details**

This, as [relevel\(\)](#), is a special case of simply calling [factor\(x, levels = levels\(x\) \[....\]\)](#).

**Value**

A factor or an ordered factor (depending on the value of `order`), with the order of the levels determined by `FUN` applied to `X` grouped by `x`. The levels are ordered such that the values returned by `FUN` are in increasing order. Empty levels will be dropped.

Additionally, the values of `FUN` applied to the subsets of `X` (in the original order of the levels of `x`) is returned as the "scores" attribute.

**See Also**

[reorder.dendrogram](#), [levels](#), [relevel](#).

**Examples**

```
require(graphics)

bymedian <- with(InsectSprays, reorder(spray, count, median))
boxplot(count ~ bymedian, data = InsectSprays,
 xlab = "Type of spray", ylab = "Insect count",
 main = "InsectSprays data", varwidth = TRUE,
 col = "lightgray")
```

---

reorder.dendrogram *Reorder a Dendrogram*

---

**Description**

A method for the generic function [reorder](#).

There are many different orderings of a dendrogram that are consistent with the structure imposed. This function takes a dendrogram and a vector of values and reorders the dendrogram in the order of the supplied vector, maintaining the constraints on the dendrogram.

**Usage**

```
S3 method for class 'dendrogram'
reorder(x, wts, agгло.FUN = sum, ...)
```

**Arguments**

|                        |                                                    |
|------------------------|----------------------------------------------------|
| <code>x</code>         | the (dendrogram) object to be reordered            |
| <code>wts</code>       | numeric weights (arbitrary values) for reordering. |
| <code>agгло.FUN</code> | a function for weights agglomeration, see below.   |
| <code>...</code>       | additional arguments                               |

**Details**

Using the weights `wts`, the leaves of the dendrogram are reordered so as to be in an order as consistent as possible with the weights. At each node, the branches are ordered in increasing weights where the weight of a branch is defined as  $f(w_j)$  where  $f$  is `agгло.FUN` and  $w_j$  is the weight of the  $j$ -th sub branch.

**Value**

A dendrogram where each node has a further attribute `value` with its corresponding weight.

**Author(s)**

R. Gentleman and M. Maechler

**See Also**

[reorder](#).

[rev.dendrogram](#) which simply reverses the nodes' order; [heatmap](#), [cophenetic](#).

## Examples

```
require(graphics)

set.seed(123)
x <- rnorm(10)
hc <- hclust(dist(x))
dd <- as.dendrogram(hc)
dd.reorder <- reorder(dd, 10:1)
plot(dd, main = "random dendrogram 'dd'")

op <- par(mfcol = 1:2)
plot(dd.reorder, main = "reorder(dd, 10:1)")
plot(reorder(dd, 10:1, agglo.FUN = mean), main = "reorder(dd, 10:1, mean)")
par(op)
```

---

|              |                                        |
|--------------|----------------------------------------|
| replications | <i>Number of Replications of Terms</i> |
|--------------|----------------------------------------|

---

## Description

Returns a vector or a list of the number of replicates for each term in the formula.

## Usage

```
replications(formula, data = NULL, na.action)
```

## Arguments

|                        |                                                                                                                                                                                                               |
|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>formula</code>   | a formula or a terms object or a data frame.                                                                                                                                                                  |
| <code>data</code>      | a data frame used to find the objects in <code>formula</code> .                                                                                                                                               |
| <code>na.action</code> | function for handling missing values. Defaults to a <code>na.action</code> attribute of <code>data</code> , then a setting of the option <code>na.action</code> , or <code>na.fail</code> if that is not set. |

## Details

If `formula` is a data frame and `data` is missing, `formula` is used for `data` with the formula ~ ..

Any character vectors in the formula are coerced to factors.

## Value

A vector or list with one entry for each term in the formula giving the number(s) of replications for each level. If all levels are balanced (have the same number of replications) the result is a vector, otherwise it is a list with a component for each terms, as a vector, matrix or array as required.

A test for balance is `!is.list(replications(formula, data))`.

## Author(s)

The design was inspired by the S function of the same name described in Chambers *et al* (1992).

---

|         |                             |
|---------|-----------------------------|
| reshape | <i>Reshape Grouped Data</i> |
|---------|-----------------------------|

---

Description

This function reshapes a data frame between ‘wide’ format with repeated measurements in separate columns of the same record and ‘long’ format with the repeated measurements in separate records.

Usage

```
reshape(data, varying = NULL, v.names = NULL, timevar = "time",
 idvar = "id", ids = 1:NROW(data),
 times = seq_along(varying[[1]]),
 drop = NULL, direction, new.row.names = NULL,
 sep = ".",
 split = if (sep == "") {
 list(regex = "[A-Za-z][0-9]", include = TRUE)
 } else {
 list(regex = sep, include = FALSE, fixed = TRUE)}
)
```

Arguments

- data                    a data frame
- varying                names of sets of variables in the wide format that correspond to single variables in long format (‘time-varying’). This is canonically a list of vectors of variable names, but it can optionally be a matrix of names, or a single vector of names. In each case, the names can be replaced by indices which are interpreted as referring to names(data). See ‘Details’ for more details and options.

|                            |                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>v.names</code>       | names of variables in the long format that correspond to multiple variables in the wide format. See ‘Details’.                                                                                                                                                                                                                                                                                                                  |
| <code>timevar</code>       | the variable in long format that differentiates multiple records from the same group or individual. If more than one record matches, the first will be taken (with a warning).                                                                                                                                                                                                                                                  |
| <code>idvar</code>         | Names of one or more variables in long format that identify multiple records from the same group/individual. These variables may also be present in wide format.                                                                                                                                                                                                                                                                |
| <code>ids</code>           | the values to use for a newly created <code>idvar</code> variable in long format.                                                                                                                                                                                                                                                                                                                                               |
| <code>times</code>         | the values to use for a newly created <code>timevar</code> variable in long format. See ‘Details’.                                                                                                                                                                                                                                                                                                                              |
| <code>drop</code>          | a vector of names of variables to drop before reshaping.                                                                                                                                                                                                                                                                                                                                                                        |
| <code>direction</code>     | character string, partially matched to either "wide" to reshape to wide format, or "long" to reshape to long format.                                                                                                                                                                                                                                                                                                            |
| <code>new.row.names</code> | character or <code>NULL</code> : a non-null value will be used for the row names of the result.                                                                                                                                                                                                                                                                                                                                 |
| <code>sep</code>           | A character vector of length 1, indicating a separating character in the variable names in the wide format. This is used for guessing <code>v.names</code> and <code>times</code> arguments based on the names in <code>varying</code> . If <code>sep == ""</code> , the split is just before the first numeral that follows an alphabetic character. This is also used to create variable names when reshaping to wide format. |
| <code>split</code>         | A list with three components, <code>regexp</code> , <code>include</code> , and (optionally) <code>fixed</code> . This allows an extended interface to variable name splitting. See ‘Details’.                                                                                                                                                                                                                                   |

## Details

The arguments to this function are described in terms of longitudinal data, as that is the application motivating the functions. A ‘wide’ longitudinal dataset will have one record for each individual with some time-constant variables that occupy single columns and some time-varying variables that occupy a column for each time point. In ‘long’ format there will be multiple records for each individual, with some variables being constant across these records and others varying across the records. A ‘long’ format dataset also needs a ‘time’ variable identifying which time point each record comes from and an ‘id’ variable showing which records refer to the same person.

If the data frame resulted from a previous `reshape` then the operation can be reversed simply by `reshape(a)`. The `direction` argument is optional and the other arguments are stored as attributes on the data frame.

If `direction = "wide"` and no `varying` or `v.names` arguments are supplied it is assumed that all variables except `idvar` and `timevar` are time-varying. They are all expanded into multiple variables in wide format.

If `direction = "long"` the `varying` argument can be a vector of column names (or a corresponding index). The function will attempt to guess the `v.names` and `times` from these names. The default is variable names like `x.1`, `x.2`, where `sep = "."` specifies to split at the dot and drop it from the name. To have alphabetic followed by numeric times use `sep = ""`.

Variable name splitting as described above is only attempted in the case where `varying` is an atomic vector, if it is a list or a matrix, `v.names` and `times` will generally need to be specified, although they will default to, respectively, the first variable name in each set, and sequential times.

Also, guessing is not attempted if `v.names` is given explicitly. Notice that the order of variables in `varying` is like `x.1,y.1,x.2,y.2`.

The `split` argument should not usually be necessary. The `split$regexp` component is passed to either `strsplit` or `regexpr`, where the latter is used if `split$include` is `TRUE`, in which case the splitting occurs after the first character of the matched string. In the `strsplit` case, the separator is not included in the result, and it is possible to specify fixed-string matching using `split$fixed`.

### Value

The reshaped data frame with added attributes to simplify reshaping back to the original form.

### See Also

`stack`, `aperm`; `relist` for reshaping the result of `unlist`.

### Examples

```
summary(Indometh)
wide <- reshape(Indometh, v.names = "conc", idvar = "Subject",
 timevar = "time", direction = "wide")
wide

reshape(wide, direction = "long")
reshape(wide, idvar = "Subject", varying = list(2:12),
 v.names = "conc", direction = "long")

times need not be numeric
df <- data.frame(id = rep(1:4, rep(2,4)),
 visit = I(rep(c("Before","After"), 4)),
 x = rnorm(4), y = runif(4))
df
reshape(df, timevar = "visit", idvar = "id", direction = "wide")
warns that y is really varying
reshape(df, timevar = "visit", idvar = "id", direction = "wide", v.names = "x")

unbalanced 'long' data leads to NA fill in 'wide' form
df2 <- df[1:7,]
df2
reshape(df2, timevar = "visit", idvar = "id", direction = "wide")

Alternative regular expressions for guessing names
df3 <- data.frame(id = 1:4, age = c(40,50,60,50), dose1 = c(1,2,1,2),
 dose2 = c(2,1,2,1), dose4 = c(3,3,3,3))
reshape(df3, direction = "long", varying = 3:5, sep = "")

an example that isn't longitudinal data
state.x77 <- as.data.frame(state.x77)
long <- reshape(state.x77, idvar = "state", ids = row.names(state.x77),
 times = names(state.x77), timevar = "Characteristic",
 varying = list(names(state.x77)), direction = "long")

reshape(long, direction = "wide")

reshape(long, direction = "wide", new.row.names = unique(long$state))

multiple id variables
```

```
df3 <- data.frame(school = rep(1:3, each = 4), class = rep(9:10, 6),
 time = rep(c(1,1,2,2), 3), score = rnorm(12))
wide <- reshape(df3, idvar = c("school","class"), direction = "wide")
wide
transform back
reshape(wide)
```

residuals

*Extract Model Residuals***Description**

`residuals` is a generic function which extracts model residuals from objects returned by modeling functions.

The abbreviated form `resid` is an alias for `residuals`. It is intended to encourage users to access object components through an accessor function rather than by directly referencing an object slot.

All object classes which are returned by model fitting functions should provide a `residuals` method. (Note that the method is for `'residuals'` and not `'resid'`.)

Methods can make use of `naresid` methods to compensate for the omission of missing values. The default, `nls` and `smooth.spline` methods do.

**Usage**

```
residuals(object, ...)
resid(object, ...)
```

**Arguments**

|                     |                                                                      |
|---------------------|----------------------------------------------------------------------|
| <code>object</code> | an object for which the extraction of model residuals is meaningful. |
| <code>...</code>    | other arguments.                                                     |

**Value**

Residuals extracted from the object `object`.

**References**

Chambers, J. M. and Hastie, T. J. (1992) *Statistical Models in S*. Wadsworth & Brooks/Cole.

**See Also**

`coefficients`, `fitted.values`, `glm`, `lm`.

`influence.measures` for standardized (`rstandard`) and studentized (`rstudent`) residuals.

runmed

*Running Medians – Robust Scatter Plot Smoothing***Description**

Compute running medians of odd span. This is the ‘most robust’ scatter plot smoothing possible. For efficiency (and historical reason), you can use one of two different algorithms giving identical results.

**Usage**

```
runmed(x, k, endrule = c("median", "keep", "constant"),
 algorithm = NULL,
 na.action = c("+Big_alterdate", "-Big_alterdate", "na.omit", "fail"),
 print.level = 0)
```

**Arguments**

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x           | numeric vector, the ‘dependent’ variable to be smoothed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| k           | integer width of median window; must be odd. Turlach had a default of $k < -1 + 2 * \min((n-1) \% \% 2, \text{ceiling}(0.1 * n))$ . Use $k = 3$ for ‘minimal’ robust smoothing eliminating isolated outliers.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| endrule     | character string indicating how the values at the beginning and the end (of the data) should be treated. Can be abbreviated. Possible values are:<br>"keep" keeps the first and last $k_2$ values at both ends, where $k_2$ is the half-bandwidth $k_2 = k \% \% 2$ , i.e., $y[j] = x[j]$ for $j \in \{1, \dots, k_2; n - k_2 + 1, \dots, n\}$ ;<br>"constant" copies <code>median(y[1:k2])</code> to the first values and analogously for the last ones making the smoothed ends <i>constant</i> ;<br>"median" the default, smooths the ends by using symmetrical medians of subsequently smaller bandwidth, but for the very first and last value where Tukey’s robust end-point rule is applied, see <a href="#">smoothEnds</a> . |
| algorithm   | character string (partially matching "Turlach" or "Stuetzle") or the default NULL, specifying which algorithm should be applied. The default choice depends on $n = \text{length}(x)$ and $k$ where "Turlach" will be used for larger problems.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| na.action   | character string determining the behavior in the case of NA or NaN in x, (partially matching) one of<br>"+Big_alterdate" Here, all the NAs in x are first replaced by alternating $\pm B$ where $B$ is a “Big” number (with $2B < M^*$ , where $M^* = .Machine\$double.xmax$ ). The replacement values are “from left” $(+B, -B, +B, \dots)$ , i.e. start with "+".<br>"-Big_alterdate" almost the same as "+Big_alterdate", just starting with $-B$ ("Big...").<br>"na.omit" the result is the same as <code>runmed(x[!is.na(x)], k, ...)</code> .<br>"fail" the presence of NAs in x will raise an error.                                                                                                                          |
| print.level | integer, indicating verbosity of algorithm; should rarely be changed by average users.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

## Details

Apart from the end values, the result `y = runmed(x, k)` simply has `y[j] = median(x[(j-k2):(j+k2)])` ( $k = 2*k2+1$ ), computed very efficiently.

The two algorithms are internally entirely different:

"Turlach" is the Härdle–Steiger algorithm (see Ref.) as implemented by Berwin Turlach. A tree algorithm is used, ensuring performance  $O(n \log k)$  where  $n = \text{length}(x)$  which is asymptotically optimal.

"Stuetzle" is the (older) Stuetzle–Friedman implementation which makes use of median *updating* when one observation enters and one leaves the smoothing window. While this performs as  $O(n \times k)$  which is slower asymptotically, it is considerably faster for small  $k$  or  $n$ .

Note that, both algorithms (and the `smoothEnds()` utility) now “work” also when `x` contains non-finite entries (`±Inf`, `NaN`, and `NA`):

"Turlach" .....

"Stuetzle" currently simply works by applying the underlying math library ('libm') arithmetic for the non-finite numbers; this may optionally change in the future.

Currently **long vectors** are only supported for `algorithm = "Stuetzle"`.

## Value

vector of smoothed values of the same length as `x` with an `attribute` `k` containing (the ‘oddified’) `k`.

## See Also

`smoothEnds` which implements Tukey’s end point rule and is called by default from `runmed(*, endrule = "median")`. `smooth` uses running medians of 3 for its compound smoothers.

## Examples

```
require(graphics)

utils::example(nhtemp)
myNHT <- as.vector(nhtemp)
myNHT[20] <- 2 * nhtemp[20]
plot(myNHT, type = "b", ylim = c(48, 60), main = "Running Medians Example")
lines(runmed(myNHT, 7), col = "red")
```

```

special: multiple y values for one x
plot(cars, main = "'cars' data and runmed(dist, 3)")
lines(cars, col = "light gray", type = "c")
with(cars, lines(speed, runmed(dist, k = 3), col = 2))

nice quadratic with a few outliers
y <- ys <- (-20:20)^2
y[c(1,10,21,41)] <- c(150, 30, 400, 450)
all(y == runmed(y, 1)) # 1-neighbourhood <==> interpolation
plot(y) ## lines(y, lwd = .1, col = "light gray")
lines(lowess(seq(y), y, f = 0.3), col = "brown")
lines(runmed(y, 7), lwd = 2, col = "blue")
lines(runmed(y, 11), lwd = 2, col = "red")

Lowess is not robust
y <- ys ; y[21] <- 6666 ; x <- seq(y)
col <- c("black", "brown", "blue")
plot(y, col = col[1])
lines(lowess(x, y, f = 0.3), col = col[2])

lines(runmed(y, 7), lwd = 2, col = col[3])
legend(length(y), max(y), c("data", "lowess(y, f = 0.3)", "runmed(y, 7)"),
 xjust = 1, col = col, lty = c(0, 1, 1), pch = c(1, NA, NA))

An example with initial NA's - used to fail badly (notably for "Turlach"):
x15 <- c(rep(NA, 4), c(9, 9, 4, 22, 6, 1, 7, 5, 2, 8, 3))
rS15 <- cbind(Sk.3 = runmed(x15, k = 3, algorithm="S"),
 Sk.7 = runmed(x15, k = 7, algorithm="S"),
 Sk.11 = runmed(x15, k = 11, algorithm="S"))
rT15 <- cbind(Tk.3 = runmed(x15, k = 3, algorithm="T", print.level=1),
 Tk.7 = runmed(x15, k = 7, algorithm="T", print.level=1),
 Tk.9 = runmed(x15, k = 9, algorithm="T", print.level=1),
 Tk.11 = runmed(x15, k = 11, algorithm="T", print.level=1))
cbind(x15, rS15, rT15) # result for k=11 maybe a bit surprising ..
Tv <- rT15[~(1:3),]
stopifnot(3 <= Tv, Tv <= 9, 5 <= Tv[1:10,])
matplot(y = cbind(x15, rT15), type = "b", ylim = c(1,9), pch=1:5, xlab = NA,
 main = "runmed(x15, k, algo = \"Turlach\")")
mtext(paste("x15 <- ", deparse(x15)))
points(x15, cex=2)
legend("bottomleft", legend=c("data", paste("k = ", c(3,7,9,11))),
 bty="n", col=1:5, lty=1:5, pch=1:5)

```

## Description

Generate  $n$  random matrices, distributed according to the Wishart distribution with parameters  $\Sigma$  and  $df$ ,  $W_p(\Sigma, m)$ ,  $m = df$ ,  $\Sigma = \text{Sigma}$ .

**Usage**

```
rWishart(n, df, Sigma)
```

**Arguments**

|       |                                                                                              |
|-------|----------------------------------------------------------------------------------------------|
| n     | integer sample size.                                                                         |
| df    | numeric parameter, “degrees of freedom”.                                                     |
| Sigma | positive definite ( $p \times p$ ) “scale” matrix, the matrix parameter of the distribution. |

**Details**

If  $X_1, \dots, X_m$ ,  $X_i \in \mathbf{R}^p$  is a sample of  $m$  independent multivariate Gaussians with mean (vector) 0, and covariance matrix  $\Sigma$ , the distribution of  $M = X'X$  is  $W_p(\Sigma, m)$ .

Consequently, the expectation of  $M$  is

$$E[M] = m \times \Sigma.$$

Further, if Sigma is scalar ( $p = 1$ ), the Wishart distribution is a scaled chi-squared ( $\chi^2$ ) distribution with df degrees of freedom,  $W_1(\sigma^2, m) = \sigma^2 \chi_m^2$ .

The component wise variance is

$$\text{Var}(M_{ij}) = m(\Sigma_{ij}^2 + \Sigma_{ii}\Sigma_{jj}).$$

**Value**

a numeric [array](#), say R, of dimension  $p \times p \times n$ , where each  $R[, , i]$  is a positive definite matrix, a realization of the Wishart distribution  $W_p(\Sigma, m)$ ,  $m = \text{df}$ ,  $\Sigma = \text{Sigma}$ .

[cov](#), [rnorm](#), [rchisq](#).

**Examples**

```
Artificial
S <- toeplitz((10:1)/10)
set.seed(11)
R <- rWishart(1000, 20, S)
dim(R) # 10 10 1000
mR <- apply(R, 1:2, mean) # ~ = E[Wish(S, 20)] = 20 * S
stopifnot(all.equal(mR, 20*S, tolerance = .009))

See Details, the variance is
Va <- 20*(S^2 + tcrossprod(diag(S)))
vR <- apply(R, 1:2, var)
stopifnot(all.equal(vR, Va, tolerance = 1/16))
```

|                |                                                       |
|----------------|-------------------------------------------------------|
| scatter.smooth | <i>Scatter Plot with Smooth Curve Fitted by Loess</i> |
|----------------|-------------------------------------------------------|

---

## Description

Plot and add a smooth curve computed by `loess` to a scatter plot.

## Usage

```
scatter.smooth(x, y = NULL, span = 2/3, degree = 1,
 family = c("symmetric", "gaussian"),
 xlab = NULL, ylab = NULL,
 ylim = range(y, pred$y, na.rm = TRUE),
 evaluation = 50, ..., lpars = list())

loess.smooth(x, y, span = 2/3, degree = 1,
 family = c("symmetric", "gaussian"), evaluation = 50, ...)
```

## Arguments

|                         |                                                                                                                                                                                                                                               |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x, y</code>       | the <code>x</code> and <code>y</code> arguments provide the <code>x</code> and <code>y</code> coordinates for the plot. Any reasonable way of defining the coordinates is acceptable. See the function <a href="#">xy.coords</a> for details. |
| <code>span</code>       | smoothness parameter for <code>loess</code> .                                                                                                                                                                                                 |
| <code>degree</code>     | degree of local polynomial used.                                                                                                                                                                                                              |
| <code>family</code>     | if <code>"gaussian"</code> fitting is by least-squares, and if <code>family = "symmetric"</code> a re-descending M estimator is used. Can be abbreviated.                                                                                     |
| <code>xlab</code>       | label for <code>x</code> axis.                                                                                                                                                                                                                |
| <code>ylab</code>       | label for <code>y</code> axis.                                                                                                                                                                                                                |
| <code>ylim</code>       | the <code>y</code> limits of the plot.                                                                                                                                                                                                        |
| <code>evaluation</code> | number of points at which to evaluate the smooth curve.                                                                                                                                                                                       |
| <code>...</code>        | For <code>scatter.smooth()</code> , graphical parameters, passed to <code>plot()</code> only. For <code>loess.smooth</code> , control parameters passed to <a href="#">loess.control</a> .                                                    |
| <code>lpars</code>      | a <a href="#">list</a> of arguments to be passed to <a href="#">lines()</a> .                                                                                                                                                                 |

## Details

`loess.smooth` is an auxiliary function which evaluates the `loess` smooth at `evaluation` equally spaced points covering the range of `x`.

## Value

For `scatter.smooth`, none.

For `loess.smooth`, a list with two components, `x` (the grid of evaluation points) and `y` (the smoothed values at the grid points).

## See Also

[loess](#); [smoothScatter](#) for scatter plots with smoothed *density* color representation.

## Examples

```
require(graphics)

with(cars, scatter.smooth(speed, dist))
or with dotted thick smoothed line results :
with(cars, scatter.smooth(speed, dist, lpars =
 list(col = "red", lwd = 3, lty = 3)))
```

---

screepLOT

*ScreepLOTS*

---

## Description

`screepLOT.default` plots the variances against the number of the principal component. This is also the plot method for classes `"princomp"` and `"prcomp"`.

## Usage

```
Default S3 method:
screepLOT(x, npcs = min(10, length(x$sdev)),
 type = c("barplot", "lines"),
 main = deparse1(substitute(x)), ...)
```

## Arguments

|                        |                                                                                                                                  |
|------------------------|----------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>         | an object containing a <code>sdev</code> component, such as that returned by <code>princomp()</code> and <code>prcomp()</code> . |
| <code>npcs</code>      | the number of components to be plotted.                                                                                          |
| <code>type</code>      | the type of plot. Can be abbreviated.                                                                                            |
| <code>main, ...</code> | graphics parameters.                                                                                                             |

## See Also

[princomp](#) and [prcomp](#).

## Examples

```
require(graphics)

The variances of the variables in the
USArrests data vary by orders of magnitude, so scaling is appropriate
(pc.cr <- princomp(USArrests, cor = TRUE)) # inappropriate
screepLOT(pc.cr)

fit <- princomp(covmat = Harman74.cor)
screepLOT(fit)
screepLOT(fit, npcs = 24, type = "lines")
```

---

|    |                           |
|----|---------------------------|
| sd | <i>Standard Deviation</i> |
|----|---------------------------|

---

### Description

This function computes the standard deviation of the values in `x`. If `na.rm` is `TRUE` then missing values are removed before computation proceeds.

### Usage

```
sd(x, na.rm = FALSE)
```

### Arguments

|                    |                                                                                                                   |
|--------------------|-------------------------------------------------------------------------------------------------------------------|
| <code>x</code>     | a numeric vector or an R object but not a <code>factor</code> coercible to numeric by <code>as.double(x)</code> . |
| <code>na.rm</code> | logical. Should missing values be removed?                                                                        |

### Details

Like `var` this uses denominator  $n - 1$ .

The standard deviation of a length-one or zero-length vector is `NA`.

### See Also

`var` for its square, and `mad`, the most robust alternative.

### Examples

```
sd(1:2) ^ 2
```

---

|             |                                                     |
|-------------|-----------------------------------------------------|
| se.contrast | <i>Standard Errors for Contrasts in Model Terms</i> |
|-------------|-----------------------------------------------------|

---

### Description

Returns the standard errors for one or more contrasts in an `aov` object.

### Usage

```
se.contrast(object, ...)
S3 method for class 'aov'
se.contrast(object, contrast.obj,
 coef = contr.helmert(ncol(contrast))[, 1],
 data = NULL, ...)
```

## Arguments

|                           |                                                                                                                                                                                                                                                                                                                                        |
|---------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code>       | A suitable fit, usually from <code>aov</code> .                                                                                                                                                                                                                                                                                        |
| <code>contrast.obj</code> | The contrasts for which standard errors are requested. This can be specified via a list or via a matrix. A single contrast can be specified by a list of logical vectors giving the cells to be contrasted. Multiple contrasts should be specified by a matrix, each column of which is a numerical contrast vector (summing to zero). |
| <code>coef</code>         | used when <code>contrast.obj</code> is a list; it should be a vector of the same length as the list with zero sum. The default value is the first Helmert contrast, which contrasts the first and second cell means specified by the list.                                                                                             |
| <code>data</code>         | The data frame used to evaluate <code>contrast.obj</code> .                                                                                                                                                                                                                                                                            |
| <code>...</code>          | further arguments passed to or from other methods.                                                                                                                                                                                                                                                                                     |

## Details

Contrasts are usually used to test if certain means are significantly different; it can be easier to use `se.contrast` than compute them directly from the coefficients.

In multistratum models, the contrasts can appear in more than one stratum, in which case the standard errors are computed in the lowest stratum and adjusted for efficiencies and comparisons between strata. (See the comments in the note in the help for `aov` about using orthogonal contrasts.) Such standard errors are often conservative.

Suitable matrices for use with `coef` can be found by calling `contrasts` and indexing the columns by a factor.

## Value

A vector giving the standard errors for each contrast.

```

## Description

Construct self-starting nonlinear models to be used in `nls`, etc. Via function `initial` to compute approximate parameter values from data, such models are “self-starting”, i.e., do not need a `start` argument in, e.g., `nls()`.

## Usage

```
selfStart(model, initial, parameters, template)
```

## Arguments

|                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>model</code>      | a function object defining a nonlinear model or a nonlinear <code>formula</code> object of the form <code>~ expression</code> .                                                                                                                                                                                                                                                                                                                             |
| <code>initial</code>    | a function object, taking three arguments: <code>mCall</code> , <code>data</code> , and <code>LHS</code> , representing, respectively, a matched call to the function <code>model</code> , a data frame in which to interpret the variables in <code>mCall</code> , and the expression from the left-hand side of the model formula in the call to <code>nls</code> . This function should return initial values for the parameters in <code>model</code> . |
| <code>parameters</code> | a character vector specifying the terms on the right hand side of <code>model</code> for which initial estimates should be calculated. Passed as the <code>namevec</code> argument to the <code>deriv</code> function.                                                                                                                                                                                                                                      |
| <code>template</code>   | an optional prototype for the calling sequence of the returned object, passed as the <code>function.arg</code> argument to the <code>deriv</code> function. By default, a template is generated with the covariates in <code>model</code> coming first and the parameters in <code>model</code> coming last in the calling sequence.                                                                                                                        |

## Details

`nls()` calls `getInitial` and the `initial` function for these self-starting models.

This function is generic; methods functions can be written to handle specific classes of objects.

## Value

a `function` object of class `"selfStart"`, for the `formula` method obtained by applying `deriv` to the right hand side of the model formula. An `initial` attribute (defined by the `initial` argument) is added to the function to calculate starting estimates for the parameters in the model automatically.

## Author(s)

José Pinheiro and Douglas Bates

## See Also

`nls`, `getInitial`.

Each of the following are `"selfStart"` models (with examples) `SSasymp`, `SSasympOff`, `SSasympOrig`, `SSbiexp`, `SSfol`, `SSfpl`, `SSgompertz`, `SSlogis`, `SSmicmen`, `SSweibull`.

Further, package `nlme`'s `nlsList`.

## Examples

```
self-starting logistic model

The "initializer" (finds initial values for parameters from data):
initLogis <- function(mCall, data, LHS) {
 xy <- data.frame(sortedXyData(mCall[["input"]], LHS, data))
 if(nrow(xy) < 4)
 stop("too few distinct input values to fit a logistic model")
 z <- xy[["y"]]
 ## transform to proportion, i.e. in (0,1) :
 rng <- range(z); dz <- diff(rng)
 z <- (z - rng[1L] + 0.05 * dz)/(1.1 * dz)
 xy[["z"]] <- log(z/(1 - z)) # logit transformation
 aux <- coef(lm(x ~ z, xy))
 pars <- coef(nls(y ~ 1/(1 + exp((xmid - x)/scal)),
 data = xy,
 start = list(xmid = aux[[1L]], scal = aux[[2L]]),
 algorithm = "plinear"))
 setNames(pars[c(".lin", "xmid", "scal")], nm = mCall[c("Asym", "xmid", "scal")])
}

SSlogis <- selfStart(~ Asym/(1 + exp((xmid - x)/scal)),
 initial = initLogis,
 parameters = c("Asym", "xmid", "scal"))

'first.order.log.model' is a function object defining a first order
compartment model
'first.order.log.initial' is a function object which calculates initial
values for the parameters in 'first.order.log.model'
#
self-starting first order compartment model
Not run:
SSfol <- selfStart(first.order.log.model, first.order.log.initial)

End(Not run)

Explore the self-starting models already available in R's "stats":
pos.st <- which("package:stats" == search())
mSS <- apropos("^SS..", where = TRUE, ignore.case = FALSE)
(mSS <- unname(mSS[names(mSS) == pos.st]))
fSS <- sapply(mSS, get, pos = pos.st, mode = "function")
all(sapply(fSS, inherits, "selfStart")) # -> TRUE

Show the argument list of each self-starting function:
str(fSS, give.attr = FALSE)
```

---

setNames

---

*Set the Names in an Object*

---

## Description

This is a convenience function that sets the names on an object and returns the object. It is most useful at the end of a function definition where one is creating the object to be returned and would prefer not to store it under a name just so the names can be assigned.

**Usage**

```
setNames(object = nm, nm)
```

**Arguments**

|        |                                                                       |
|--------|-----------------------------------------------------------------------|
| object | an object for which a <code>names</code> attribute will be meaningful |
| nm     | a character vector of names to assign to the object                   |

**Value**

An object of the same sort as `object` with the new names assigned.

**Author(s)**

Douglas M. Bates and Saikat DebRoy

**See Also**

[unname](#) for removing names.

**Examples**

```
setNames(1:3, c("foo", "bar", "baz"))
this is just a short form of
tmp <- 1:3
names(tmp) <- c("foo", "bar", "baz")
tmp

special case of character vector, using default
setNames(nm = c("First", "2nd"))
```

---

`shapiro.test`*Shapiro-Wilk Normality Test*

---

**Description**

Performs the Shapiro-Wilk test of normality.

**Usage**

```
shapiro.test(x)
```

**Arguments**

|   |                                                                                                                               |
|---|-------------------------------------------------------------------------------------------------------------------------------|
| x | a numeric vector of data values. Missing values are allowed, but the number of non-missing values must be between 3 and 5000. |
|---|-------------------------------------------------------------------------------------------------------------------------------|

**Value**

A list with class "htest" containing the following components:

|           |                                                                                                          |
|-----------|----------------------------------------------------------------------------------------------------------|
| statistic | the value of the Shapiro-Wilk statistic.                                                                 |
| p.value   | an approximate p-value for the test. This is said in Royston (1995) to be adequate for $p.value < 0.1$ . |
| method    | the character string "Shapiro-Wilk normality test".                                                      |
| data.name | a character string giving the name(s) of the data.                                                       |

**Source**

The algorithm used is a C translation of the Fortran code described in Royston (1995). The calculation of the p value is exact for  $n = 3$ , otherwise approximations are used, separately for  $4 \leq n \leq 11$  and  $n \geq 12$ .

```

---

sigma

---

*Extract Residual Standard Deviation 'Sigma'*

---

**Description**

Extract the estimated standard deviation of the errors, the “residual standard deviation” (misnamed also “residual standard error”, e.g., in [summary.lm\(\)](#)’s output, from a fitted model).

Many classical statistical models have a *scale parameter*, typically the standard deviation of a zero-mean normal (or Gaussian) random variable which is denoted as  $\sigma$ . `sigma(.)` extracts the *estimated* parameter from a fitted model, i.e.,  $\hat{\sigma}$ .

**Usage**

```
sigma(object, ...)
```

## Default S3 method:

```
sigma(object, use.fallback = TRUE, ...)
```

## Arguments

`object` an R object, typically resulting from a model fitting function such as `lm`.  
`use.fallback` logical, passed to `nobs`.  
`...` potentially further arguments passed to and from methods. Passed to `deviance`(`*`, `...`) for the default method.

## Details

The **stats** package provides the S3 generic and a default method. The latter is correct typically for (asymptotically / approximately) generalized gaussian (“least squares”) problems, since it is defined as

```
sigma.default <- function (object, use.fallback = TRUE, ...)
 sqrt(deviance(object, ...) / (NN - PP))
```

where `NN <- nobs(object, use.fallback = use.fallback)` and `PP <- sum(!is.na(coef(object)))` — where in older R versions this was `length(coef(object))` which is too large in case of undetermined coefficients, e.g., for rank deficient model fits.

## Value

typically a number, the estimated standard deviation of the errors (“residual standard deviation”) for Gaussian models, and—less interpretably—the square root of the residual deviance per degree of freedom in more general models. In some generalized linear modelling (`glm`) contexts,  $\sigma^2$  (`sigma(.)^2`) is called “dispersion (parameter)”. Consequently, for well-fitting binomial or Poisson GLMs, `sigma` is around 1.

Very strictly speaking,  $\hat{\sigma}$  (“ $\sigma$  hat”) is actually  $\sqrt{\hat{\sigma}^2}$ .

For multivariate linear models (class “`mlm`”), a *vector* of sigmas is returned, each corresponding to one column of  $Y$ .

## Note

The misnomer “Residual standard **error**” has been part of too many R (and S) outputs to be easily changed there.

## See Also

`deviance`, `nobs`, `vcov`.

## Examples

```
-- lm() -----
lm1 <- lm(Fertility ~ ., data = swiss)
sigma(lm1) # ~= 7.165 = "Residual standard error" printed from summary(lm1)
stopifnot(all.equal(sigma(lm1), summary(lm1)$sigma, tol=1e-15))

-- nls() -----
DNase1 <- subset(DNase, Run == 1)
fm.DN1 <- nls(density ~ SSlogis(log(conc), Asym, xmid, scal), DNase1)
sigma(fm.DN1) # ~= 0.01919 as from summary(..)
```

```
stopifnot(all.equal(sigma(fm.DN1), summary(fm.DN1)$sigma, tol=1e-15))

-- glm() -----
-- a) Binomial -- Example from MASS

utils::example("SSD", echo=FALSE)
sigma(mlmfit) # is the same as {but more efficient than}
sqrt(diag(estVar(mlmfit)))
```

SignRank

*Distribution of the Wilcoxon Signed Rank Statistic***Description**

Density, distribution function, quantile function and random generation for the distribution of the Wilcoxon Signed Rank statistic obtained from a sample with size  $n$ .

**Usage**

```
dsignrank(x, n, log = FALSE)
psignrank(q, n, lower.tail = TRUE, log.p = FALSE)
qsignrank(p, n, lower.tail = TRUE, log.p = FALSE)
rsignrank(nn, n)
```

**Arguments**

|        |                                                                                                     |
|--------|-----------------------------------------------------------------------------------------------------|
| $x, q$ | vector of quantiles.                                                                                |
| $p$    | vector of probabilities.                                                                            |
| $nn$   | number of observations. If $\text{length}(nn) > 1$ , the length is taken to be the number required. |
| $n$    | number(s) of observations in the sample(s). A positive integer, or a vector of such integers.       |

`log, log.p` logical; if TRUE, probabilities `p` are given as  $\log(p)$ .  
`lower.tail` logical; if TRUE (default), probabilities are  $P[X \leq x]$ , otherwise,  $P[X > x]$ .

### Details

This distribution is obtained as follows. Let  $x$  be a sample of size  $n$  from a continuous distribution symmetric about the origin. Then the Wilcoxon signed rank statistic is the sum of the ranks of the absolute values  $x[i]$  for which  $x[i]$  is positive. This statistic takes values between 0 and  $n(n+1)/2$ , and its mean and variance are  $n(n+1)/4$  and  $n(n+1)(2n+1)/24$ , respectively.

If either of the first two arguments is a vector, the recycling rule is used to do the calculations for all combinations of the two up to the length of the longer vector.

### Value

`dsignrank` gives the density, `psignrank` gives the distribution function, `qsignrank` gives the quantile function, and `rsignrank` generates random deviates.

The length of the result is determined by `nn` for `rsignrank`, and is the maximum of the lengths of the numerical arguments for the other functions.

The numerical arguments other than `nn` are recycled to the length of the result. Only the first elements of the logical arguments are used.

### Author(s)

Kurt Hornik; efficiency improvement by Ivo Ugrina.

### See Also

### Examples

```
require(graphics)

par(mfrow = c(2,2))
for(n in c(4:5,10,40)) {
 x <- seq(0, n*(n+1)/2, length = 501)
 plot(x, dsignrank(x, n = n), type = "l",
 main = paste0("dsignrank(x, n = ", n, ")"))
}
```

### Description

Simulate one or more responses from the distribution corresponding to a fitted model object.

## Usage

```
simulate(object, nsim = 1, seed = NULL, ...)
```

## Arguments

|                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code> | an object representing a fitted model.                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>nsim</code>   | number of response vectors to simulate. Defaults to 1.                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>seed</code>   | an object specifying if and how the random number generator should be initialized ('seeded').<br>For the "lm" method, either <code>NULL</code> or an integer that will be used in a call to <code>set.seed</code> before simulating the response vectors. If set, the value is saved as the "seed" attribute of the returned value. The default, <code>NULL</code> will not change the random generator state, and return <code>.Random.seed</code> as the "seed" attribute, see 'Value'. |
| <code>...</code>    | additional optional arguments.                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

## Details

This is a generic function. Consult the individual modeling functions for details on how to use this function.

Package **stats** has a method for "lm" objects which is used for `lm` and `glm` fits. There is a method for fits from `glm.nb` in package **MASS**, and hence the case of negative binomial families is not covered by the "lm" method.

The methods for linear models fitted by `lm` or `glm(family = "gaussian")` assume that any weights which have been supplied are inversely proportional to the error variance. For other GLMs the (optional) `simulate` component of the `family` object is used—there is no appropriate simulation method for 'quasi' models as they are specified only up to two moments.

For binomial and Poisson GLMs the dispersion is fixed at one. Integer prior weights  $w_i$  can be interpreted as meaning that observation  $i$  is an average of  $w_i$  observations, which is natural for binomials specified as proportions but less so for a Poisson, for which prior weights are ignored with a warning.

For a gamma GLM the shape parameter is estimated by maximum likelihood (using function `gamma.shape` in package **MASS**). The interpretation of weights is as multipliers to a basic shape parameter, since dispersion is inversely proportional to shape.

For an inverse gaussian GLM the model assumed is  $IG(\mu_i, \lambda w_i)$  (see [https://en.wikipedia.org/wiki/Inverse\\_Gaussian\\_distribution](https://en.wikipedia.org/wiki/Inverse_Gaussian_distribution)) where  $\lambda$  is estimated by the inverse of the dispersion estimate for the fit. The variance is  $\mu_i^3/(\lambda w_i)$  and hence inversely proportional to the prior weights. The simulation is done by function `rinvGauss` from the **SuppDists** package, which must be installed.

## Value

Typically, a list of length `nsim` of simulated responses. Where appropriate the result can be a data frame (which is a special type of list).

For the "lm" method, the result is a data frame with an attribute "seed". If argument `seed` is `NULL`, the attribute is the value of `.Random.seed` before the simulation was started; otherwise it is the value of the argument with a "kind" attribute with value `as.list(RNGkind())`.

## See Also

[RNG](#) about random number generation in R, [fitted.values](#) and [residuals](#) for related methods; [glm](#), [lm](#) for model fitting.

There are further examples in the ‘simulate.R’ tests file in the sources for package **stats**.

## Examples

```
x <- 1:5
mod1 <- lm(c(1:3, 7, 6) ~ x)
S1 <- simulate(mod1, nsim = 4)
repeat the simulation:
.Random.seed <- attr(S1, "seed")
identical(S1, simulate(mod1, nsim = 4))

S2 <- simulate(mod1, nsim = 200, seed = 101)
rowMeans(S2) # should be about the same as
fitted(mod1)

repeat identically:
(sseed <- attr(S2, "seed")) # seed; RNGkind as attribute
stopifnot(identical(S2, simulate(mod1, nsim = 200, seed = sseed)))

To be sure about the proper RNGkind, e.g., after
RNGversion("2.7.0")
first set the RNG kind, then simulate
do.call(RNGkind, attr(sseed, "kind"))
identical(S2, simulate(mod1, nsim = 200, seed = sseed))

Binomial GLM examples
yb1 <- matrix(c(4, 4, 5, 7, 8, 6, 6, 5, 3, 2), ncol = 2)
modb1 <- glm(yb1 ~ x, family = binomial)
S3 <- simulate(modb1, nsim = 4)
each column of S3 is a two-column matrix.

x2 <- sort(runif(100))
yb2 <- rbinom(100, prob = plogis(2*(x2-1)), size = 1)
yb2 <- factor(1 + yb2, labels = c("failure", "success"))
modb2 <- glm(yb2 ~ x2, family = binomial)
S4 <- simulate(modb2, nsim = 4)
each column of S4 is a factor
```

smooth

*Tukey's (Running Median) Smoothing*

---

## Description

Tukey's smoothers, *3RS3R*, *3RSS*, *3R*, etc.

## Usage

```
smooth(x, kind = c("3RS3R", "3RSS", "3RSR", "3R", "3", "S"),
 twiceit = FALSE, endrule = c("Tukey", "copy"), do.ends = FALSE)
```

## Arguments

|                      |                                                                                                                                                                                                                 |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>       | a vector or time series                                                                                                                                                                                         |
| <code>kind</code>    | a character string indicating the kind of smoother required; defaults to "3RS3R".                                                                                                                               |
| <code>twiceit</code> | logical, indicating if the result should be 'twiced'. Twicing a smoother $S(y)$ means $S(y) + S(y - S(y))$ , i.e., adding smoothed residuals to the smoothed values. This decreases bias (increasing variance). |
| <code>endrule</code> | a character string indicating the rule for smoothing at the boundary. Either "Tukey" (default) or "copy".                                                                                                       |
| <code>do.ends</code> | logical, indicating if the 3-splitting of ties should also happen at the boundaries (ends). This is only used for <code>kind = "S"</code> .                                                                     |

## Details

3 is Tukey's short notation for running [medians](#) of length 3, 3R stands for **R**epeated 3 until convergence, and S for **S**plitting of horizontal stretches of length 2 or 3.

Hence, 3RS3R is a concatenation of 3R, S and 3R, 3RSS similarly, whereas 3RSR means first 3R and then (S and 3) **R**epeated until convergence – which can be bad.

## Value

An object of class "tukeysmooth" (which has `print` and `summary` methods) and is a vector or time series containing the smoothed values with additional attributes.

## Note

S and S-PLUS use a different (somewhat better) Tukey smoother in `smooth(*)`. Note that there are other smoothing methods which provide rather better results. These were designed for hand calculations and may be used mainly for didactical purposes.

Since R version 1.2, `smooth` *does* really implement Tukey's end-point rule correctly (see argument `endrule`).

`kind = "3RSR"` has been the default till R-1.1, but it can have very bad properties, see the examples.

Note that repeated application of `smooth(*)` *does* smooth more, for the "3RS\*" kinds.

smooth.spline

*Fit a Smoothing Spline***Description**

Fits a cubic smoothing spline to the supplied data.

**Usage**

```

smooth.spline(x, y = NULL, w = NULL, df, spar = NULL, lambda = NULL, cv = FALSE,
 all.knots = FALSE, nknots = .nknots.smspl,
 keep.data = TRUE, df.offset = 0, penalty = 1,
 control.spar = list(), tol = 1e-6 * IQR(x), keep.stuff = FALSE)

```

**Arguments**

|                 |                                                                                                                                                                          |
|-----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>  | a vector giving the values of the predictor variable, or a list or a two-column matrix specifying <code>x</code> and <code>y</code> .                                    |
| <code>y</code>  | responses. If <code>y</code> is missing or <code>NULL</code> , the responses are assumed to be specified by <code>x</code> , with <code>x</code> the index vector.       |
| <code>w</code>  | optional vector of weights of the same length as <code>x</code> ; defaults to all 1.                                                                                     |
| <code>df</code> | the desired equivalent number of degrees of freedom (trace of the smoother matrix). Must be in $(1, n_x]$ , $n_x$ the number of unique <code>x</code> values, see below. |

|                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|---------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>spar</code>         | smoothing parameter, typically (but not necessarily) in $(0, 1]$ . When <code>spar</code> is specified, the coefficient $\lambda$ of the integral of the squared second derivative in the fit (penalized log likelihood) criterion is a monotone function of <code>spar</code> , see the details below. Alternatively <code>lambda</code> may be specified instead of the <i>scale free</i> <code>spar=s</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>lambda</code>       | if desired, the internal (design-dependent) smoothing parameter $\lambda$ can be specified instead of <code>spar</code> . This may be desirable for resampling algorithms such as cross validation or the bootstrap.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <code>cv</code>           | ordinary leave-one-out (TRUE) or ‘generalized’ cross-validation (GCV) when FALSE; is used for smoothing parameter computation only when both <code>spar</code> and <code>df</code> are not specified; it is used however to determine <code>cv.crit</code> in the result. Setting it to NA for speedup skips the evaluation of leverages and any score.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <code>all.knots</code>    | if TRUE, all distinct points in <code>x</code> are used as knots. If FALSE (default), a subset of <code>x[]</code> is used, specifically <code>x[j]</code> where the <code>nknots</code> indices are evenly spaced in $1:n$ , see also the next argument <code>nknots</code> .<br><br>Alternatively, a strictly increasing <code>numeric</code> vector specifying “all the knots” to be used; must be rescaled to $[0, 1]$ already such that it corresponds to the <code>ans\$fit\$knots</code> sequence returned, not repeating the boundary knots.                                                                                                                                                                                                                                                                                                                                                                                                 |
| <code>nknots</code>       | integer or <code>function</code> giving the number of knots to use when <code>all.knots = FALSE</code> . If a function (as by default), the number of knots is <code>nknots(nx)</code> . By default for $n_x > 49$ this is less than $n_x$ , the number of unique <code>x</code> values, see the Note.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>keep.data</code>    | logical specifying if the input data should be kept in the result. If TRUE (as per default), fitted values and residuals are available from the result.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <code>df.offset</code>    | allows the degrees of freedom to be increased by <code>df.offset</code> in the GCV criterion.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <code>penalty</code>      | the coefficient of the penalty for degrees of freedom in the GCV criterion.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <code>control.spar</code> | optional list with named components controlling the root finding when the smoothing parameter <code>spar</code> is computed, i.e., missing or NULL, see below.<br><br><b>Note</b> that this is partly <i>experimental</i> and may change with general <code>spar</code> computation improvements!<br><br><b>low:</b> lower bound for <code>spar</code> ; defaults to -1.5 (used to implicitly default to 0 in R versions earlier than 1.4).<br><b>high:</b> upper bound for <code>spar</code> ; defaults to +1.5.<br><b>tol:</b> the absolute precision ( <b>tolerance</b> ) used; defaults to 1e-4 (formerly 1e-3).<br><b>eps:</b> the relative precision used; defaults to 2e-8 (formerly 0.00244).<br><b>trace:</b> logical indicating if iterations should be traced.<br><b>maxit:</b> integer giving the maximal number of iterations; defaults to 500.<br><br>Note that <code>spar</code> is only searched for in the interval $[low, high]$ . |
| <code>tol</code>          | a tolerance for same-ness or uniqueness of the <code>x</code> values. The values are binned into bins of size <code>tol</code> and values which fall into the same bin are regarded as the same. Must be strictly positive (and finite).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>keep.stuff</code>   | an experimental <code>logical</code> indicating if the result should keep extras from the internal computations. Should allow to reconstruct the $X$ matrix and more.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

## Details

Neither `x` nor `y` are allowed to containing missing or infinite values.

The `x` vector should contain at least four distinct values. ‘Distinct’ here is controlled by `tol`: values which are regarded as the same are replaced by the first of their values and the corresponding `y` and `w` are pooled accordingly.

Unless `lambda` has been specified instead of `spar`, the computational  $\lambda$  used (as a function of  $s = \text{spar}$ ) is  $\lambda = r * 256^{3s-1}$  where  $r = \text{tr}(X'WX)/\text{tr}(\Sigma)$ ,  $\Sigma$  is the matrix given by  $\Sigma_{ij} = \int B_i''(t)B_j''(t)dt$ ,  $X$  is given by  $X_{ij} = B_j(x_i)$ ,  $W$  is the diagonal matrix of weights (scaled such that its trace is  $n$ , the original number of observations) and  $B_k(\cdot)$  is the  $k$ -th B-spline.

Note that with these definitions,  $f_i = f(x_i)$ , and the B-spline basis representation  $f = Xc$  (i.e.,  $c$  is the vector of spline coefficients), the penalized log likelihood is  $L = (y - f)'W(y - f) + \lambda c' \Sigma c$ , and hence  $c$  is the solution of the (ridge regression)  $(X'WX + \lambda \Sigma)c = X'Wy$ .

If `spar` and `lambda` are missing or `NULL`, the value of `df` is used to determine the degree of smoothing. If `df` is missing as well, leave-one-out cross-validation (ordinary or ‘generalized’ as determined by `cv`) is used to determine  $\lambda$ .

Note that from the above relation,

`spar` is  $s = s_0 + 0.0601 * \log \lambda$ , which is intentionally *different* from the S-PLUS implementation of `smooth.spline` (where `spar` is proportional to  $\lambda$ ). In R’s  $(\log \lambda)$  scale, it makes more sense to vary `spar` linearly.

Note however that currently the results may become very unreliable for `spar` values smaller than about -1 or -2. The same may happen for values larger than 2 or so. Don’t think of setting `spar` or the controls `low` and `high` outside such a safe range, unless you know what you are doing! Similarly, specifying `lambda` instead of `spar` is delicate, notably as the range of “safe” values for `lambda` is not scale-invariant and hence entirely data dependent.

The ‘generalized’ cross-validation method GCV will work correctly when there are duplicated points in `x`. However, it is ambiguous what leave-one-out cross-validation means with duplicated points, and the internal code uses an approximation that involves leaving out groups of duplicated points. `cv = TRUE` is best avoided in that case.

## Value

An object of class "`smooth.spline`" with components

|                       |                                                                                                                                                                                                                                                                                                                                                               |
|-----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>        | the <i>distinct</i> <code>x</code> values in increasing order, see the ‘Details’ above.                                                                                                                                                                                                                                                                       |
| <code>y</code>        | the fitted values corresponding to <code>x</code> .                                                                                                                                                                                                                                                                                                           |
| <code>w</code>        | the weights used at the unique values of <code>x</code> .                                                                                                                                                                                                                                                                                                     |
| <code>yin</code>      | the <code>y</code> values used at the unique <code>y</code> values.                                                                                                                                                                                                                                                                                           |
| <code>tol</code>      | the <code>tol</code> argument (whose default depends on <code>x</code> ).                                                                                                                                                                                                                                                                                     |
| <code>data</code>     | only if <code>keep.data = TRUE</code> : itself a <code>list</code> with components <code>x</code> , <code>y</code> and <code>w</code> of the same length. These are the original $(x_i, y_i, w_i)$ , $i = 1, \dots, n$ , values where <code>data\$x</code> may have repeated values and hence be longer than the above <code>x</code> component; see details. |
| <code>lev</code>      | (when <code>cv</code> was not <code>NA</code> ) leverages, the diagonal values of the smoother matrix.                                                                                                                                                                                                                                                        |
| <code>cv.crit</code>  | cross-validation score, ‘generalized’ or <code>true</code> , depending on <code>cv</code> . The CV score is often called “PRESS” (and labeled on <code>print()</code> ), for ‘PREdiction Sum of Squares’.                                                                                                                                                     |
| <code>pen.crit</code> | the penalized criterion, a non-negative number; simply the (weighted) residual sum of squares (RSS), <code>sum(. \$w * residuals(.)^2)</code> .                                                                                                                                                                                                               |

|                     |                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>crit</code>   | the criterion value minimized in the underlying <code>.Fortran</code> routine <code>'sslvrg'</code> . When <code>df</code> has been specified, the criterion is $3 + (tr(S_\lambda) - df)^2$ , where the 3+ is there for numerical (and historical) reasons.                                                                                                                                                                     |
| <code>df</code>     | equivalent degrees of freedom used. Note that (currently) this value may become quite imprecise when the true <code>df</code> is between and 1 and 2.                                                                                                                                                                                                                                                                            |
| <code>spar</code>   | the value of <code>spar</code> computed or given, unless it has been given as <code>c(lambda = *)</code> , when it set to NA here.                                                                                                                                                                                                                                                                                               |
| <code>ratio</code>  | (when <code>spar</code> above is not NA), the value $r$ , the ratio of two matrix traces.                                                                                                                                                                                                                                                                                                                                        |
| <code>lambda</code> | the value of $\lambda$ corresponding to <code>spar</code> , see the details above.                                                                                                                                                                                                                                                                                                                                               |
| <code>iparms</code> | named integer(3) vector where <code>..\$ipars["iter"]</code> gives number of <code>spar</code> computing iterations used.                                                                                                                                                                                                                                                                                                        |
| <code>auxMat</code> | experimental; when <code>keep.stuff</code> was true, a “flat” numeric vector containing parts of the internal computations.                                                                                                                                                                                                                                                                                                      |
| <code>fit</code>    | list for use by <code>predict.smooth.spline</code> , with components<br><b>knot:</b> the knot sequence (including the repeated boundary knots), scaled into $[0, 1]$ (via <code>min</code> and <code>range</code> ).<br><b>nk:</b> number of coefficients or number of ‘proper’ knots plus 2.<br><b>coef:</b> coefficients for the spline basis used.<br><b>min, range:</b> numbers giving the corresponding quantities of $x$ . |
| <code>call</code>   | the matched call.                                                                                                                                                                                                                                                                                                                                                                                                                |

`method(class = "smooth.spline")` shows a `hatvalues()` method based on the `lev` vector above.

### Note

The number of unique  $x$  values,  $n_x = n_x$ , are determined by the `tol` argument, equivalently to

```
n_x <- length(x) - sum(duplicated(round((x - mean(x)) / tol)))
```

The default `all.knots = FALSE` and `nknots = .nknots.smspl`, entails using only  $O(n_x^{0.2})$  knots instead of  $n_x$  for  $n_x > 49$ . This cuts speed and memory requirements, but not drastically anymore since R version 1.5.1 where it is only  $O(n_k) + O(n)$  where  $n_k$  is the number of knots.

In this case where not all unique  $x$  values are used as knots, the result is not a smoothing spline in the strict sense, but very close unless a small smoothing parameter (or large `df`) is used.

### Author(s)

R implementation by B. D. Ripley and Martin Maechler (`spar/lambda`, etc).

### Source

This function is based on code in the `GAMFIT` Fortran program by T. Hastie and R. Tibshirani (originally taken from <http://lib.stat.cmu.edu/general/gamfit>) which makes use of spline code by Finbarr O’Sullivan. Its design parallels the `smooth.spline` function of Chambers & Hastie (1992).

[predict.smooth.spline](#) for evaluating the spline and its derivatives.

## Examples

```
require(graphics)
plot(dist ~ speed, data = cars, main = "data(cars) & smoothing splines")
cars.spl <- with(cars, smooth.spline(speed, dist))
cars.spl
This example has duplicate points, so avoid cv = TRUE

lines(cars.spl, col = "blue")
ss10 <- smooth.spline(cars[, "speed"], cars[, "dist"], df = 10)
lines(ss10, lty = 2, col = "red")
legend(5, 120, c(paste("default [C.V.] => df =", round(cars.spl$df, 1)),
 "s(* , df = 10)"), col = c("blue", "red"), lty = 1:2,
 bg = 'bisque')

Residual (Tukey Anscombe) plot:
plot(residuals(cars.spl) ~ fitted(cars.spl))
abline(h = 0, col = "gray")

consistency check:
stopifnot(all.equal(cars$dist,
 fitted(cars.spl) + residuals(cars.spl)))

The chosen inner knots in original x-scale :
with(cars.spl$fit, min + range * knot[-c(1:3, nk+1 + 1:3)]) # == unique(cars$speed)

Visualize the behavior of .nknots.smspl()
nKnots <- Vectorize(.nknots.smspl) ; c.. <- adjustcolor("gray20", .5)
curve(nKnots, 1, 250, n=250)
abline(0, 1, lty=2, col=c..); text(90, 90, "y = x", col=c.., adj=-.25)
abline(h=100, lty=2); abline(v=200, lty=2)

n <- c(1:799, seq(800, 3490, by=10), seq(3500, 10000, by = 50))
plot(n, nKnots(n), type="l", main = "Vectorize(.nknots.smspl) (n)")
abline(0, 1, lty=2, col=c..); text(180, 180, "y = x", col=c..)
n0 <- c(50, 200, 800, 3200); c0 <- adjustcolor("blue3", .5)
lines(n0, nKnots(n0), type="h", col=c0)
axis(1, at=n0, line=-2, col.ticks=c0, col=NA, col.axis=c0)
axis(4, at=.nknots.smspl(10000), line=-.5, col=c.., col.axis=c.., las=1)

##-- artificial example
y18 <- c(1:3, 5, 4, 7:3, 2*(2:5), rep(10, 4))
xx <- seq(1, length(y18), len = 201)
(s2 <- smooth.spline(y18)) # GCV
(s02 <- smooth.spline(y18, spar = 0.2))
```

```
(s02. <- smooth.spline(y18, spar = 0.2, cv = NA))
plot(y18, main = deparse(s2$call), col.main = 2)
lines(s2, col = "gray"); lines(predict(s2, xx), col = 2)
lines(predict(s02, xx), col = 3); mtext(deparse(s02$call), col = 3)

Specifying 'lambda' instead of usual spar :
(s2. <- smooth.spline(y18, lambda = s2$lambda, tol = s2$tol))

The following shows the problematic behavior of 'spar' searching:
(s2 <- smooth.spline(y18, control =
 list(trace = TRUE, tol = 1e-6, low = -1.5)))
(s2m <- smooth.spline(y18, cv = TRUE, control =
 list(trace = TRUE, tol = 1e-6, low = -1.5)))
both above do quite similarly (Df = 8.5 +- 0.2)
```

smoothEnds

*End Points Smoothing (for Running Medians)***Description**

Smooth end points of a vector *y* using subsequently smaller medians and Tukey's end point rule at the very end. (of odd span),

**Usage**

```
smoothEnds(y, k = 3)
```

**Arguments**

|          |                                              |
|----------|----------------------------------------------|
| <i>y</i> | dependent variable to be smoothed (vector).  |
| <i>k</i> | width of largest median window; must be odd. |

**Details**

`smoothEnds` is used to only do the 'end point smoothing', i.e., change at most the observations closer to the beginning/end than half the window *k*. The first and last value are computed using *Tukey's end point rule*, i.e., `sm[1] = median(y[1], sm[2], 3*sm[2] - 2*sm[3], na.rm=TRUE)`.

In R versions 3.6.0 and earlier, missing values ([NA](#)) in *y* typically lead to an error, whereas now the equivalent of `median(*, na.rm=TRUE)` is used.

**Value**

vector of smoothed values, the same length as *y*.

**Author(s)**

Martin Maechler

`runmed(*, endrule = "median")` which calls `smoothEnds()`.

## Examples

```
require(graphics)

y <- ys <- (-20:20)^2
y [c(1,10,21,41)] <- c(100, 30, 400, 470)
s7k <- runmed(y, 7, endrule = "keep")
s7. <- runmed(y, 7, endrule = "const")
s7m <- runmed(y, 7)
col3 <- c("midnightblue", "blue", "steelblue")
plot(y, main = "Running Medians -- runmed(*, k=7, endrule = X)")
lines(ys, col = "light gray")
matlines(cbind(s7k, s7., s7m), lwd = 1.5, lty = 1, col = col3)
eRules <- c("keep", "constant", "median")
legend("topleft", paste("endrule", eRules, sep = " = "),
 col = col3, lwd = 1.5, lty = 1, bty = "n")

stopifnot(identical(s7m, smoothEnds(s7k, 7)))

With missing values (for R >= 3.6.1):
yN <- y; yN[c(2,40)] <- NA
rN <- sapply(eRules, function(R) runmed(yN, 7, endrule=R))
matlines(rN, type = "b", pch = 4, lwd = 3, lty=2,
 col = adjustcolor(c("red", "orange4", "orange1"), 0.5))
yN[c(1, 20:21)] <- NA # additionally
rN. <- sapply(eRules, function(R) runmed(yN, 7, endrule=R))
head(rN., 4); tail(rN.) # more NA's too, still not *so* many:
stopifnot(exprs = {
 !anyNA(rN[,2:3])
 identical(which(is.na(rN[, "keep"])), c(2L, 40L))
 identical(which(is.na(rN.), arr.ind=TRUE, useNames=FALSE),
 cbind(c(1:2, 40L), 1L))
 identical(rN.[38:41, "median"], c(289, 289, 397, 470))
})
```

---

sortedXyData

*Create a sortedXyData Object*

---

## Description

This is a constructor function for the class of `sortedXyData` objects. These objects are mostly used in the `initial` function for a self-starting nonlinear regression model, which will be of the `selfStart` class.

**Usage**

```
sortedXyData(x, y, data)
```

**Arguments**

|                   |                                                                                                                                  |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>    | a numeric vector or an expression that will evaluate in <code>data</code> to a numeric vector                                    |
| <code>y</code>    | a numeric vector or an expression that will evaluate in <code>data</code> to a numeric vector                                    |
| <code>data</code> | an optional data frame in which to evaluate expressions for <code>x</code> and <code>y</code> , if they are given as expressions |

**Value**

A `sortedXyData` object. This is a data frame with exactly two numeric columns, named `x` and `y`. The rows are sorted so the `x` column is in increasing order. Duplicate `x` values are eliminated by averaging the corresponding `y` values.

**Author(s)**

José Pinheiro and Douglas Bates

**Examples**

```
DNase.2 <- DNase[DNase$Run == "2",]
sortedXyData(expression(log(conc)), expression(density), DNase.2)
```

---

spec.ar

*Estimate Spectral Density of a Time Series from AR Fit*

---

**Description**

Fits an AR model to `x` (or uses the existing fit) and computes (and by default plots) the spectral density of the fitted model.

**Usage**

```
spec.ar(x, n.freq, order = NULL, plot = TRUE, na.action = na.fail,
 method = "yule-walker", ...)
```

**Arguments**

|                        |                                                                                                   |
|------------------------|---------------------------------------------------------------------------------------------------|
| <code>x</code>         | A univariate (not yet:or multivariate) time series or the result of a fit by <a href="#">ar</a> . |
| <code>n.freq</code>    | The number of points at which to plot.                                                            |
| <code>order</code>     | The order of the AR model to be fitted. If omitted, the order is chosen by AIC.                   |
| <code>plot</code>      | Plot the periodogram?                                                                             |
| <code>na.action</code> | NA action function.                                                                               |
| <code>method</code>    | method for <a href="#">ar</a> fit.                                                                |
| <code>...</code>       | Graphical arguments passed to <a href="#">plot.spec</a> .                                         |

**Value**

An object of class "spec". The result is returned invisibly if `plot` is true.

**Warning**

Some authors, for example Thomson (1990), warn strongly that AR spectra can be misleading.

**Note**

The multivariate case is not yet implemented.

|------------|-----------------------------------------------------------------------------|
| spec.pgram | <i>Estimate Spectral Density of a Time Series by a Smoothed Periodogram</i> |
|------------|-----------------------------------------------------------------------------|

---

**Description**

`spec.pgram` calculates the periodogram using a fast Fourier transform, and optionally smooths the result with a series of modified Daniell smoothers (moving averages giving half weight to the end values).

**Usage**

```
spec.pgram(x, spans = NULL, kernel, taper = 0.1,
 pad = 0, fast = TRUE, demean = FALSE, detrend = TRUE,
 plot = TRUE, na.action = na.fail, ...)
```

**Arguments**

|                        |                                                                                                                                                        |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>         | univariate or multivariate time series.                                                                                                                |
| <code>spans</code>     | vector of odd integers giving the widths of modified Daniell smoothers to be used to smooth the periodogram.                                           |
| <code>kernel</code>    | alternatively, a kernel smoother of class <code>"tskernel"</code> .                                                                                    |
| <code>taper</code>     | specifies the proportion of data to taper. A split cosine bell taper is applied to this proportion of the data at the beginning and end of the series. |
| <code>pad</code>       | proportion of data to pad. Zeros are added to the end of the series to increase its length by the proportion <code>pad</code> .                        |
| <code>fast</code>      | logical; if <code>TRUE</code> , pad the series to a highly composite length.                                                                           |
| <code>demean</code>    | logical. If <code>TRUE</code> , subtract the mean of the series.                                                                                       |
| <code>detrend</code>   | logical. If <code>TRUE</code> , remove a linear trend from the series. This will also remove the mean.                                                 |
| <code>plot</code>      | plot the periodogram?                                                                                                                                  |
| <code>na.action</code> | NA action function.                                                                                                                                    |
| <code>...</code>       | graphical arguments passed to <code>plot.spec</code> .                                                                                                 |

**Details**

The raw periodogram is not a consistent estimator of the spectral density, but adjacent values are asymptotically independent. Hence a consistent estimator can be derived by smoothing the raw periodogram, assuming that the spectral density is smooth.

The series will be automatically padded with zeros until the series length is a highly composite number in order to help the Fast Fourier Transform. This is controlled by the `fast` and not the `pad` argument.

The periodogram at zero is in theory zero as the mean of the series is removed (but this may be affected by tapering); it is replaced by an interpolation of adjacent values during smoothing, and no value is returned for that frequency.

**Value**

A list object of class `"spec"` (see [spectrum](#)) with the following additional components:

|                        |                                                                                                                                                      |
|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>kernel</code>    | The kernel argument, or the kernel constructed from <code>spans</code> .                                                                             |
| <code>df</code>        | The distribution of the spectral density estimate can be approximated by a (scaled) chi square distribution with <code>df</code> degrees of freedom. |
| <code>bandwidth</code> | The equivalent bandwidth of the kernel smoother as defined by Bloomfield (1976, page 201).                                                           |
| <code>taper</code>     | The value of the <code>taper</code> argument.                                                                                                        |
| <code>pad</code>       | The value of the <code>pad</code> argument.                                                                                                          |
| <code>detrend</code>   | The value of the <code>detrend</code> argument.                                                                                                      |
| <code>demean</code>    | The value of the <code>demean</code> argument.                                                                                                       |

The result is returned invisibly if `plot` is true.

spec.taper

*Taper a Time Series by a Cosine Bell*

---

## Description

Apply a cosine-bell taper to a time series.

## Usage

```
spec.taper(x, p = 0.1)
```

**Arguments**

|                |                                                                                                                                                                                                           |
|----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code> | A univariate or multivariate time series                                                                                                                                                                  |
| <code>p</code> | The proportion to be tapered at each end of the series, either a scalar (giving the proportion for all series) or a vector of the length of the number of series (giving the proportion for each series). |

**Details**

The cosine-bell taper is applied to the first and last `p[i]` observations of time series `x[, i]`.

**Value**

A new time series object.

**See Also**

[spec.pgram](#), [cpgram](#)

---

spectrum

*Spectral Density Estimation*

---

**Description**

The `spectrum` function estimates the spectral density of a time series.

**Usage**

```
spectrum(x, ..., method = c("pgram", "ar"))
```

**Arguments**

|                     |                                                                                                                                             |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>      | A univariate or multivariate time series.                                                                                                   |
| <code>method</code> | String specifying the method used to estimate the spectral density. Allowed methods are "pgram" (the default) and "ar". Can be abbreviated. |
| <code>...</code>    | Further arguments to specific spec methods or <code>plot.spec</code> .                                                                      |

**Details**

`spectrum` is a wrapper function which calls the methods [spec.pgram](#) and [spec.ar](#).

The spectrum here is defined with scaling  $1/\text{frequency}(x)$ , following S-PLUS. This makes the spectral density a density over the range  $(-\text{frequency}(x)/2, +\text{frequency}(x)/2]$ , whereas a more common scaling is  $2\pi$  and range  $(-0.5, 0.5]$  (e.g., Bloomfield) or 1 and range  $(-\pi, \pi]$ .

If available, a confidence interval will be plotted by `plot.spec`: this is asymmetric, and the width of the centre mark indicates the equivalent bandwidth.

**Value**

An object of class "spec", which is a list containing at least the following components:

|        |                                                                                                                                                                                                                                                                 |
|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| freq   | vector of frequencies at which the spectral density is estimated. (Possibly approximate Fourier frequencies.) The units are the reciprocal of cycles per unit time (and not per observation spacing): see 'Details' below.                                      |
| spec   | Vector (for univariate series) or matrix (for multivariate series) of estimates of the spectral density at frequencies corresponding to freq.                                                                                                                   |
| coh    | NULL for univariate series. For multivariate time series, a matrix containing the <i>squared</i> coherency between different series. Column $i + (j - 1) * (j - 2) / 2$ of coh contains the squared coherency between columns $i$ and $j$ of x, where $i < j$ . |
| phase  | NULL for univariate series. For multivariate time series a matrix containing the cross-spectrum phase between different series. The format is the same as coh.                                                                                                  |
| series | The name of the time series.                                                                                                                                                                                                                                    |
| snames | For multivariate input, the names of the component series.                                                                                                                                                                                                      |
| method | The method used to calculate the spectrum.                                                                                                                                                                                                                      |

The result is returned invisibly if plot is true.

**Note**

The default plot for objects of class "spec" is quite complex, including an error bar and default title, subtitle and axis labels. The defaults can all be overridden by supplying the appropriate graphical parameters.

splinefun

*Interpolating Splines*

## Description

Perform cubic (or Hermite) spline interpolation of given data points, returning either a list of points obtained by the interpolation or a *function* performing the interpolation.

## Usage

```

splinefun(x, y = NULL,
 method = c("fmm", "periodic", "natural", "monoH.FC", "hyman"),
 ties = mean)

spline(x, y = NULL, n = 3*length(x), method = "fmm",
 xmin = min(x), xmax = max(x), xout, ties = mean)

splinefunH(x, y, m)

```

## Arguments

|                         |                                                                                                                                                                                                                                                                                               |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x, y</code>       | vectors giving the coordinates of the points to be interpolated. Alternatively a single plotting structure can be specified: see <a href="#">xy.coords</a> .<br><code>y</code> must be increasing or decreasing for <code>method = "hyman"</code> .                                           |
| <code>m</code>          | (for <code>splinefunH()</code> ): vector of <i>slopes</i> $m_i$ at the points $(x_i, y_i)$ ; these together determine the <b>H</b> ermite “spline” which is piecewise cubic, (only) <i>once</i> differentiable continuously.                                                                  |
| <code>method</code>     | specifies the type of spline to be used. Possible values are "fmm", "natural", "periodic", "monoH.FC" and "hyman". Can be abbreviated.                                                                                                                                                        |
| <code>n</code>          | if <code>xout</code> is left unspecified, interpolation takes place at <code>n</code> equally spaced points spanning the interval <code>[xmin, xmax]</code> .                                                                                                                                 |
| <code>xmin, xmax</code> | left-hand and right-hand endpoint of the interpolation interval (when <code>xout</code> is unspecified).                                                                                                                                                                                      |
| <code>xout</code>       | an optional set of values specifying where interpolation is to take place.                                                                                                                                                                                                                    |
| <code>ties</code>       | handling of tied <code>x</code> values. The string "ordered" or a function (or the name of a function) taking a single vector argument and returning a single number or a length-2 <a href="#">list</a> of both, see <a href="#">approx</a> and its ‘Details’ section, and the example below. |

## Details

The inputs can contain missing values which are deleted, so at least one complete  $(x, y)$  pair is required. If `method = "fmm"`, the spline used is that of Forsythe, Malcolm and Moler (an exact cubic is fitted through the four points at each end of the data, and this is used to determine the end conditions). Natural splines are used when `method = "natural"`, and periodic splines when `method = "periodic"`.

The method `"monoH.FC"` computes a *monotone* Hermite spline according to the method of Fritsch and Carlson. It does so by determining slopes such that the Hermite spline, determined by  $(x_i, y_i, m_i)$ , is monotone (increasing or decreasing) **iff** the data are.

Method `"hyman"` computes a *monotone* cubic spline using Hyman filtering of an `method = "fmm"` fit for strictly monotonic inputs.

These interpolation splines can also be used for extrapolation, that is prediction at points outside the range of  $x$ . Extrapolation makes little sense for `method = "fmm"`; for natural splines it is linear using the slope of the interpolating curve at the nearest data point.

## Value

`spline` returns a list containing components `x` and `y` which give the ordinates where interpolation took place and the interpolated values.

`splinefun` returns a function with formal arguments `x` and `deriv`, the latter defaulting to zero. This function can be used to evaluate the interpolating cubic spline (`deriv = 0`), or its derivatives (`deriv = 1, 2, 3`) at the points `x`, where the spline function interpolates the data points originally specified. It uses data stored in its environment when it was created, the details of which are subject to change.

## Warning

The value returned by `splinefun` contains references to the code in the current version of R: it is not intended to be saved and loaded into a different R session. This is safer in R  $\geq 3.0.0$ .

## Author(s)

R Core Team.

Simon Wood for the original code for Hyman filtering.

**Examples**

```
require(graphics)

op <- par(mfrow = c(2,1), mgp = c(2,.8,0), mar = 0.1+c(3,3,3,1))
n <- 9
x <- 1:n
y <- rnorm(n)
plot(x, y, main = paste("spline[fun](.) through", n, "points"))
lines(spline(x, y))
lines(spline(x, y, n = 201), col = 2)

y <- (x-6)^2
plot(x, y, main = "spline(.) -- 3 methods")
lines(spline(x, y, n = 201), col = 2)
lines(spline(x, y, n = 201, method = "natural"), col = 3)
lines(spline(x, y, n = 201, method = "periodic"), col = 4)
legend(6, 25, c("fmm","natural","periodic"), col = 2:4, lty = 1)

y <- sin((x-0.5)*pi)
f <- splinefun(x, y)
ls(envir = environment(f))
splinecoef <- get("z", envir = environment(f))
curve(f(x), 1, 10, col = "green", lwd = 1.5)
points(splinecoef, col = "purple", cex = 2)
curve(f(x, deriv = 1), 1, 10, col = 2, lwd = 1.5)
curve(f(x, deriv = 2), 1, 10, col = 2, lwd = 1.5, n = 401)
curve(f(x, deriv = 3), 1, 10, col = 2, lwd = 1.5, n = 401)
par(op)

Manual spline evaluation --- demo the coefficients :
.x <- splinecoef$x
u <- seq(3, 6, by = 0.25)
(iii <- findInterval(u, .x))
dx <- u - .x[iii]
f.u <- with(splinecoef,
 y[iii] + dx*(b[iii] + dx*(c[iii] + dx*d[iii])))
stopifnot(all.equal(f(u), f.u))

An example with ties (non-unique x values):
set.seed(1); x <- round(rnorm(30), 1); y <- sin(pi * x) + rnorm(30)/10
plot(x, y, main = "spline(x,y) when x has ties")
lines(spline(x, y, n = 201), col = 2)
visualizes the non-unique ones:
tx <- table(x); mx <- as.numeric(names(tx[tx > 1]))
ry <- matrix(unlist(tapply(y, match(x, mx), range, simplify = FALSE)),
 ncol = 2, byrow = TRUE)
segments(mx, ry[, 1], mx, ry[, 2], col = "blue", lwd = 2)

Another example with sorted x, but ties:
```

```

set.seed(8); x <- sort(round(rnorm(30), 1)); y <- round(sin(pi * x) + rnorm(30)/10, 3)
summary(diff(x) == 0) # -> 7 duplicated x-values
str(spline(x, y, n = 201, ties="ordered")) # all '$y' entries are NaN
The default (ties=mean) is ok, but most efficient to use instead is
sxyo <- spline(x, y, n = 201, ties= list("ordered", mean))
sapply(sxyo, summary)# all fine now
plot(x, y, main = "spline(x,y, ties=list(\"ordered\", mean)) for when x has ties")
lines(sxyo, col="blue")

An example of monotone interpolation
n <- 20
set.seed(11)
x. <- sort(runif(n)) ; y. <- cumsum(abs(rnorm(n)))
plot(x., y.)
curve(splinefun(x., y.)(x), add = TRUE, col = 2, n = 1001)
curve(splinefun(x., y., method = "monoH.FC")(x), add = TRUE, col = 3, n = 1001)
curve(splinefun(x., y., method = "hyman")(x), add = TRUE, col = 4, n = 1001)
legend("topleft",
 paste0("splinefun(\"", c("fmm", "monoH.FC", "hyman"), "\")"),
 col = 2:4, lty = 1, bty = "n")

and one from Fritsch and Carlson (1980), Dougherty et al (1989)
x. <- c(7.09, 8.09, 8.19, 8.7, 9.2, 10, 12, 15, 20)
f <- c(0, 2.76429e-5, 4.37498e-2, 0.169183, 0.469428, 0.943740,
 0.998636, 0.999919, 0.999994)
s0 <- splinefun(x., f)
s1 <- splinefun(x., f, method = "monoH.FC")
s2 <- splinefun(x., f, method = "hyman")
plot(x., f, ylim = c(-0.2, 1.2))
curve(s0(x), add = TRUE, col = 2, n = 1001) -> m0
curve(s1(x), add = TRUE, col = 3, n = 1001)
curve(s2(x), add = TRUE, col = 4, n = 1001)
legend("right",
 paste0("splinefun(\"", c("fmm", "monoH.FC", "hyman"), "\")"),
 col = 2:4, lty = 1, bty = "n")

they seem identical, but are not quite:
xx <- m0$x
plot(xx, s1(xx) - s2(xx), type = "l", col = 2, lwd = 2,
 main = "Difference monoH.FC - hyman"); abline(h = 0, lty = 3)

x <- xx[xx < 10.2] ## full range: x <- xx .. does not show enough
ccol <- adjustcolor(2:4, 0.8)
matplot(x, cbind(s0(x, deriv = 2), s1(x, deriv = 2), s2(x, deriv = 2))^2,
 lwd = 2, col = ccol, type = "l", ylab = quote({{f*second}(x)}^2),
 main = expression({{f*second}(x)}^2 ~" for the three 'splines'"))
legend("topright",
 paste0("splinefun(\"", c("fmm", "monoH.FC", "hyman"), "\")"),
 lwd = 2, col = ccol, lty = 1:3, bty = "n")
--> "hyman" has slightly smaller Integral f''(x)^2 dx than "FC",
here, and both are 'much worse' than the regular fmm spline.

```

## Description

This `selfStart` model evaluates the asymptotic regression function and its gradient. It has an `initial` attribute that will evaluate initial estimates of the parameters `Asym`, `R0`, and `lrc` for a given set of data.

Note that `SSweibull()` generalizes this asymptotic model with an extra parameter.

## Usage

```
SSasymp(input, Asym, R0, lrc)
```

## Arguments

|                    |                                                                                                                         |
|--------------------|-------------------------------------------------------------------------------------------------------------------------|
| <code>input</code> | a numeric vector of values at which to evaluate the model.                                                              |
| <code>Asym</code>  | a numeric parameter representing the horizontal asymptote on the right side (very large values of <code>input</code> ). |
| <code>R0</code>    | a numeric parameter representing the response when <code>input</code> is zero.                                          |
| <code>lrc</code>   | a numeric parameter representing the natural logarithm of the rate constant.                                            |

## Value

a numeric vector of the same length as `input`. It is the value of the expression `Asym + (R0 - Asym) * exp(-exp(lrc) * input)`. If all of the arguments `Asym`, `R0`, and `lrc` are names of objects, the gradient matrix with respect to these names is attached as an attribute named `gradient`.

SSasympOff

*Self-Starting Nls Asymptotic Regression Model with an Offset*

## Description

This `selfStart` model evaluates an alternative parametrization of the asymptotic regression function and the gradient with respect to those parameters. It has an `initial` attribute that creates initial estimates of the parameters `Asym`, `lrc`, and `c0`.

## Usage

```
SSasympOff(input, Asym, lrc, c0)
```

## Arguments

|                    |                                                                                                                         |
|--------------------|-------------------------------------------------------------------------------------------------------------------------|
| <code>input</code> | a numeric vector of values at which to evaluate the model.                                                              |
| <code>Asym</code>  | a numeric parameter representing the horizontal asymptote on the right side (very large values of <code>input</code> ). |
| <code>lrc</code>   | a numeric parameter representing the natural logarithm of the rate constant.                                            |
| <code>c0</code>    | a numeric parameter representing the <code>input</code> for which the response is zero.                                 |

## Value

a numeric vector of the same length as `input`. It is the value of the expression `Asym*(1-exp(-exp(lrc)*(input-c0)))`. If all of the arguments `Asym`, `lrc`, and `c0` are names of objects, the gradient matrix with respect to these names is attached as an attribute named `gradient`.

## Description

This `selfStart` model evaluates the asymptotic regression function through the origin and its gradient. It has an `initial` attribute that will evaluate initial estimates of the parameters `Asym` and `lrc` for a given set of data.

## Usage

```
SSasympOrig(input, Asym, lrc)
```

## Arguments

|                    |                                                                              |
|--------------------|------------------------------------------------------------------------------|
| <code>input</code> | a numeric vector of values at which to evaluate the model.                   |
| <code>Asym</code>  | a numeric parameter representing the horizontal asymptote.                   |
| <code>lrc</code>   | a numeric parameter representing the natural logarithm of the rate constant. |

## Value

a numeric vector of the same length as `input`. It is the value of the expression `Asym*(1 - exp(-exp(lrc)*input))`. If all of the arguments `Asym` and `lrc` are names of objects, the gradient matrix with respect to these names is attached as an attribute named `gradient`.

SSbiexp

*Self-Starting Nls Biexponential model***Description**

This `selfStart` model evaluates the biexponential model function and its gradient. It has an `initial` attribute that creates initial estimates of the parameters `A1`, `lrc1`, `A2`, and `lrc2`.

**Usage**

```
SSbiexp(input, A1, lrc1, A2, lrc2)
```

**Arguments**

|                    |                                                                                                        |
|--------------------|--------------------------------------------------------------------------------------------------------|
| <code>input</code> | a numeric vector of values at which to evaluate the model.                                             |
| <code>A1</code>    | a numeric parameter representing the multiplier of the first exponential.                              |
| <code>lrc1</code>  | a numeric parameter representing the natural logarithm of the rate constant of the first exponential.  |
| <code>A2</code>    | a numeric parameter representing the multiplier of the second exponential.                             |
| <code>lrc2</code>  | a numeric parameter representing the natural logarithm of the rate constant of the second exponential. |

**Value**

a numeric vector of the same length as `input`. It is the value of the expression `A1*exp(-exp(lrc1)*input)+A2*exp(-exp(lrc2)*input)`. If all of the arguments `A1`, `lrc1`, `A2`, and `lrc2` are names of objects, the gradient matrix with respect to these names is attached as an attribute named `gradient`.

stopifnot(all.equal(y1+y2, ySS, tolerance = 1e-15))
```

## Description

Functions to compute matrix of residual sums of squares and products, or the estimated variance matrix for multivariate linear models.

## Usage

```
S3 method for class 'mlm'
SSD(object, ...)

S3 methods for class 'SSD' and 'mlm'
estVar(object, ...)
```

## Arguments

|        |                                                        |
|--------|--------------------------------------------------------|
| object | object of class "mlm", or "SSD" in the case of estVar. |
| ...    | Unused                                                 |

**Value**

`SSD()` returns a list of class "SSD" containing the following components

|                   |                                                  |
|-------------------|--------------------------------------------------|
| <code>SSD</code>  | The residual sums of squares and products matrix |
| <code>df</code>   | Degrees of freedom                               |
| <code>call</code> | Copied from object                               |

`estVar` returns a matrix with the estimated variances and covariances.

*Self-Starting Nls First-order Compartment Model*

---

**Description**

This `selfStart` model evaluates the first-order compartment function and its gradient. It has an initial attribute that creates initial estimates of the parameters `lKe`, `lKa`, and `lCl`.

**Usage**

```
SSfol(Dose, input, lKe, lKa, lCl)
```

**Arguments**

|       |                                                                                          |
|-------|------------------------------------------------------------------------------------------|
| Dose  | a numeric value representing the initial dose.                                           |
| input | a numeric vector at which to evaluate the model.                                         |
| lKe   | a numeric parameter representing the natural logarithm of the elimination rate constant. |
| lKa   | a numeric parameter representing the natural logarithm of the absorption rate constant.  |
| lCl   | a numeric parameter representing the natural logarithm of the clearance.                 |

**Value**

a numeric vector of the same length as `input`, which is the value of the expression

$$\text{Dose} * \exp(lKe + lKa - lCl) * (\exp(-\exp(lKe) * \text{input}) - \exp(-\exp(lKa) * \text{input})) / (\exp(lKa) - \exp(lKe))$$

If all of the arguments `lKe`, `lKa`, and `lCl` are names of objects, the gradient matrix with respect to these names is attached as an attribute named `gradient`.

SSlogis

*Self-Starting Nls Logistic Model*

---

## Description

This `selfStart` model evaluates the logistic function and its gradient. It has an `initial` attribute that creates initial estimates of the parameters `Asym`, `xmid`, and `scal`. In R 3.4.2 and earlier, that `init` function failed when `min(input)` was exactly zero.

## Usage

```
SSlogis(input, Asym, xmid, scal)
```

## Arguments

|                    |                                                                                                                                                                           |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>input</code> | a numeric vector of values at which to evaluate the model.                                                                                                                |
| <code>Asym</code>  | a numeric parameter representing the asymptote.                                                                                                                           |
| <code>xmid</code>  | a numeric parameter representing the $x$ value at the inflection point of the curve. The value of <code>SSlogis</code> will be <code>Asym/2</code> at <code>xmid</code> . |
| <code>scal</code>  | a numeric scale parameter on the <code>input</code> axis.                                                                                                                 |

## Value

a numeric vector of the same length as `input`. It is the value of the expression `Asym/(1+exp((xmid-input)/scal))`. If all of the arguments `Asym`, `xmid`, and `scal` are names of objects the gradient matrix with respect to these names is attached as an attribute named `gradient`.

SSmicmen

*Self-Starting Nls Michaelis-Menten Model***Description**

This `selfStart` model evaluates the Michaelis-Menten model and its gradient. It has an `initial` attribute that will evaluate initial estimates of the parameters `Vm` and `K`

**Usage**

```
SSmicmen(input, Vm, K)
```

**Arguments**

|                    |                                                                                                                                                                                       |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>input</code> | a numeric vector of values at which to evaluate the model.                                                                                                                            |
| <code>Vm</code>    | a numeric parameter representing the maximum value of the response.                                                                                                                   |
| <code>K</code>     | a numeric parameter representing the <code>input</code> value at which half the maximum response is attained. In the field of enzyme kinetics this is called the Michaelis parameter. |

**Value**

a numeric vector of the same length as `input`. It is the value of the expression  $Vm \cdot input / (K + input)$ . If both the arguments `Vm` and `K` are names of objects, the gradient matrix with respect to these names is attached as an attribute named `gradient`.

SSweibull

*Self-Starting Nls Weibull Growth Curve Model*

## Description

This `selfStart` model evaluates the Weibull model for growth curve data and its gradient. It has an initial attribute that will evaluate initial estimates of the parameters `Asym`, `Drop`, `lrc`, and `pwr` for a given set of data.

## Usage

```
SSweibull(x, Asym, Drop, lrc, pwr)
```

## Arguments

|                   |                                                                                                                     |
|-------------------|---------------------------------------------------------------------------------------------------------------------|
| <code>x</code>    | a numeric vector of values at which to evaluate the model.                                                          |
| <code>Asym</code> | a numeric parameter representing the horizontal asymptote on the right side (very small values of <code>x</code> ). |
| <code>Drop</code> | a numeric parameter representing the change from <code>Asym</code> to the <code>y</code> intercept.                 |
| <code>lrc</code>  | a numeric parameter representing the natural logarithm of the rate constant.                                        |
| <code>pwr</code>  | a numeric parameter representing the power to which <code>x</code> is raised.                                       |

## Details

This model is a generalization of the [SSasymp](#) model in that it reduces to `SSasymp` when `pwr` is unity.

## Value

a numeric vector of the same length as `x`. It is the value of the expression `Asym-Drop*exp(-exp(lrc)*x^pwr)`. If all of the arguments `Asym`, `Drop`, `lrc`, and `pwr` are names of objects, the gradient matrix with respect to these names is attached as an attribute named `gradient`.

start

*Encode the Terminal Times of Time Series***Description**

Extract and encode the times the first and last observations were taken. Provided only for compatibility with S version 2.

**Usage**

```

start(x, ...)
end(x, ...)

```

**Arguments**

**x** a univariate or multivariate time-series, or a vector or matrix.  
**...** extra arguments for future methods.

**Details**

These are generic functions, which will use the [tsp](#) attribute of **x** if it exists. Their default methods decode the start time from the original time units, so that for a monthly series 1995.5 is represented as `c(1995, 7)`. For a series of frequency *f*, time  $n+i/f$  is presented as `c(n, i+1)` (even for  $i = 0$  and  $f = 1$ ).

**Warning**

The representation used by `start` and `end` has no meaning unless the frequency is supplied.

**See Also**

[ts](#), [time](#), [tsp](#).

---

stat.anova

GLM Anova Statistics

---

**Description**

This is a utility function, used in `lm` and `glm` methods for `anova(..., test != NULL)` and should not be used by the average user.

**Usage**

```
stat.anova(table, test = c("Rao", "LRT", "Chisq", "F", "Cp"),
 scale, df.scale, n)
```

**Arguments**

|                       |                                                                                            |
|-----------------------|--------------------------------------------------------------------------------------------|
| <code>table</code>    | numeric matrix as results from <code>anova.glm(..., test = NULL)</code> .                  |
| <code>test</code>     | a character string, partially matching one of "Rao", "LRT", "Chisq", "F" or "Cp".          |
| <code>scale</code>    | a residual mean square or other scale estimate to be used as the denominator in an F test. |
| <code>df.scale</code> | degrees of freedom corresponding to <code>scale</code> .                                   |
| <code>n</code>        | number of observations.                                                                    |

**Value**

A matrix which is the original `table`, augmented by a column of test statistics, depending on the `test` argument.

**References**

**See Also**

[anova.lm](#), [anova.glm](#).

**Examples**

```
##-- Continued from '?glm':

print(ag <- anova(glm.D93))
stat.anova(ag$table, test = "Cp",
 scale = sum(resid(glm.D93, "pearson")^2)/4,
 df.scale = 4, n = 9)
```

---

stats-deprecated      *Deprecated Functions in Package **stats***

---

**Description**

These functions are provided for compatibility with older versions of **R** only, and may be defunct as soon as the next release.

**Usage**

```
plclust(tree, hang = 0.1, unit = FALSE, level = FALSE, hmin = 0,
 square = TRUE, labels = NULL, plot. = TRUE,
 axes = TRUE, frame.plot = FALSE, ann = TRUE,
 main = "", sub = NULL, xlab = NULL, ylab = "Height")
```

**Arguments**

|                       |                                                                                                                                                                                              |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| tree                  | an object of the type produced by <a href="#">hclust</a> .                                                                                                                                   |
| hang                  | The fraction of the plot height by which labels should hang below the rest of the plot. A negative value will cause the labels to hang down from 0.                                          |
| unit                  | logical. If true, the splits are plotted at equally-spaced heights rather than at the height in the object.                                                                                  |
| labels                | A character vector of labels for the leaves of the tree. By default the row names or row numbers of the original data are used. If <code>labels = FALSE</code> no labels at all are plotted. |
| axes, frame.plot, ann | logical flags as in <a href="#">plot.default</a> .                                                                                                                                           |
| main, sub, xlab, ylab | character strings for <a href="#">title</a> . <code>sub</code> and <code>xlab</code> have a non-NULL default when there's a <code>tree\$call</code> .                                        |
| hmin                  | numeric. All heights less than <code>hmin</code> are regarded as being <code>hmin</code> : this can be used to suppress detail at the bottom of the tree.                                    |
| level, square, plot.  | unimplemented arguments for S-PLUS compatibility.                                                                                                                                            |

**Details**

`plclust` is a deprecated wrapper for the `plot` method for [hclust](#), provided long ago for S-PLUS compatibility.

**See Also**

[Deprecated](#)

step

*Choose a model by AIC in a Stepwise Algorithm***Description**

Select a formula-based model by AIC.

**Usage**

```
step(object, scope, scale = 0,
 direction = c("both", "backward", "forward"),
 trace = 1, keep = NULL, steps = 1000, k = 2, ...)
```

**Arguments**

|           |                                                                                                                                                                                                                                                                        |
|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object    | an object representing a model of an appropriate class (mainly "lm" and "glm"). This is used as the initial model in the stepwise search.                                                                                                                              |
| scope     | defines the range of models examined in the stepwise search. This should be either a single formula, or a list containing components <code>upper</code> and <code>lower</code> , both formulae. See the details for how to specify the formulae and how they are used. |
| scale     | used in the definition of the AIC statistic for selecting the models, currently only for <code>lm</code> , <code>ao</code> and <code>glm</code> models. The default value, 0, indicates the scale should be estimated: see <code>extractAIC</code> .                   |
| direction | the mode of stepwise search, can be one of "both", "backward", or "forward", with a default of "both". If the <code>scope</code> argument is missing the default for <code>direction</code> is "backward". Values can be abbreviated.                                  |
| trace     | if positive, information is printed during the running of <code>step</code> . Larger values may give more detailed information.                                                                                                                                        |
| keep      | a filter function whose input is a fitted model object and the associated AIC statistic, and whose output is arbitrary. Typically <code>keep</code> will select a subset of the components of the object and return them. The default is not to keep anything.         |
| steps     | the maximum number of steps to be considered. The default is 1000 (essentially as many as required). It is typically used to stop the process early.                                                                                                                   |
| k         | the multiple of the number of degrees of freedom used for the penalty. Only $k = 2$ gives the genuine AIC: $k = \log(n)$ is sometimes referred to as BIC or SBC.                                                                                                       |
| ...       | any additional arguments to <code>extractAIC</code> .                                                                                                                                                                                                                  |

**Details**

`step` uses `add1` and `drop1` repeatedly; it will work for any method for which they work, and that is determined by having a valid method for `extractAIC`. When the additive constant can be chosen so that AIC is equal to Mallows'  $C_p$ , this is done and the tables are labelled appropriately.

The set of models searched is determined by the `scope` argument. The right-hand-side of its `lower` component is always included in the model, and right-hand-side of the model is included in the `upper` component. If `scope` is a single formula, it specifies the `upper` component, and the `lower` model is empty. If `scope` is missing, the initial model is used as the `upper` model.

Models specified by `scope` can be templates to update `object` as used by `update.formula`. So using `.` in a `scope` formula means ‘what is already there’, with `.^2` indicating all interactions of existing terms.

There is a potential problem in using `glm` fits with a variable `scale`, as in that case the deviance is not simply related to the maximized log-likelihood. The `"glm"` method for function `extractAIC` makes the appropriate adjustment for a gaussian family, but may need to be amended for other cases. (The `binomial` and `poisson` families have fixed `scale` by default and do not correspond to a particular maximum-likelihood problem for variable `scale`.)

### Value

the stepwise-selected model is returned, with up to two additional components. There is an `"anova"` component corresponding to the steps taken in the search, as well as a `"keep"` component if the `keep=` argument was supplied in the call. The `"Resid. Dev"` column of the analysis of deviance table refers to a constant minus twice the maximized log likelihood: it will be a deviance only in cases where a saturated model is well-defined (thus excluding `lm`, `aov` and `survreg` fits, for example).

### Warning

The model fitting must apply the models to the same dataset. This may be a problem if there are missing values and R's default of `na.action = na.omit` is used. We suggest you remove the missing values first.

Calls to the function `nobs` are used to check that the number of observations involved in the fitting process remains unchanged.

### Note

This function differs considerably from the function in S, which uses a number of approximations and does not in general compute the correct AIC.

This is a minimal implementation. Use `stepAIC` in package **MASS** for a wider range of object classes.

### Author(s)

B. D. Ripley: `step` is a slightly simplified version of `stepAIC` in package **MASS** (Venables & Ripley, 2002 and earlier editions).

The idea of a `step` function follows that described in Hastie & Pregibon (1992); but the implementation in R is more general.

slm1 <- step(lm1)
summary(slm1)
slm1$anova
```

stepfun

Step Functions - Creation and Class

## Description

Given the vectors  $(x_1, \dots, x_n)$  and  $(y_0, y_1, \dots, y_n)$  (one value more!), `stepfun(x, y, ...)` returns an interpolating ‘step’ function, say `fn`. I.e.,  $fn(t) = c_i$  (constant) for  $t \in (x_i, x_{i+1})$  and at the abscissa values, if (by default) `right = FALSE`,  $fn(x_i) = y_i$  and for `right = TRUE`,  $fn(x_i) = y_{i-1}$ , for  $i = 1, \dots, n$ .

The value of the constant  $c_i$  above depends on the ‘continuity’ parameter `f`. For the default, `right = FALSE`, `f = 0`, `fn` is a *cadlag* function, i.e., continuous from the right, limits from the left, so that the function is piecewise constant on intervals that include their *left* endpoint. In general,  $c_i$  is interpolated in between the neighbouring  $y$  values,  $c_i = (1 - f)y_i + f \cdot y_{i+1}$ . Therefore, for non-0 values of `f`, `fn` may no longer be a proper step function, since it can be discontinuous from both sides, unless `right = TRUE`, `f = 1` which is left-continuous (i.e., constant pieces contain their right endpoint).

## Usage

```
stepfun(x, y, f = as.numeric(right), ties = "ordered",
 right = FALSE)

is.stepfun(x)
knots(Fn, ...)
as.stepfun(x, ...)

S3 method for class 'stepfun'
print(x, digits = getOption("digits") - 2, ...)

S3 method for class 'stepfun'
summary(object, ...)
```

## Arguments

- `x` numeric vector giving the knots or jump locations of the step function for `stepfun()`. For the other functions, `x` is as object below.
- `y` numeric vector one longer than `x`, giving the heights of the function values *between* the `x` values.
- `f` a number between 0 and 1, indicating how interpolation outside the given `x` values should happen. See [approxfun](#).

|                          |                                                                                                                    |
|--------------------------|--------------------------------------------------------------------------------------------------------------------|
| <code>ties</code>        | Handling of tied <code>x</code> values. Either a function or the string "ordered". See <a href="#">approxfun</a> . |
| <code>right</code>       | logical, indicating if the intervals should be closed on the right (and open on the left) or vice versa.           |
| <code>Fn</code> , object | an R object inheriting from "stepfun".                                                                             |
| <code>digits</code>      | number of significant digits to use, see <a href="#">print</a> .                                                   |
| <code>...</code>         | potentially further arguments (required by the generic).                                                           |

### Value

A function of class "stepfun", say `fn`.

There are methods available for summarizing (`summary(.)`), representing (`print(.)`) and plotting (`plot(.)`), see [plot.stepfun](#) "stepfun" objects.

The [environment](#) of `fn` contains all the information needed;

|                                |                                                             |
|--------------------------------|-------------------------------------------------------------|
| <code>"x", "y"</code>          | the original arguments                                      |
| <code>"n"</code>               | number of knots (x values)                                  |
| <code>"f"</code>               | continuity parameter                                        |
| <code>"yleft", "yright"</code> | the function values <i>outside</i> the knots                |
| <code>"method"</code>          | (always == "constant", from <a href="#">approxfun(.)</a> ). |

The knots are also available via `knots(fn)`.

### Note

The objects of class "stepfun" are not intended to be used for permanent storage and may change structure between versions of R (and did at R 3.0.0). They can usually be re-created by

```
eval(attr(old_obj, "call"), environment(old_obj))
```

since the data used is stored as part of the object's environment.

stl

---

*Seasonal Decomposition of Time Series by Loess*

---

## Description

Decompose a time series into seasonal, trend and irregular components using `loess`, acronym STL.

## Usage

```

stl(x, s.window, s.degree = 0,
 t.window = NULL, t.degree = 1,
 l.window = nextodd(period), l.degree = t.degree,
 s.jump = ceiling(s.window/10),
 t.jump = ceiling(t.window/10),
 l.jump = ceiling(l.window/10),
 robust = FALSE,
 inner = if(robust) 1 else 2,
 outer = if(robust) 15 else 0,
 na.action = na.fail)

```

## Arguments

|                       |                                                                                                                                                                                                  |
|-----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>        | univariate time series to be decomposed. This should be an object of class "ts" with a frequency greater than one.                                                                               |
| <code>s.window</code> | either the character string "periodic" or the span (in lags) of the loess window for seasonal extraction, which should be odd and at least 7, according to Cleveland et al. This has no default. |
| <code>s.degree</code> | degree of locally-fitted polynomial in seasonal extraction. Should be zero or one.                                                                                                               |

|                                     |                                                                                                                                                                                                                                                                                                                                                      |
|-------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>t.window</code>               | the span (in lags) of the loess window for trend extraction, which should be odd. If <code>NULL</code> , the default, <code>nextodd(ceiling((1.5*period)/(1-(1.5/s.window))))</code> , is taken.                                                                                                                                                     |
| <code>t.degree</code>               | degree of locally-fitted polynomial in trend extraction. Should be zero or one.                                                                                                                                                                                                                                                                      |
| <code>l.window</code>               | the span (in lags) of the loess window of the low-pass filter used for each subseries. Defaults to the smallest odd integer greater than or equal to <code>frequency(x)</code> which is recommended since it prevents competition between the trend and seasonal components. If not an odd integer its given value is increased to the next odd one. |
| <code>l.degree</code>               | degree of locally-fitted polynomial for the subseries low-pass filter. Must be 0 or 1.                                                                                                                                                                                                                                                               |
| <code>s.jump, t.jump, l.jump</code> | integers at least one to increase speed of the respective smoother. Linear interpolation happens between every <code>*.jumpth</code> value.                                                                                                                                                                                                          |
| <code>robust</code>                 | logical indicating if robust fitting be used in the <code>loess</code> procedure.                                                                                                                                                                                                                                                                    |
| <code>inner</code>                  | integer; the number of 'inner' (backfitting) iterations; usually very few (2) iterations suffice.                                                                                                                                                                                                                                                    |
| <code>outer</code>                  | integer; the number of 'outer' robustness iterations.                                                                                                                                                                                                                                                                                                |
| <code>na.action</code>              | action on missing values.                                                                                                                                                                                                                                                                                                                            |

### Details

The seasonal component is found by *loess* smoothing the seasonal sub-series (the series of all January values, ...); if `s.window = "periodic"` smoothing is effectively replaced by taking the mean. The seasonal values are removed, and the remainder smoothed to find the trend. The overall level is removed from the seasonal component and added to the trend component. This process is iterated a few times. The `remainder` component is the residuals from the seasonal plus trend fit.

Several methods for the resulting class "`stl`" objects, see, [plot.stl](#).

### Value

`stl` returns an object of class "`stl`" with components

|                          |                                                                                                                                 |
|--------------------------|---------------------------------------------------------------------------------------------------------------------------------|
| <code>time.series</code> | a multiple time series with columns <code>seasonal</code> , <code>trend</code> and <code>remainder</code> .                     |
| <code>weights</code>     | the final robust weights (all one if fitting is not done robustly).                                                             |
| <code>call</code>        | the matched call.                                                                                                               |
| <code>win</code>         | integer (length 3 vector) with the spans used for the " <code>s</code> ", " <code>t</code> ", and " <code>l</code> " smoothers. |
| <code>deg</code>         | integer (length 3) vector with the polynomial degrees for these smoothers.                                                      |
| <code>jump</code>        | integer (length 3) vector with the 'jumps' (skips) used for these smoothers.                                                    |
| <code>ni</code>          | number of inner iterations                                                                                                      |
| <code>no</code>          | number of outer robustness iterations                                                                                           |

### Note

This is similar to but not identical to the `stl` function in S-PLUS. The `remainder` component given by S-PLUS is the sum of the `trend` and `remainder` series from this function.

**Author(s)**

B.D. Ripley; Fortran code by Cleveland *et al* (1990) from ‘netlib’.

**References**

R. B. Cleveland, W. S. Cleveland, J.E. McRae, and I. Terpenning (1990) STL: A Seasonal-Trend Decomposition Procedure Based on Loess. *Journal of Official Statistics*, **6**, 3–73.

**See Also**

`plot.stl` for stl methods; `loess` in package **stats** (which is not actually used in `stl`).

`StructTS` for different kind of decomposition.

**Examples**

```
require(graphics)

plot(stl(nottem, "per"))
plot(stl(nottem, s.window = 7, t.window = 50, t.jump = 1))

plot(stllc <- stl(log(co2), s.window = 21))
summary(stllc)
linear trend, strict period.
plot(stl(log(co2), s.window = "per", t.window = 1000))

Two STL plotted side by side :
stmd <- stl(mdeaths, s.window = "per") # non-robust
summary(stmR <- stl(mdeaths, s.window = "per", robust = TRUE))
op <- par(mar = c(0, 4, 0, 3), oma = c(5, 0, 4, 0), mfcol = c(4, 2))
plot(stmd, set.pars = NULL, labels = NULL,
 main = "stl(mdeaths, s.w = \"per\", robust = FALSE / TRUE)")
plot(stmR, set.pars = NULL)
mark the 'outliers' :
(iO <- which(stmR $ weights < 1e-8)) # 10 were considered outliers
sts <- stmR$time.series
points(time(sts)[iO], 0.8* sts[,"remainder"][iO], pch = 4, col = "red")
par(op) # reset
```

**Description**

Methods for objects of class `stl`, typically the result of `stl`. The `plot` method does a multiple figure plot with some flexibility.

There are also (non-visible) `print` and `summary` methods.

**Usage**

```
S3 method for class 'stl'
plot(x, labels = colnames(X),
 set.pars = list(mar = c(0, 6, 0, 6), oma = c(6, 0, 4, 0),
 tck = -0.01, mfrow = c(nplot, 1)),
 main = NULL, range.bars = TRUE, ...,
 col.range = "light gray")
```

**Arguments**

|                         |                                                                                                                          |
|-------------------------|--------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>          | <code>stl</code> object.                                                                                                 |
| <code>labels</code>     | character of length 4 giving the names of the component time-series.                                                     |
| <code>set.pars</code>   | settings for <code>par ( . )</code> when setting up the plot.                                                            |
| <code>main</code>       | plot main title.                                                                                                         |
| <code>range.bars</code> | logical indicating if each plot should have a bar at its right side which are of equal heights in user coordinates.      |
| <code>...</code>        | further arguments passed to or from other methods.                                                                       |
| <code>col.range</code>  | colour to be used for the range bars, if plotted. Note this appears after <code>...</code> and so cannot be abbreviated. |

**See Also**

`plot.ts` and `stl`, particularly for examples.

---

StructTS

*Fit Structural Time Series*

---

**Description**

Fit a structural model for a time series by maximum likelihood.

**Usage**

```
StructTS(x, type = c("level", "trend", "BSM"), init = NULL,
 fixed = NULL, optim.control = NULL)
```

**Arguments**

|                            |                                                                                                                                                                                                      |
|----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>             | a univariate numeric time series. Missing values are allowed.                                                                                                                                        |
| <code>type</code>          | the class of structural model. If omitted, a BSM is used for a time series with <code>frequency(x) &gt; 1</code> , and a local trend model otherwise. Can be abbreviated.                            |
| <code>init</code>          | initial values of the variance parameters.                                                                                                                                                           |
| <code>fixed</code>         | optional numeric vector of the same length as the total number of parameters. If supplied, only NA entries in <code>fixed</code> will be varied. Probably most useful for setting variances to zero. |
| <code>optim.control</code> | List of control parameters for <code>optim</code> . Method "L-BFGS-B" is used.                                                                                                                       |

## Details

*Structural time series* models are (linear Gaussian) state-space models for (univariate) time series based on a decomposition of the series into a number of components. They are specified by a set of error variances, some of which may be zero.

The simplest model is the *local level* model specified by `type = "level"`. This has an underlying level  $\mu_t$  which evolves by

$$\mu_{t+1} = \mu_t + \xi_t, \quad \xi_t \sim N(0, \sigma_\xi^2)$$

The observations are

$$x_t = \mu_t + \epsilon_t, \quad \epsilon_t \sim N(0, \sigma_\epsilon^2)$$

There are two parameters,  $\sigma_\xi^2$  and  $\sigma_\epsilon^2$ . It is an ARIMA(0,1,1) model, but with restrictions on the parameter set.

The *local linear trend model*, `type = "trend"`, has the same measurement equation, but with a time-varying slope in the dynamics for  $\mu_t$ , given by

$$\mu_{t+1} = \mu_t + \nu_t + \xi_t, \quad \xi_t \sim N(0, \sigma_\xi^2)$$

$$\nu_{t+1} = \nu_t + \zeta_t, \quad \zeta_t \sim N(0, \sigma_\zeta^2)$$

with three variance parameters. It is not uncommon to find  $\sigma_\xi^2 = 0$  (which reduces to the local level model) or  $\sigma_\zeta^2 = 0$ , which ensures a smooth trend. This is a restricted ARIMA(0,2,2) model.

The *basic structural model*, `type = "BSM"`, is a local trend model with an additional seasonal component. Thus the measurement equation is

$$x_t = \mu_t + \gamma_t + \epsilon_t, \quad \epsilon_t \sim N(0, \sigma_\epsilon^2)$$

where  $\gamma_t$  is a seasonal component with dynamics

$$\gamma_{t+1} = -\gamma_t + \dots + \gamma_{t-s+2} + \omega_t, \quad \omega_t \sim N(0, \sigma_\omega^2)$$

The boundary case  $\sigma_\omega^2 = 0$  corresponds to a deterministic (but arbitrary) seasonal pattern. (This is sometimes known as the ‘dummy variable’ version of the BSM.)

## Value

A list of class `"StructTS"` with components:

|                            |                                                                                                                                                                                                                                   |
|----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>coef</code>          | the estimated variances of the components.                                                                                                                                                                                        |
| <code>loglik</code>        | the maximized log-likelihood. Note that as all these models are non-stationary this includes a diffuse prior for some observations and hence is not comparable to <a href="#">arima</a> nor different types of structural models. |
| <code>loglik0</code>       | the maximized log-likelihood with the constant used prior to R 3.0.0, for backwards compatibility.                                                                                                                                |
| <code>data</code>          | the time series <code>x</code> .                                                                                                                                                                                                  |
| <code>residuals</code>     | the standardized residuals.                                                                                                                                                                                                       |
| <code>fitted</code>        | a multiple time series with one component for the level, slope and seasonal components, estimated contemporaneously (that is at time $t$ and not at the end of the series).                                                       |
| <code>call</code>          | the matched call.                                                                                                                                                                                                                 |
| <code>series</code>        | the name of the series <code>x</code> .                                                                                                                                                                                           |
| <code>code</code>          | the convergence code returned by <a href="#">optim</a> .                                                                                                                                                                          |
| <code>model, model0</code> | Lists representing the Kalman Filter used in the fitting. See <a href="#">KalmanLike</a> . <code>model0</code> is the initial state of the filter, <code>model</code> its final state.                                            |
| <code>xtsp</code>          | the <code>tsp</code> attributes of <code>x</code> .                                                                                                                                                                               |

**Note**

Optimization of structural models is a lot harder than many of the references admit. For example, the [AirPassengers](#) data are considered in Brockwell & Davis (1996): their solution appears to be a local maximum, but nowhere near as good a fit as that produced by `StructTS`. It is quite common to find fits with one or more variances zero, and this can include  $\sigma_\epsilon^2$ .

**Examples**

```
see also JohnsonJohnson, Nile and AirPassengers
require(graphics)

trees <- window(treering, start = 0)
(fit <- StructTS(trees, type = "level"))
plot(trees)
lines(fitted(fit), col = "green")
tsdiag(fit)

(fit <- StructTS(log10(UKgas), type = "BSM"))
par(mfrow = c(4, 1)) # to give appropriate aspect ratio for next plot.
plot(log10(UKgas))
plot(cbind(fitted(fit), resid=resid(fit)), main = "UK gas consumption")

keep some parameters fixed; trace optimizer:
StructTS(log10(UKgas), type = "BSM", fixed = c(0.1, 0.001, NA, NA),
 optim.control = list(trace = TRUE))
```

---

summary.aov

---

*Summarize an Analysis of Variance Model*

---

**Description**

Summarize an analysis of variance model.

**Usage**

```
S3 method for class 'aov'
summary(object, intercept = FALSE, split,
 expand.split = TRUE, keep.zero.df = TRUE, ...)

S3 method for class 'aovlist'
summary(object, ...)
```

**Arguments**

|                           |                                                                                                                                                                                        |
|---------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code>       | An object of class "aov" or "aovlist".                                                                                                                                                 |
| <code>intercept</code>    | logical: should intercept terms be included?                                                                                                                                           |
| <code>split</code>        | an optional named list, with names corresponding to terms in the model. Each component is itself a list with integer components giving contrasts whose contributions are to be summed. |
| <code>expand.split</code> | logical: should the split apply also to interactions involving the factor?                                                                                                             |
| <code>keep.zero.df</code> | logical: should terms with no degrees of freedom be included?                                                                                                                          |
| <code>...</code>          | Arguments to be passed to or from other methods, for <code>summary.aovlist</code> including those for <code>summary.aov</code> .                                                       |

**Value**

An object of class `c("summary.aov", "listof")` or `"summary.aovlist"` respectively. For fits with a single stratum the result will be a list of ANOVA tables, one for each response (even if there is only one response): the tables are of class "anova" inheriting from class "data.frame". They have columns "Df", "Sum Sq", "Mean Sq", as well as "F value" and "Pr(>F)" if there are non-zero residual degrees of freedom. There is a row for each term in the model, plus one for "Residuals" if there are any.

For multistratum fits the return value is a list of such summaries, one for each stratum.

**Note**

The use of `expand.split = TRUE` is little tested: it is always possible to set it to `FALSE` and specify exactly all the splits required.

**See Also**

[aov](#), [summary](#), [model.tables](#), [TukeyHSD](#)

**Examples**

```
For a simple example see example(aov)

Cochran and Cox (1957, p.164)
3x3 factorial with ordered factors, each is average of 12.
CC <- data.frame(
 y = c(449, 413, 326, 409, 358, 291, 341, 278, 312)/12,
 P = ordered(gl(3, 3)), N = ordered(gl(3, 1, 9))
)
CC.aov <- aov(y ~ N * P, data = CC, weights = rep(12, 9))
summary(CC.aov)
```

```
Split both main effects into linear and quadratic parts.
summary(CC.aov, split = list(N = list(L = 1, Q = 2),
 P = list(L = 1, Q = 2)))

Split only the interaction
summary(CC.aov, split = list("N:P" = list(L.L = 1, Q = 2:4)))

split on just one var
summary(CC.aov, split = list(P = list(lin = 1, quad = 2)))
summary(CC.aov, split = list(P = list(lin = 1, quad = 2)),
 expand.split = FALSE)
```

summary.glm

*Summarizing Generalized Linear Model Fits*

## Description

These functions are all [methods](#) for class `glm` or `summary.glm` objects.

## Usage

```
S3 method for class 'glm'
summary(object, dispersion = NULL, correlation = FALSE,
 symbolic.cor = FALSE, ...)

S3 method for class 'summary.glm'
print(x, digits = max(3, getOption("digits") - 3),
 symbolic.cor = x$symbolic.cor,
 signif.stars = getOption("show.signif.stars"), ...)
```

## Arguments

|                           |                                                                                                                                                                                 |
|---------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code>       | an object of class <code>"glm"</code> , usually, a result of a call to <a href="#">glm</a> .                                                                                    |
| <code>x</code>            | an object of class <code>"summary.glm"</code> , usually, a result of a call to <code>summary.glm</code> .                                                                       |
| <code>dispersion</code>   | the dispersion parameter for the family used. Either a single numerical value or <code>NULL</code> (the default), when it is inferred from <code>object</code> (see ‘Details’). |
| <code>correlation</code>  | logical; if <code>TRUE</code> , the correlation matrix of the estimated parameters is returned and printed.                                                                     |
| <code>digits</code>       | the number of significant digits to use when printing.                                                                                                                          |
| <code>symbolic.cor</code> | logical. If <code>TRUE</code> , print the correlations in a symbolic form (see <a href="#">symnum</a> ) rather than as numbers.                                                 |
| <code>signif.stars</code> | logical. If <code>TRUE</code> , ‘significance stars’ are printed for each coefficient.                                                                                          |
| <code>...</code>          | further arguments passed to or from other methods.                                                                                                                              |

## Details

`print.summary.glm` tries to be smart about formatting the coefficients, standard errors, etc. and additionally gives ‘significance stars’ if `signif.stars` is `TRUE`. The `coefficients` component of the result gives the estimated coefficients and their estimated standard errors, together with their ratio. This third column is labelled `t ratio` if the dispersion is estimated, and `z ratio` if the dispersion is known (or fixed by the family). A fourth column gives the two-tailed p-value corresponding to the t or z ratio based on a Student t or Normal reference distribution. (It is possible that the dispersion is not known and there are no residual degrees of freedom from which to estimate it. In that case the estimate is `NaN`.)

Aliased coefficients are omitted in the returned object but restored by the `print` method.

Correlations are printed to two decimal places (or symbolically): to see the actual correlations print `summary(object)$correlation` directly.

The dispersion of a GLM is not used in the fitting process, but it is needed to find standard errors. If `dispersion` is not supplied or `NULL`, the dispersion is taken as 1 for the `binomial` and `Poisson` families, and otherwise estimated by the residual Chisquared statistic (calculated from cases with non-zero weights) divided by the residual degrees of freedom.

`summary` can be used with Gaussian `glm` fits to handle the case of a linear regression with known error variance, something not handled by `summary.lm`.

## Value

`summary.glm` returns an object of class `"summary.glm"`, a list with components

|                             |                                                                                                                                          |
|-----------------------------|------------------------------------------------------------------------------------------------------------------------------------------|
| <code>call</code>           | the component from <code>object</code> .                                                                                                 |
| <code>family</code>         | the component from <code>object</code> .                                                                                                 |
| <code>deviance</code>       | the component from <code>object</code> .                                                                                                 |
| <code>contrasts</code>      | the component from <code>object</code> .                                                                                                 |
| <code>df.residual</code>    | the component from <code>object</code> .                                                                                                 |
| <code>null.deviance</code>  | the component from <code>object</code> .                                                                                                 |
| <code>df.null</code>        | the component from <code>object</code> .                                                                                                 |
| <code>deviance.resid</code> | the deviance residuals: see <code>residuals.glm</code> .                                                                                 |
| <code>coefficients</code>   | the matrix of coefficients, standard errors, z-values and p-values. Aliased coefficients are omitted.                                    |
| <code>aliased</code>        | named logical vector showing if the original coefficients are aliased.                                                                   |
| <code>dispersion</code>     | either the supplied argument or the inferred/estimated dispersion if the latter is <code>NULL</code> .                                   |
| <code>df</code>             | a 3-vector of the rank of the model and the number of residual degrees of freedom, plus number of coefficients (including aliased ones). |
| <code>cov.unscaled</code>   | the unscaled ( <code>dispersion = 1</code> ) estimated covariance matrix of the estimated coefficients.                                  |
| <code>cov.scaled</code>     | ditto, scaled by dispersion.                                                                                                             |
| <code>correlation</code>    | (only if <code>correlation</code> is true.) The estimated correlations of the estimated coefficients.                                    |
| <code>symbolic.cor</code>   | (only if <code>correlation</code> is true.) The value of the argument <code>symbolic.cor</code> .                                        |

summary.lm

*Summarizing Linear Model Fits*

---

**Description**

summary method for class "lm".

**Usage**

```
S3 method for class 'lm'
summary(object, correlation = FALSE, symbolic.cor = FALSE, ...)

S3 method for class 'summary.lm'
print(x, digits = max(3, getOption("digits") - 3),
 symbolic.cor = x$symbolic.cor,
 signif.stars = getOption("show.signif.stars"), ...)
```

**Arguments**

|              |                                                                                                                   |
|--------------|-------------------------------------------------------------------------------------------------------------------|
| object       | an object of class "lm", usually, a result of a call to <a href="#">lm</a> .                                      |
| x            | an object of class "summary.lm", usually, a result of a call to <code>summary.lm</code> .                         |
| correlation  | logical; if TRUE, the correlation matrix of the estimated parameters is returned and printed.                     |
| digits       | the number of significant digits to use when printing.                                                            |
| symbolic.cor | logical. If TRUE, print the correlations in a symbolic form (see <a href="#">symnum</a> ) rather than as numbers. |
| signif.stars | logical. If TRUE, ‘significance stars’ are printed for each coefficient.                                          |
| ...          | further arguments passed to or from other methods.                                                                |

**Details**

`print.summary.lm` tries to be smart about formatting the coefficients, standard errors, etc. and additionally gives ‘significance stars’ if `signif.stars` is TRUE.

Aliased coefficients are omitted in the returned object but restored by the `print` method.

Correlations are printed to two decimal places (or symbolically): to see the actual correlations print `summary(object)$correlation` directly.

**Value**

The function `summary.lm` computes and returns a list of summary statistics of the fitted linear model given in `object`, using the components (list elements) `"call"` and `"terms"` from its argument, plus

`residuals` the *weighted* residuals, the usual residuals rescaled by the square root of the weights specified in the call to `lm`.

`coefficients` a  $p \times 4$  matrix with columns for the estimated coefficient, its standard error, t-statistic and corresponding (two-sided) p-value. Aliased coefficients are omitted.

`aliased` named logical vector showing if the original coefficients are aliased.

`sigma` the square root of the estimated variance of the random error

$$\hat{\sigma}^2 = \frac{1}{n-p} \sum_i w_i R_i^2,$$

where  $R_i$  is the  $i$ -th residual, `residuals[i]`.

`df` degrees of freedom, a 3-vector  $(p, n-p, p^*)$ , the first being the number of non-aliased coefficients, the last being the total number of coefficients.

`fstatistic` (for models including non-intercept terms) a 3-vector with the value of the F-statistic with its numerator and denominator degrees of freedom.

`r.squared`  $R^2$ , the ‘fraction of variance explained by the model’,

$$R^2 = 1 - \frac{\sum_i R_i^2}{\sum_i (y_i - y^*)^2},$$

where  $y^*$  is the mean of  $y_i$  if there is an intercept and zero otherwise.

`adj.r.squared` the above  $R^2$  statistic ‘*adjusted*’, penalizing for higher  $p$ .

`cov.unscaled` a  $p \times p$  matrix of (unscaled) covariances of the  $\hat{\beta}_j, j = 1, \dots, p$ .

`correlation` the correlation matrix corresponding to the above `cov.unscaled`, if `correlation = TRUE` is specified.

`symbolic.cor` (only if `correlation` is true.) The value of the argument `symbolic.cor`.

`na.action` from `object`, if present there.

**See Also**

The model fitting function [lm](#), [summary](#).

Function `coef` will extract the matrix of coefficients with standard errors, t-statistics and p-values.

**Examples**

```
##-- Continuing the lm(.) example:
coef(lm.D90) # the bare coefficients
sld90 <- summary(lm.D90 <- lm(weight ~ group -1)) # omitting intercept
sld90
coef(sld90) # much more

model with *aliased* coefficient:
lm.D9. <- lm(weight ~ group + I(group != "Ctl"))
Sm.D9. <- summary(lm.D9.)
Sm.D9. # shows the NA NA NA NA line
stopifnot(length(cc <- coef(lm.D9.)) == 3, is.na(cc[3]),
 dim(coef(Sm.D9.)) == c(2,4), Sm.D9.$df == c(2, 18, 3))
```

summary.manova

*Summary Method for Multivariate Analysis of Variance***Description**

A summary method for class "manova".

**Usage**

```
S3 method for class 'manova'
summary(object,
 test = c("Pillai", "Wilks", "Hotelling-Lawley", "Roy"),
 intercept = FALSE, tol = 1e-7, ...)
```

**Arguments**

|           |                                                                                                     |
|-----------|-----------------------------------------------------------------------------------------------------|
| object    | An object of class "manova" or an aov object with multiple responses.                               |
| test      | The name of the test statistic to be used. Partial matching is used so the name can be abbreviated. |
| intercept | logical. If TRUE, the intercept term is included in the table.                                      |
| tol       | tolerance to be used in deciding if the residuals are rank-deficient: see <a href="#">qr</a> .      |
| ...       | further arguments passed to or from other methods.                                                  |

**Details**

The `summary.manova` method uses a multivariate test statistic for the summary table. Wilks' statistic is most popular in the literature, but the default Pillai–Bartlett statistic is recommended by Hand and Taylor (1987).

The table gives a transformation of the test statistic which has approximately an F distribution. The approximations used follow S-PLUS and SAS (the latter apart from some cases of the Hotelling–Lawley statistic), but many other distributional approximations exist: see Anderson (1984) and Krzanowski and Marriott (1994) for further references. All four approximate F statistics are the same when the term being tested has one degree of freedom, but in other cases that for the Roy statistic is an upper bound.

The tolerance `tol` is applied to the QR decomposition of the residual correlation matrix (unless some response has essentially zero residuals, when it is unscaled). Thus the default value guards against very highly correlated responses: it can be reduced but doing so will allow rather inaccurate results and it will normally be better to transform the responses to remove the high correlation.

**Value**

An object of class "summary.manova". If there is a positive residual degrees of freedom, this is a list with components

|             |                                                                                   |
|-------------|-----------------------------------------------------------------------------------|
| row.names   | The names of the terms, the row names of the <code>stats</code> table if present. |
| SS          | A named list of sums of squares and product matrices.                             |
| Eigenvalues | A matrix of eigenvalues.                                                          |
| stats       | A matrix of the statistics, approximate F value, degrees of freedom and P value.  |

otherwise components `row.names`, `SS` and `Df` (degrees of freedom) for the terms (and not the residuals).

| <code>correlation</code>  | logical; if TRUE, the correlation matrix of the estimated parameters is returned and printed.                     |
| <code>digits</code>       | the number of significant digits to use when printing.                                                            |
| <code>symbolic.cor</code> | logical. If TRUE, print the correlations in a symbolic form (see <a href="#">symnum</a> ) rather than as numbers. |
| <code>signif.stars</code> | logical. If TRUE, 'significance stars' are printed for each coefficient.                                          |
| <code>...</code>          | further arguments passed to or from other methods.                                                                |

## Details

The distribution theory used to find the distribution of the standard errors and of the residual standard error (for t ratios) is based on linearization and is approximate, maybe very approximate.

`print.summary.nls` tries to be smart about formatting the coefficients, standard errors, etc. and additionally gives 'significance stars' if `signif.stars` is TRUE.

Correlations are printed to two decimal places (or symbolically): to see the actual correlations print `summary(object)$correlation` directly.

## Value

The function `summary.nls` computes and returns a list of summary statistics of the fitted model given in `object`, using the component "formula" from its argument, plus

|                           |                                                                                                                                           |
|---------------------------|-------------------------------------------------------------------------------------------------------------------------------------------|
| <code>residuals</code>    | the <i>weighted</i> residuals, the usual residuals rescaled by the square root of the weights specified in the call to <code>nls</code> . |
| <code>coefficients</code> | a $p \times 4$ matrix with columns for the estimated coefficient, its standard error, t-statistic and corresponding (two-sided) p-value.  |
| <code>sigma</code>        | the square root of the estimated variance of the random error                                                                             |

$$\hat{\sigma}^2 = \frac{1}{n-p} \sum_i R_i^2,$$

where  $R_i$  is the  $i$ -th weighted residual.

|                           |                                                                                                                                                                                               |
|---------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>df</code>           | degrees of freedom, a 2-vector $(p, n-p)$ . (Here and elsewhere $n$ omits observations with zero weights.)                                                                                    |
| <code>cov.unscaled</code> | a $p \times p$ matrix of (unscaled) covariances of the parameter estimates.                                                                                                                   |
| <code>correlation</code>  | the correlation matrix corresponding to the above <code>cov.unscaled</code> , if <code>correlation = TRUE</code> is specified and there are a non-zero number of residual degrees of freedom. |
| <code>symbolic.cor</code> | (only if <code>correlation</code> is true.) The value of the argument <code>symbolic.cor</code> .                                                                                             |

|                  |                                                         |
|------------------|---------------------------------------------------------|
| summary.princomp | <i>Summary method for Principal Components Analysis</i> |
|------------------|---------------------------------------------------------|

---

## Description

The `summary` method for class "princomp".

## Usage

```
S3 method for class 'princomp'
summary(object, loadings = FALSE, cutoff = 0.1, ...)

S3 method for class 'summary.princomp'
print(x, digits = 3, loadings = x$print.loadings,
 cutoff = x$cutoff, ...)
```

## Arguments

|                       |                                                                                         |
|-----------------------|-----------------------------------------------------------------------------------------|
| <code>object</code>   | an object of class "princomp", as from <code>princomp()</code> .                        |
| <code>loadings</code> | logical. Should loadings be included?                                                   |
| <code>cutoff</code>   | numeric. Loadings below this cutoff in absolute value are shown as blank in the output. |
| <code>x</code>        | an object of class "summary.princomp".                                                  |
| <code>digits</code>   | the number of significant digits to be used in listing loadings.                        |
| <code>...</code>      | arguments to be passed to or from other methods.                                        |

## Value

object with additional components `cutoff` and `print.loadings`.

## See Also

[princomp](#)

## Examples

```
summary(pc.cr <- princomp(USArrests, cor = TRUE))
The signs of the loading columns are arbitrary
print(summary(princomp(USArrests, cor = TRUE),
 loadings = TRUE, cutoff = 0.2), digits = 2)
```

supsmu

*Friedman's SuperSmoother***Description**

Smooth the (x, y) values by Friedman's 'super smoother'.

**Usage**

```
supsmu(x, y, wt =, span = "cv", periodic = FALSE, bass = 0, trace = FALSE)
```

**Arguments**

|          |                                                                                                                                       |
|----------|---------------------------------------------------------------------------------------------------------------------------------------|
| x        | x values for smoothing                                                                                                                |
| y        | y values for smoothing                                                                                                                |
| wt       | case weights, by default all equal                                                                                                    |
| span     | the fraction of the observations in the span of the running lines smoother, or "cv" to choose this by leave-one-out cross-validation. |
| periodic | if TRUE, the x values are assumed to be in $[0, 1]$ and of period 1.                                                                  |
| bass     | controls the smoothness of the fitted curve. Values of up to 10 indicate increasing smoothness.                                       |
| trace    | logical, if true, prints one line of info "per spar", notably useful for "cv".                                                        |

**Details**

supsmu is a running lines smoother which chooses between three spans for the lines. The running lines smoothers are symmetric, with  $k/2$  data points each side of the predicted point, and values of  $k$  as  $0.5 * n$ ,  $0.2 * n$  and  $0.05 * n$ , where  $n$  is the number of data points. If span is specified, a single smoother with span  $span * n$  is used.

The best of the three smoothers is chosen by cross-validation for each prediction. The best spans are then smoothed by a running lines smoother and the final prediction chosen by linear interpolation.

The FORTRAN code says: "For small samples ( $n < 40$ ) or if there are substantial serial correlations between observations close in x-value, then a pre-specified fixed span smoother ( $span > 0$ ) should be used. Reasonable span values are 0.2 to 0.4."

Cases with non-finite values of x, y or wt are dropped, with a warning.

**Value**

A list with components

|   |                                                               |
|---|---------------------------------------------------------------|
| x | the input values in increasing order with duplicates removed. |
| y | the corresponding y values on the fitted curve.               |

})
```

symnum

*Symbolic Number Coding***Description**

Symbolically encode a given numeric or logical vector or array. Particularly useful for visualization of structured matrices, e.g., correlation, sparse, or logical ones.

**Usage**

```
symnum(x, cutpoints = c(0.3, 0.6, 0.8, 0.9, 0.95),
 symbols = if(numeric.x) c(" ", ".", ",", "+", "*", "B")
 else c(".", "|"),
 legend = length(symbols) >= 3,
 na = "?", eps = 1e-5, numeric.x = is.numeric(x),
 corr = missing(cutpoints) && numeric.x,
 show.max = if(corr) "1", show.min = NULL,
 abbr.colnames = has.colnames,
 lower.triangular = corr && is.numeric(x) && is.matrix(x),
 diag.lower.tri = corr && !is.null(show.max))
```

**Arguments**

|                        |                                                                                                                                                                                                                                                                                                                                                                            |
|------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>         | numeric or logical vector or array.                                                                                                                                                                                                                                                                                                                                        |
| <code>cutpoints</code> | numeric vector whose values $\text{cutpoints}[j] = c_j$ (after augmentation, see <code>corr</code> below) are used for intervals.                                                                                                                                                                                                                                          |
| <code>symbols</code>   | character vector, one shorter than (the <i>augmented</i> , see <code>corr</code> below) <code>cutpoints</code> . $\text{symbols}[j] = s_j$ are used as ‘code’ for the (half open) interval $(c_j, c_{j+1}]$ .<br>When <code>numeric.x</code> is FALSE, i.e., by default when argument <code>x</code> is logical, the default is <code>c(" ", " ")</code> (graphical 0/1s). |
| <code>legend</code>    | logical indicating if a "legend" attribute is desired.                                                                                                                                                                                                                                                                                                                     |
| <code>na</code>        | character or logical. How NAs are coded. If <code>na == FALSE</code> , NAs are coded invisibly, <i>including</i> the "legend" attribute below, which otherwise mentions NA coding.                                                                                                                                                                                         |
| <code>eps</code>       | absolute precision to be used at left and right boundary.                                                                                                                                                                                                                                                                                                                  |

`numeric.x`      logical indicating if `x` should be treated as numbers, otherwise as logical.  
`corr`            logical. If TRUE, `x` contains correlations. The cutpoints are augmented by 0 and 1 and `abs(x)` is coded.  
`show.max`        if TRUE, or of mode character, the maximal cutpoint is coded especially.  
`show.min`        if TRUE, or of mode character, the minimal cutpoint is coded especially.  
`abbr.colnames`   logical, integer or NULL indicating how column names should be abbreviated (if they are); if NULL (or FALSE and `x` has no column names), the column names will all be empty, i.e., ""; otherwise if `abbr.colnames` is false, they are left unchanged. If TRUE or integer, existing column names will be abbreviated to `abbreviate(*, minlength = abbr.colnames)`.  
`lower.triangular` logical. If TRUE and `x` is a matrix, only the *lower triangular* part of the matrix is coded as non-blank.  
`diag.lower.tri`   logical. If `lower.triangular` and this are TRUE, the *diagonal* part of the matrix is shown.

### Value

An atomic character object of class `noquote` and the same dimensions as `x`.

If `legend` is TRUE (as by default when there are more than two classes), the result has an attribute "legend" containing a legend of the returned character codes, in the form

$$c_1 s_1 c_2 s_2 \dots s_n c_{n+1}$$

where  $c_j = \text{cutpoints}[j]$  and  $s_j = \text{symbols}[j]$ .

### Note

The optional (mostly logical) arguments all try to use smart defaults. Specifying them explicitly may lead to considerably improved output in many cases.

NA's:
Cm <- cor(matrix(rnorm(60), 10, 6)); Cm[c(3,6), 2] <- NA
symnum(Cm, show.max = NULL)

Graphical P-values (aka "significance stars"):
pval <- rev(sort(c(outer(1:6, 10^-(1:3))))))
symp <- symnum(pval, corr = FALSE,
 cutpoints = c(0, .001, .01, .05, .1, 1),
 symbols = c("***", "**", "*", ".", " "))
noquote(cbind(P.val = format(pval), Signif = symp))

```

t.test

*Student's t-Test*

## Description

Performs one and two sample t-tests on vectors of data.

## Usage

```

t.test(x, ...)

Default S3 method:
t.test(x, y = NULL,
 alternative = c("two.sided", "less", "greater"),
 mu = 0, paired = FALSE, var.equal = FALSE,
 conf.level = 0.95, ...)

S3 method for class 'formula'
t.test(formula, data, subset, na.action, ...)

```

## Arguments

|             |                                                                                                                                                               |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x           | a (non-empty) numeric vector of data values.                                                                                                                  |
| y           | an optional (non-empty) numeric vector of data values.                                                                                                        |
| alternative | a character string specifying the alternative hypothesis, must be one of "two.sided" (default), "greater" or "less". You can specify just the initial letter. |

|                         |                                                                                                                                                                                                                                                                                                                                                  |
|-------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>mu</code>         | a number indicating the true value of the mean (or difference in means if you are performing a two sample test).                                                                                                                                                                                                                                 |
| <code>paired</code>     | a logical indicating whether you want a paired t-test.                                                                                                                                                                                                                                                                                           |
| <code>var.equal</code>  | a logical variable indicating whether to treat the two variances as being equal. If <code>TRUE</code> then the pooled variance is used to estimate the variance otherwise the Welch (or Satterthwaite) approximation to the degrees of freedom is used.                                                                                          |
| <code>conf.level</code> | confidence level of the interval.                                                                                                                                                                                                                                                                                                                |
| <code>formula</code>    | a formula of the form <code>lhs ~ rhs</code> where <code>lhs</code> is a numeric variable giving the data values and <code>rhs</code> either 1 for a one-sample or paired test or a factor with two levels giving the corresponding groups. If <code>lhs</code> is of class <code>"Pair"</code> and <code>rhs</code> is 1, a paired test is done |
| <code>data</code>       | an optional matrix or data frame (or similar: see <code>model.frame</code> ) containing the variables in the formula <code>formula</code> . By default the variables are taken from <code>environment(formula)</code> .                                                                                                                          |
| <code>subset</code>     | an optional vector specifying a subset of observations to be used.                                                                                                                                                                                                                                                                               |
| <code>na.action</code>  | a function which indicates what should happen when the data contain NAs. Defaults to <code>getOption("na.action")</code> .                                                                                                                                                                                                                       |
| <code>...</code>        | further arguments to be passed to or from methods.                                                                                                                                                                                                                                                                                               |

### Details

`alternative = "greater"` is the alternative that `x` has a larger mean than `y`. For the one-sample case: that the mean is positive.

If `paired` is `TRUE` then both `x` and `y` must be specified and they must be the same length. Missing values are silently removed (in pairs if `paired` is `TRUE`). If `var.equal` is `TRUE` then the pooled estimate of the variance is used. By default, if `var.equal` is `FALSE` then the variance is estimated separately for both groups and the Welch modification to the degrees of freedom is used.

If the input data are effectively constant (compared to the larger of the two means) an error is generated.

### Value

A list with class `"htest"` containing the following components:

|                          |                                                                                                                                     |
|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------|
| <code>statistic</code>   | the value of the t-statistic.                                                                                                       |
| <code>parameter</code>   | the degrees of freedom for the t-statistic.                                                                                         |
| <code>p.value</code>     | the p-value for the test.                                                                                                           |
| <code>conf.int</code>    | a confidence interval for the mean appropriate to the specified alternative hypothesis.                                             |
| <code>estimate</code>    | the estimated mean or difference in means depending on whether it was a one-sample test or a two-sample test.                       |
| <code>null.value</code>  | the specified hypothesized value of the mean or mean difference depending on whether it was a one-sample test or a two-sample test. |
| <code>stderr</code>      | the standard error of the mean (difference), used as denominator in the t-statistic formula.                                        |
| <code>alternative</code> | a character string describing the alternative hypothesis.                                                                           |
| <code>method</code>      | a character string indicating what type of t-test was performed.                                                                    |
| <code>data.name</code>   | a character string giving the name(s) of the data.                                                                                  |

**See Also**[prop.test](#)**Examples**

```
require(graphics)

t.test(1:10, y = c(7:20)) # P = .00001855
t.test(1:10, y = c(7:20, 200)) # P = .1245 -- NOT significant anymore

Classical example: Student's sleep data
plot(extra ~ group, data = sleep)
Traditional interface
with(sleep, t.test(extra[group == 1], extra[group == 2]))

Formula interface
t.test(extra ~ group, data = sleep)

Formula interface to one-sample test
t.test(extra ~ 1, data = sleep)

Formula interface to paired test
The sleep data are actually paired, so could have been in wide format:
sleep2 <- reshape(sleep, direction = "wide",
 idvar = "ID", timevar = "group")
t.test(Pair(extra.1, extra.2) ~ 1, data = sleep2)
```

TDist

*The Student t Distribution***Description**

Density, distribution function, quantile function and random generation for the t distribution with `df` degrees of freedom (and optional non-centrality parameter `ncp`).

**Usage**

```
dt(x, df, ncp, log = FALSE)
pt(q, df, ncp, lower.tail = TRUE, log.p = FALSE)
qt(p, df, ncp, lower.tail = TRUE, log.p = FALSE)
rt(n, df, ncp)
```

**Arguments**

|                         |                                                                                                                                                                       |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x, q</code>       | vector of quantiles.                                                                                                                                                  |
| <code>p</code>          | vector of probabilities.                                                                                                                                              |
| <code>n</code>          | number of observations. If <code>length(n) &gt; 1</code> , the length is taken to be the number required.                                                             |
| <code>df</code>         | degrees of freedom ( $> 0$ , maybe non-integer). <code>df = Inf</code> is allowed.                                                                                    |
| <code>ncp</code>        | non-centrality parameter $\delta$ ; currently except for <code>rt()</code> , only for <code>abs(ncp) &lt;= 37.62</code> . If omitted, use the central t distribution. |
| <code>log, log.p</code> | logical; if TRUE, probabilities <code>p</code> are given as <code>log(p)</code> .                                                                                     |
| <code>lower.tail</code> | logical; if TRUE (default), probabilities are $P[X \leq x]$ , otherwise, $P[X > x]$ .                                                                                 |

## Details

The  $t$  distribution with  $\text{df} = \nu$  degrees of freedom has density

$$f(x) = \frac{\Gamma((\nu + 1)/2)}{\sqrt{\pi\nu}\Gamma(\nu/2)}(1 + x^2/\nu)^{-(\nu+1)/2}$$

for all real  $x$ . It has mean 0 (for  $\nu > 1$ ) and variance  $\frac{\nu}{\nu-2}$  (for  $\nu > 2$ ).

The general *non-central  $t$*  with parameters  $(\nu, \delta) = (\text{df}, \text{ncp})$  is defined as the distribution of  $T_\nu(\delta) := (U + \delta)/\sqrt{V/\nu}$  where  $U$  and  $V$  are independent random variables,  $U \sim \mathcal{N}(0, 1)$  and  $V \sim \chi_\nu^2$  (see [Chisquare](#)).

The most used applications are power calculations for  $t$ -tests:

Let  $T = \frac{\bar{X} - \mu_0}{S/\sqrt{n}}$  where  $\bar{X}$  is the [mean](#) and  $S$  the sample standard deviation ([sd](#)) of  $X_1, X_2, \dots, X_n$  which are i.i.d.  $\mathcal{N}(\mu, \sigma^2)$ . Then  $T$  is distributed as non-central  $t$  with  $\text{df} = n - 1$  degrees of freedom and non-centrality parameter  $\text{ncp} = (\mu - \mu_0)\sqrt{n}/\sigma$ .

## Value

`dt` gives the density, `pt` gives the distribution function, `qt` gives the quantile function, and `rt` generates random deviates.

Invalid arguments will result in return value `NaN`, with a warning.

The length of the result is determined by `n` for `rt`, and is the maximum of the lengths of the numerical arguments for the other functions.

The numerical arguments other than `n` are recycled to the length of the result. Only the first elements of the logical arguments are used.

## Note

Supplying `ncp = 0` uses the algorithm for the non-central distribution, which is not the same algorithm used if `ncp` is omitted. This is to give consistent behaviour in extreme cases with values of `ncp` very near zero.

The code for non-zero `ncp` is principally intended to be used for moderate values of `ncp`: it will not be highly accurate, especially in the tails, for large values.

## Source

The central `dt` is computed via an accurate formula provided by Catherine Loader (see the reference in [dbinom](#)).

For the non-central case of `dt`, C code contributed by Claus Ekstrøm based on the relationship (for  $x \neq 0$ ) to the cumulative distribution.

For the central case of `pt`, a normal approximation in the tails, otherwise via [pbeta](#).

For the non-central case of `pt` based on a C translation of

Lenth, R. V. (1989). *Algorithm AS 243* — Cumulative distribution function of the non-central  $t$  distribution, *Applied Statistics* **38**, 185–189.

This computes the lower tail only, so the upper tail suffers from cancellation and a warning will be given when this is likely to be significant.

For central `qt`, a C translation of

Hill, G. W. (1970) Algorithm 396: Student's  $t$ -quantiles. *Communications of the ACM*, **13**(10), 619–620.

altered to take account of

Hill, G. W. (1981) Remark on Algorithm 396, *ACM Transactions on Mathematical Software*, **7**, 250–1.

The non-central case is done by inversion.

termplot

*Plot Regression Terms*

---

## Description

Plots regression terms against their predictors, optionally with standard errors and partial residuals added.

## Usage

```
termplot(model, data = NULL, envir = environment(formula(model)),
 partial.resid = FALSE, rug = FALSE,
 terms = NULL, se = FALSE,
 xlabs = NULL, ylabs = NULL, main = NULL,
 col.term = 2, lwd.term = 1.5,
 col.se = "orange", lty.se = 2, lwd.se = 1,
 col.res = "gray", cex = 1, pch = par("pch"),
```

```
col.smth = "darkred", lty.smth = 2, span.smth = 2/3,
ask = dev.interactive() && nb.fig < n.tms,
use.factor.levels = TRUE, smooth = NULL, ylim = "common",
plot = TRUE, transform.x = FALSE, ...)
```

### Arguments

|                                            |                                                                                                                                                                                                                                                                                                                                  |
|--------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>model</code>                         | fitted model object                                                                                                                                                                                                                                                                                                              |
| <code>data</code>                          | data frame in which variables in <code>model</code> can be found                                                                                                                                                                                                                                                                 |
| <code>envir</code>                         | environment in which variables in <code>model</code> can be found                                                                                                                                                                                                                                                                |
| <code>partial.resid</code>                 | logical; should partial residuals be plotted?                                                                                                                                                                                                                                                                                    |
| <code>rug</code>                           | add <a href="#">rugplots</a> (jittered 1-d histograms) to the axes?                                                                                                                                                                                                                                                              |
| <code>terms</code>                         | which terms to plot (default <code>NULL</code> means all terms); a vector passed to <a href="#">predict</a> ( <code>..</code> , <code>type = "terms"</code> , <code>terms = *</code> ).                                                                                                                                          |
| <code>se</code>                            | plot pointwise standard errors?                                                                                                                                                                                                                                                                                                  |

| <code>col.res, cex, pch</code>             | color, plotting character expansion and type for partial residuals, when <code>partial.resid = TRUE</code> , see <a href="#">points</a> .                                                                                                                                                                                        |
| <code>ask</code>                           | logical; if <code>TRUE</code> , the user is <i>asked</i> before each plot, see <a href="#">par</a> ( <code>ask=.</code> ).                                                                                                                                                                                                       |
| <code>use.factor.levels</code>             | Should x-axis ticks use factor levels or numbers for factor terms?                                                                                                                                                                                                                                                               |
| <code>smooth</code>                        | <code>NULL</code> or a function with the same arguments as <a href="#">panel.smooth</a> to draw a smooth through the partial residuals for non-factor terms                                                                                                                                                                      |
| <code>lty.smth, col.smth, span.smth</code> | Passed to <code>smooth</code>                                                                                                                                                                                                                                                                                                    |
| <code>ylim</code>                          | an optional range for the y axis, or <code>"common"</code> when a range sufficient for all the plot will be computed, or <code>"free"</code> when limits are computed for each plot.                                                                                                                                             |
| <code>plot</code>                          | if set to <code>FALSE</code> plots are not produced: instead a list is returned containing the data that would have been plotted.                                                                                                                                                                                                |
| <code>transform.x</code>                   | logical vector; if an element (recycled as necessary) is <code>TRUE</code> , partial residuals for the corresponding term are plotted against transformed values. The model response is then a straight line, allowing a ready comparison against the data or against the curve obtained from <code>smooth-panel.smooth</code> . |
| <code>...</code>                           | other graphical parameters.                                                                                                                                                                                                                                                                                                      |

## Details

The model object must have a `predict` method that accepts `type = "terms"`, e.g., `glm` in the **stats** package, `coxph` and `survreg` in the **survival** package.

For the `partial.resid = TRUE` option model must have a `residuals` method that accepts `type = "partial"`, which `lm` and `glm` do.

The `data` argument should rarely be needed, but in some cases `termplot` may be unable to reconstruct the original data frame. Using `na.action=na.exclude` makes these problems less likely.

Nothing sensible happens for interaction terms, and they may cause errors.

The `plot = FALSE` option is useful when some special action is needed, e.g. to overlay the results of two different models or to plot confidence bands.

## Value

For `plot = FALSE`, a list with one element for each plot which would have been produced. Each element of the list is a data frame with variables `x`, `y`, and optionally the pointwise standard errors `se`. For continuous predictors `x` will contain the ordered unique values and for a factor it will be a factor containing one instance of each level. The list has attribute `"constant"` copied from the predicted terms object.

Otherwise, the number of terms, invisibly.

## See Also

For (generalized) linear models, `plot.lm` and `predict.glm`.

## Examples

```
require(graphics)

had.splines <- "package:splines" %in% search()
if(!had.splines) rs <- require(splines)
x <- 1:100
z <- factor(rep(LETTERS[1:4], 25))
y <- rnorm(100, sin(x/10)+as.numeric(z))
model <- glm(y ~ ns(x, 6) + z)

par(mfrow = c(2,2)) ## 2 x 2 plots for same model :
termplot(model, main = paste("termplot(", deparse(model$call), " ..."))
termplot(model, rug = TRUE)
termplot(model, partial.resid = TRUE, se = TRUE, main = TRUE)
termplot(model, partial.resid = TRUE, smooth = panel.smooth, span.smth = 1/4)
if(!had.splines && rs) detach("package:splines")

requires recommended package MASS
hills.lm <- lm(log(time) ~ log(climb)+log(dist), data = MASS::hills)
termplot(hills.lm, partial.resid = TRUE, smooth = panel.smooth,
 terms = "log(dist)", main = "Original")
termplot(hills.lm, transform.x = TRUE,
 partial.resid = TRUE, smooth = panel.smooth,
 terms = "log(dist)", main = "Transformed")
```

terms

*Model Terms***Description**

The function `terms` is a generic function which can be used to extract *terms* objects from various kinds of R data objects.

**Usage**

```
terms(x, ...)
```

**Arguments**

`x`                      object used to select a method to dispatch.  
`...`                    further arguments passed to or from other methods.

**Details**

There are methods for classes "aovlist", and "terms" "formula" (see [terms.formula](#)): the default method just extracts the `terms` component of the object, or failing that a "terms" attribute (as used by [model.frame](#)).

There are [print](#) and [labels](#) methods for class "terms": the latter prints the term labels (see [terms.object](#)).

**Value**

An object of class `c("terms", "formula")` which contains the *terms* representation of a symbolic model. See [terms.object](#) for its structure.

terms.formula

*Construct a terms Object from a Formula***Description**

This function takes a formula and some optional arguments and constructs a terms object. The terms object can then be used to construct a [model.matrix](#).

**Usage**

```
S3 method for class 'formula'
terms(x, specials = NULL, abb = NULL, data = NULL, neg.out = TRUE,
 keep.order = FALSE, simplify = FALSE, ...,
 allowDotAsName = FALSE)
```

**Arguments**

|                             |                                                                                                                                                                                                                                                                                               |
|-----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>              | a formula.                                                                                                                                                                                                                                                                                    |
| <code>specials</code>       | which functions in the formula should be marked as special in the <code>terms</code> object? A character vector or <code>NULL</code> .                                                                                                                                                        |
| <code>abb</code>            | Not implemented in R.                                                                                                                                                                                                                                                                         |
| <code>data</code>           | a data frame from which the meaning of the special symbol <code>.</code> can be inferred. It is unused if there is no <code>.</code> in the formula.                                                                                                                                          |
| <code>neg.out</code>        | Not implemented in R.                                                                                                                                                                                                                                                                         |
| <code>keep.order</code>     | a logical value indicating whether the terms should keep their positions. If <code>FALSE</code> the terms are reordered so that main effects come first, followed by the interactions, all second-order, all third-order and so on. Effects of a given order are kept in the order specified. |
| <code>simplify</code>       | should the formula be expanded and simplified, the pre-1.7.0 behaviour?                                                                                                                                                                                                                       |
| <code>...</code>            | further arguments passed to or from other methods.                                                                                                                                                                                                                                            |
| <code>allowDotAsName</code> | normally <code>.</code> in a formula refers to the remaining variables contained in <code>data</code> . Exceptionally, <code>.</code> can be treated as a name for non-standard uses of formulae.                                                                                             |

**Details**

Not all of the options work in the same way that they do in S and not all are implemented.

**Value**

A `terms.object` object is returned. The object itself is the re-ordered (unless `keep.order = TRUE`) formula. In all cases variables within an interaction term in the formula are re-ordered by the ordering of the `"variables"` attribute, which is the order in which the variables occur in the formula.

`terms.object`

*Description of Terms Objects*

---

**Description**

An object of class `terms` holds information about a model. Usually the model was specified in terms of a `formula` and that formula was used to determine the terms object.

**Value**

The object itself is simply the formula supplied to the call of `terms.formula`. The object has a number of attributes and they are used to construct the model frame:

|                          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>factors</code>     | A matrix of variables by terms showing which variables appear in which terms. The entries are 0 if the variable does not occur in the term, 1 if it does occur and should be coded by contrasts, and 2 if it occurs and should be coded via dummy variables for all levels (as when a lower-order term is missing). Note that variables in main effects always receive 1, even if the intercept is missing (in which case the first one should be coded with dummy variables). If there are no terms other than an intercept and offsets, this is <code>numeric(0)</code> . |
| <code>term.labels</code> | A character vector containing the labels for each of the terms in the model, except for offsets. Note that these are after possible re-ordering of terms.<br>Non-syntactic names will be quoted by backticks: this makes it easier to re-construct the formula from the term labels.                                                                                                                                                                                                                                                                                        |
| <code>variables</code>   | A call to <code>list</code> of the variables in the model.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <code>intercept</code>   | Either 0, indicating no intercept is to be fit, or 1 indicating that an intercept is to be fit.                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>order</code>       | A vector of the same length as <code>term.labels</code> indicating the order of interaction for each term.                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <code>response</code>    | The index of the variable (in <code>variables</code> ) of the response (the left hand side of the formula). Zero, if there is no response.                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <code>offset</code>      | If the model contains <code>offset</code> terms there is an <code>offset</code> attribute indicating which variable(s) are offsets                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <code>specials</code>    | If a <code>specials</code> argument was given to <code>terms.formula</code> there is a <code>specials</code> attribute, a pairlist of vectors (one for each specified special function) giving numeric indices of the arguments of the list returned as the <code>variables</code> attribute which contain these special functions.                                                                                                                                                                                                                                         |
| <code>dataClasses</code> | optional. A named character vector giving the classes (as given by <code>.MFclass</code> ) of the variables used in a fit.                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <code>predvars</code>    | optional. An expression to help in computing predictions at new covariate values; see <code>makepredictcall</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

The object has class `c("terms", "formula")`.

**Note**

These objects are different from those found in S. In particular there is no `formula` attribute: instead the object is itself a formula. (Thus, the mode of a terms object is different.)

Examples of the `specials` argument can be seen in the `aov` and `coxph` functions, the latter from package **survival**.

**See Also**

`terms`, `formula`.

## Examples

```
use of specials (as used for gam() in packages mgcv and gam)
(tf <- terms(y ~ x + x:z + s(x), specials = "s"))
Note that the "factors" attribute has variables as row names
and term labels as column names, both as character vectors.
attr(tf, "specials") # index 's' variable(s)
rownames(attr(tf, "factors"))[attr(tf, "specials")]$s

we can keep the order by
terms(y ~ x + x:z + s(x), specials = "s", keep.order = TRUE)
```

time

*Sampling Times of Time Series*

## Description

`time` creates the vector of times at which a time series was sampled.

`cycle` gives the positions in the cycle of each observation.

`frequency` returns the number of samples per unit time and `deltat` the time interval between observations (see [ts](#)).

## Usage

```
time(x, ...)
Default S3 method:
time(x, offset = 0, ...)

cycle(x, ...)
frequency(x, ...)
deltat(x, ...)
```

## Arguments

|                     |                                                                                                                                                                   |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>      | a univariate or multivariate time-series, or a vector or matrix.                                                                                                  |
| <code>offset</code> | can be used to indicate when sampling took place in the time unit. 0 (the default) indicates the start of the unit, 0.5 the middle and 1 the end of the interval. |
| <code>...</code>    | extra arguments for future methods.                                                                                                                               |

## Details

These are all generic functions, which will use the `tsp` attribute of `x` if it exists. `time` and `cycle` have methods for class `ts` that coerce the result to that class.

**Examples**

```
require(graphics)

cycle(presidents)
a simple series plot
plot(as.vector(time(presidents)), as.vector(presidents), type = "l")
```

---

toeplitz

*Form Symmetric Toeplitz Matrix*

---

**Description**

Forms a symmetric Toeplitz matrix given its first row.

**Usage**

```
toeplitz(x)
```

**Arguments**

`x` the first row to form the Toeplitz matrix.

**Value**

The Toeplitz matrix.

**Author(s)**

A. Trapletti

**Examples**

```
x <- 1:5
toeplitz(x)
```

---

ts

*Time-Series Objects*

---

**Description**

The function `ts` is used to create time-series objects.

`as.ts` and `is.ts` coerce an object to a time-series and test whether an object is a time series.

**Usage**

```
ts(data = NA, start = 1, end = numeric(), frequency = 1,
 deltat = 1, ts.eps = getOption("ts.eps"), class = , names =)
as.ts(x, ...)
is.ts(x)
```

## Arguments

|                        |                                                                                                                                                                                                                                                                    |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>data</code>      | a vector or matrix of the observed time-series values. A data frame will be coerced to a numeric matrix via <code>data.matrix</code> . (See also ‘Details’.)                                                                                                       |
| <code>start</code>     | the time of the first observation. Either a single number or a vector of two numbers (the second of which is an integer), which specify a natural time unit and a (1-based) number of samples into the time unit. See the examples for the use of the second form. |
| <code>end</code>       | the time of the last observation, specified in the same way as <code>start</code> .                                                                                                                                                                                |
| <code>frequency</code> | the number of observations per unit of time.                                                                                                                                                                                                                       |
| <code>deltat</code>    | the fraction of the sampling period between successive observations; e.g., 1/12 for monthly data. Only one of <code>frequency</code> or <code>deltat</code> should be provided.                                                                                    |
| <code>ts.eps</code>    | time series comparison tolerance. Frequencies are considered equal if their absolute difference is less than <code>ts.eps</code> .                                                                                                                                 |
| <code>class</code>     | class to be given to the result, or none if <code>NULL</code> or <code>"none"</code> . The default is <code>"ts"</code> for a single series, <code>c("mts", "ts", "matrix")</code> for multiple series.                                                            |
| <code>names</code>     | a character vector of names for the series in a multiple series: defaults to the <code>colnames</code> of <code>data</code> , or <code>Series 1, Series 2, ...</code> .                                                                                            |
| <code>x</code>         | an arbitrary R object.                                                                                                                                                                                                                                             |
| <code>...</code>       | arguments passed to methods (unused for the default method).                                                                                                                                                                                                       |

## Details

The function `ts` is used to create time-series objects. These are vectors or matrices with class of `"ts"` (and additional attributes) which represent data which has been sampled at equispaced points in time. In the matrix case, each column of the matrix `data` is assumed to contain a single (univariate) time series. Time series must have at least one observation, and although they need not be numeric there is very limited support for non-numeric series.

Class `"ts"` has a number of methods. In particular arithmetic will attempt to align time axes, and subsetting to extract subsets of series can be used (e.g., `EuStockMarkets[, "DAX"]`). However, subsetting the first (or only) dimension will return a matrix or vector, as will matrix subsetting. Subassignment can be used to replace values but not to extend a series (see [window](#)). There is a method for `t` that transposes the series as a matrix (a one-column matrix if a vector) and hence returns a result that does not inherit from class `"ts"`.

Argument `frequency` indicates the sampling frequency of the time series, with the default value 1 indicating one sample in each unit time interval. For example, one could use a value of 7 for `frequency` when the data are sampled daily, and the natural time period is a week, or 12 when the data are sampled monthly and the natural time period is a year. Values of 4 and 12 are assumed in (e.g.) `print` methods to imply a quarterly and monthly series respectively. As from R 4.0.0, `frequency` need not be a whole number. For example, `frequency = 0.2` would imply sampling once every five time units.

`as.ts` is generic. Its default method will use the `ts$` attribute of the object if it has one to set the start and end times and frequency.

`is.ts` tests if an object is a time series. It is generic: you can write methods to handle specific classes of objects, see [InternalMethods](#).

**See Also**

`tsp`, `frequency`, `start`, `end`, `time`, `window`; `print.ts`, the print method for time series objects; `plot.ts`, the plot method for time series objects.

For other definitions of ‘time series’ (e.g., time-ordered observations) see the CRAN task view at <https://CRAN.R-project.org/view=TimeSeries>.

**Examples**

```
require(graphics)

ts(1:10, frequency = 4, start = c(1959, 2)) # 2nd Quarter of 1959
print(ts(1:10, frequency = 7, start = c(12, 2)), calendar = TRUE)
print.ts(.)
Using July 1954 as start date:
gnp <- ts(cumsum(1 + round(rnorm(100), 2)),
 start = c(1954, 7), frequency = 12)
plot(gnp) # using 'plot.ts' for time-series plot

Multivariate
z <- ts(matrix(rnorm(300), 100, 3), start = c(1961, 1), frequency = 12)
class(z)
head(z) # as "matrix"
plot(z)
plot(z, plot.type = "single", lty = 1:3)

A phase plot:
plot(nhtemp, lag(nhtemp, 1), cex = .8, col = "blue",
 main = "Lag plot of New Haven temperatures")
```

ts-methods

*Methods for Time Series Objects***Description**

Methods for objects of class "ts", typically the result of `ts`.

**Usage**

```
S3 method for class 'ts'
diff(x, lag = 1, differences = 1, ...)

S3 method for class 'ts'
na.omit(object, ...)
```

**Arguments**

|                          |                                                                  |
|--------------------------|------------------------------------------------------------------|
| <code>x</code>           | an object of class "ts" containing the values to be differenced. |
| <code>lag</code>         | an integer indicating which lag to use.                          |
| <code>differences</code> | an integer indicating the order of the difference.               |
| <code>object</code>      | a univariate or multivariate time series.                        |
| <code>...</code>         | further arguments to be passed to or from methods.               |

**Details**

The `na.omit` method omits initial and final segments with missing values in one or more of the series. ‘Internal’ missing values will lead to failure.

**Value**

For the `na.omit` method, a time series without missing values. The class of object will be preserved.

**See Also**

[diff](#); [na.omit](#), [na.fail](#), [na.contiguous](#).

---

|         |                                  |
|---------|----------------------------------|
| ts.plot | <i>Plot Multiple Time Series</i> |
|---------|----------------------------------|

---

**Description**

Plot several time series on a common plot. Unlike [plot.ts](#) the series can have a different time bases, but they should have the same frequency.

**Usage**

```
ts.plot(..., gpars = list())
```

**Arguments**

|                    |                                                                                                                                            |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------|
| <code>...</code>   | one or more univariate or multivariate time series.                                                                                        |
| <code>gpars</code> | list of named graphics parameters to be passed to the plotting functions. Those commonly used can be supplied directly in <code>...</code> |

**Value**

None.

**Note**

Although this can be used for a single time series, `plot` is easier to use and is preferred.

**See Also**

[plot.ts](#)

**Examples**

```
require(graphics)

ts.plot(ldeaths, mdeaths, fdeaths,
 gpars=list(xlab="year", ylab="deaths", lty=c(1:3)))
```

---

`ts.union`*Bind Two or More Time Series*

---

## Description

Bind time series which have a common frequency. `ts.union` pads with NAs to the total time coverage, `ts.intersect` restricts to the time covered by all the series.

## Usage

```
ts.intersect(..., dframe = FALSE)
ts.union(..., dframe = FALSE)
```

## Arguments

|                     |                                                                                                  |
|---------------------|--------------------------------------------------------------------------------------------------|
| <code>...</code>    | two or more univariate or multivariate time series, or objects which can coerced to time series. |
| <code>dframe</code> | logical; if TRUE return the result as a data frame.                                              |

## Details

As a special case, `...` can contain vectors or matrices of the same length as the combined time series of the time series present, as well as those of a single row.

## Value

A time series object if `dframe` is FALSE, otherwise a data frame.

## See Also

[cbind](#).

## Examples

```
ts.union(mdeaths, fdeaths)
cbind(mdeaths, fdeaths) # same as the previous line
ts.intersect(window(mdeaths, 1976), window(fdeaths, 1974, 1978))

sales1 <- ts.union(BJsales, lead = BJsales.lead)
ts.intersect(sales1, lead3 = lag(BJsales.lead, -3))
```

---

tsdiag*Diagnostic Plots for Time-Series Fits*

---

## Description

A generic function to plot time-series diagnostics.

## Usage

```
tsdiag(object, gof.lag, ...)
```

## Arguments

|                      |                                                                   |
|----------------------|-------------------------------------------------------------------|
| <code>object</code>  | a fitted time-series model                                        |
| <code>gof.lag</code> | the maximum number of lags for a Portmanteau goodness-of-fit test |
| <code>...</code>     | further arguments to be passed to particular methods              |

## Details

This is a generic function. It will generally plot the residuals, often standardized, the autocorrelation function of the residuals, and the p-values of a Portmanteau test for all lags up to `gof.lag`.

The methods for [arima](#) and [StructTS](#) objects plots residuals scaled by the estimate of their (individual) variance, and use the Ljung–Box version of the portmanteau test.

## Value

None. Diagnostics are plotted.

## See Also

[arima](#), [StructTS](#), [Box.test](#)

## Examples

```
require(graphics)

fit <- arima(lh, c(1,0,0))
tsdiag(fit)

see also examples(arima)

(fit <- StructTS(log10(JohnsonJohnson), type = "BSM"))
tsdiag(fit)
```

tsp

*Tsp Attribute of Time-Series-like Objects***Description**

tsp returns the tsp attribute (or NULL). It is included for compatibility with S version 2. tsp<- sets the tsp attribute. hasTsp ensures x has a tsp attribute, by adding one if needed.

**Usage**

```
tsp(x)
tsp(x) <- value
hasTsp(x)
```

**Arguments**

x                    a vector or matrix or univariate or multivariate time-series.  
 value                a numeric vector of length 3 or NULL.

**Details**

The tsp attribute gives the start time *in time units*, the end time and the frequency (the number of observations per unit of time, e.g. 12 for a monthly series).

Assignments are checked for consistency.

Assigning NULL which removes the tsp attribute *and* any "ts" (or "mts") class of x.

**Value**

An object which differs from x only in the tsp attribute (unless NULL is assigned).

hasTsp adds, if needed, an attribute with a start time and frequency of 1 and end time [NROW](#)(x).

**See Also**

[ts](#), [time](#), [start](#).

---

tsSmooth

*Use Fixed-Interval Smoothing on Time Series*

---

**Description**

Performs fixed-interval smoothing on a univariate time series via a state-space model. Fixed-interval smoothing gives the best estimate of the state at each time point based on the whole observed series.

**Usage**

```
tsSmooth(object, ...)
```

**Arguments**

`object` a time-series fit. Currently only class "[StructTS](#)" is supported  
`...` possible arguments for future methods.

**Value**

A time series, with as many dimensions as the state space and results at each time point of the original series. (For seasonal models, only the current seasonal component is returned.)

**Author(s)**

B. D. Ripley

---

Tukey

*The Studentized Range Distribution*

---

**Description**

Functions of the distribution of the studentized range,  $R/s$ , where  $R$  is the range of a standard normal sample and  $df \times s^2$  is independently distributed as chi-squared with  $df$  degrees of freedom, see [pchisq](#).

**Usage**

```
ptukey(q, nmeans, df, nranges = 1, lower.tail = TRUE, log.p = FALSE)
qtukey(p, nmeans, df, nranges = 1, lower.tail = TRUE, log.p = FALSE)
```

## Arguments

|                         |                                                                                       |
|-------------------------|---------------------------------------------------------------------------------------|
| <code>q</code>          | vector of quantiles.                                                                  |
| <code>p</code>          | vector of probabilities.                                                              |
| <code>nmeans</code>     | sample size for range (same for each group).                                          |
| <code>df</code>         | degrees of freedom for $s$ (see below).                                               |
| <code>nranges</code>    | number of <i>groups</i> whose <b>maximum</b> range is considered.                     |
| <code>log.p</code>      | logical; if TRUE, probabilities <code>p</code> are given as $\log(p)$ .               |
| <code>lower.tail</code> | logical; if TRUE (default), probabilities are $P[X \leq x]$ , otherwise, $P[X > x]$ . |

## Details

If  $n_g = \text{nranges}$  is greater than one,  $R$  is the *maximum* of  $n_g$  groups of `nmeans` observations each.

## Value

`ptukey` gives the distribution function and `qtukey` its inverse, the quantile function.

The length of the result is the maximum of the lengths of the numerical arguments. The other numerical arguments are recycled to that length. Only the first elements of the logical arguments are used.

## Note

A Legendre 16-point formula is used for the integral of `ptukey`. The computations are relatively expensive, especially for `qtukey` which uses a simple secant method for finding the inverse of `ptukey`. `qtukey` will be accurate to the 4th decimal place.

## Source

`qtukey` is in part adapted from Odeh and Evans (1974).

**Examples**

```

if(interactive())
 curve(ptukey(x, nm = 6, df = 5), from = -1, to = 8, n = 101)
(ptt <- ptukey(0:10, 2, df = 5))
(qtt <- qtukey(.95, 2, df = 2:11))
The precision may be not much more than about 8 digits:
summary(abs(.95 - ptukey(qtt, 2, df = 2:11)))

```

TukeyHSD

*Compute Tukey Honest Significant Differences***Description**

Create a set of confidence intervals on the differences between the means of the levels of a factor with the specified family-wise probability of coverage. The intervals are based on the Studentized range statistic, Tukey's 'Honest Significant Difference' method.

**Usage**

```
TukeyHSD(x, which, ordered = FALSE, conf.level = 0.95, ...)
```

**Arguments**

|                         |                                                                                                                                                                                                                                                                                                                                                      |
|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>          | A fitted model object, usually an <code>aoV</code> fit.                                                                                                                                                                                                                                                                                              |
| <code>which</code>      | A character vector listing terms in the fitted model for which the intervals should be calculated. Defaults to all the terms.                                                                                                                                                                                                                        |
| <code>ordered</code>    | A logical value indicating if the levels of the factor should be ordered according to increasing average in the sample before taking differences. If <code>ordered</code> is true then the calculated differences in the means will all be positive. The significant differences will be those for which the <code>lwr</code> end point is positive. |
| <code>conf.level</code> | A numeric value between zero and one giving the family-wise confidence level to use.                                                                                                                                                                                                                                                                 |
| <code>...</code>        | Optional additional arguments. None are used at present.                                                                                                                                                                                                                                                                                             |

**Details**

This is a generic function: the description here applies to the method for fits of class `"aoV"`.

When comparing the means for the levels of a factor in an analysis of variance, a simple comparison using t-tests will inflate the probability of declaring a significant difference when it is not in fact present. This because the intervals are calculated with a given coverage probability for each interval but the interpretation of the coverage is usually with respect to the entire family of intervals.

John Tukey introduced intervals based on the range of the sample means rather than the individual differences. The intervals returned by this function are based on this Studentized range statistics.

The intervals constructed in this way would only apply exactly to balanced designs where there are the same number of observations made at each level of the factor. This function incorporates an adjustment for sample size that produces sensible intervals for mildly unbalanced designs.

If `which` specifies non-factor terms these will be dropped with a warning: if no terms are left this is an error.

**Value**

A list of class `c("multicomp", "TukeyHSD")`, with one component for each term requested in which. Each component is a matrix with columns `diff` giving the difference in the observed means, `lwr` giving the lower end point of the interval, `upr` giving the upper end point and `p.adj` giving the p-value after adjustment for the multiple comparisons.

There are `print` and `plot` methods for class `"TukeyHSD"`. The `plot` method does not accept `xlab`, `ylab` or `main` arguments and creates its own values for each plot.

summary(fm1 <- aov(breaks ~ wool + tension, data = warpbreaks))
TukeyHSD(fm1, "tension", ordered = TRUE)
plot(TukeyHSD(fm1, "tension"))
```

---

Uniform

---

*The Uniform Distribution*

---

**Description**

These functions provide information about the uniform distribution on the interval from `min` to `max`. `dunif` gives the density, `punif` gives the distribution function, `qunif` gives the quantile function and `runif` generates random deviates.

**Usage**

```
dunif(x, min = 0, max = 1, log = FALSE)
punif(q, min = 0, max = 1, lower.tail = TRUE, log.p = FALSE)
qunif(p, min = 0, max = 1, lower.tail = TRUE, log.p = FALSE)
runif(n, min = 0, max = 1)
```

**Arguments**

|                         |                                                                                                           |
|-------------------------|-----------------------------------------------------------------------------------------------------------|
| <code>x, q</code>       | vector of quantiles.                                                                                      |
| <code>p</code>          | vector of probabilities.                                                                                  |
| <code>n</code>          | number of observations. If <code>length(n) &gt; 1</code> , the length is taken to be the number required. |
| <code>min, max</code>   | lower and upper limits of the distribution. Must be finite.                                               |
| <code>log, log.p</code> | logical; if TRUE, probabilities <code>p</code> are given as $\log(p)$ .                                   |
| <code>lower.tail</code> | logical; if TRUE (default), probabilities are $P[X \leq x]$ , otherwise, $P[X > x]$ .                     |

**Details**

If `min` or `max` are not specified they assume the default values of 0 and 1 respectively.

The uniform distribution has density

$$f(x) = \frac{1}{\max - \min}$$

for  $\min \leq x \leq \max$ .

For the case of  $u := \min == \max$ , the limit case of  $X \equiv u$  is assumed, although there is no density in that case and `dunif` will return `NaN` (the error condition).

`runif` will not generate either of the extreme values unless  $\max = \min$  or  $\max - \min$  is small compared to `min`, and in particular not for the default arguments.

**Value**

`dunif` gives the density, `punif` gives the distribution function, `qunif` gives the quantile function, and `runif` generates random deviates.

The length of the result is determined by `n` for `runif`, and is the maximum of the lengths of the numerical arguments for the other functions.

The numerical arguments other than `n` are recycled to the length of the result. Only the first elements of the logical arguments are used.

**Note**

The characteristics of output from pseudo-random number generators (such as precision and periodicity) vary widely. See [.Random.seed](#) for more information on R's random number generation algorithms.

## Examples

```
u <- runif(20)

The following relations always hold :
punif(u) == u
dunif(u) == 1

var(runif(10000)) #- ~ = 1/12 = .08333
```

---

uniroot

*One Dimensional Root (Zero) Finding*

---

## Description

The function `uniroot` searches the interval from `lower` to `upper` for a root (i.e., zero) of the function `f` with respect to its first argument.

Setting `extendInt` to a non-"no" string, means searching for the correct interval = `c(lower, upper)` if `sign(f(x))` does not satisfy the requirements at the interval end points; see the 'Details' section.

## Usage

```
uniroot(f, interval, ...,
 lower = min(interval), upper = max(interval),
 f.lower = f(lower, ...), f.upper = f(upper, ...),
 extendInt = c("no", "yes", "downX", "upX"), check.conv = FALSE,
 tol = .Machine$double.eps^0.25, maxiter = 1000, trace = 0)
```

## Arguments

|                               |                                                                                                                                                                                                                                                                                              |
|-------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>f</code>                | the function for which the root is sought.                                                                                                                                                                                                                                                   |
| <code>interval</code>         | a vector containing the end-points of the interval to be searched for the root.                                                                                                                                                                                                              |
| <code>...</code>              | additional named or unnamed arguments to be passed to <code>f</code>                                                                                                                                                                                                                         |
| <code>lower, upper</code>     | the lower and upper end points of the interval to be searched.                                                                                                                                                                                                                               |
| <code>f.lower, f.upper</code> | the same as <code>f(upper)</code> and <code>f(lower)</code> , respectively. Passing these values from the caller where they are often known is more economical as soon as <code>f()</code> contains non-trivial computations.                                                                |
| <code>extendInt</code>        | character string specifying if the interval <code>c(lower, upper)</code> should be extended or directly produce an error when <code>f()</code> does not have differing signs at the endpoints. The default, "no", keeps the search interval and hence produces an error. Can be abbreviated. |
| <code>check.conv</code>       | logical indicating whether a convergence warning of the underlying <code>uniroot</code> should be caught as an error and if non-convergence in <code>maxiter</code> iterations should be an error instead of a warning.                                                                      |
| <code>tol</code>              | the desired accuracy (convergence tolerance).                                                                                                                                                                                                                                                |
| <code>maxiter</code>          | the maximum number of iterations.                                                                                                                                                                                                                                                            |
| <code>trace</code>            | integer number; if positive, tracing information is produced. Higher values giving more details.                                                                                                                                                                                             |

## Details

Note that arguments after `...` must be matched exactly.

Either `interval` or both `lower` and `upper` must be specified: the upper endpoint must be strictly larger than the lower endpoint. The function values at the endpoints must be of opposite signs (or zero), for `extendInt="no"`, the default. Otherwise, if `extendInt="yes"`, the interval is extended on both sides, in search of a sign change, i.e., until the search interval  $[l, u]$  satisfies  $f(l) \cdot f(u) \leq 0$ .

If it is *known how*  $f$  changes sign at the root  $x_0$ , that is, if the function is increasing or decreasing there, `extendInt` can (and typically should) be specified as `"upX"` (for “upward crossing”) or `"downX"`, respectively. Equivalently, define  $S := \pm 1$ , to require  $S = \text{sign}(f(x_0 + \epsilon))$  at the solution. In that case, the search interval  $[l, u]$  possibly is extended to be such that  $S \cdot f(l) \leq 0$  and  $S \cdot f(u) \geq 0$ .

`uniroot()` uses Fortran subroutine `"zeroin"` (from Netlib) based on algorithms given in the reference below. They assume a continuous function (which then is known to have at least one root in the interval).

Convergence is declared either if  $f(x) == 0$  or the change in  $x$  for one step of the algorithm is less than `tol` (plus an allowance for representation error in  $x$ ).

If the algorithm does not converge in `maxiter` steps, a warning is printed and the current approximation is returned.

$f$  will be called as  $f(x, \dots)$  for a numeric value of  $x$ .

The argument passed to  $f$  has special semantics and used to be shared between calls. The function should not copy it.

## Value

A list with at least four components: `root` and `f.root` give the location of the root and the value of the function evaluated at that point. `iter` and `estim.prec` give the number of iterations used and an approximate estimated precision for `root`. (If the root occurs at one of the endpoints, the estimated precision is NA.)

Further components may be added in future: component `init.it` was added in R 3.1.0.

## Source

Based on `'zeroin.c'` in <https://www.netlib.org/c/brent.shar>.

## References

## See Also

[polyroot](#) for all complex roots of a polynomial; [optimize](#), [nlm](#).

## Examples

```
require(utils) # for str

some platforms hit zero exactly on the first step:
if so the estimated precision is 2/3.
f <- function (x, a) x - a
```

```

str(xmin <- uniroot(f, c(0, 1), tol = 0.0001, a = 1/3))

handheld calculator example: fixed point of cos(.):
uniroot(function(x) cos(x) - x, lower = -pi, upper = pi, tol = 1e-9)$root

str(uniroot(function(x) x*(x^2-1) + .5, lower = -2, upper = 2,
 tol = 0.0001))
str(uniroot(function(x) x*(x^2-1) + .5, lower = -2, upper = 2,
 tol = 1e-10))

Find the smallest value x for which exp(x) > 0 (numerically):
r <- uniroot(function(x) 1e80*exp(x) - 1e-300, c(-1000, 0), tol = 1e-15)
str(r, digits.d = 15) # around -745, depending on the platform.

exp(r$root) # = 0, but not for r$root * 0.999...
minexp <- r$root * (1 - 10*.Machine$double.eps)
exp(minexp) # typically denormalized

##--- uniroot() with new interval extension + checking features: -----

f1 <- function(x) (121 - x^2)/(x^2+1)
f2 <- function(x) exp(-x)*(x - 12)

try(uniroot(f1, c(0,10)))
try(uniroot(f2, c(0, 2)))
##--> error: f() .. end points not of opposite sign

where as 'extendInt="yes"' simply first enlarges the search interval:
u1 <- uniroot(f1, c(0,10),extendInt="yes", trace=1)
u2 <- uniroot(f2, c(0,2), extendInt="yes", trace=2)
stopifnot(all.equal(u1$root, 11, tolerance = 1e-5),
 all.equal(u2$root, 12, tolerance = 6e-6))

The *danger* of interval extension:
No way to find a zero of a positive function, but
numerically, f(-|M|) becomes zero :
u3 <- uniroot(exp, c(0,2), extendInt="yes", trace=TRUE)

Nonsense example (must give an error):
tools::assertCondition(uniroot(function(x) 1, 0:1, extendInt="yes"),
 "error", verbose=TRUE)

Convergence checking :
sinc <- function(x) ifelse(x == 0, 1, sin(x)/x)
curve(sinc, -6,18); abline(h=0,v=0, lty=3, col=adjustcolor("gray", 0.8))

uniroot(sinc, c(0,5), extendInt="yes", maxiter=4) #-> "just" a warning

now with check.conv=TRUE, must signal a convergence error :

uniroot(sinc, c(0,5), extendInt="yes", maxiter=4, check.conv=TRUE)

Weibull cumulative hazard (example origin, Ravi Varadhan):
cumhaz <- function(t, a, b) b * (t/b)^a

```

```

froot <- function(x, u, a, b) cumhaz(x, a, b) - u

n <- 1000
u <- -log(runif(n))
a <- 1/2
b <- 1
Find failure times
ru <- sapply(u, function(x)
 uniroot(froot, u=x, a=a, b=b, interval= c(1.e-14, 1e04),
 extendInt="yes")$root)
ru2 <- sapply(u, function(x)
 uniroot(froot, u=x, a=a, b=b, interval= c(0.01, 10),
 extendInt="yes")$root)
stopifnot(all.equal(ru, ru2, tolerance = 6e-6))

r1 <- uniroot(froot, u= 0.99, a=a, b=b, interval= c(0.01, 10),
 extendInt="up")
stopifnot(all.equal(0.99, cumhaz(r1$root, a=a, b=b)))

An error if 'extendInt' assumes "wrong zero-crossing direction":
uniroot(froot, u= 0.99, a=a, b=b, interval= c(0.1, 10), extendInt="down")

```

---

update

---

*Update and Re-fit a Model Call*

---

## Description

`update` will update and (by default) re-fit a model. It does this by extracting the call stored in the object, updating the call and (by default) evaluating that call. Sometimes it is useful to call `update` with only one argument, for example if the data frame has been corrected.

“Extracting the call” in `update()` and similar functions uses `getCall()` which itself is a (S3) generic function with a default method that simply gets `x$call`.

Because of this, `update()` will often work (via its default method) on new model classes, either automatically, or by providing a simple `getCall()` method for that class.

## Usage

```

update(object, ...)
Default S3 method:
update(object, formula., ..., evaluate = TRUE)

getCall(x, ...)

```

## Arguments

|                        |                                                                                                                               |
|------------------------|-------------------------------------------------------------------------------------------------------------------------------|
| <code>object, x</code> | An existing fit from a model function such as <code>lm</code> , <code>glm</code> and many others.                             |
| <code>formula.</code>  | Changes to the formula – see <code>update.formula</code> for details.                                                         |
| <code>...</code>       | Additional arguments to the call, or arguments with changed values. Use <code>name = NULL</code> to remove the argument name. |
| <code>evaluate</code>  | If true evaluate the new call else return the call.                                                                           |

**Value**

If `evaluate = TRUE` the fitted object, otherwise the updated call.

|                |                       |
|----------------|-----------------------|
| update.formula | <i>Model Updating</i> |
|----------------|-----------------------|

---

**Description**

`update.formula` is used to update model formulae. This typically involves adding or dropping terms, but updates can be more general.

**Usage**

```
S3 method for class 'formula'
update(old, new, ...)
```

**Arguments**

|                  |                                                            |
|------------------|------------------------------------------------------------|
| <code>old</code> | a model formula to be updated.                             |
| <code>new</code> | a formula giving a template which specifies how to update. |
| <code>...</code> | further arguments passed to or from other methods.         |

## Details

Either or both of `old` and `new` can be objects such as length-one character vectors which can be coerced to a formula via `as.formula`.

The function works by first identifying the *left-hand side* and *right-hand side* of the `old` formula. It then examines the `new` formula and substitutes the *lhs* of the `old` formula for any occurrence of `'.'` on the left of `new`, and substitutes the *rhs* of the `old` formula for any occurrence of `'.'` on the right of `new`. The result is then simplified via `terms.formula(simplify = TRUE)`.

## Value

The updated formula is returned. The environment of the result is that of `old`.

## See Also

`terms.model.matrix`.

## Examples

```
update(y ~ x, ~ . + x2) #> y ~ x + x2
update(y ~ x, log(.) ~ .) #> log(y) ~ x
update(. ~ u+v, res ~ .) #> res ~ u + v
```

---

var.test

*F Test to Compare Two Variances*

---

## Description

Performs an F test to compare the variances of two samples from normal populations.

## Usage

```
var.test(x, ...)

Default S3 method:
var.test(x, y, ratio = 1,
 alternative = c("two.sided", "less", "greater"),
 conf.level = 0.95, ...)

S3 method for class 'formula'
var.test(formula, data, subset, na.action, ...)
```

## Arguments

|                          |                                                                                                                                                                                                       |
|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x, y</code>        | numeric vectors of data values, or fitted linear model objects (inheriting from class <code>"lm"</code> ).                                                                                            |
| <code>ratio</code>       | the hypothesized ratio of the population variances of <code>x</code> and <code>y</code> .                                                                                                             |
| <code>alternative</code> | a character string specifying the alternative hypothesis, must be one of <code>"two.sided"</code> (default), <code>"greater"</code> or <code>"less"</code> . You can specify just the initial letter. |
| <code>conf.level</code>  | confidence level for the returned confidence interval.                                                                                                                                                |

|                        |                                                                                                                                                                                                                            |
|------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>formula</code>   | a formula of the form <code>lhs ~ rhs</code> where <code>lhs</code> is a numeric variable giving the data values and <code>rhs</code> a factor with two levels giving the corresponding groups.                            |
| <code>data</code>      | an optional matrix or data frame (or similar: see <a href="#">model.frame</a> ) containing the variables in the formula <code>formula</code> . By default the variables are taken from <code>environment(formula)</code> . |
| <code>subset</code>    | an optional vector specifying a subset of observations to be used.                                                                                                                                                         |
| <code>na.action</code> | a function which indicates what should happen when the data contain NAs. Defaults to <code>getOption("na.action")</code> .                                                                                                 |
| <code>...</code>       | further arguments to be passed to or from methods.                                                                                                                                                                         |

### Details

The null hypothesis is that the ratio of the variances of the populations from which `x` and `y` were drawn, or in the data to which the linear models `x` and `y` were fitted, is equal to `ratio`.

### Value

A list with class `"htest"` containing the following components:

|                          |                                                                          |
|--------------------------|--------------------------------------------------------------------------|
| <code>statistic</code>   | the value of the F test statistic.                                       |
| <code>parameter</code>   | the degrees of the freedom of the F distribution of the test statistic.  |
| <code>p.value</code>     | the p-value of the test.                                                 |
| <code>conf.int</code>    | a confidence interval for the ratio of the population variances.         |
| <code>estimate</code>    | the ratio of the sample variances of <code>x</code> and <code>y</code> . |
| <code>null.value</code>  | the ratio of population variances under the null.                        |
| <code>alternative</code> | a character string describing the alternative hypothesis.                |
| <code>method</code>      | the character string <code>"F test to compare two variances"</code> .    |
| <code>data.name</code>   | a character string giving the names of the data.                         |

### See Also

[bartlett.test](#) for testing homogeneity of variances in more than two samples from normal distributions; [ansari.test](#) and [mood.test](#) for two rank based (nonparametric) two-sample tests for difference in scale.

### Examples

```
x <- rnorm(50, mean = 0, sd = 2)
y <- rnorm(30, mean = 1, sd = 1)
var.test(x, y) # Do x and y have the same variance?
var.test(lm(x ~ 1), lm(y ~ 1)) # The same.
```

---

|         |                                             |
|---------|---------------------------------------------|
| varimax | <i>Rotation Methods for Factor Analysis</i> |
|---------|---------------------------------------------|

---

**Description**

These functions ‘rotate’ loading matrices in factor analysis.

**Usage**

```
varimax(x, normalize = TRUE, eps = 1e-5)
promax(x, m = 4)
```

**Arguments**

|           |                                                                                                                                                               |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x         | A loadings matrix, with $p$ rows and $k < p$ columns                                                                                                          |
| m         | The power used the target for <code>promax</code> . Values of 2 to 4 are recommended.                                                                         |
| normalize | logical. Should Kaiser normalization be performed? If so the rows of <code>x</code> are re-scaled to unit length before rotation, and scaled back afterwards. |
| eps       | The tolerance for stopping: the relative change in the sum of singular values.                                                                                |

**Details**

These seek a ‘rotation’ of the factors `x %*% T` that aims to clarify the structure of the loadings matrix. The matrix `T` is a rotation (possibly with reflection) for `varimax`, but a general linear transformation for `promax`, with the variance of the factors being preserved.

**Value**

|                        |                                                                                 |
|------------------------|---------------------------------------------------------------------------------|
| A list with components |                                                                                 |
| loadings               | The ‘rotated’ loadings matrix, <code>x %*% rotmat</code> , of class “loadings”. |
| rotmat                 | The ‘rotation’ matrix.                                                          |

## Examples

```
varimax with normalize = TRUE is the default
fa <- factanal(~., 2, data = swiss)
varimax(loadings(fa), normalize = FALSE)
promax(loadings(fa))
```

vcov

*Calculate Variance-Covariance Matrix for a Fitted Model Object*

## Description

Returns the variance-covariance matrix of the main parameters of a fitted model object. The “main” parameters of model correspond to those returned by `coef`, and typically do not contain a nuisance scale parameter (`sigma`).

## Usage

```
vcov(object, ...)
S3 method for class 'lm'
vcov(object, complete = TRUE, ...)
and also for '[summary.]glm' and 'mlm'
S3 method for class 'aov'
vcov(object, complete = FALSE, ...)

.vcov.aliased(alias, vc, complete = TRUE)
```

## Arguments

|                       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code>   | a fitted model object, typically. Sometimes also a <code>summary()</code> object of such a fitted model.                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>complete</code> | for the <code>aov</code> , <code>lm</code> , <code>glm</code> , <code>mlm</code> , and where applicable <code>summary.lm</code> etc methods: logical indicating if the full variance-covariance matrix should be returned also in case of an over-determined system where some coefficients are undefined and <code>coef(.)</code> contains NAs correspondingly. When <code>complete = TRUE</code> , <code>vcov()</code> is compatible with <code>coef()</code> also in this singular case. |
| <code>...</code>      | additional arguments for method functions. For the <code>glm</code> method this can be used to pass a dispersion parameter.                                                                                                                                                                                                                                                                                                                                                                 |
| <code>alias</code>    | a <code>logical</code> vector typically identical to <code>is.na(coef(.))</code> indicating which coefficients are ‘aliased’.                                                                                                                                                                                                                                                                                                                                                               |
| <code>vc</code>       | a variance-covariance matrix, typically “incomplete”, i.e., with no rows and columns for aliased coefficients.                                                                                                                                                                                                                                                                                                                                                                              |

## Details

`vcov()` is a generic function and functions with names beginning in `vcov.` will be methods for this function. Classes with methods for this function include: `lm`, `mlm`, `glm`, `nls`, `summary.lm`, `summary.glm`, `negbin`, `polr`, `rlm` (in package **MASS**), `multinom` (in package **nnet**) `gls`, `lme` (in package **nlme**), `coxph` and `survreg` (in package **survival**).

(`vcov()` methods for summary objects allow more efficient and still encapsulated access when both `summary(mod)` and `vcov(mod)` are needed.)

`.vcov.aliased()` is an auxiliary function useful for `vcov` method implementations which have to deal with singular model fits encoded via NA coefficients: It augments a `vcov`-matrix `vc` by NA rows and columns where needed, i.e., when some entries of `aliased` are true and `vc` is of smaller dimension than `length(aliased)`.

### Value

A matrix of the estimated covariances between the parameter estimates in the linear or non-linear predictor of the model. This should have row and column names corresponding to the parameter names given by the `coef` method.

When some coefficients of the (linear) model are undetermined and hence NA because of linearly dependent terms (or an “over specified” model), also called “aliased”, see [alias](#), then since R version 3.5.0, `vcov()` (iff `complete = TRUE`, i.e., by default for `lm` etc, but not for `aov`) contains corresponding rows and columns of NAs, wherever `coef()` has always contained such NAs.

---

Weibull

---

*The Weibull Distribution*

---

### Description

Density, distribution function, quantile function and random generation for the Weibull distribution with parameters `shape` and `scale`.

### Usage

```
dweibull(x, shape, scale = 1, log = FALSE)
pweibull(q, shape, scale = 1, lower.tail = TRUE, log.p = FALSE)
qweibull(p, shape, scale = 1, lower.tail = TRUE, log.p = FALSE)
rweibull(n, shape, scale = 1)
```

### Arguments

|                           |                                                                                                           |
|---------------------------|-----------------------------------------------------------------------------------------------------------|
| <code>x, q</code>         | vector of quantiles.                                                                                      |
| <code>p</code>            | vector of probabilities.                                                                                  |
| <code>n</code>            | number of observations. If <code>length(n) &gt; 1</code> , the length is taken to be the number required. |
| <code>shape, scale</code> | shape and scale parameters, the latter defaulting to 1.                                                   |
| <code>log, log.p</code>   | logical; if TRUE, probabilities <code>p</code> are given as <code>log(p)</code> .                         |
| <code>lower.tail</code>   | logical; if TRUE (default), probabilities are $P[X \leq x]$ , otherwise, $P[X > x]$ .                     |

### Details

The Weibull distribution with `shape` parameter  $a$  and `scale` parameter  $\sigma$  has density given by

$$f(x) = (a/\sigma)(x/\sigma)^{a-1} \exp(-(x/\sigma)^a)$$

for  $x > 0$ . The cumulative distribution function is  $F(x) = 1 - \exp(-(x/\sigma)^a)$  on  $x > 0$ , the mean is  $E(X) = \sigma\Gamma(1 + 1/a)$ , and the  $Var(X) = \sigma^2(\Gamma(1 + 2/a) - (\Gamma(1 + 1/a))^2)$ .

**Value**

dweibull gives the density, pweibull gives the distribution function, qweibull gives the quantile function, and rweibull generates random deviates.

Invalid arguments will result in return value NaN, with a warning.

The length of the result is determined by n for rweibull, and is the maximum of the lengths of the numerical arguments for the other functions.

The numerical arguments other than n are recycled to the length of the result. Only the first elements of the logical arguments are used.

**Note**

The cumulative hazard  $H(t) = -\log(1 - F(t))$  is

```
-pweibull(t, a, b, lower = FALSE, log = TRUE)
```

which is just  $H(t) = (t/b)^a$ .

**Source**

[dpq]weibull are calculated directly from the definitions. rweibull uses inversion.

[Distributions](#) for other standard distributions, including the [Exponential](#) which is a special case of the Weibull distribution.

**Examples**

```
x <- c(0, rlnorm(50))
all.equal(dweibull(x, shape = 1), dexp(x))
all.equal(pweibull(x, shape = 1, scale = pi), pexp(x, rate = 1/pi))
Cumulative hazard H():
all.equal(pweibull(x, 2.5, pi, lower.tail = FALSE, log.p = TRUE),
 -(x/pi)^2.5, tolerance = 1e-15)
all.equal(qweibull(x/11, shape = 1, scale = pi), qexp(x/11, rate = 1/pi))
```

---

weighted.mean

*Weighted Arithmetic Mean*

---

**Description**

Compute a weighted mean.

## Usage

```
weighted.mean(x, w, ...)

Default S3 method:
weighted.mean(x, w, ..., na.rm = FALSE)
```

## Arguments

|                    |                                                                                                                            |
|--------------------|----------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>     | an object containing the values whose weighted mean is to be computed.                                                     |
| <code>w</code>     | a numerical vector of weights the same length as <code>x</code> giving the weights to use for elements of <code>x</code> . |
| <code>...</code>   | arguments to be passed to or from methods.                                                                                 |
| <code>na.rm</code> | a logical value indicating whether NA values in <code>x</code> should be stripped before the computation proceeds.         |

## Details

This is a generic function and methods can be defined for the first argument `x`: apart from the default methods there are methods for the date-time classes "POSIXct", "POSIXlt", "difftime" and "Date". The default method will work for any numeric-like object for which `[]`, multiplication, division and `sum` have suitable methods, including complex vectors.

If `w` is missing then all elements of `x` are given the same weight, otherwise the weights coerced to numeric by `as.numeric` and normalized to sum to one (if possible: if their sum is zero or infinite the value is likely to be NaN).

Missing values in `w` are not handled specially and so give a missing value as the result. However, zero weights *are* handled specially and the corresponding `x` values are omitted from the sum.

## Value

For the default method, a length-one numeric vector.

## See Also

[mean](#)

## Examples

```
GPA from Siegel 1994
wt <- c(5, 5, 4, 1)/15
x <- c(3.7, 3.3, 3.5, 2.8)
xm <- weighted.mean(x, wt)
```

---

`weighted.residuals` *Compute Weighted Residuals*

---

## Description

Computed weighted residuals from a linear model fit.

## Usage

```
weighted.residuals(obj, drop0 = TRUE)
```

## Arguments

|                    |                                                                    |
|--------------------|--------------------------------------------------------------------|
| <code>obj</code>   | R object, typically of class <code>lm</code> or <code>glm</code> . |
| <code>drop0</code> | logical. If TRUE, drop all cases with <code>weights == 0</code> .  |

## Details

Weighted residuals are based on the deviance residuals, which for a `lm` fit are the raw residuals  $R_i$  multiplied by  $\sqrt{w_i}$ , where  $w_i$  are the `weights` as specified in `lm`'s call.

Dropping cases with weights zero is compatible with `influence` and related functions.

## Value

Numeric vector of length  $n'$ , where  $n'$  is the number of non-0 weights (`drop0 = TRUE`) or the number of observations, otherwise.

## See Also

`residuals`, `lm.influence`, etc.

## Examples

```
following on from example(lm)

all.equal(weighted.residuals(lm.D9),
 residuals(lm.D9))

x <- 1:10
w <- 0:9
y <- rnorm(x)
weighted.residuals(lmxy <- lm(y ~ x, weights = w))
weighted.residuals(lmxy, drop0 = FALSE)
```

---

|         |                              |
|---------|------------------------------|
| weights | <i>Extract Model Weights</i> |
|---------|------------------------------|

---

**Description**

`weights` is a generic function which extracts fitting weights from objects returned by modeling functions.

Methods can make use of `napredict` methods to compensate for the omission of missing values. The default methods does so.

**Usage**

```
weights(object, ...)
```

**Arguments**

|                     |                                                                    |
|---------------------|--------------------------------------------------------------------|
| <code>object</code> | an object for which the extraction of model weights is meaningful. |
| <code>...</code>    | other arguments passed to methods.                                 |

**Value**

Weights extracted from the object `object`: the default method looks for component "weights" and if not NULL calls `napredict` on it.

**References**

Chambers, J. M. and Hastie, T. J. (1992) *Statistical Models in S*. Wadsworth & Brooks/Cole.

|                          |                                                |
|--------------------------|------------------------------------------------|
| <code>wilcox.test</code> | <i>Wilcoxon Rank Sum and Signed Rank Tests</i> |
|--------------------------|------------------------------------------------|

---

**Description**

Performs one- and two-sample Wilcoxon tests on vectors of data; the latter is also known as ‘Mann-Whitney’ test.

**Usage**

```
wilcox.test(x, ...)

Default S3 method:
wilcox.test(x, y = NULL,
 alternative = c("two.sided", "less", "greater"),
 mu = 0, paired = FALSE, exact = NULL, correct = TRUE,
 conf.int = FALSE, conf.level = 0.95,
```

```

 tol.root = 1e-4, digits.rank = Inf, ...)

S3 method for class 'formula'
wilcox.test(formula, data, subset, na.action, ...)

```

### Arguments

|                          |                                                                                                                                                                                                                                                                                                                                     |
|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>           | numeric vector of data values. Non-finite (e.g., infinite or missing) values will be omitted.                                                                                                                                                                                                                                       |
| <code>y</code>           | an optional numeric vector of data values: as with <code>x</code> non-finite values will be omitted.                                                                                                                                                                                                                                |
| <code>alternative</code> | a character string specifying the alternative hypothesis, must be one of "two.sided" (default), "greater" or "less". You can specify just the initial letter.                                                                                                                                                                       |
| <code>mu</code>          | a number specifying an optional parameter used to form the null hypothesis. See 'Details'.                                                                                                                                                                                                                                          |
| <code>paired</code>      | a logical indicating whether you want a paired test.                                                                                                                                                                                                                                                                                |
| <code>exact</code>       | a logical indicating whether an exact p-value should be computed.                                                                                                                                                                                                                                                                   |
| <code>correct</code>     | a logical indicating whether to apply continuity correction in the normal approximation for the p-value.                                                                                                                                                                                                                            |
| <code>conf.int</code>    | a logical indicating whether a confidence interval should be computed.                                                                                                                                                                                                                                                              |
| <code>conf.level</code>  | confidence level of the interval.                                                                                                                                                                                                                                                                                                   |
| <code>tol.root</code>    | (when <code>conf.int</code> is true:) a positive numeric tolerance, used in <code>uniroot(*,tol=tol.root)</code> calls.                                                                                                                                                                                                             |
| <code>digits.rank</code> | a number; if finite, <code>rank(signif(r,digits.rank))</code> will be used to compute ranks for the test statistic instead of (the default) <code>rank(r)</code> .                                                                                                                                                                  |
| <code>formula</code>     | a formula of the form <code>lhs ~ rhs</code> where <code>lhs</code> is a numeric variable giving the data values and <code>rhs</code> either 1 for a one-sample or paired test or a factor with two levels giving the corresponding groups. If <code>lhs</code> is of class "Pair" and <code>rhs</code> is 1, a paired test is done |
| <code>data</code>        | an optional matrix or data frame (or similar: see <code>model.frame</code> ) containing the variables in the formula <code>formula</code> . By default the variables are taken from <code>environment(formula)</code> .                                                                                                             |
| <code>subset</code>      | an optional vector specifying a subset of observations to be used.                                                                                                                                                                                                                                                                  |
| <code>na.action</code>   | a function which indicates what should happen when the data contain NAs. Defaults to <code>getOption("na.action")</code> .                                                                                                                                                                                                          |
| <code>...</code>         | further arguments to be passed to or from methods.                                                                                                                                                                                                                                                                                  |

### Details

The formula interface is only applicable for the 2-sample tests.

If only `x` is given, or if both `x` and `y` are given and `paired` is `TRUE`, a Wilcoxon signed rank test of the null that the distribution of `x` (in the one sample case) or of `x - y` (in the paired two sample case) is symmetric about `mu` is performed.

Otherwise, if both `x` and `y` are given and `paired` is `FALSE`, a Wilcoxon rank sum test (equivalent to the Mann-Whitney test: see the Note) is carried out. In this case, the null hypothesis is that the distributions of `x` and `y` differ by a location shift of `mu` and the alternative is that they differ by some other location shift (and the one-sided alternative "greater" is that `x` is shifted to the right of `y`).

By default (if `exact` is not specified), an exact p-value is computed if the samples contain less than 50 finite values and there are no ties. Otherwise, a normal approximation is used.

For stability reasons, it may be advisable to use rounded data or to set `digits.rank = 7`, say, such that determination of ties does not depend on very small numeric differences (see the example).

Optionally (if argument `conf.int` is true), a nonparametric confidence interval and an estimator for the pseudomedian (one-sample case) or for the difference of the location parameters  $x - y$  is computed. (The pseudomedian of a distribution  $F$  is the median of the distribution of  $(u + v)/2$ , where  $u$  and  $v$  are independent, each with distribution  $F$ . If  $F$  is symmetric, then the pseudomedian and median coincide. See Hollander & Wolfe (1973), page 34.) Note that in the two-sample case the estimator for the difference in location parameters does **not** estimate the difference in medians (a common misconception) but rather the median of the difference between a sample from  $x$  and a sample from  $y$ .

If exact p-values are available, an exact confidence interval is obtained by the algorithm described in Bauer (1972), and the Hodges-Lehmann estimator is employed. Otherwise, the returned confidence interval and point estimate are based on normal approximations. These are continuity-corrected for the interval but *not* the estimate (as the correction depends on the `alternative`).

With small samples it may not be possible to achieve very high confidence interval coverages. If this happens a warning will be given and an interval with lower coverage will be substituted.

When  $x$  (and  $y$  if applicable) are valid, the function now always returns, also in the `conf.int = TRUE` case when a confidence interval cannot be computed, in which case the interval boundaries and sometimes the `estimate` now contain `NaN`.

### Value

A list with class `"htest"` containing the following components:

|                          |                                                                                                             |
|--------------------------|-------------------------------------------------------------------------------------------------------------|
| <code>statistic</code>   | the value of the test statistic with a name describing it.                                                  |
| <code>parameter</code>   | the parameter(s) for the exact distribution of the test statistic.                                          |
| <code>p.value</code>     | the p-value for the test.                                                                                   |
| <code>null.value</code>  | the location parameter $\mu$ .                                                                              |
| <code>alternative</code> | a character string describing the alternative hypothesis.                                                   |
| <code>method</code>      | the type of test applied.                                                                                   |
| <code>data.name</code>   | a character string giving the names of the data.                                                            |
| <code>conf.int</code>    | a confidence interval for the location parameter. (Only present if argument <code>conf.int = TRUE</code> .) |
| <code>estimate</code>    | an estimate of the location parameter. (Only present if argument <code>conf.int = TRUE</code> .)            |

### Warning

This function can use large amounts of memory and stack (and even crash R if the stack limit is exceeded) if `exact = TRUE` and one sample is large (several thousands or more).

### Note

The literature is not unanimous about the definitions of the Wilcoxon rank sum and Mann-Whitney tests. The two most common definitions correspond to the sum of the ranks of the first sample with the minimum value subtracted or not: R subtracts and S-PLUS does not, giving a value which is larger by  $m(m + 1)/2$  for a first sample of size  $m$ . (It seems Wilcoxon's original paper used the unadjusted sum of the ranks but subsequent tables subtracted the minimum.)

```

wilcox.test(rnorm(10), rnorm(10, 2), conf.int = TRUE)

Formula interface.
boxplot(Ozone ~ Month, data = airquality)
wilcox.test(Ozone ~ Month, data = airquality,
 subset = Month %in% c(5, 8))

accuracy in ties determination via 'digits.rank':
wilcox.test(4:2, 3:1, paired=TRUE) # Warning: cannot compute exact p-value with ties
wilcox.test((4:2)/10, (3:1)/10, paired=TRUE) # no ties => *no* warning
wilcox.test((4:2)/10, (3:1)/10, paired=TRUE, digits.rank = 9) # same ties as (4:2, 3:1)

```

---

Wilcoxon

---

*Distribution of the Wilcoxon Rank Sum Statistic*

---

## Description

Density, distribution function, quantile function and random generation for the distribution of the Wilcoxon rank sum statistic obtained from samples with size  $m$  and  $n$ , respectively.

## Usage

```

dwilcox(x, m, n, log = FALSE)
pwilcox(q, m, n, lower.tail = TRUE, log.p = FALSE)
qwilcox(p, m, n, lower.tail = TRUE, log.p = FALSE)
rwilcox(nn, m, n)

```

## Arguments

|                         |                                                                                                            |
|-------------------------|------------------------------------------------------------------------------------------------------------|
| <code>x, q</code>       | vector of quantiles.                                                                                       |
| <code>p</code>          | vector of probabilities.                                                                                   |
| <code>nn</code>         | number of observations. If <code>length(nn) &gt; 1</code> , the length is taken to be the number required. |
| <code>m, n</code>       | numbers of observations in the first and second sample, respectively. Can be vectors of positive integers. |
| <code>log, log.p</code> | logical; if TRUE, probabilities <code>p</code> are given as $\log(p)$ .                                    |
| <code>lower.tail</code> | logical; if TRUE (default), probabilities are $P[X \leq x]$ , otherwise, $P[X > x]$ .                      |

## Details

This distribution is obtained as follows. Let  $x$  and  $y$  be two random, independent samples of size  $m$  and  $n$ . Then the Wilcoxon rank sum statistic is the number of all pairs  $(x[i], y[j])$  for which  $y[j]$  is not greater than  $x[i]$ . This statistic takes values between 0 and  $m * n$ , and its mean and variance are  $m * n / 2$  and  $m * n * (m + n + 1) / 12$ , respectively.

If any of the first three arguments are vectors, the recycling rule is used to do the calculations for all combinations of the three up to the length of the longest vector.

**Value**

`dwilcox` gives the density, `pwilcox` gives the distribution function, `qwilcox` gives the quantile function, and `rwilcox` generates random deviates.

The length of the result is determined by `nn` for `rwilcox`, and is the maximum of the lengths of the numerical arguments for the other functions.

The numerical arguments other than `nn` are recycled to the length of the result. Only the first elements of the logical arguments are used.

**Warning**

These functions can use large amounts of memory and stack (and even crash R if the stack limit is exceeded and stack-checking is not in place) if one sample is large (several thousands or more).

**Note**

S-PLUS uses a different (but equivalent) definition of the Wilcoxon statistic: see `wilcox.test` for details.

**Author(s)**

Kurt Hornik

**Source**

These ("d","p","q") are calculated via recursion, based on `cwilcox(k,m,n)`, the number of choices with statistic `k` from samples of size `m` and `n`, which is itself calculated recursively and the results cached. Then `dwilcox` and `pwilcox` sum appropriate values of `cwilcox`, and `qwilcox` is based on inversion.

`rwilcox` generates a random permutation of ranks and evaluates the statistic. Note that it is based on the same C code as `sample()`, and hence is determined by `.Random.seed`, notably from `RNGkind(sample.kind = .)` which changed with R version 3.6.0.

**See Also**

`wilcox.test` to calculate the statistic from data, find p values and so on.

**Distributions** for standard distributions, including `dsignrank` for the distribution of the *one-sample* Wilcoxon signed rank statistic.

**Examples**

```
require(graphics)

x <- -1:(4*6 + 1)
fx <- dwilcox(x, 4, 6)
Fx <- pwilcox(x, 4, 6)

layout(rbind(1,2), widths = 1, heights = c(3,2))
plot(x, fx, type = "h", col = "violet",
 main = "Probabilities (density) of Wilcoxon-Statist.(n=6, m=4)")
plot(x, Fx, type = "s", col = "blue",
 main = "Distribution of Wilcoxon-Statist.(n=6, m=4)")
abline(h = 0:1, col = "gray20", lty = 2)
layout(1) # set back
```

```

N <- 200
hist(U <- rwilcox(N, m = 4, n = 6), breaks = 0:25 - 1/2,
 border = "red", col = "pink", sub = paste("N =", N))
mtext("N * f(x), f() = true \"density\"", side = 3, col = "blue")
lines(x, N*fx, type = "h", col = "blue", lwd = 2)
points(x, N*fx, cex = 2)

Better is a Quantile-Quantile Plot
qqplot(U, qw <- qwilcox((1:N - 1/2)/N, m = 4, n = 6),
 main = paste("Q-Q-Plot of empirical and theoretical quantiles",
 "Wilcoxon Statistic, (m=4, n=6)", sep = "\n"))
n <- as.numeric(names(print(tU <- table(U))))
text(n+.2, n+.5, labels = tU, col = "red")

```

window

*Time (Series) Windows***Description**

`window` is a generic function which extracts the subset of the object `x` observed between the times `start` and `end`. If a frequency is specified, the series is then re-sampled at the new frequency.

**Usage**

```

window(x, ...)
S3 method for class 'ts'
window(x, ...)
Default S3 method:
window(x, start = NULL, end = NULL,
 frequency = NULL, deltat = NULL, extend = FALSE, ts.eps = getOption("ts.ep

window(x, ...) <- value
S3 replacement method for class 'ts'
window(x, start, end, frequency, deltat, ...) <- value

```

**Arguments**

|                                |                                                                                                                                                                                |
|--------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>                 | a time-series (or other object if not replacing values).                                                                                                                       |
| <code>start</code>             | the start time of the period of interest.                                                                                                                                      |
| <code>end</code>               | the end time of the period of interest.                                                                                                                                        |
| <code>frequency, deltat</code> | the new frequency can be specified by either (or both if they are consistent).                                                                                                 |
| <code>extend</code>            | logical. If true, the <code>start</code> and <code>end</code> values are allowed to extend the series. If false, attempts to extend the series give a warning and are ignored. |
| <code>ts.eps</code>            | time series comparison tolerance. Frequencies are considered equal if their absolute difference is less than <code>ts.eps</code> .                                             |
| <code>...</code>               | further arguments passed to or from other methods.                                                                                                                             |
| <code>value</code>             | replacement values.                                                                                                                                                            |

## Details

The start and end times can be specified as for `ts`. If there is no observation at the new `start` or `end`, the immediately following (`start`) or preceding (`end`) observation time is used.

The replacement function has a method for `ts` objects, and is allowed to extend the series (with a warning). There is no default method.

## Value

The value depends on the method. `window.default` will return a vector or matrix with an appropriate `tsp` attribute.

`window.ts` differs from `window.default` only in ensuring the result is a `ts` object.

If `extend = TRUE` the series will be padded with NAs if needed.

xtabs

---

*Cross Tabulation*

---

## Description

Create a contingency table (optionally a sparse matrix) from cross-classifying factors, usually contained in a data frame, using a formula interface.

## Usage

```
xtabs(formula = ~., data = parent.frame(), subset, sparse = FALSE,
 na.action, addNA = FALSE, exclude = if(!addNA) c(NA, NaN),
 drop.unused.levels = FALSE)

S3 method for class 'xtabs'
print(x, na.print = "", ...)
```

## Arguments

|                                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|---------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>formula</code>            | a <a href="#">formula</a> object with the cross-classifying variables (separated by <code>+</code> ) on the right hand side (or an object which can be coerced to a formula). Interactions are not allowed. On the left hand side, one may optionally give a vector or a matrix of counts; in the latter case, the columns are interpreted as corresponding to the levels of a variable. This is useful if the data have already been tabulated, see the examples below. |
| <code>data</code>               | an optional matrix or data frame (or similar: see <a href="#">model.frame</a> ) containing the variables in the formula <code>formula</code> . By default the variables are taken from <code>environment(formula)</code> .                                                                                                                                                                                                                                               |
| <code>subset</code>             | an optional vector specifying a subset of observations to be used.                                                                                                                                                                                                                                                                                                                                                                                                       |
| <code>sparse</code>             | logical specifying if the result should be a <i>sparse</i> matrix, i.e., inheriting from <a href="#">sparseMatrix</a> . Only works for two factors (since there are no higher-order sparse array classes yet).                                                                                                                                                                                                                                                           |
| <code>na.action</code>          | a function which indicates what should happen when the data contain NAs. If unspecified, and <code>addNA</code> is true, this is set to <a href="#">na.pass</a> . When it is <code>na.pass</code> and <code>formula</code> has a left hand side (with counts), <a href="#">sum(*, na.rm = TRUE)</a> is used instead of <code>sum(*)</code> for the counts.                                                                                                               |
| <code>addNA</code>              | logical indicating if NAs should get a separate level and be counted, using <a href="#">addNA(*, ifany=TRUE)</a> and setting the default for <code>na.action</code> .                                                                                                                                                                                                                                                                                                    |
| <code>exclude</code>            | a vector of values to be excluded when forming the set of levels of the classifying factors.                                                                                                                                                                                                                                                                                                                                                                             |
| <code>drop.unused.levels</code> | a logical indicating whether to drop unused levels in the classifying factors. If this is <code>FALSE</code> and there are unused levels, the table will contain zero marginals, and a subsequent chi-squared test for independence of the factors will not work.                                                                                                                                                                                                        |
| <code>x</code>                  | an object of class <code>"xtabs"</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>na.print</code>           | character string (or <code>NULL</code> ) indicating how NA are printed. The default <code>("")</code> does not show NAs clearly, and <code>na.print = "NA"</code> maybe advisable instead.                                                                                                                                                                                                                                                                               |
| <code>...</code>                | further arguments passed to or from other methods.                                                                                                                                                                                                                                                                                                                                                                                                                       |

## Details

There is a `summary` method for contingency table objects created by `table` or `xtabs(*, sparse = FALSE)`, which gives basic information and performs a chi-squared test for independence of factors (note that the function [chisq.test](#) currently only handles 2-d tables).

If a left hand side is given in `formula`, its entries are simply summed over the cells corresponding to the right hand side; this also works if the lhs does not give counts.

For variables in `formula` which are factors, `exclude` must be specified explicitly; the default exclusions will not be used.

In R versions before 3.4.0, e.g., when `na.action = na.pass`, sometimes zeroes (0) were returned instead of NAs.

## Value

By default, when `sparse = FALSE`, a contingency table in array representation of S3 class `c("xtabs", "table")`, with a `"call"` attribute storing the matched call.

When `sparse = TRUE`, a sparse numeric matrix, specifically an object of S4 class [dgTMatrix](#) from package **Matrix**.

**See Also**

[table](#) for traditional cross-tabulation, and [as.data.frame.table](#) which is the inverse operation of `xtabs` (see the DF example below).

[sparseMatrix](#) on sparse matrices in package **Matrix**.

**Examples**

```
'esoph' has the frequencies of cases and controls for all levels of
the variables 'agegp', 'alcgp', and 'tobgp'.
xtabs(cbind(ncases, ncontrols) ~ ., data = esoph)
Output is not really helpful ... flat tables are better:
ftable(xtabs(cbind(ncases, ncontrols) ~ ., data = esoph))
In particular if we have fewer factors ...
ftable(xtabs(cbind(ncases, ncontrols) ~ agegp, data = esoph))

This is already a contingency table in array form.
DF <- as.data.frame(UCBAdmissions)
Now 'DF' is a data frame with a grid of the factors and the counts
in variable 'Freq'.
DF
Nice for taking margins ...
xtabs(Freq ~ Gender + Admit, DF)
And for testing independence ...
summary(xtabs(Freq ~ ., DF))

with NA's
DN <- DF; DN[cbind(6:9, c(1:2,4,1))] <- NA; DN
tools::assertError(# 'na.fail' should fail :
 xtabs(Freq ~ Gender + Admit, DN, na.action=na.fail))
xtabs(Freq ~ Gender + Admit, DN)
xtabs(Freq ~ Gender + Admit, DN, na.action = na.pass)
The Female:Rejected combination has NA 'Freq' (and NA prints 'invisibly' as "")
xtabs(Freq ~ Gender + Admit, DN, addNA = TRUE) # ==> count NAs

Create a nice display for the warp break data.
warpbreaks$replicate <- rep_len(1:9, 54)
ftable(xtabs(breaks ~ wool + tension + replicate, data = warpbreaks))

---- Sparse Examples ----

if(require("Matrix")) withAutoprint({
 ## similar to "nlme"s 'ergoStool' :
 d.ergo <- data.frame(Type = paste0("T", rep(1:4, 9*4)),
 Subj = gl(9, 4, 36*4))
 xtabs(~ Type + Subj, data = d.ergo) # 4 replicates each
 set.seed(15) # a subset of cases:
 xtabs(~ Type + Subj, data = d.ergo[sample(36, 10),], sparse = TRUE)

 ## Hypothetical two-level setup:
 inner <- factor(sample(letters[1:25], 100, replace = TRUE))
 inout <- factor(sample(LETTERS[1:5], 25, replace = TRUE))
 fr <- data.frame(inner = inner, outer = inout[as.integer(inner)])
 xtabs(~ inner + outer, fr, sparse = TRUE)
})
```

# Chapter 11

## The `stats4` package

---

`stats4-package`

*Statistical Functions using S4 Classes*

---

### Description

Statistical Functions using S4 classes.

### Details

This package contains functions and classes for statistics using the [S version 4](#) class system.

The methods currently support maximum likelihood (function `mle()` returning class "`mle`"), including methods for `logLik` for use with [AIC](#).

### Author(s)

R Core Team and contributors worldwide

Maintainer: R Core Team <[R-core@r-project.org](mailto:R-core@r-project.org)>

---

`coef-methods`

*Methods for Function `coef` in Package `stats4`*

---

### Description

Extract the coefficient vector from "`mle`" objects.

### Methods

`signature(object = "ANY")` Generic function: see `coef`.

`signature(object = "mle")` Extract the full coefficient vector (including any fixed coefficients) from the fit.

`signature(object = "summary.mle")` Extract the coefficient vector and standard errors from the summary of the fit.

---

|                 |                                                       |
|-----------------|-------------------------------------------------------|
| confint-methods | <i>Methods for Function confint in Package stats4</i> |
|-----------------|-------------------------------------------------------|

---

**Description**

Generate confidence intervals

**Methods**

signature(object = "ANY") Generic function: see [confint](#).

signature(object = "mle") First generate profile and then confidence intervals from the profile.

signature(object = "profile.mle") Generate confidence intervals based on likelihood profile.

---

|                |                                                      |
|----------------|------------------------------------------------------|
| logLik-methods | <i>Methods for Function logLik in Package stats4</i> |
|----------------|------------------------------------------------------|

---

**Description**

Extract the maximized log-likelihood from "mle" objects.

**Methods**

signature(object = "ANY") Generic function: see [logLik](#).

signature(object = "mle") Extract log-likelihood from the fit.

**Note**

The `mle` method does not know about the number of observations unless `nobs` was specified on the call and so may not be suitable for use with [BIC](#).

---

|     |                                      |
|-----|--------------------------------------|
| mle | <i>Maximum Likelihood Estimation</i> |
|-----|--------------------------------------|

---

**Description**

Estimate parameters by the method of maximum likelihood.

**Usage**

```
mle(minuslogl, start,
 optim = stats::optim,
 method = if(!useLim) "BFGS" else "L-BFGS-B",
 fixed = list(), nobs, lower, upper, ...)
```

## Arguments

|                           |                                                                                                                                               |
|---------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------|
| <code>minuslogl</code>    | Function to calculate negative log-likelihood.                                                                                                |
| <code>start</code>        | Named list of vectors or single vector. Initial values for optimizer. By default taken from the default arguments of <code>minuslogl</code> . |
| <code>optim</code>        | Optimizer function. (Experimental)                                                                                                            |
| <code>method</code>       | Optimization method to use. See <a href="#">optim</a> .                                                                                       |
| <code>fixed</code>        | Named list of vectors or single vector. Parameter values to keep fixed during optimization.                                                   |
| <code>nobs</code>         | optional integer: the number of observations, to be used for e.g. computing <a href="#">BIC</a> .                                             |
| <code>lower, upper</code> | Named lists of vectors or single vectors. Bounds for <a href="#">optim</a> , if relevant.                                                     |
| <code>...</code>          | Further arguments to pass to <a href="#">optim</a> .                                                                                          |

## Details

The `optim` optimizer is used to find the minimum of the negative log-likelihood. An approximate covariance matrix for the parameters is obtained by inverting the Hessian matrix at the optimum. By default, [optim](#) from the `stats` package is used; other optimizers need to be plug-compatible, both with respect to arguments and return values.

The function `minuslogl` should take one or several arguments, each of which can be a vector. The optimizer optimizes a function which takes a single vector argument, containing the concatenation of the arguments to `minuslogl`, removing any values that should be held fixed. This function internally unpacks the argument vector, inserts the fixed values and calls `minuslogl`.

The vector arguments `start`, `fixed`, `upper`, and `lower`, can be given in both packed and unpacked form, either as a single vector or as a list of vectors. In the latter case, you only need to specify those list elements that are actually affected. For vector arguments, including those inside lists, use a default marker for those values that you don't want to set: `NA` for `fixed` and `start`, and `+Inf`, `-Inf` for `upper`, and `lower`.

## Value

An object of class [mle-class](#).

## Note

Notice that the `mll` argument should calculate  $-\log L$  (not  $-2 \log L$ ). It is for the user to ensure that the likelihood is correct, and that asymptotic likelihood inference is valid.

## See Also

[mle-class](#)

## Examples

```
Avoid printing to unwarranted accuracy
od <- options(digits = 5)

Simulated EC50 experiment with count data
x <- 0:10
y <- c(26, 17, 13, 12, 20, 5, 9, 8, 5, 4, 8)

Easy one-dimensional MLE:
```

```

nLL <- function(lambda) -sum(stats::dpois(y, lambda, log = TRUE))
fit0 <- mle(nLL, start = list(lambda = 5), nobs = NROW(y))

sanity check --- notice that "nobs" must be input
(not guaranteed to be meaningful for any likelihood)
stopifnot(nobs(fit0) == length(y))

For 1D, this is preferable:
fit1 <- mle(nLL, start = list(lambda = 5), nobs = NROW(y),
 method = "Brent", lower = 1, upper = 20)

This needs a constrained parameter space: most methods will accept NA
ll <- function(ymax = 15, xhalf = 6) {
 if(ymax > 0 && xhalf > 0)
 -sum(stats::dpois(y, lambda = ymax/(1+x/xhalf), log = TRUE))
 else NA
}
(fit <- mle(ll, nobs = length(y)))
mle(ll, fixed = list(xhalf = 6))

Alternative using bounds on optimization
ll2 <- function(ymax = 15, xhalf = 6)
 -sum(stats::dpois(y, lambda = ymax/(1+x/xhalf), log = TRUE))
mle(ll2, lower = rep(0, 2))

AIC(fit)
BIC(fit)

summary(fit)
logLik(fit)
vcov(fit)
plot(profile(fit), absVal = FALSE)
confint(fit)

Use bounded optimization
The lower bounds are really > 0,
but we use >=0 to stress-test profiling
(fit2 <- mle(ll2, lower = c(0, 0)))
plot(profile(fit2), absVal = FALSE)

A better parametrization:
ll3 <- function(lymax = log(15), lxhalf = log(6))
 -sum(stats::dpois(y, lambda = exp(lymax)/(1+x/exp(lxhalf)), log = TRUE))
(fit3 <- mle(ll3))
plot(profile(fit3), absVal = FALSE)
exp(confint(fit3))

Regression tests for bounded cases (this was broken in R 3.x)
fit4 <- mle(ll, lower = c(0, 4)) # has max on boundary
confint(fit4)

direct check that fixed= and constraints work together
mle(ll, lower = c(0, 4), fixed=list(ymax=23)) # has max on boundary

Linear regression using MLE
x <- 1:10

```

```

y <- c(0.48, 2.24, 2.22, 5.15, 4.64, 5.53, 7, 8.8, 7.67, 9.23)

LM_mll <- function(formula, data = environment(formula))
{
 y <- model.response(model.frame(formula, data))
 X <- model.matrix(formula, data)
 b0 <- numeric(NCOL(X))
 names(b0) <- colnames(X)
 function(b=b0, sigma=1)
 -sum(dnorm(y, X %*% b, sigma, log=TRUE))
}

mll <- LM_mll(y ~ x)

summary(lm(y~x)) # for comparison -- notice variance bias in MLE
summary(mle(mll, lower=c(-Inf,-Inf, 0.01)))
summary(mle(mll, lower=list(sigma = 0.01))) # alternative specification

confint(mle(mll, lower=list(sigma = 0.01)))
plot(profile(mle(mll, lower=list(sigma = 0.01))))

Binom_mll <- function(x, n)
{
 force(x); force(n) ## beware lazy evaluation
 function(p=.5) -dbinom(x, n, p, log=TRUE)
}

Likelihood functions for different x.
This code goes wrong, if force(x) is not used in Binom_mll:

curve(Binom_mll(0, 10)(p), xname="p", ylim=c(0, 10))
mll_list <- list(10)
for (x in 1:10)
 mll_list[[x]] <- Binom_mll(x, 10)
for (mll in mll_list)
 curve(mll(p), xname="p", add=TRUE)

mll <- Binom_mll(4,10)
mle(mll, lower = 1e-16, upper = 1-1e-16) # limits must be inside (0,1)

Boundary case: This works, but fails if limits are set closer to 0 and 1
mll <- Binom_mll(0, 10)
mle(mll, lower=.005, upper=.995)

Not run:
We can use limits closer to the boundaries if we use the
drop-in replacement optimr() from the optimx package.

mle(mll, lower = 1e-16, upper = 1-1e-16, optim=optimx::optimr)

End(Not run)

options(od)

```

---

mle-class

---

Class "mle" for Results of Maximum Likelihood Estimation

---

## Description

This class encapsulates results of a generic maximum likelihood procedure.

## Objects from the Class

Objects can be created by calls of the form `new("mle", ...)`, but most often as the result of a call to `mle`.

## Slots

**call:** Object of class "language". The call to `mle`.

**coef:** Object of class "numeric". Estimated parameters.

**fullcoef:** Object of class "numeric". Full parameter set of fixed and estimated parameters.

**fixed:** Object of class "numeric". Fixed parameter values (NA for non-fixed parameters).

**vcov:** Object of class "matrix". Approximate variance-covariance matrix.

**min:** Object of class "numeric". Minimum value of objective function.

**details:** a "list", as returned from `optim`.

**minuslogl:** Object of class "function". The negative loglikelihood function.

**nobs:** "integer" of length one. The number of observations (often NA, when not set in call explicitly).

**method:** Object of class "character". The optimization method used.

## Methods

**confint** signature(object = "mle"): Confidence intervals from likelihood profiles.

**logLik** signature(object = "mle"): Extract maximized log-likelihood.

**profile** signature(fitted = "mle"): Likelihood profile generation.

**nobs** signature(object = "mle"): Number of observations, here simply accessing the nobs slot mentioned above.

**show** signature(object = "mle"): Display object briefly.

**summary** signature(object = "mle"): Generate object summary.

**update** signature(object = "mle"): Update fit.

**vcov** signature(object = "mle"): Extract variance-covariance matrix.

plot-methods

*Methods for Function plot in Package stats4***Description**

Plot profile likelihoods for "mle" objects.

**Usage**

```
S4 method for signature 'profile.mle,missing'
plot(x, levels, conf = c(99, 95, 90, 80, 50)/100, nseg = 50,
 absVal = TRUE, ...)
```

**Arguments**

|        |                                                                                                                                                           |
|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| x      | an object of class "profile.mle"                                                                                                                          |
| levels | levels, on the scale of the absolute value of a t statistic, at which to interpolate intervals. Usually conf is used instead of giving levels explicitly. |
| conf   | a numeric vector of confidence levels for profile-based confidence intervals on the parameters.                                                           |
| nseg   | an integer value giving the number of segments to use in the spline interpolation of the profile t curves.                                                |
| absVal | a logical value indicating whether or not the plots should be on the scale of the absolute value of the profile t. Defaults to TRUE.                      |
| ...    | other arguments to the plot function can be passed here.                                                                                                  |

**Methods**

signature(x = "ANY", y = "ANY") Generic function: see [plot](#).

signature(x = "profile.mle", y = "missing") Plot likelihood profiles for x.

profile-methods

*Methods for Function profile in Package stats4***Description**

Profile likelihood for "mle" objects.

**Usage**

```
S4 method for signature 'mle'
profile(fitted, which = 1:p, maxsteps = 100, alpha = 0.01,
 zmax = sqrt(qchisq(1 - alpha, 1L)), del = zmax/5,
 trace = FALSE, ...)
```

**Arguments**

|                       |                                                                                                                                                        |
|-----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>fitted</code>   | Object to be profiled                                                                                                                                  |
| <code>which</code>    | Optionally select subset of parameters to profile.                                                                                                     |
| <code>maxsteps</code> | Maximum number of steps to bracket <code>zmax</code> .                                                                                                 |
| <code>alpha</code>    | Significance level corresponding to <code>zmax</code> , based on a Scheffe-style multiple testing interval. Ignored if <code>zmax</code> is specified. |
| <code>zmax</code>     | Cutoff for the profiled value of the signed root-likelihood.                                                                                           |
| <code>del</code>      | Initial stepsize on root-likelihood scale.                                                                                                             |
| <code>trace</code>    | Logical. Print intermediate results.                                                                                                                   |
| <code>...</code>      | Currently unused.                                                                                                                                      |

**Details**

The profiling algorithm tries to find an approximately evenly spaced set of at least five parameter values (in each direction from the optimum) to cover the root-likelihood function. Some care is taken to try and get sensible results in cases of high parameter curvature. Notice that it may not always be possible to obtain the cutoff value, since the likelihood might level off.

**Value**

An object of class `"profile.mle"`, see `"profile.mle-class"`.

**Methods**

`signature(fitted = "ANY")` Generic function: see [profile](#).  
`signature(fitted = "mle")` Profile the likelihood in the vicinity of the optimum of an `"mle"` object.

---

`profile.mle-class`    *Class "profile.mle"; Profiling information for "mle" object*

---

**Description**

Likelihood profiles along each parameter of likelihood function

**Objects from the Class**

Objects can be created by calls of the form `new("profile.mle", ...)`, but most often by invoking `profile` on an `"mle"` object.

**Slots**

`profile`: Object of class `"list"`. List of profiles, one for each requested parameter. Each profile is a data frame with the first column called `z` being the signed square root of the  $-2 \log$  likelihood ratio, and the others being the parameters with names prefixed by `par.vals`.  
`summary`: Object of class `"summary.mle"`. Summary of object being profiled.

Methods

**confint** signature(object = "profile.mle"): Use profile to generate approximate confidence intervals for parameters.

**plot** signature(x = "profile.mle", y = "missing"): Plot profiles for each parameter.

|--------------|----------------------------------------------------|

---

Description

Show objects of classes `mle` and `summary.mle`

Methods

signature(object = "mle") Print simple summary of `mle` object. Just the coefficients and the call.

signature(object = "summary.mle") Shows call, table of coefficients and standard errors, and  $-2\log L$ .

---

|                 |                                                       |
|-----------------|-------------------------------------------------------|
| summary-methods | <i>Methods for Function summary in Package stats4</i> |
|-----------------|-------------------------------------------------------|

---

Description

Summarize objects

Methods

signature(object = "ANY") Generic function

signature(object = "mle") Generate a summary as an object of class `"summary.mle"`, containing estimates, asymptotic SE, and value of  $-2\log L$ .

---

```
summary.mle-class Class "summary.mle", Summary of "mle" Objects
```

---

### Description

Extract of "mle" object

### Objects from the Class

Objects can be created by calls of the form `new("summary.mle", ...)`, but most often by invoking `summary` on an "mle" object. They contain values meant for printing by `show`.

### Slots

**call:** Object of class "language" The call that generated the "mle" object.

**coef:** Object of class "matrix". Estimated coefficients and standard errors

**m2logL:** Object of class "numeric". Minus twice the log likelihood.

### Methods

**show** signature(object = "summary.mle"): Pretty-prints object

**coef** signature(object = "summary.mle"): Extracts the contents of the `coef` slot

update(object, ..., evaluate = TRUE)
```

### Arguments

|                       |                                                                                                                                             |
|-----------------------|---------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code>   | An existing fit.                                                                                                                            |
| <code>...</code>      | Additional arguments to the call, or arguments with changed values. Use <code>name = NULL</code> to remove the argument <code>name</code> . |
| <code>evaluate</code> | If true evaluate the new call else return the call.                                                                                         |

**Methods**

`signature(object = "ANY")` Generic function: see [update](#).

`signature(object = "mle")` Update a fit.

**Examples**

```
x <- 0:10
y <- c(26, 17, 13, 12, 20, 5, 9, 8, 5, 4, 8)
ll <- function(ymax = 15, xhalf = 6)
 -sum(stats::dpois(y, lambda = ymax/(1+x/xhalf), log = TRUE))
fit <- mle(ll)
note the recorded call contains ..1, a problem with S4 dispatch
update(fit, fixed = list(xhalf = 3))
```

---

vcov-methods

*Methods for Function `vcov` in Package **stats4***

---

**Description**

Extract the approximate variance-covariance matrix from "mle" objects.

**Methods**

`signature(object = "ANY")` Generic function: see [vcov](#).

`signature(object = "mle")` Extract the estimated variance-covariance matrix for the estimated parameters (if any).

## Chapter 12

# The `tcltk` package

---

`tcltk-package`

*Tcl/Tk Interface*

---

### Description

Interface and language bindings to Tcl/Tk GUI elements.

### Details

This package provides access to the platform-independent Tcl scripting language and Tk GUI elements. See [TkWidgets](#) for a list of supported widgets, [TkWidgetcmds](#) for commands to work with them, and references in those files for more.

The Tcl/Tk documentation is in the system man pages.

For a complete list of functions, use `ls ("package:tcltk")`.

Note that Tk will not be initialized if there is no `DISPLAY` variable set, but Tcl can still be used. This is most useful to allow the loading of a package which depends on `tcltk` in a session that does not actually use it (e.g., during installation).

### Author(s)

R Core Team

Maintainer: R Core Team <R-core@r-project.org>

---

`TclInterface`

*Low-level Tcl/Tk Interface*

---

### Description

These functions and variables provide the basic glue between R and the Tcl interpreter and Tk GUI toolkit. Tk windows may be represented via R objects. Tcl variables can be accessed via objects of class `tclVar` and the C level interface to Tcl objects is accessed via objects of class `tclObj`.

**Usage**

```

.Tcl(...)
.Tcl.objv(objv)
.Tcl.args(...)
.Tcl.args.objv(...)
.Tcl.callback(...)
.Tk.ID(win)
.Tk.newwin(ID)
.Tk.subwin(parent)
.TkRoot

tkdestroy(win)
is.tkwin(x)

tclvalue(x)
tclvalue(x) <- value

tclVar(init = "")
S3 method for class 'tclVar'
as.character(x, ...)
S3 method for class 'tclVar'
tclvalue(x)
S3 replacement method for class 'tclVar'
tclvalue(x) <- value

tclArray()
S3 method for class 'tclArray'
x[[...]]
S3 replacement method for class 'tclArray'
x[[...]] <- value
S3 method for class 'tclArray'
x$i
S3 replacement method for class 'tclArray'
x$i <- value

S3 method for class 'tclArray'
names(x)
S3 method for class 'tclArray'
length(x)

tclObj(x)
tclObj(x) <- value
S3 method for class 'tclVar'
tclObj(x)
S3 replacement method for class 'tclVar'
tclObj(x) <- value

as.tclObj(x, drop = FALSE)
is.tclObj(x)

S3 method for class 'tclObj'
as.character(x, ...)

```

```
S3 method for class 'tclObj'
as.integer(x, ...)
S3 method for class 'tclObj'
as.double(x, ...)
S3 method for class 'tclObj'
as.logical(x, ...)
S3 method for class 'tclObj'
as.raw(x, ...)
S3 method for class 'tclObj'
tclvalue(x)

Default S3 method:
tclvalue(x)
Default S3 replacement method:
tclvalue(x) <- value

addTclPath(path = ".")
tclRequire(package, warn = TRUE)
tclVersion()
```

### Arguments

|                      |                                                                                                                                        |
|----------------------|----------------------------------------------------------------------------------------------------------------------------------------|
| <code>objv</code>    | a named vector of Tcl objects                                                                                                          |
| <code>win</code>     | a window structure                                                                                                                     |
| <code>x</code>       | an object                                                                                                                              |
| <code>i</code>       | character or (unquoted) name                                                                                                           |
| <code>drop</code>    | logical. Indicates whether a single-element vector should be made into a simple Tcl object or a list of length one                     |
| <code>value</code>   | For <code>tclvalue</code> assignments, a character string. For <code>tclObj</code> assignments, an object of class <code>tclObj</code> |
| <code>ID</code>      | a window ID                                                                                                                            |
| <code>parent</code>  | a window which becomes the parent of the resulting window                                                                              |
| <code>path</code>    | path to a directory containing Tcl packages                                                                                            |
| <code>package</code> | a Tcl package name                                                                                                                     |
| <code>warn</code>    | logical. Warn if not found?                                                                                                            |
| <code>...</code>     | Additional arguments. See below.                                                                                                       |
| <code>init</code>    | initialization value                                                                                                                   |

### Details

Many of these functions are not intended for general use but are used internally by the commands that create and manipulate Tk widgets and Tcl objects. At the lowest level `.Tcl` sends a command as a text string to the Tcl interpreter and returns the result as an object of class `tclObj` (see below). A newer variant `.Tcl.objv` accepts arguments in the form of a named list of `tclObj` objects.

`.Tcl.args` converts an R argument list of `tag = value` pairs to the Tcl `-option value` style, thus enabling a simple translation between the two languages. To send a value with no preceding option flag to Tcl, just use an untagged argument. In the rare case one needs an option with no subsequent value `tag = NULL` can be used. Most values are just converted to character mode

and inserted in the command string, but window objects are passed using their ID string, and callbacks are passed via the result of `.Tcl.callback`. Tags are converted to option flags simply by prepending a `-`

`.Tcl.args.objv` serves a similar purpose as `.Tcl.args` but produces a list of `tclObj` objects suitable for passing to `.Tcl.objv`. The names of the list are converted to Tcl option style internally by `.Tcl.objv`.

Callbacks can be either *atomic callbacks* handled by `.Tcl.callback` or expressions. An expression is treated as a list of atomic callbacks, with the following exceptions: if an element is a name, it is first evaluated in the callers frame, and likewise if it is an explicit function definition; the `break` expression is translated directly to the Tcl counterpart. `.Tcl.callback` converts R functions and unevaluated calls to Tcl command strings. The argument must be either a function closure or an object of mode `"call"` followed by an environment. The return value in the first case is of the form `R_call 0x408b94d4` in which the hexadecimal number is the memory address of the function. In the second case it will be of the form `R_call_lang 0x8a95904 0x819bfd0`. For expressions, a sequence of similar items is generated, separated by semicolons. `.Tcl.args` takes special precautions to ensure that functions or calls will continue to exist at the specified address by assigning the callback into the relevant window environment (see below).

Tk windows are represented as objects of class `tkwin` which are lists containing a `ID` field and an `env` field which is an R environments, enclosed in the global environment. The value of the `ID` field is identical to the Tk window name. The `env` environment contains a `parent` variable and a `num.subwin` variable. If the window obtains sub-windows and callbacks, they are added as variables to the environment. `.TkRoot` is the top window with ID `"."`; this window is not displayed in order to avoid ill effects of closing it via window manager controls. The `parent` variable is undefined for `.TkRoot`.

`.Tk.ID` extracts the ID of a window, `.Tk.newwin` creates a new window environment with a given ID and `.Tk.subwin` creates a new window which is a sub-window of a given parent window.

`tkdestroy` destroys a window and also removes the reference to a window from its parent.

`is.tkwin` can be used to test whether a given object is a window environment.

`tclVar` creates a new Tcl variable and initializes it to `init`. An R object of class `tclVar` is created to represent it. Using `as.character` on the object returns the Tcl variable name. Accessing the Tcl variable from R is done using the `tclvalue` function, which can also occur on the left-hand side of assignments. If `tclvalue` is passed an argument which is not a `tclVar` object, then it will assume that it is a character string explicitly naming global Tcl variable. Tcl variables created by `tclVar` are uniquely named and automatically unset by the garbage collector when the representing object is no longer in use.

`tclArray` creates a new Tcl array and initializes it to the empty array. An R object of class `tclArray` and inheriting from class `tclVar` is created to represent it. You can access elements of the Tcl array using indexing with `[]` or `$`, which also allow replacement forms. Notice that Tcl arrays are associative by nature and hence unordered; indexing with a numeric index `i` refers to the element with the *name* `as.character(i)`. Multiple indices are pasted together separated by commas to form a single name. You can query the length and the set of names in an array using methods for `length` and `names`, respectively; these cannot meaningfully be set so assignment forms exist only to print an error message.

It is possible to access Tcl's 'dual-ported' objects directly, thus avoiding parsing and deparsing of their string representation. This works by using objects of class `tclObj`. The string representation of such objects can be extracted (but not set) using `tclvalue` and conversion to vectors of mode `"character"`, `"double"`, `"integer"`, `"logical"`, and `"raw"` is performed using the standard coercion functions `as.character`, etc. Conversely, such vectors can be converted using `as.tclObj`. There is an ambiguity as to what should happen for length one vectors, controlled by

the drop argument; there are cases where the distinction matters to Tcl, although mostly it treats them equivalently. Notice that `tclvalue` and `as.character` differ on an object whose string representation has embedded spaces, the former is sometimes to be preferred, in particular when applied to the result of `tclread`, `tkgetOpenFile`, and similar functions. The `as.raw` method returns a raw vector or a list of raw vectors and can be used to return binary data from Tcl.

The object behind a `tclVar` object is extracted using `tclObj(x)` which also allows an assignment form, in which the right hand side of the assignment is automatically converted using `as.tclObj`. There is a print method for `tclObj` objects; it prints `<Tcl>` followed by the string representation of the object. Notice that `as.character` on a `tclVar` object is the *name* of the corresponding Tcl variable and not the value.

Tcl packages can be loaded with `tclRequire`; it may be necessary to add the directory where they are found to the Tcl search path with `addTclPath`. The return value is a class `"tclObj"` object if it succeeds, or `FALSE` if it fails (when a warning is issued). To see the current search path as an R character vector, use

```
strsplit(tclvalue('auto_path'), " ") [[1]]
```

.

The Tcl version (including patchlevel) is returned as a character string (such as `"8.6.3"`).

## Note

Strings containing unbalanced braces are currently not handled well in many circumstances.

## See Also

[TkWidgets](#), [TkCommands](#), [TkWidgetcmds](#).

`capabilities("tcltk")` to see if Tcl/Tk support was compiled into this build of R.

## Examples

```
tclVersion()

Not run:
These cannot be run by example() but should be OK when pasted
into an interactive R session with the tcltk package loaded
.Tcl("format \"%s\n\" \"Hello, World!\")
f <- function() cat("HI!\n")
.Tcl.callback(f)
.Tcl.args(text = "Push!", command = f) # NB: Different address

xyzzzy <- tclVar(7913)
tclvalue(xyzzzy)
tclvalue(xyzzzy) <- "foo"
as.character(xyzzzy)
tcl("set", as.character(xyzzzy))

top <- tktoplevel() # a Tk widget, see Tk-widgets
ls(envir = top$env, all.names = TRUE)
ls(envir = .TkRoot$env, all.names = TRUE) # .Tcl.args put a callback ref in here

End(Not run)
```

---

|                |                                               |
|----------------|-----------------------------------------------|
| tclServiceMode | <i>Allow Tcl events to be serviced or not</i> |
|----------------|-----------------------------------------------|

---

### Description

This function controls or reports on the Tcl service mode, i.e., whether Tcl will respond to events.

### Usage

```
tclServiceMode(on = NULL)
```

### Arguments

`on` (logical) Whether event servicing is turned on.

### Details

If called with `on == NULL` (the default), no change is made.

Note that this blocks all Tcl/Tk activity, including for widgets from other packages. It may be better to manage mapping of windows individually.

### Value

The value of the Tcl service mode before the call.

### Examples

```
see demo(tkcanvas) for an example
Not run:
oldmode <- tclServiceMode(FALSE)
Do some work to create a nice picture.
Nothing will be displayed until...
tclServiceMode(oldmode)

End(Not run)
another idea is to use tkwm.withdraw() ... tkwm.deiconify()
```

---

|            |                               |
|------------|-------------------------------|
| TkCommands | <i>Tk non-widget commands</i> |
|------------|-------------------------------|

---

### Description

These functions interface to Tk non-widget commands, such as the window manager interface commands and the geometry managers.

**Usage**

```
tcl(...)
tktitle(x)

tktitle(x) <- value

tkbell(...)
tkbind(...)
tkbindtags(...)
tkfocus(...)
tklower(...)
tkraise(...)

tkclipboard.append(...)
tkclipboard.clear(...)

tkevent.add(...)
tkevent.delete(...)
tkevent.generate(...)
tkevent.info(...)

tkfont.actual(...)
tkfont.configure(...)
tkfont.create(...)
tkfont.delete(...)
tkfont.families(...)
tkfont.measure(...)
tkfont.metrics(...)
tkfont.names(...)

tkgrab(...)
tkgrab.current(...)
tkgrab.release(...)
tkgrab.set(...)
tkgrab.status(...)

tkimage.create(...)
tkimage.delete(...)
tkimage.height(...)
tkimage.inuse(...)
tkimage.names(...)
tkimage.type(...)
tkimage.types(...)
tkimage.width(...)

NB: some widgets also have a selection.clear command,
hence the "X".

tkXselection.clear(...)
tkXselection.get(...)
tkXselection.handle(...)
tkXselection.own(...)
```

```
tkwait.variable(...)
tkwait.visibility(...)
tkwait.window(...)

wininfo actually has a large number of subcommands,
but it's rarely used,
so use tkwininfo("atom", ...) etc. instead.

tkwininfo(...)

Window manager interface

tkwm.aspect(...)
tkwm.client(...)
tkwm.colormapwindows(...)
tkwm.command(...)
tkwm.deiconify(...)
tkwm.focusmodel(...)
tkwm.frame(...)
tkwm.geometry(...)
tkwm.grid(...)
tkwm.group(...)
tkwm.iconbitmap(...)
tkwm.iconify(...)
tkwm.iconmask(...)
tkwm.iconname(...)
tkwm.iconposition(...)
tkwm.iconwindow(...)
tkwm.maxsize(...)
tkwm.minsize(...)
tkwm.overrideredirect(...)
tkwm.positionfrom(...)
tkwm.protocol(...)
tkwm.resizable(...)
tkwm.sizefrom(...)
tkwm.state(...)
tkwm.title(...)
tkwm.transient(...)
tkwm.withdraw(...)

Geometry managers

tkgrid(...)
tkgrid.bbox(...)
tkgrid.columnconfigure(...)
tkgrid.configure(...)
tkgrid.forget(...)
tkgrid.info(...)
tkgrid.location(...)
tkgrid.propagate(...)
```

```

tkgrid.rowconfigure(...)
tkgrid.remove(...)
tkgrid.size(...)
tkgrid.slaves(...)

tkpack(...)
tkpack.configure(...)
tkpack.forget(...)
tkpack.info(...)
tkpack.propagate(...)
tkpack.slaves(...)

tkplace(...)
tkplace.configure(...)
tkplace.forget(...)
tkplace.info(...)
tkplace.slaves(...)

Standard dialogs
tkgetOpenFile(...)
tkgetSaveFile(...)
tkchooseDirectory(...)
tkmessageBox(...)
tkdialog(...)
tkpopup(...)

File handling functions
tclfile.tail(...)
tclfile.dir(...)
tclopen(...)
tclclose(...)
tclputs(...)
tclread(...)

```

### Arguments

|                    |                                                           |
|--------------------|-----------------------------------------------------------|
| <code>x</code>     | A window object                                           |
| <code>value</code> | For <code>tktitle</code> assignments, a character string. |
| <code>...</code>   | Handled via <code>.Tcl.args</code>                        |

### Details

`tcl` provides a generic interface to calling any Tk or Tcl command by simply running `.Tcl.args.objv` on the argument list and passing the result to `.Tcl.objv`. Most of the other commands simply call `tcl` with a particular first argument and sometimes also a second argument giving the subcommand.

`tktitle` and its assignment form provides an alternate interface to Tk's `wm title`

There are far too many of these commands to describe them and their arguments in full. Please refer to the Tcl/Tk documentation for details. With a few exceptions, the pattern is that Tk subcommands like `pack` `configure` are converted to function names like `tkpack.configure`, and Tcl subcommands are like `tclfile.dir`.

**See Also**

[TclInterface](#), [TkWidgets](#), [TkWidgetcmds](#)

**Examples**

```
Not run:
These cannot be run by examples() but should be OK when pasted
into an interactive R session with the tcltk package loaded

tt <- tktoplevel()
tkpack(l1 <- tklabel(tt, text = "Heave"), l2 <- tklabel(tt, text = "Ho"))
tkpack.configure(l1, side = "left")

Try stretching the window and then

tkdestroy(tt)

End(Not run)
```

---

tkpager

---

*Page file using Tk text widget*

---

**Description**

This plugs into `file.show`, showing files in separate windows.

**Usage**

```
tkpager(file, header, title, delete.file)
```

**Arguments**

|                          |                                                                                                     |
|--------------------------|-----------------------------------------------------------------------------------------------------|
| <code>file</code>        | character vector containing the names of the files to be displayed                                  |
| <code>header</code>      | headers to use for each file                                                                        |
| <code>title</code>       | common title to use for the window(s). Pasted together with the header to form actual window title. |
| <code>delete.file</code> | logical. Should file(s) be deleted after display?                                                   |

**Note**

The "`\b_`" string used for underlining is currently quietly removed. The font and background colour are currently hardcoded to Courier and gray90.

**See Also**

[file.show](#)

---

tkProgressBar      *Progress Bars via Tk*

---

## Description

Put up a Tk progress bar widget.

## Usage

```
tkProgressBar(title = "R progress bar", label = "",
 min = 0, max = 1, initial = 0, width = 300)

getTkProgressBar(pb)
setTkProgressBar(pb, value, title = NULL, label = NULL)
S3 method for class 'tkProgressBar'
close(con, ...)
```

## Arguments

|                             |                                                                                               |
|-----------------------------|-----------------------------------------------------------------------------------------------|
| <code>title, label</code>   | character strings, giving the window title and the label on the dialog box respectively.      |
| <code>min, max</code>       | (finite) numeric values for the extremes of the progress bar.                                 |
| <code>initial, value</code> | initial or new value for the progress bar.                                                    |
| <code>width</code>          | the width of the progress bar in pixels: the dialog box will be 40 pixels wider (plus frame). |
| <code>pb, con</code>        | an object of class "tkProgressBar".                                                           |
| <code>...</code>            | for consistency with the generic.                                                             |

## Details

`tkProgressBar` will display a widget containing a label and progress bar.

`setTkProgressBar` will update the value and for non-NULL values, the title and label (provided there was one when the widget was created). Missing (NA) and out-of-range values of `value` will be (silently) ignored.

The progress bar should be `closed` when finished with.

This will use the `ttk::progressbar` widget for Tk version 8.5 or later, otherwise R's copy of `BWidget's progressbar`.

## Value

For `tkProgressBar` an object of class "tkProgressBar".

For `getTkProgressBar` and `setTkProgressBar`, a length-one numeric vector giving the previous value (invisibly for `setTkProgressBar`).

## See Also

[txtProgressBar](#)

**Examples**

```
pb <- tkProgressBar("test progress bar", "Some information in %",
 0, 100, 50)

Sys.sleep(0.5)
u <- c(0, sort(runif(20, 0, 100)), 100)
for(i in u) {
 Sys.sleep(0.1)
 info <- sprintf("%d%% done", round(i))
 setTkProgressBar(pb, i, sprintf("test (%s)", info), info)
}
Sys.sleep(5)
close(pb)
```

---

tkStartGUI

*Tcl/Tk GUI startup*

---

**Description**

Starts up the Tcl/Tk GUI

**Usage**

```
tkStartGUI()
```

**Details**

Starts a GUI console implemented via a Tk text widget. This should probably be called at most once per session. Also redefines the file pager (as used by `help()`) to be the Tk pager.

**Note**

`tkStartGUI()` saves its evaluation environment as `.GUIenv`. This means that the user interface elements can be accessed in order to extend the interface. The three main objects are named `Term`, `Menu`, and `Toolbar`, and the various submenus and callback functions can be seen with `ls(envir = .GUIenv)`.

TkWidgetcmds

*Tk widget commands*

---

**Description**

These functions interface to Tk widget commands.

**Usage**

```
tkactivate(widget, ...)
tkadd(widget, ...)
tkaddtag(widget, ...)
tkbbox(widget, ...)
tkcanvasx(widget, ...)
tkcanvasy(widget, ...)
tkcget(widget, ...)
tkcompare(widget, ...)
tkconfigure(widget, ...)
tkcoords(widget, ...)
tkcreate(widget, ...)
tkcurselection(widget, ...)
tkdchars(widget, ...)
tkdebug(widget, ...)
tkdelete(widget, ...)
tkdelta(widget, ...)
tkdeselect(widget, ...)
tkdlineinfo(widget, ...)
tkdtag(widget, ...)
tkdump(widget, ...)
tkentrycget(widget, ...)
tkentryconfigure(widget, ...)
tkfind(widget, ...)
tkflash(widget, ...)
tkfraction(widget, ...)
tkget(widget, ...)
tkgettags(widget, ...)
tkicursor(widget, ...)
tkidentify(widget, ...)
tkindex(widget, ...)
tkinsert(widget, ...)
tkinvoke(widget, ...)
tkitembind(widget, ...)
tkitemcget(widget, ...)
tkitemconfigure(widget, ...)
tkitemfocus(widget, ...)
tkitemlower(widget, ...)
tkitemraise(widget, ...)
tkitemscale(widget, ...)
tkmark.gravity(widget, ...)
tkmark.names(widget, ...)
tkmark.next(widget, ...)
tkmark.previous(widget, ...)
tkmark.set(widget, ...)
tkmark.unset(widget, ...)
tkmove(widget, ...)
tknearest(widget, ...)
tkpost(widget, ...)
tkpostcascade(widget, ...)
tkpostscript(widget, ...)
tkscan.mark(widget, ...)
```

```
tkscan.dragto(widget, ...)
tksearch(widget, ...)
tksee(widget, ...)
tkselect(widget, ...)
tkselection.adjust(widget, ...)
tkselection.anchor(widget, ...)
tkselection.clear(widget, ...)
tkselection.from(widget, ...)
tkselection.includes(widget, ...)
tkselection.present(widget, ...)
tkselection.range(widget, ...)
tkselection.set(widget, ...)
tkselection.to(widget, ...)
tkset(widget, ...)
tksize(widget, ...)
tktoggle(widget, ...)
tktag.add(widget, ...)
tktag.bind(widget, ...)
tktag.cget(widget, ...)
tktag.configure(widget, ...)
tktag.delete(widget, ...)
tktag.lower(widget, ...)
tktag.names(widget, ...)
tktag.nextrange(widget, ...)
tktag.prevrange(widget, ...)
tktag.raise(widget, ...)
tktag.ranges(widget, ...)
tktag.remove(widget, ...)
tktype(widget, ...)
tkunpost(widget, ...)
tkwindow.cget(widget, ...)
tkwindow.configure(widget, ...)
tkwindow.create(widget, ...)
tkwindow.names(widget, ...)
tkxview(widget, ...)
tkxview.moveto(widget, ...)
tkxview.scroll(widget, ...)
tkyposition(widget, ...)
tkyview(widget, ...)
tkyview.moveto(widget, ...)
tkyview.scroll(widget, ...)
```

### Arguments

|        |                                    |
|--------|------------------------------------|
| widget | The widget this applies to         |
| ...    | Handled via <code>.Tcl.args</code> |

### Details

There are far too many of these commands to describe them and their arguments in full. Please refer to the Tcl/Tk documentation for details. Except for a few exceptions, the pattern is that Tcl widget commands possibly with subcommands like `.a.b selection clear` are converted to function names like `tkselection.clear` and the widget is given as the first argument.

**See Also**

**Examples**

```
Not run:
These cannot be run by examples() but should be OK when pasted
into an interactive R session with the tcltk package loaded

tt <- tktoplevel()
tkpack(txt.w <- tktext(tt))
tkinsert(txt.w, "0.0", "plot(1:10)")

callback function
eval.txt <- function() eval(str2lang(tclvalue(tkget(txt.w, "0.0", "end"))))
tkpack(but.w <- tkbutton(tt, text = "Submit", command = eval.txt))

Try pressing the button, edit the text and when finished:

tkdestroy(tt)

End(Not run)
```

---

TkWidgets

*Tk widgets*

---

**Description**

Create Tk widgets and associated R objects.

**Usage**

```
tkwidget(parent, type, ...)

tkbutton(parent, ...)
tkcanvas(parent, ...)
tkcheckboxbutton(parent, ...)
tkentry(parent, ...)
ttkentry(parent, ...)
tkframe(parent, ...)
tklabel(parent, ...)
tklistbox(parent, ...)
tkmenu(parent, ...)
tkmenubutton(parent, ...)
tkmessage(parent, ...)
tkradiobutton(parent, ...)
tkscale(parent, ...)
tkscrollbar(parent, ...)
tktext(parent, ...)
tktoplevel(parent = .TkRoot, ...)
```

```

ttkbutton(parent, ...)
ttkcheckbutton(parent, ...)
ttkcombobox(parent, ...)
ttkframe(parent, ...)
ttklabel(parent, ...)
ttklabelframe(parent, ...)
ttkmenubutton(parent, ...)
ttknotebook(parent, ...)
ttkpanedwindow(parent, ...)
ttkprogressbar(parent, ...)
ttkradiobutton(parent, ...)
ttkscale(parent, ...)
ttkscrollbar(parent, ...)
ttkseparator(parent, ...)
ttksizégrip(parent, ...)
ttkspinbox(parent, ...)
ttktreeview(parent, ...)

```

### Arguments

|        |                                               |
|--------|-----------------------------------------------|
| parent | Parent of widget window.                      |
| type   | string describing the type of widget desired. |
| ...    | handled via <code>.Tcl.args</code> .          |

### Details

These functions create Tk widgets. `tkwidget` creates a widget of a given type, the others simply call `tkwidget` with the respective `type` argument.

The functions starting `ttk` are for the themed widget set for Tk 8.5 or later. A tutorial can be found at <https://tkdocs.com/>.

It is not possible to describe the widgets and their arguments in full. Please refer to the Tcl/Tk documentation.

### Examples

```

Not run:
These cannot be run by examples() but should be OK when pasted
into an interactive R session with the tcltk package loaded

tt <- tktoplevel()
label.widget <- tklabel(tt, text = "Hello, World!")
button.widget <- tkbutton(tt, text = "Push",
 command = function() cat("OW!\n"))
tkpack(label.widget, button.widget) # geometry manager
 # see Tk-commands

Push the button and then...

tkdestroy(tt)

```

```
test for themed widgets
if(as.character(tcl("info", "tclversion")) >= "8.5") {
 # make use of themed widgets
 # list themes
 as.character(tcl("ttk::style", "theme", "names"))
 # select a theme -- here pre-XP windows
 tcl("ttk::style", "theme", "use", "winnative")
} else {
 # use Tk 8.0 widgets
}

End(Not run)
```

---

|               |                                      |
|---------------|--------------------------------------|
| tk_choose.dir | <i>Choose a Folder Interactively</i> |
|---------------|--------------------------------------|

---

## Description

Use a Tk widget to choose a directory interactively.

## Usage

```
tk_choose.dir(default = "", caption = "Select directory")
```

## Arguments

|         |                                      |
|---------|--------------------------------------|
| default | which directory to show initially.   |
| caption | the caption on the selection dialog. |

## Value

A length-one character vector, character NA if 'Cancel' was selected.

## See Also

[tk\\_choose.files](#)

## Examples

```
Not run:
tk_choose.dir(getwd(), "Choose a suitable folder")

End(Not run)
```

---

|                 |                                             |
|-----------------|---------------------------------------------|
| tk_choose.files | <i>Choose a List of Files Interactively</i> |
|-----------------|---------------------------------------------|

---

## Description

Use a Tk file dialog to choose a list of zero or more files interactively.

## Usage

```
tk_choose.files(default = "", caption = "Select files",
 multi = TRUE, filters = NULL, index = 1)
```

## Arguments

|         |                                                  |
|---------|--------------------------------------------------|
| default | which filename to show initially.                |
| caption | the caption on the file selection dialog.        |
| multi   | whether to allow multiple files to be selected.  |
| filters | two-column character matrix of filename filters. |
| index   | unused.                                          |

## Details

Unlike `file.choose`, `tk_choose.files` will always attempt to return a character vector giving a list of files. If the user cancels the dialog, then zero files are returned, whereas `file.choose` would signal an error.

The format of `filters` can be seen from the example. File patterns are specified via extensions, with "\*" meaning any file, and "" any file without an extension (a filename not containing a period). (Other forms may work on specific platforms.) Note that the way to have multiple extensions for one file type is to have multiple rows with the same name in the first column, and that whether the extensions are named in file chooser widget is platform-specific. **The format may change before release.**

## Value

A character vector giving zero or more file paths.

## Note

A bug in Tk 8.5.0–8.5.4 prevented multiple selections being used.

## See Also

`file.choose`, `tk_choose.dir`

## Examples

```
Filters <- matrix(c("R code", ".R", "R code", ".s",
 "Text", ".txt", "All files", "*"),
 4, 2, byrow = TRUE)

Filters
if(interactive()) tk_choose.files(filter = Filters)
```

---

|               |                       |
|---------------|-----------------------|
| tk_messageBox | <i>Tk Message Box</i> |
|---------------|-----------------------|

---

**Description**

An implementation of a generic message box using Tk.

**Usage**

```
tk_messageBox(type = c("ok", "okcancel", "yesno", "yesnocancel",
 "retrycancel", "abortretryignore"),
 message, caption = "", default = "", ...)
```

**Arguments**

|         |                                                                                                          |
|---------|----------------------------------------------------------------------------------------------------------|
| type    | character. The type of dialog box. It will have the buttons implied by its name. Can be abbreviated.     |
| message | character. The information field of the dialog box.                                                      |
| caption | the caption on the widget displayed.                                                                     |
| default | character. The name of the button to be used as the default.                                             |
| ...     | additional named arguments to be passed to the Tk function of this name. An example is icon = "warning". |

**Value**

A character string giving the name of the button pressed.

**See Also**

[tkmessageBox](#) for a 'raw' interface.

---

|                |                                 |
|----------------|---------------------------------|
| tk_select.list | <i>Select Items from a List</i> |
|----------------|---------------------------------|

---

**Description**

Select item(s) from a character vector using a Tk listbox.

**Usage**

```
tk_select.list(choices, preselect = NULL, multiple = FALSE,
 title = NULL)
```

**Arguments**

|           |                                                                                                                       |
|-----------|-----------------------------------------------------------------------------------------------------------------------|
| choices   | a character vector of items.                                                                                          |
| preselect | a character vector, or NULL. If non-null and if the string(s) appear in the list, the item(s) are selected initially. |
| multiple  | logical: can more than one item be selected?                                                                          |
| title     | optional character string for window title, or NULL for no title.                                                     |

**Details**

This is a version of `select.list` implemented as a Tk list box plus OK and Cancel buttons. There will be a scrollbar if the list is too long to fit comfortably on the screen.

The dialog box is *modal*, so a selection must be made or cancelled before the R session can proceed. Double-clicking on an item is equivalent to selecting it and then clicking OK.

If Tk is version 8.5 or later, themed widgets will be used.

**Value**

A character vector of selected items. If `multiple` is false and no item was selected (or Cancel was used), "" is returned. If `multiple` is true and no item was selected (or Cancel was used) then a character vector of length 0 is returned.

**See Also**

`select.list` (a text version except on Windows and the macOS GUI), `menu` (whose `graphics = TRUE` mode uses this on most Unix-alikes).

## Chapter 13

# The `tools` package

---

`tools-package`

*Tools for Package Development*

---

### Description

Tools for package development, administration and documentation.

### Details

This package contains tools for manipulating R packages and their documentation.

For a complete list of functions, use `library(help = "tools")`.

### Author(s)

Kurt Hornik and Friedrich Leisch

Maintainer: R Core Team <R-core@r-project.org>

---

`.print.via.format`

*Printing Utilities*

---

### Description

`.print.via.format` is a “prototype” `print()` method, useful, at least as a start, by a simple

```
print.<myS3class> <- .print.via.format
```

### Usage

```
.print.via.format(x, ...)
```

### Arguments

`x` object to be printed.

`...` optional further arguments, passed to `format`.

**Value**

`x`, invisibly (by `invisible()`), as `print` methods should.

**See Also**

The `print` generic; its default method `print.default` (used for many basic implicit classes such as "numeric", "character" and arrays of them, `lists` etc).

**Examples**

```
The function is simply defined as
function (x, ...) {
 writeLines(format(x, ...))
 invisible(x)
}

is used for simple print methods in R, and as prototype for new methods.
```

---

add\_datalist

---

Add a 'datalist' File to a Source Package

---

**Description**

The `data()` command with no arguments lists all the datasets available via data in attached packages, and to do so a per-package list is installed. Creating that list at install time can be slow for packages with huge datasets, and can be expedited by supplying a 'data/datalist' file.

**Usage**

```
add_datalist(pkgpath, force = FALSE, small.size = 1024^2)
```

**Arguments**

|                         |                                                                                                                                  |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------|
| <code>pkgpath</code>    | The path to a (source) package.                                                                                                  |
| <code>force</code>      | logical: can an existing 'data/datalist' file be over-written?                                                                   |
| <code>small.size</code> | number: a 'data/datalist' file is created only if the total size of the data files is larger than <code>small.size</code> bytes. |

**Details**

R CMD build will call this function to add a data list to packages with 1MB or more of file in the 'data' directory.

It can also be also helpful to give a 'data/datalist' file in packages whose datasets have many dependencies, including loading the packages itself (and maybe others).

**See Also**

`data`.

The 'Writing R Extensions' manual.

---

|                 |                                   |
|-----------------|-----------------------------------|
| assertCondition | <i>Asserting Error Conditions</i> |
|-----------------|-----------------------------------|

---

## Description

When testing code, it is not sufficient to check that results are correct, but also that errors or warnings are signalled in appropriate situations. The functions described here provide a convenient facility for doing so. The three functions check that evaluating the supplied expression produces an error, a warning or one of a specified list of conditions, respectively. If the assertion fails, an error is signalled.

## Usage

```
assertError(expr, classes = "error", verbose = FALSE)
assertWarning(expr, classes = "warning", verbose = FALSE)
assertCondition(expr, ..., .exprString = , verbose = FALSE)
```

## Arguments

|                           |                                                                                                                                                                                                                                                                                                                                                                                  |
|---------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>expr</code>         | an unevaluated R expression which will be evaluated via <code>tryCatch(expr, ...)</code> .                                                                                                                                                                                                                                                                                       |
| <code>classes, ...</code> | <code>character</code> strings corresponding to the classes of the conditions that would satisfy the assertion; e.g., "error" or "warning". If none are specified, any condition will satisfy the assertion. See the details section.                                                                                                                                            |
| <code>.exprString</code>  | The string to be printed corresponding to <code>expr</code> . By default, the actual <code>expr</code> will be deparsed. Will be omitted if the function is supplied with the actual expression to be tested. If <code>assertCondition()</code> is called from another function, with the actual expression passed as an argument to that function, supply the deparsed version. |
| <code>verbose</code>      | If <code>TRUE</code> , a message is printed when the condition is satisfied.                                                                                                                                                                                                                                                                                                     |

## Details

`assertCondition()` uses the general condition mechanism to check all the conditions generated in evaluating `expr`. The occurrence of any of the supplied condition classes among these satisfies the assertion regardless of what other conditions may be signalled.

`assertError()` is a convenience function for asserting errors; it calls `assertCondition()`.

`assertWarning()` asserts that a warning will be signalled, but *not* an error, whereas `assertCondition(expr, "warning")` will be satisfied even if an error follows the warning. See the examples.

## Value

If the assertion is satisfied, a list of all the condition objects signalled is returned, invisibly. See `conditionMessage` for the interpretation of these objects. Note that *all* conditions signalled during the evaluation are returned, whether or not they were among the requirements.

## Author(s)

John Chambers and Martin Maechler

**See Also**

`stop`, `warning`, `signalCondition`, `tryCatch`.

**Examples**

```

assertError(sqrt("abc"))
assertWarning(matrix(1:8, 4,3))

assertCondition("-1 ") # ok, any condition would satisfy this

try(assertCondition(sqrt(2), "warning"))
.. Failed to get warning in evaluating sqrt(2)
 assertCondition(sqrt("abc"), "error") # ok
try(assertCondition(sqrt("abc"), "warning")) # -> error: had no warning
 assertCondition(sqrt("abc"), "error")
identical to assertError() call above

assertCondition(matrix(1:5, 2,3), "warning")
try(assertCondition(matrix(1:8, 4,3), "error"))
.. Failed to get expected error

either warning or worse:
assertCondition(matrix(1:8, 4,3), "error","warning") # OK
assertCondition(matrix(1:8, 4, 3), "warning") # OK

when both are signalled:
ff <- function() { warning("my warning"); stop("my error") }
 assertCondition(ff(), "warning")
but assertWarning does not allow an error to follow
try(assertWarning(ff()))
 assertCondition(ff(), "error") # ok
assertCondition(ff(), "error", "warning") # ok (quietly, catching warning)

assert that assertC..() does not assert [and use *one* argument only]
assertCondition(assertCondition(sqrt(2), "warning"))
assertCondition(assertCondition(sqrt("abc"), "warning"), "error")
assertCondition(assertCondition(matrix(1:8, 4,3), "error"),
 "error")

```

---

bibstyle

*Select or Define a Bibliography Style*

---

**Description**

This function defines and registers styles for rendering `bibentry` objects into ‘Rd’ format, for later conversion to text, HTML, etc.

**Usage**

```

bibstyle(style, envir, ..., .init = FALSE, .default = TRUE)
getBibstyle(all = FALSE)

```

## Arguments

|                       |                                                                         |
|-----------------------|-------------------------------------------------------------------------|
| <code>style</code>    | A character string naming the style.                                    |
| <code>envir</code>    | (optional) An environment holding the functions to implement the style. |
| <code>...</code>      | Named arguments to add to the environment.                              |
| <code>.init</code>    | Whether to initialize the environment from the default style "JSS".     |
| <code>.default</code> | Whether to set the specified style as the default style.                |
| <code>all</code>      | Whether to return the names of all registered styles.                   |

## Details

Rendering of `bibentry` objects may be done using routines modelled after those used by BibTeX. This function allows environments to be created and manipulated to contain those routines.

There are two ways to create a new style environment. The easiest is to set `.init = TRUE`, in which case the environment will be initialized with a copy of the default "JSS" environment. (This style is modelled after the 'jss.bst' style used by the *Journal of Statistical Software*.) Alternatively, the `envir` argument can be used to specify a completely new style environment.

To find the name of the default style, use `getBibstyle()`. To retrieve an existing style without setting it as the default, use `bibstyle(style, .default = FALSE)`. To modify an existing style, specify `style` and some named entries via `...` (Modifying the default "JSS" style is discouraged.) Setting `style` to `NULL` or leaving it missing will retrieve the default style, but modifications will not be allowed.

At a minimum, the environment should contain routines to render each of the 12 types of bibliographic entry supported by `bibentry` as well as several other routines described below. The former must be named `formatArticle`, `formatBook`, `formatInbook`, `formatIncollection`, `formatInProceedings`, `formatManual`, `formatMastersthesis`, `formatMisc`, `formatPhdthesis`, `formatProceedings`, `formatTechreport` and `formatUnpublished`. Each of these takes one argument, a single `unclass`'ed entry from the `bibentry` vector passed to the renderer, and should produce a single element character vector (possibly containing newlines).

The other routines are as follows. `sortKeys`, a function to produce a sort key to sort the entries, is passed the original `bibentry` vector and should produce a sortable vector of the same length to define the sort order. Finally, the optional function `cite` should have the same argument list as `utils::cite`, and should produce a citation to be used in text.

The `format` method for "bibentry" objects adds a field named `".index"` to each entry after sorting and before formatting. This is a 1-based index within the complete object that can be used in styles that require numbering. Although the "JSS" style doesn't use numbers, it includes a `fmtPrefix()` stub function that may be used to display them. See the example below.

## Value

`bibstyle` returns the environment which has been selected or created.

`getBibstyle` returns the name of the default style, or all style names.

```

buildVignette

*Build One Vignette***Description**

Run [Sweave](#) (or other custom weave function), [texi2pdf](#), and/or [Stangle](#) (or other custom tangle function) on one vignette.

This is the workhorse of R CMD Sweave.

**Usage**

```

buildVignette(file, dir = ".", weave = TRUE, latex = TRUE, tangle = TRUE,
 quiet = TRUE, clean = TRUE, keep = character(),
 engine = NULL, buildPkg = NULL, encoding, ...)

```

**Arguments**

|        |                                                                                               |
|--------|-----------------------------------------------------------------------------------------------|
| file   | character; the vignette source file.                                                          |
| dir    | character; the working directory in which the intermediate and output files will be produced. |
| weave  | logical; should weave be run?                                                                 |
| latex  | logical; should <a href="#">texi2pdf</a> be run if weaving produces a ‘.tex’ file?            |
| tangle | logical; should tangle be run?                                                                |
| quiet  | logical; run in quiet mode?                                                                   |
| clean  | logical; whether to remove some newly created, often intermediate, files. See details below.  |

|          |                                                                                                                                                                                                                                                                               |
|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| keep     | a list of file names to keep in any case when cleaning. Note that “target” files are kept anyway.                                                                                                                                                                             |
| engine   | NULL or character; name of vignette engine to use. Overrides any <code>\VignetteEngine{}</code> markup in the vignette.                                                                                                                                                       |
| buildPkg | NULL or a character vector; optional packages in which to find the vignette engine.                                                                                                                                                                                           |
| encoding | the encoding to assume for the file. If not specified, it will be read if possible from the file’s contents. Note that if the vignette is part of a package, <code>buildVignettes</code> reads the package’s encoding from the ‘DESCRIPTION’ file but this function does not. |
| ...      | Additional arguments passed to weave and tangle.                                                                                                                                                                                                                              |

### Details

This function determines the vignette engine for the vignette (default `utils::Sweave`), then weaves and/or tangles the vignette using that engine. Finally, if `clean` is `TRUE`, newly created intermediate files (non “targets”, where these depend on the engine, etc, and not any in `keep`) will be deleted. If `clean` is `NA`, and `weave` is true, newly created intermediate output files (e.g., ‘.tex’) will not be deleted even if a ‘.pdf’ file has been produced from them.

If `buildPkg` is specified, those packages will be loaded before the vignette is processed and will be used as the default packages in the search for a vignette engine, but an explicitly specified package in the vignette source (e.g., using `\VignetteEngine{utils::Sweave}` to specify the `Sweave` engine in the `utils` package) will override it. In contrast, if the `engine` argument is given, it will override the vignette source.

### Value

A character vector naming the files that have been produced.

### Author(s)

Henrik Bengtsson and Duncan Murdoch

### See Also

`buildVignettes` for building all vignettes in a package.

---

|                |                                         |
|----------------|-----------------------------------------|
| buildVignettes | <i>List and Build Package Vignettes</i> |
|----------------|-----------------------------------------|

---

### Description

Run `Sweave` (or other custom weave function) and `texi2pdf` on all vignettes of a package, or list the vignettes.

### Usage

```
buildVignettes(package, dir, lib.loc = NULL, quiet = TRUE,
 clean = TRUE, tangle = FALSE, ser_elibs = NULL)

pkgVignettes(package, dir, subdirs = NULL, lib.loc = NULL,
 output = FALSE, source = FALSE, check = FALSE)
```

**Arguments**

|                        |                                                                                                                                                                                                                                                                        |
|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>package</code>   | a character string naming an installed package. If given, vignette source files are by default looked for in subdirectory <code>'doc'</code> .                                                                                                                         |
| <code>dir</code>       | a character string specifying the path to a package's root source directory. If given, vignette source files are by default looked for in subdirectory <code>'vignettes'</code> .                                                                                      |
| <code>lib.loc</code>   | a character vector of directory names of R libraries, or <code>NULL</code> . The default value of <code>NULL</code> corresponds to all libraries currently known. The specified library trees are used to search for <code>package</code> .                            |
| <code>quiet</code>     | logical. Weave and run <code>texi2pdf</code> in quiet mode.                                                                                                                                                                                                            |
| <code>clean</code>     | Remove all files generated by the build, even if there were copies there before.                                                                                                                                                                                       |
| <code>tangle</code>    | logical. Do tangling as well as weaving.                                                                                                                                                                                                                               |
| <code>ser_elibs</code> | For use from R CMD check.                                                                                                                                                                                                                                              |
| <code>subdirs</code>   | a character vector of subdirectories of <code>dir</code> in which to look for vignettes. The first which exists is used. Defaults to <code>"doc"</code> if <code>package</code> is supplied, otherwise <code>"vignettes"</code> .                                      |
| <code>output</code>    | logical indicating if the output filenames for each vignette should be returned (in component <code>outputs</code> ).                                                                                                                                                  |
| <code>source</code>    | logical indicating if the <i>tangled</i> output filenames for each vignette should be returned (in component <code>sources</code> ).                                                                                                                                   |
| <code>check</code>     | logical. If <code>TRUE</code> , check whether all files that have vignette-like filenames have an identifiable vignette engine. This may be a false positive if a file is not a vignette but has a filename matching a pattern defined by one of the vignette engines. |

**Details**

`buildVignettes` is used by R CMD `build` and R CMD `check` to (re-)build vignette outputs from their sources.

As from R 3.4.1, both of these functions ignore files that are listed in the `'.Rbuildignore'` file in `dir`.

**Value**

`buildVignettes` is called for its side effect of creating the outputs of all vignettes, and if `tangle = TRUE`, extracting the R code.

`pkgVignettes` returns an object of class `"pkgVignettes"` if a vignette directory is found, otherwise `NULL`.

**Examples**

```
gVigns <- pkgVignettes("grid")
str(gVigns)
```

## Description

`charset_to_Unicode` is a matrix of Unicode code points with columns for the common 8-bit encodings.

`Adobe_glyphs` is a data frame which gives Adobe glyph names for Unicode code points. It has two character columns, "adobe" and "unicode" (a 4-digit hex representation).

## Usage

```
charset_to_Unicode
```

```
Adobe_glyphs
```

## Details

`charset_to_Unicode` is an integer matrix of class `c("noquote", "hexmode")` so prints in hexadecimal. The mappings are those used by `libiconv`: there are differences in the way quotes and minus/hyphen are mapped between sources (and the postscript encoding files use a different mapping).

`Adobe_glyphs` includes all the Adobe glyph names which correspond to single Unicode characters. It is sorted by Unicode code point and within a point alphabetically on the glyph (there can be more than one name for a Unicode code point). The data are in the file '[R\\_HOME](#)/share/encodings/Adobe\_glyphlist'.

## Examples

```
find Adobe names for ISOLatin2 chars.
latin2 <- charset_to_Unicode[, "ISOLatin2"]
aUnicode <- as.numeric(paste0("0x", Adobe_glyphs$unicode))
keep <- aUnicode %in% latin2
aUnicode <- aUnicode[keep]
aAdobe <- Adobe_glyphs[keep, 1]
first match
aLatin2 <- aAdobe[match(latin2, aUnicode)]
all matches
bLatin2 <- lapply(1:256, function(x) aAdobe[aUnicode == latin2[x]])
format(bLatin2, justify = "none")
```

## Description

Performs checks on calls to compiled code from R code. Currently only checks whether the interface functions such as `.C` and `.Fortran` are called with a "[NativeSymbolInfo](#)" first argument or with argument `PACKAGE` specified, which is highly recommended to avoid name clashes in foreign function calls.

## Usage

```
checkFF(package, dir, file, lib.loc = NULL,
 registration = FALSE, check_DUP = FALSE,
 verbose = getOption("verbose"))
```

## Arguments

|                           |                                                                                                                                                                                                                                             |
|---------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>package</code>      | a character string naming an installed package. If given, the installed R code of the package is checked.                                                                                                                                   |
| <code>dir</code>          | a character string specifying the path to a package's root source directory. This should contain the subdirectory 'R' (for R code). Only used if <code>package</code> is not given.                                                         |
| <code>file</code>         | the name of a file containing R code to be checked. Used if neither <code>package</code> nor <code>dir</code> are given.                                                                                                                    |
| <code>lib.loc</code>      | a character vector of directory names of R libraries, or <code>NULL</code> . The default value of <code>NULL</code> corresponds to all libraries currently known. The specified library trees are used to search for <code>package</code> . |
| <code>registration</code> | a logical. If <code>TRUE</code> , checks the registration information on the call (if available).                                                                                                                                           |
| <code>check_DUP</code>    | a logical. If <code>TRUE</code> , <code>.C</code> and <code>.Fortran</code> calls with <code>DUP = FALSE</code> are reported.                                                                                                               |
| <code>verbose</code>      | a logical. If <code>TRUE</code> , additional diagnostics are printed (and the result is returned invisibly).                                                                                                                                |

## Details

Note that we can only check if the `name` argument is a symbol or a character string, not what class of object the symbol resolves to at run-time.

If the package has a namespace which contains a `useDynLib` directive, calls in top-level functions in the package are not reported as their symbols will be preferentially looked up in the DLL named in the first `useDynLib` directive.

This checks that calls with `PACKAGE` specified are to the same package, and reports separately those which are in base packages and those which are in other packages (and if those packages are specified in the 'DESCRIPTION' file).

## Value

An object of class "checkFF".

There are `format` and `print` methods to display the information contained in such objects.

## See Also

`.C`, `.Fortran`; `Foreign`.

## Examples

```
order is pretty much random
checkFF(package = "stats", verbose = TRUE)
```

---

`checkMD5sums`*Check and Create MD5 Checksum Files*

---

**Description**

`checkMD5sums` checks the files against a file ‘MD5’.

**Usage**

```
checkMD5sums(package, dir)
```

**Arguments**

|                      |                                                              |
|----------------------|--------------------------------------------------------------|
| <code>package</code> | the name of an installed package                             |
| <code>dir</code>     | the path to the top-level directory of an installed package. |

**Details**

The file ‘MD5’ which is created is in a format which can be checked by `md5sum -c MD5` if a suitable command-line version of `md5sum` is available. (For Windows, one is supplied in the bundle at <https://cran.r-project.org/bin/windows/Rtools/>.)

If `dir` is missing, an installed package of name `package` is searched for.

The private function `tools:::installMD5sums` is used to create MD5 files in the Windows build.

**Value**

`checkMD5sums` returns a logical, NA if there is no ‘MD5’ file to be checked.

**See Also**

[md5sum](#)

---

`checkPoFiles`*Check Translation Files for Inconsistent Format Strings*

---

**Description**

These functions compare formats embedded in English messages with translated strings to check for consistency. `checkPoFile` checks one file, while `checkPoFiles` checks all files for a specified language.

**Usage**

```
checkPoFile(f, strictPlural = FALSE)
checkPoFiles(language, dir = ".")
```

## Arguments

|                           |                                                                          |
|---------------------------|--------------------------------------------------------------------------|
| <code>f</code>            | a character string giving a single filepath.                             |
| <code>strictPlural</code> | whether to compare formats of singular and plural forms in a strict way. |
| <code>language</code>     | a character string giving a language code.                               |
| <code>dir</code>          | a path to a directory in which to check files.                           |

## Details

Part of R's internationalization depends on translations of messages in `‘.po’` files. In these files an ‘English’ message taken from the R sources is followed by a translation into another language. Many of these messages are format strings for C or R `sprintf` and related functions. In these cases, the translation must give a compatible format or an error will be generated when the message is displayed.

The rules for compatibility differ between C and R in several ways. C supports several conversions not supported by R, namely `c`, `u`, `p`, `n`. It is allowed in C's `sprintf()` function to have more arguments than are needed by the format string, but in R the counts must match exactly. R requires types of arguments to match, whereas C will do the display whether it makes sense or not.

These functions compromise on the testing as follows. The additional formats allowed in C are accepted, and all differences in argument type or count are reported. As a consequence some reported differences are not errors.

If the `strictPlural` argument is `TRUE`, then argument lists must agree exactly between singular and plural forms of messages; if `FALSE`, then translations only need to match one or the other of the two forms. When `checkPoFiles` calls `checkPoFile`, the `strictPlural` argument is set to `TRUE` for files with names starting `‘R-’`, and to `FALSE` otherwise.

Items marked as ‘fuzzy’ in the `‘.po’` file are not processed (as they are ignored by the message compiler).

If a difference is found, the translated string is checked for variant percent signs (e.g., the wide percent sign `"\uFF05"`). Such signs will not be recognized as format specifiers, and are likely to be errors.

## Value

Both functions return an object of S3 class `"check_po_files"`. A `print` method is defined for this class to display a report on the differences.

checkPoFiles("de", "/path/to/R/src/directory")

End (Not run)
```

---

checkRd

---

*Check an Rd Object*

---

## Description

Check an help file or the output of the [parse\\_Rd](#) function.

## Usage

```
checkRd(Rd, defines = .Platform$OS.type, stages = "render",
 unknownOK = TRUE, listOK = TRUE, ..., def_enc = FALSE)
```

## Arguments

|           |                                                                                                                                        |
|-----------|----------------------------------------------------------------------------------------------------------------------------------------|
| Rd        | a filename or Rd object to use as input.                                                                                               |
| defines   | string(s) to use in <code>#ifdef</code> tests.                                                                                         |
| stages    | at which stage ("build", "install", or "render") should <code>\Sexpr</code> macros be executed? See the notes below.                   |
| unknownOK | unrecognized macros are treated as errors if <code>FALSE</code> , otherwise warnings.                                                  |
| listOK    | unnecessary non-empty braces (e.g., around text, not as an argument) are treated as errors if <code>FALSE</code> , otherwise warnings. |
| ...       | additional parameters to pass to <a href="#">parse_Rd</a> when Rd is a filename. One that is often useful is <code>encoding</code> .   |
| def_enc   | logical: has the package declared an encoding, so tests for non-ASCII text are suppressed?                                             |

## Details

`checkRd` performs consistency checks on an Rd file, confirming that required sections are present, etc.

It accepts a filename for an Rd file, and will use [parse\\_Rd](#) to parse it before applying the checks. If so, warnings from `parse_Rd` are collected, together with those from the internal function `prepare_Rd`, which does the `#ifdef` and `\Sexpr` processing, drops sections that would not be rendered or are duplicated (and should not be) and removes empty sections.

An Rd object is passed through `prepare_Rd`, but it may already have been (and installed Rd objects have).

Warnings are given a ‘level’: those from `prepare_Rd` have level 0. These include

- All text must be in a section
- Only one *tag name* section is allowed: the first will be used
- Section *name* is unrecognized and will be dropped
- Dropping empty section *name*

checkRd itself can show

```

7 Tag tag name not recognized
7 \tabular format must be simple text
7 Unrecognized \tabular format: ...
7 Only n columns allowed in this table
7 Must have a tag name
7 Only one tag name is allowed
7 Tag tag name must not be empty
7 \docType must be plain text
5 Tag \method is only valid in \usage
5 Tag \dontrun is only valid in \examples
5 Tag tag name is invalid in a block name block
5 Title of \section must be non-empty plain text
5 \title content must be plain text
3 Empty section tag name
-1 Non-ASCII contents without declared encoding
-1 Non-ASCII contents in second part of \enc
-3 Tag ... is not valid in a code block
-3 Apparent non-ASCII contents without declared encoding
-3 Apparent non-ASCII contents in second part of \enc
-3 Unnecessary braces at ...
-3 \method not valid outside a code block

```

and variations with \method replaced by \S3method or \S4method.

Note that both `prepare_Rd` and `checkRd` have tests for an empty section: that in `checkRd` is stricter (essentially that nothing is output).

### Value

This may fail through an R error, but otherwise warnings are collected as returned as an object of class "checkRd", a character vector of messages. This class has a `print` method which only prints unique messages, and has argument `minlevel` that can be used to select only more serious messages. (This is set to `-1` in R CMD check.)

Possible fatal errors are those from running the parser (e.g., a non-existent file, unclosed quoted string, non-ASCII input without a specified encoding) or from `prepare_Rd` (multiple `\Rdversion` declarations, invalid `\encoding` or `\docType` or `\name` sections, and missing or duplicate `\name` or `\title` sections).

[parse\\_Rd](#), [Rd2HTML](#).

checkRdaFiles

*Report on Details of Saved Images or Re-saves them***Description**

This reports for each of the files produced by `save` the size, if it was saved in ASCII or XDR binary format, and if it was compressed (and if so in what format).

Usually such files have extension `‘.rda’` or `‘.RData’`, hence the name of the function.

**Usage**

```
checkRdaFiles(paths)
resaveRdaFiles(paths, compress = c("auto", "gzip", "bzip2", "xz"),
 compression_level, version = NULL)
```

**Arguments**

|                                          |                                                                                                                                                                                     |
|------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>paths</code>                       | A character vector of paths to save files. If this specifies a single directory, it is taken to refer to all <code>‘.rda’</code> and <code>‘.RData’</code> files in that directory. |
| <code>compress, compression_level</code> | Type and level of compression: see <a href="#">save</a> . Values of <code>compress</code> can be abbreviated.                                                                       |
| <code>version</code>                     | The format to be used when re-saving: see <a href="#">save</a> .                                                                                                                    |

**Details**

`compress = "auto"` asks **R** to choose the compression and ignores `compression_level`. It will try "gzip", "bzip2" and if the "gzip" compressed size is over 10Kb, "xz" and choose the smallest compressed file (but with a 10% bias towards "gzip"). This can be slow.

For back-compatibility, `version = NULL` is interpreted to mean version 2: however version-3 files will only be saved as version 3.

**Value**

For `checkRdaFiles`, a data frame with rows names `paths` and columns

|                       |                                                                                                                                                                                |
|-----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>size</code>     | numeric: file size in bytes, NA if the file does not exist.                                                                                                                    |
| <code>ASCII</code>    | logical: true for <code>save(ASCII = TRUE)</code> , NA if the format is not that of an <b>R</b> save file.                                                                     |
| <code>compress</code> | character: type of compression. One of "gzip", "bzip2", "xz", "none" or "unknown" (which means that if this is an <b>R</b> save file it is from a later version of <b>R</b> ). |
| <code>version</code>  | integer: positive with the version(s) of the <code>save()</code> , see there on which versions have been default in which versions of <b>R</b> , and NA for non-Rda files.     |

## Examples

```
Not run:
from a package top-level source directory
paths <- sort(Sys.glob(c("data/*.rda", "data/*.RData")))
(res <- checkRdaFiles(paths))
pick out some that may need attention
bad <- is.na(res$ASCII) | res$ASCII | (res$size > 1e4 & res$compress == "none")
res[bad,]

End(Not run)
```

---

checkTnF

---

*Check R Packages or Code for T/F*

---

## Description

Checks the specified R package or code file for occurrences of T or F, and gathers the expression containing these. This is useful as in R T and F are just variables which are set to the logicals TRUE and FALSE by default, but are not reserved words and hence can be overwritten by the user. Hence, one should always use TRUE and FALSE for the logicals.

## Usage

```
checkTnF(package, dir, file, lib.loc = NULL)
```

## Arguments

|                      |                                                                                                                                                                                                                                                                                                                         |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>package</code> | a character string naming an installed package. If given, the installed R code and the examples in the documentation files of the package are checked. R code installed as an image file cannot be checked.                                                                                                             |
| <code>dir</code>     | a character string specifying the path to a package's root source directory. This must contain the subdirectory 'R' (for R code), and should also contain 'man' (for documentation). Only used if <code>package</code> is not given. If used, the R code files and the examples in the documentation files are checked. |
| <code>file</code>    | the name of a file containing R code to be checked. Used if neither <code>package</code> nor <code>dir</code> are given.                                                                                                                                                                                                |
| <code>lib.loc</code> | a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known. The specified library trees are used to search for <code>package</code> .                                                                                                        |

## Value

An object of class "checkTnF" which is a list containing, for each file where occurrences of T or F were found, a list with the expressions containing these occurrences. The names of the list are the corresponding file names.

There is a `print` method for nicely displaying the information contained in such objects.

---

|                |                                |
|----------------|--------------------------------|
| checkVignettes | <i>Check Package Vignettes</i> |
|----------------|--------------------------------|

---

## Description

Check all vignettes of a package by running [Sweave](#) (or other custom weave function) and/or [Stangle](#) (or other custom tangle function) on them. All R source code files found after the tangling step are [source](#)d to check whether all code can be executed without errors.

## Usage

```
checkVignettes(package, dir, lib.loc = NULL,
 tangle = TRUE, weave = TRUE, latex = FALSE,
 workdir = c("tmp", "src", "cur"),
 keepfiles = FALSE)
```

## Arguments

|           |                                                                                                                                                                                                                                                                       |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| package   | a character string naming an installed package. If given, vignette source files are looked for in subdirectory ‘doc’.                                                                                                                                                 |
| dir       | a character string specifying the path to a package’s root source directory. If given, vignette source files are looked for in subdirectory ‘vignettes’.                                                                                                              |
| lib.loc   | a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known. The specified library trees are used to search for package.                                                                    |
| tangle    | Perform a tangle and <a href="#">source</a> the extracted code?                                                                                                                                                                                                       |
| weave     | Perform a weave?                                                                                                                                                                                                                                                      |
| latex     | logical: if weave and latex are TRUE and there is no ‘Makefile’ in the vignettes directory, run the intermediate ‘.tex’ outputs from weaving through <a href="#">texi2pdf</a> .                                                                                       |
| workdir   | Directory used as working directory while checking the vignettes. If "tmp" then a temporary directory is created, this is the default. If "src" then the directory containing the vignettes itself is used, if "cur" then the current working directory of R is used. |
| keepfiles | Delete files in the temporary directory? This option is ignored when workdir != "tmp".                                                                                                                                                                                |

## Details

This function first uses [pkgVignettes](#) to find the package vignettes, and in particular their vignette engines (see [vignetteEngine](#)).

If tangle is true, it then runs [Stangle](#) (or other custom tangle function provided by the engine) to produce (one or more) R code files from each vignette, then [sources](#) each code file in turn.

If weave is true, the vignettes are run through [Sweave](#) (or other custom weave function provided by the engine). If latex is also true and there is no ‘Makefile’ in the vignettes directory, [texi2pdf](#) is run on the intermediate ‘.tex’ files from weaving for those vignettes which did not give errors in the previous steps.

**Value**

An object of class "checkVignettes", which is a list with the error messages found during the tangle, source, weave and latex steps. There is a `print` method for displaying the information contained in such objects.

---

```
check_packages_in_dir
```

*Check Source Packages and Their Reverse Dependencies*

---

**Description**

Check source packages in a given directory, optionally with their reverse dependencies.

**Usage**

```
check_packages_in_dir(dir,
 check_args = character(),
 check_args_db = list(),
 reverse = NULL,
 check_env = character(),
 xvfb = FALSE,
 Ncpus = getOption("Ncpus", 1L),
 clean = TRUE,
 ...)

summarize_check_packages_in_dir_results(dir, all = TRUE,
 full = FALSE, ...)
summarize_check_packages_in_dir_timings(dir, all = FALSE,
 full = FALSE)
summarize_check_packages_in_dir_depends(dir, all = FALSE,
 which = c("Depends",
 "Imports",
 "LinkingTo"))

check_packages_in_dir_changes(dir, old,
 outputs = FALSE, sources = FALSE, ...)
check_packages_in_dir_details(dir, logs = NULL, drop_ok = TRUE, ...)
```

**Arguments**

|                            |                                                                                                                                                                                                         |
|----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>dir</code>           | a character string giving the path to the directory with the source <code>‘.tar.gz’</code> files to be checked.                                                                                         |
| <code>check_args</code>    | a character vector with arguments to be passed to R CMD <code>check</code> , or a list of length two of such character vectors to be used for checking packages and reverse dependencies, respectively. |
| <code>check_args_db</code> | a named list of character vectors with arguments to be passed to R CMD <code>check</code> , with names the respective package names.                                                                    |

|           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| reverse   | a list with names partially matching "repos", "which", or "recursive", giving the repositories to use for locating reverse dependencies (default: <code>getOption("repos")</code> ), the types of reverse dependencies (default: <code>c("Depends", "Imports", "LinkingTo")</code> ), with shorthands "most" and "all" as for <a href="#">package_dependencies</a> ), and indicating whether to also check reverse dependencies of reverse dependencies and so on (default: FALSE), or NULL (default), in which case no reverse dependencies are checked. |
| check_env | a character vector of name=value strings to set environment variables for checking, or a list of length two of such character vectors to be used for checking packages and reverse dependencies, respectively.                                                                                                                                                                                                                                                                                                                                            |
| xvfb      | a logical indicating whether to perform checking inside a virtual framebuffer X server (Unix only), or a character vector of Xvfb options for doing so.                                                                                                                                                                                                                                                                                                                                                                                                   |
| Ncpus     | the number of parallel processes to use for parallel installation and checking.                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| clean     | a logical indicating whether to remove the downloaded reverse dependency sources.                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| ...       | passed to <a href="#">readLines</a> , e.g. for reading log files produced in a different encoding; currently not used by <code>check_packages_in_dir</code> .                                                                                                                                                                                                                                                                                                                                                                                             |
| all       | a logical indicating whether to also summarize the reverse dependencies checked.                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| full      | a logical indicating whether to also give details for checks with non-ok results, or summarize check example timings (if available).                                                                                                                                                                                                                                                                                                                                                                                                                      |
| which     | see <a href="#">package_dependencies</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| old       | a character string giving the path to the directory of a previous <code>check_packages_in_dir</code> run.                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| outputs   | a logical indicating whether to analyze changes in the outputs of the checks performed, or only (default) the status of the checks.                                                                                                                                                                                                                                                                                                                                                                                                                       |
| sources   | a logical indicating whether to also investigate the changes in the source files checked (default: FALSE).                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| logs      | a character vector with the paths of '00check.log' to analyze. Only used if <code>dir</code> was not given.                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| drop_ok   | a logical indicating whether to drop checks with 'ok' status, or a character vector with the 'ok' status tags to drop. The default corresponds to tags 'OK', 'NONE' and 'SKIPPED'.                                                                                                                                                                                                                                                                                                                                                                        |

## Details

`check_packages_in_dir` allows to conveniently check source package `'tar.gz'` files in the given directory `dir`, along with their reverse dependencies as controlled by `reverse`.

The "which" component of `reverse` can also be a list, in which case reverse dependencies are obtained for each element of the list and the corresponding element of the "recursive" component of `reverse` (which is recycled as needed).

If needed, the source `'tar.gz'` files of the reverse dependencies to be checked as well are downloaded into `dir` (and removed at the end if `clean` is true). Next, all packages (additionally) needed for checking are installed to the 'Library' subdirectory of `dir`. Then, all `'tar.gz'` files are checked using the given arguments and environment variables, with outputs and messages to files in the 'Outputs' subdirectory of `dir`. The `'*.Rcheck'` directories with the check results of the reverse dependencies are renamed by prefixing their base names with `'rdepends_'`.

Results and timings can conveniently be summarized using `summarize_check_packages_in_dir_results` and `summarize_check_packages_in_dir_timings`, respectively.

Installation and checking is performed in parallel if `Ncpus` is greater than one: this will use `mclapply` on Unix and `parLapply` on Windows.

`check_packages_in_dir` returns an object inheriting from class `"check_packages_in_dir"` which has `print` and `summary` methods.

`check_packages_in_dir_changes` allows to analyze the effect of changing (some of) the sources. With `dir` and `old` the paths to the directories with the new and old sources, respectively, and the corresponding check results, possible changes in the check results can conveniently be analyzed as controlled via options `outputs` and `sources`. The changes object returned can be subscripted according to change in severity from the old to the new results by using one of `"=="`, `"!="`, `"<"`, `"<="`, `">"` or `">="` as row index.

`check_packages_in_dir_details` analyzes check log files to obtain check details as a data frame which can be used for further processing, providing check name, status and output for every check performed and not dropped according to status tag (via variables `Check`, `Status` and `Output`, respectively).

Environment variable `_R_CHECK_ELAPSED_TIMEOUT_` can be used to set a limit on the elapsed time of each check run. See the 'R Internals' manual for how the value is interpreted and for other environment variables which can be used for finer-grained control on timeouts within a check run.

## Note

This functionality is still experimental: interfaces may change in future versions.

## Examples

```
Not run:
Check packages in dir without reverse dependencies:
check_packages_in_dir(dir)
Check packages in dir and their reverse dependencies using the
defaults (all repositories in getOption("repos"), all "strong"
reverse dependencies, no recursive reverse dependencies):
check_packages_in_dir(dir, reverse = list())
Check packages in dir with their reverse dependencies from CRAN,
using all strong reverse dependencies and reverse suggests:
check_packages_in_dir(dir,
 reverse = list(repos = getOption("repos")["CRAN"],
 which = "most"))
Check packages in dir with their reverse dependencies from CRAN,
using '--as-cran' for the former but not the latter:
check_packages_in_dir(dir,
 check_args = c("--as-cran", ""),
 reverse = list(repos = getOption("repos")["CRAN"]))

End(Not run)
```

codoc

*Check Code/Documentation Consistency***Description**

Find inconsistencies between actual and documented ‘structure’ of R objects in a package. `codoc` compares names and optionally also corresponding positions and default values of the arguments of functions. `codocClasses` and `codocData` compare slot names of S4 classes and variable names of data sets, respectively.

**Usage**

```
codoc(package, dir, lib.loc = NULL,
 use.values = NULL, verbose = getOption("verbose"))
codocClasses(package, lib.loc = NULL)
codocData(package, lib.loc = NULL)
```

**Arguments**

|                         |                                                                                                                                                                                                                                             |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>package</code>    | a character string naming an installed package.                                                                                                                                                                                             |
| <code>dir</code>        | a character string specifying the path to a package’s root source directory. This must contain the subdirectories ‘man’ with R documentation sources (in Rd format) and ‘R’ with R code. Only used if <code>package</code> is not given.    |
| <code>lib.loc</code>    | a character vector of directory names of R libraries, or <code>NULL</code> . The default value of <code>NULL</code> corresponds to all libraries currently known. The specified library trees are used to search for <code>package</code> . |
| <code>use.values</code> | if <code>FALSE</code> , do not use function default values when comparing code and docs. Otherwise, compare <i>all</i> default values if <code>TRUE</code> , and only the ones documented in the usage otherwise (default).                 |
| <code>verbose</code>    | a logical. If <code>TRUE</code> , additional diagnostics are printed.                                                                                                                                                                       |

**Details**

The purpose of `codoc` is to check whether the documented usage of function objects agrees with their formal arguments as defined in the R code. This is not always straightforward, in particular as the usage information for methods to generic functions often employs the name of the generic rather than the method.

The following algorithm is used. If an installed package is used, it is loaded (unless it is the **base** package), after possibly detaching an already loaded version of the package. Otherwise, if the sources are used, the R code files of the package are collected and sourced in a new environment. Then, the usage sections of the Rd files are extracted and parsed ‘as much as possible’ to give the formals documented. For interpreted functions in the code environment, the formals are compared between code and documentation according to the values of the argument `use.values`. Synopsis sections are used if present; their occurrence is reported if `verbose` is `true`.

If a package has a namespace both exported and unexported objects are checked, as well as registered S3 methods. (In the unlikely event of differences the order is exported objects in the package, registered S3 methods and finally objects in the namespace and only the first found is checked.)

Currently, the R documentation format has no high-level markup for the basic ‘structure’ of classes and data sets (similar to the usage sections for function synopses). Variable names for data frames in

documentation objects obtained by suitably editing ‘templates’ created by `prompt` are recognized by `codocData` and used provided that the documentation object is for a single data frame (i.e., only has one alias). `codocClasses` analogously handles slot names for classes in documentation objects obtained by editing shells created by `promptClass`.

Help files named ‘*pkgname*-defunct.Rd’ for the appropriate *pkgname* are checked more loosely, as they may have undocumented arguments.

### Value

`codoc` returns an object of class “`codoc`”. Currently, this is a list which, for each Rd object in the package where an inconsistency was found, contains an element with a list of the mismatches (which in turn are lists with elements `code` and `docs`, giving the corresponding arguments obtained from the function’s code and documented usage).

`codocClasses` and `codocData` return objects of class “`codocClasses`” and “`codocData`”, respectively, with a structure similar to class “`codoc`”.

There are `print` methods for nicely displaying the information contained in such objects.

### Note

The default for `use.values` has been changed from `FALSE` to `NULL`, for R versions 1.9.0 and later.

compactPDF

*Compact PDF Files*

---

### Description

Re-save PDF files (especially vignettes) more compactly. Support function for R CMD build `--compact-vignettes`.

### Usage

```
compactPDF(paths,
 qpdf = Sys.which(Sys.getenv("R_QPDF", "qpdf")),
 gs_cmd = Sys.getenv("R_GSCMD", ""),
 gs_quality = Sys.getenv("GS_QUALITY", "none"),
 gs_extras = character())

S3 method for class 'compactPDF'
format(x, ratio = 0.9, diff = 1e4, ...)
```

**Arguments**

|                          |                                                                                                                                                                                                                                                                                                             |
|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>paths</code>       | A character vector of paths to PDF files, or a length-one character vector naming a directory, when all <code>' .pdf'</code> files in that directory will be used.                                                                                                                                          |
| <code>qpdf</code>        | Character string giving the path to the <code>qpdf</code> command. If empty, <code>qpdf</code> will not be used.                                                                                                                                                                                            |
| <code>gs_cmd</code>      | Character string giving the path to the GhostScript executable, if that is to be used. On Windows this is the path to <code>'gswin32c.exe'</code> or <code>'gswin64c.exe'</code> . If <code>" "</code> (the default), the function will try to find a platform-specific path to GhostScript where required. |
| <code>gs_quality</code>  | A character string indicating the quality required: the options are <code>"none"</code> (so GhostScript is not used), <code>"printer"</code> (300dpi), <code>"ebook"</code> (150dpi) and <code>"screen"</code> (72dpi). Can be abbreviated.                                                                 |
| <code>gs_extras</code>   | An optional character vector of further options to be passed to GhostScript.                                                                                                                                                                                                                                |
| <code>x</code>           | An object of class <code>"compactPDF"</code> .                                                                                                                                                                                                                                                              |
| <code>ratio, diff</code> | Limits for reporting: files are only reported whose sizes are reduced both by a factor of <code>ratio</code> and by <code>diff</code> bytes.                                                                                                                                                                |
| <code>...</code>         | Further arguments to be passed to or from other methods.                                                                                                                                                                                                                                                    |

**Details**

This by default makes use of `qpdf`, available from <http://qpdf.sourceforge.net/> (including as a Windows binary) and included with the CRAN macOS distribution of R. If `gs_cmd` is non-empty and `gs_quality != "none"`, GhostScript will be used first, then `qpdf` if it is available. If `gs_quality != "none"` and `gs_cmd` is `" "`, an attempt will be made to find a GhostScript executable.

`qpdf` and/or `gs_cmd` are run on all PDF files found, and those which are reduced in size by at least 10% and 10Kb are replaced.

The strategy of our use of `qpdf` is to (losslessly) compress both PDF streams and objects. GhostScript compresses streams and more (including downsampling and compressing embedded images) and consequently is much slower and may lose quality (but can also produce much smaller PDF files). However, quality `"ebook"` is perfectly adequate for screen viewing and printing on laser printers.

Where PDF files are changed they will become PDF version 1.5 files: these have been supported by Acrobat Reader since version 6 in 2003, so this is very unlikely to cause difficulties.

Stream compression is what most often has large gains. Most PDF documents are generated with object compression, but this does not seem to be the default for MiKTeX's `pdflatex`. For some PDF files (and especially package vignettes), using GhostScript can dramatically reduce the space taken by embedded images (often screenshots).

Where both GhostScript and `qpdf` are selected (when `gs_quality != "none"` and both executables are found), they are run in that order and the size reductions apply to the total compression achieved.

**Value**

An object of class `c("compactPDF", "data.frame")`. This has two columns, the old and new sizes in bytes for the files that were changed.

There are `format` and `print` methods: the latter passes `...` to the `format` method, so will accept `ratio` and `diff` arguments.

**Note**

The external tools used may change in future releases.

Versions of GhostScript 9.06 and later give several times better compression than 9.05 on some vignettes in CRAN packages.

**See Also**

[resaveRdaFiles](#).

Many other (and sometimes more effective) tools to compact PDF files are available, including Adobe Acrobat (not Reader). See the ‘Writing R Extensions’ manual.

---

 CRANtools

---

*CRAN Package Repository Tools*

---

**Description**

Tools for obtaining information about current packages in the CRAN package repository, and their check status.

**Usage**

```
CRAN_package_db()

CRAN_check_results(flavors = NULL)
CRAN_check_details(flavors = NULL)
CRAN_check_issues()
summarize_CRAN_check_status(packages,
 results = NULL,
 details = NULL,
 issues = NULL)
```

**Arguments**

|                       |                                                                                                                        |
|-----------------------|------------------------------------------------------------------------------------------------------------------------|
| <code>packages</code> | a character vector of package names.                                                                                   |
| <code>flavors</code>  | a character vector of CRAN check flavor names, or <code>NULL</code> (default), corresponding to all available flavors. |
| <code>results</code>  | the return value of <code>CRAN_check_results()</code> (default), or a subset of this.                                  |
| <code>details</code>  | the return value of <code>CRAN_check_details()</code> (default), or a subset of this.                                  |
| <code>issues</code>   | the return value of <code>CRAN_check_issues()</code> (default), or a subset of this.                                   |

**Details**

`CRAN_package_db()` returns a character data frame with most ‘DESCRIPTION’ metadata for the current packages in the CRAN package repository, including in particular the Description and Maintainer information not provided by `utils::available.packages()`.

`CRAN_check_results()` returns a data frame with the basic CRAN package check results including timings, with columns `Package`, `Flavor` and `Status` giving the package name, check flavor, and overall check status, respectively.

`CRAN_check_details()` returns a data frame inheriting from class "check\_details" (which has useful `print` and `format` methods) with details on the check results, providing check name, status and output for every non-OK check (via columns `Check`, `Status` and `Output`, respectively). Packages with all-OK checks are indicated via a `* Check` wildcard name and OK `Status`.

`CRAN_check_issues()` returns a character frame with additional check issues (including the memory-access check results made available from <https://www.stats.ox.ac.uk/pub/bdr/memtests/> and the without-long-double check results from <https://www.stats.ox.ac.uk/pub/bdr/noLD/>), as a character frame with variables `Package`, `Version`, `kind` (an identifier for the issue) and `href` (a URL with information on the issue).

`CRAN_memtest_notes()` is now deprecated, with its functionality integrated into that of `CRAN_check_issues()`.

### Value

See 'Details'. Note that the results are collated on CRAN: currently this is done in a locale which sorts `aAbB....`.

### Which CRAN?

The main functions access a CRAN mirror specified by the environment variable `R_CRAN_WEB`, defaulting to one specified in the 'repositories' file (see [setRepositories](#)): if that specifies `@CRAN@` (the default) then <https://CRAN.R-project.org> is used. (Note that `options("repos")` is not consulted.)

Note that these access parts of CRAN under 'web/contrib' and 'web/packages' so if you have specified a mirror of just 'src/contrib' for installing packages you will need to set `R_CRAN_WEB` to point to a full mirror.

### Examples

```
This can be rather slow, especially with a non-local CRAN mirror
and would fail (slowly) without Internet access in that case.

set.seed(11) # but the packages chosen will change as soon as CRAN does.
pdb <- CRAN_package_db()
dim(pdb)
DESCRIPTION fields included:
colnames(pdb)
Summarize publication dates:
summary(as.Date(pdb$Published))
Summarize numbers of packages according to maintainer:
summary(lengths(split(pdb$Package, pdb$Maintainer)))
Packages with 'LASSO' in their Description:
pdb$Package[grepl("LASSO", pdb$Description)]

results <- CRAN_check_results()
Available variables:
names(results)
Tabulate overall check status according to flavor:
with(results, table(Flavor, Status))

details <- CRAN_check_details()
Available variables:
names(details)
```

```
Tabulate checks according to their status:
tab <- with(details, table(Check, Status))
Inspect some installation problems:
bad <- subset(details,
 ((Check == "whether package can be installed") &
 (Status != "OK")))
Show a random sample of up to 6
head(bad[sample(seq_len(NROW(bad)), NROW(bad)),])

issues <- CRAN_check_issues()
head(issues)
Show counts of issues according to kind:
table(issues[, "kind"])

Summarize CRAN check status for 10 randomly-selected packages
(reusing the information already read in):
pos <- sample(seq_len(NROW(pdb)), 10L)
summarize_CRAN_check_status(pdb[pos, "Package"],
 results, details, issues)
```

delimMatch

*Delimited Pattern Matching***Description**

Match delimited substrings in a character vector, with proper nesting.

**Usage**

```
delimMatch(x, delim = c("{", "}"), syntax = "Rd")
```

**Arguments**

|                     |                                                                                                                                                                                                                                                                                         |
|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>      | a character vector.                                                                                                                                                                                                                                                                     |
| <code>delim</code>  | a character vector of length 2 giving the start and end delimiters. Future versions might allow for arbitrary regular expressions.                                                                                                                                                      |
| <code>syntax</code> | currently, always the string "Rd" indicating Rd syntax (i.e., '%' starts a comment extending till the end of the line, and '\' escapes). Future versions might know about other syntax, perhaps via 'syntax tables' allowing to flexibly specify comment, escape, and quote characters. |

**Value**

An integer vector of the same length as `x` giving the starting position (in characters) of the first match, or `-1` if there is none, with attribute `"match.length"` giving the length (in characters) of the matched text (or `-1` for no match).

**See Also**

[regexr](#) for 'simple' pattern matching.

**Examples**

```
x <- c("\\value{foo}", "function(bar)")
delimMatch(x)
delimMatch(x, c("(", ")"))
```

---

|               |                                  |
|---------------|----------------------------------|
| dependsOnPkgs | <i>Find Reverse Dependencies</i> |
|---------------|----------------------------------|

---

**Description**

Find ‘reverse’ dependencies of packages, that is those packages which depend on this one, and (optionally) so on recursively.

**Usage**

```
dependsOnPkgs(pkgs,
 dependencies = c("Depends", "Imports", "LinkingTo"),
 recursive = TRUE, lib.loc = NULL,
 installed =
 utils::installed.packages(lib.loc, fields = "Enhances"))
```

**Arguments**

|                           |                                                                                                                                                                                                                                                                    |
|---------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>pkgs</code>         | a character vector of package names.                                                                                                                                                                                                                               |
| <code>dependencies</code> | a character vector listing the types of dependencies, a subset of <code>c("Depends", "Imports", "LinkingTo", "Suggests", "Enhances")</code> . Character string "all" is shorthand for that vector, and "most" currently shorthand for these apart from "Enhances". |
| <code>recursive</code>    | logical: should reverse dependencies of reverse dependencies (and so on) be included?                                                                                                                                                                              |
| <code>lib.loc</code>      | a character vector of R library trees, or NULL for all known trees (see <a href="#">.libPaths</a> ).                                                                                                                                                               |
| <code>installed</code>    | a result of calling <code>installed.packages</code> .                                                                                                                                                                                                              |

**Value**

A character vector of package names, which does not include any from `pkgs`.

**Examples**

```
there are few dependencies in a vanilla R installation:
lattice may not be installed
dependsOnPkgs("lattice")
```

---

 encoded\_text\_to\_latex

*Translate non-ASCII Text to LaTeX Escapes*

---

## Description

Translate non-ASCII characters in text to LaTeX escape sequences.

## Usage

```
encoded_text_to_latex(x,
 encoding = c("latin1", "latin2", "latin9",
 "UTF-8", "utf8"))
```

## Arguments

|                       |                                                                                                                             |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>        | a character vector.                                                                                                         |
| <code>encoding</code> | the encoding to be assumed. "latin9" is officially ISO-8859-15 or Latin-9, but known as latin9 to LaTeX's inputenc package. |

## Details

Non-ASCII characters in `x` are replaced by an appropriate LaTeX escape sequence, or '?' if there is no appropriate sequence.

Even if there is an appropriate sequence, it may not be supported by the font in use. Hyphen is mapped to '\-'.

## Value

A character vector of the same length as `x`.

## See Also

writeLines(paste0(xx, "\\\"), con)
writeLines(trailer, con)
close(con)
and some UTF_8 chars
x <- intToUtf8(as.integer(
 c(160:383, 0x0192, 0x02C6, 0x02C7, 0x02CA, 0x02D8,
 0x02D9, 0x02DD, 0x200C, 0x2018, 0x2019, 0x201C,
 0x201D, 0x2020, 0x2022, 0x2026, 0x20AC)),
 multiple = TRUE)
x <- matrix(x, ncol = 16, byrow = TRUE)
xx <- x
xx[] <- encoded_text_to_latex(x, "UTF-8")
xx <- apply(xx, 1, paste, collapse = "&")
con <- file("test-utf8.tex", "w")
writeLines(header, con)
writeLines(paste(xx, "\\\"), sep = "\"), con)
writeLines(trailer, con)
close(con)

End(Not run)

```

fileutils

*File Utilities***Description**

Utilities for listing files, and manipulating file paths.

**Usage**

```

file_ext(x)
file_path_as_absolute(x)
file_path_sans_ext(x, compression = FALSE)

list_files_with_exts(dir, exts, all.files = FALSE,
 full.names = TRUE)
list_files_with_type(dir, type, all.files = FALSE,
 full.names = TRUE, OS_subdirs = .OSType())

```

**Arguments**

|                          |                                                                                                                           |
|--------------------------|---------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>           | character vector giving file paths.                                                                                       |
| <code>compression</code> | logical: should compression extension <code>‘.gz’</code> , <code>‘.bz2’</code> or <code>‘.xz’</code> be removed first?    |
| <code>dir</code>         | a character string with the path name to a directory.                                                                     |
| <code>exts</code>        | a character vector of possible file extensions (excluding the leading dot).                                               |
| <code>all.files</code>   | a logical. If <code>FALSE</code> (default), only visible files are considered; if <code>TRUE</code> , all files are used. |

|                         |                                                                                                                                                                                                                                                                                              |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>full.names</code> | a logical indicating whether the full paths of the files found are returned (default), or just the file names.                                                                                                                                                                               |
| <code>type</code>       | a character string giving the ‘type’ of the files to be listed, as characterized by their extensions. Currently, possible values are "code" (R code), "data" (data sets), "demo" (demos), "docs" (R documentation), and "vignette" (vignettes).                                              |
| <code>OS_subdirs</code> | a character vector with the names of OS-specific subdirectories to possibly include in the listing of R code and documentation files. By default, the value of the environment variable <code>R_OSTYPE</code> , or if this is empty, the value of <code>.Platform\$OS.type</code> , is used. |

### Details

`file_ext` returns the file (name) extensions (excluding the leading dot). (Only purely alphanumeric extensions are recognized.)

`file_path_as_absolute` turns a possibly relative file path absolute, performing tilde expansion if necessary. This is a wrapper for `normalizePath`. Currently, `x` must be a single existing path.

`file_path_sans_ext` returns the file paths without extensions (and the leading dot). (Only purely alphanumeric extensions are recognized.)

`list_files_with_exts` returns the paths or names of the files in directory `dir` with extension matching one of the elements of `exts`. Note that by default, full paths are returned, and that only visible files are used.

`list_files_with_type` returns the paths of the files in `dir` of the given ‘type’, as determined by the extensions recognized by R. When listing R code and documentation files, files in OS-specific subdirectories are included if present according to the value of `OS_subdirs`. Note that by default, full paths are returned, and that only visible files are used.

### See Also

`file.path`, `file.info`, `list.files`

### Examples

```
dir <- file.path(R.home(), "library", "stats")
list_files_with_exts(file.path(dir, "demo"), "R")
list_files_with_type(file.path(dir, "demo"), "demo") # the same
file_path_sans_ext(list.files(file.path(R.home("modules"))))
```

---

find\_gs\_cmd

*Find a GhostScript Executable*

---

### Description

Find a GhostScript executable in a cross-platform way.

### Usage

```
find_gs_cmd(gs_cmd = "")
```

**Arguments**

`gs_cmd`                      The name, full or partial path of a GhostScript executable.

**Details**

The details differ by platform.

On a Unix-alike, the GhostScript executable is usually called `gs`. The name (and possibly path) of the command is taken first from argument `gs_cmd` then from the environment variable `R_GSCMD` and default `gs`. This is then looked for on the system path and the value returned if a match is found.

On Windows, the name of the command is taken from argument `gs_cmd` then from the environment variables `R_GSCMD` and `GSC`. If neither of those produces a suitable command name, `gswin64c` and `gswin32c` are tried in turn. In all cases the command is looked for on the system `PATH`.

Note that on Windows (and some other OSes) there are separate GhostScript executables to display Postscript/PDF files and to manipulate them: this function looks for the latter.

**Value**

A character string giving the full path to a GhostScript executable if one was found, otherwise an empty string.

**Examples**

```
Not run:
Suppose a Solaris system has GhostScript 9.00 on the path and
9.07 in /opt/csw/bin. Then one might set
Sys.setenv(R_GSCMD = "/opt/csw/bin/gs")

End(Not run)
```

---

|                              |                                               |
|------------------------------|-----------------------------------------------|
| <code>getVignetteInfo</code> | <i>Get Information on Installed Vignettes</i> |
|------------------------------|-----------------------------------------------|

---

**Description**

This function gets information on installed vignettes.

**Usage**

```
getVignetteInfo(package = NULL, lib.loc = NULL, all = TRUE)
```

**Arguments**

`package`                      Which package to look in, or `NULL` for all packages.  
`lib.loc`                        Which library to look in.  
`all`                            Whether to search all installed packages, or just attached packages.

**Value**

A matrix with columns

|         |                                                 |
|---------|-------------------------------------------------|
| Package | the name of the package                         |
| Dir     | the directory where the package is installed    |
| Topic   | the name of the vignette                        |
| File    | the base filename of the source of the vignette |
| Title   | the title of the vignette                       |
| R       | the tangled R source from the vignette          |
| PDF     | the PDF or HTML file for display                |

**Note**

The last column of the result is named PDF for historical reasons, but it may contain a filename of a PDF or HTML document.

**See Also**

[pkgVignettes](#) is a similar function that can work on an uninstalled package.

**Examples**

```
getVignetteInfo("grid")
```

---

HTMLheader

---

*Generate a Standard HTML Header for R Help*

---

**Description**

This function generates the standard HTML header used on R help pages.

**Usage**

```
HTMLheader(title = "R", logo = TRUE, up = NULL,
 top = file.path(Rhome, "doc/html/index.html"),
 Rhome = "",
 css = file.path(Rhome, "doc/html/R.css"),
 headerTitle = paste("R:", title),
 outputEncoding = "UTF-8")
```

**Arguments**

|       |                                                                                                   |
|-------|---------------------------------------------------------------------------------------------------|
| title | The title to display and use in the HTML headers. Should have had any HTML escaping already done. |
| logo  | Whether to display the R logo after the title.                                                    |
| up    | Which page (if any) to link to on the “up” button.                                                |
| top   | Which page (if any) to link to on the “top” button.                                               |
| Rhome | A <b>relative</b> path to the R home directory. See the ‘Details’.                                |

css                    The relative URL for the Cascading Style Sheet.  
 headerTitle        The title used in the headers.  
 outputEncoding      The declared encoding for the whole page.

### Details

The `up` and `top` links should be relative to the current page. The `Rhome` path default works with dynamic help; for static help, a relative path (e.g., `'../..'`) to it should be used.

### Value

A character vector containing the lines of an HTML header which can be used to start a page in the R help system.

### Examples

```
cat(HTMLheader("This is a sample header"), sep="\n")
```

---

|           |                                                      |
|-----------|------------------------------------------------------|
| HTMLlinks | <i>Collect HTML Links from Package Documentation</i> |
|-----------|------------------------------------------------------|

---

### Description

Compute relative file paths for URLs to other package's installed HTML documentation.

### Usage

```
findHTMLlinks(pkgDir = "", lib.loc = NULL, level = 0:2)
```

### Arguments

pkgDir                the top-level directory of an installed package. The default indicates no package.  
 lib.loc              character vector describing the location of R library trees to scan: the default indicates `.libPaths()`.  
 level                Which level(s) to include.

### Details

`findHTMLlinks` tries to resolve links from one help page to another. It uses in decreasing priority

- The package in `pkgDir`: this is used when converting HTML help for that package (level 0).
- The base and recommended packages (level 1).
- Other packages found in the library trees specified by `lib.loc` in the order of the trees and alphabetically within a library tree (level 2).

### Value

A named character vector of file paths, relative to the `'html'` directory of an installed package. So these are of the form `"../..../somepkg/html/sometopic.html"`.

---

loadRdMacros*Load User-defined Rd Help System Macros*

---

## Description

Loads macros from an ‘.Rd’ file, or from several ‘.Rd’ files contained in a package.

## Usage

```
loadRdMacros(file, macros = TRUE)
loadPkgRdMacros(pkgdir, macros)
```

## Arguments

|        |                                                                                                                      |
|--------|----------------------------------------------------------------------------------------------------------------------|
| file   | A file in Rd format containing macro definitions.                                                                    |
| macros | TRUE or a previous set of macro definitions, in the format expected by the <a href="#">parse_Rd</a> macros argument. |
| pkgdir | The base directory of a source package or an installed package.                                                      |

## Details

The files parsed by this function should contain only macro definitions; a warning will be issued if anything else other than comments or white space is found.

The macros argument may be a filename of a base set of macros, or the result of a previous call to `loadRdMacros` or `loadPkgRdMacros` in the same session. These results should be assumed to be valid only within the current session.

The `loadPkgRdMacros` function first looks for an "RdMacros" entry in the package ‘DESCRIPTION’ file. If present, it should contain a comma-separated list of other package names; their macros will be loaded before those of the current package. It will then look in the current package for ‘.Rd’ files in the ‘man/macros’ or ‘help/macros’ subdirectories, and load those.

## Value

These functions each return an environment containing objects with the names of the newly defined macros from the last file processed. The parent environment will be macros from the previous file, and so on. The first file processed will have `emptyenv()` as its parent.

## Author(s)

Duncan Murdoch

## References

writeLines(paste0("\\newcommand{\\logo}{\\if{html}{\\figure{Rlogo.svg}{options: width=100%}
 \"\\if{latex}{\\figure{Rlogo.pdf}{options: width=0.5in}}}\"),
 f)
m <- loadRdMacros(f)
ls(m)
ls(parent.env(m))
ls(parent.env(parent.env(m)))
```

makevars

*User and Site Compilation Variables***Description**

Determine the location of the user and site specific ‘Makevars’ files for customizing package compilation.

**Usage**

```
makevars_user()
makevars_site()
```

**Details**

Package maintainers can use these functions to employ user and site specific compilation settings also for compilations not using R’s mechanisms (in particular, custom compilations in subdirectories of ‘src’), e.g., by adding configure code calling R with `cat(tools::makevars_user())` or `cat(tools::makevars_site())`, and if non-empty passing this with ‘-f’ to custom Make invocations.

**Value**

A character string with the path to the user or site specific ‘Makevars’ file, or an empty character vector if there is no such file.

**See Also**

Section ‘Customizing package compilation’ in the ‘R Installation and Administration’ manual.

**Examples**

```
makevars_user()
makevars_site()
```

---

```
make_translations_pkg
```

*Package the Current Translations in the R Sources*

---

### Description

A utility for R Core members to prepare a package of updated translations.

### Usage

```
make_translations_pkg(srcdir, outDir = ".", append = "-1")
```

### Arguments

|                     |                                                                                         |
|---------------------|-----------------------------------------------------------------------------------------|
| <code>srcdir</code> | The R source directory.                                                                 |
| <code>outDir</code> | The directory into which to place the prepared package.                                 |
| <code>append</code> | The suffix for the package version number, e.g. 3.0.0-1 will be the default in R 3.0.0. |

### Details

This extracts the translations in a current R source distribution and packages them as a source package called **translations** which can be distributed on CRAN and installed by [update.packages](#). This allows e.g. the translations shipped in R 3.x.y to be updated to those currently in ‘R-patched’, even by a user without administrative privileges.

The package has a ‘Depends’ field which restricts it to versions 3.x.\* for a single x.

---

```
md5sum
```

*Compute MD5 Checksums*

---

### Description

Compute the 32-byte MD5 hashes of one or more files.

### Usage

```
md5sum(files)
```

### Arguments

|                    |                                                                  |
|--------------------|------------------------------------------------------------------|
| <code>files</code> | character. The paths of file(s) whose contents are to be hashed. |
|--------------------|------------------------------------------------------------------|

### Details

A MD5 ‘hash’ or ‘checksum’ or ‘message digest’ is a 128-bit summary of the file contents represented by 32 hexadecimal digits. Files with different MD5 sums are different: only very exceptionally (and usually with the intent to deceive) are those with the same sums different.

On Windows all files are read in binary mode (as the `md5sum` utilities there do): on other OSes the files are read in the default mode (almost always text mode where there is more than one).

MD5 sums are used as a check that R packages have been unpacked correctly and not subsequently modified.

**Value**

A character vector of the same length as `files`, with names equal to `files` (possibly expanded). The elements will be `NA` for non-existent or unreadable files, otherwise a 32-character string of hexadecimal digits.

**Source**

The underlying C code was written by Ulrich Drepper and extracted from a 2001 release of `glibc`.

**See Also**

[checkMD5sums](#)

**Examples**

```
as.vector(md5sum(dir(R.home(), pattern = "^COPY", full.names = TRUE)))
```

---

package\_dependencies

*Computations on the Dependency Hierarchy of Packages*

---

**Description**

Find (recursively) dependencies or reverse dependencies of packages.

**Usage**

```
package_dependencies(packages = NULL, db = NULL,
 which = c("Depends", "Imports", "LinkingTo"),
 recursive = FALSE, reverse = FALSE, verbose = getOption("verbose"))
```

**Arguments**

|                        |                                                                                                                                                                                                                                                                                                                                                     |
|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>packages</code>  | a character vector of package names.                                                                                                                                                                                                                                                                                                                |
| <code>db</code>        | character matrix as from <a href="#">available.packages()</a> (with the default <code>NULL</code> the results of this call) or data frame variants thereof. Alternatively, a package database like the one available from <a href="https://cran.r-project.org/web/packages/packages.rds">https://cran.r-project.org/web/packages/packages.rds</a> . |
| <code>which</code>     | a character vector listing the types of dependencies, a subset of <code>c("Depends", "Imports", "LinkingTo", "Suggests", "Enhances")</code> . Character string <code>"all"</code> is shorthand for that vector, character string <code>"most"</code> for the same vector without <code>"Enhances"</code> .                                          |
| <code>recursive</code> | logical: should (reverse) dependencies of (reverse) dependencies (and so on) be included?                                                                                                                                                                                                                                                           |
| <code>reverse</code>   | logical: if <code>FALSE</code> (default), regular dependencies are calculated, otherwise reverse dependencies.                                                                                                                                                                                                                                      |
| <code>verbose</code>   | logical indicating if output should monitor the package search cycles.                                                                                                                                                                                                                                                                              |

**Value**

Named list with one element for each package in argument `packages`, each consists of a character vector naming the (recursive) (reverse) dependencies of that package.

For given packages which are not found in the db, `NULL` entries are returned, as opposed to `character(0)` entries which indicate no dependencies.

**See Also**

[dependsOnPkgs](#), and [package.dependencies](#) for checking dependencies.

**Examples**

```
myPkgs <- c("MASS", "Matrix", "KernSmooth", "class", "cluster", "codetools")
pdb <- available.packages()
system.time(
 depl <- package_dependencies(myPkgs, db = pdb) # all arguments at default
) # very fast
utils::str(depl, vec.len=10)

system.time(## reverse dependencies, recursively --- takes much longer:
 deps <- package_dependencies(myPkgs, db = pdb,
 which = c("Depends", "Imports", "LinkingTo", "Suggests"),
 recursive = TRUE, reverse = TRUE)
) # seen ~ 10 seconds

lengths(deps) # 2015-01-14: all are 7040, but codetools with 7046
```

---

package\_native\_routine\_registration\_skeleton

*Write Skeleton for Adding Native Routine Registration to a Package*

---

**Description**

Write a skeleton for adding native routine registration to a package.

**Usage**

```
package_native_routine_registration_skeleton(dir, con = stdout(),
 align = TRUE, character_only = TRUE, include_declarations = TRUE)
```

**Arguments**

|                                   |                                                                                                                                                |
|-----------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>dir</code>                  | Top-level directory of a package.                                                                                                              |
| <code>con</code>                  | Connection on which to write the skeleton: can be specified as a file path.                                                                    |
| <code>align</code>                | Logical: should the registration tables be lined up in three columns each?                                                                     |
| <code>character_only</code>       | Logical: should only <code>.NAME</code> arguments specified by character strings (and not as names of R objects nor expressions) be extracted? |
| <code>include_declarations</code> | Logical: should the output include declarations (also known as ‘prototypes’) for the registered routines?                                      |

## Details

Registration is described in section ‘Registering native routines’ of ‘Writing R Extensions’. This function produces a skeleton of the C code which needs to be added to enable registration, conventionally as file ‘src/init.c’ or appended to the sole C file of the package.

This function examines the code in the ‘R’ directory of the package for calls to `.C`, `.Fortran`, `.Call` and `.External` and creates registration information for those it can make sense of. If the number of arguments used cannot be determined it will be recorded as `-1`: such values should be corrected.

Optionally the skeleton will include declarations for the registered routines: they should be checked against the C/Fortran source code, not least as the number of arguments is taken from the R code. For `.Call` and `.External` calls they will often suffice, but for `.C` and `.Fortran` calls the `void *` arguments would ideally be replaced by the actual types. Otherwise declarations need to be included (they may exist earlier in that file if appending to a file, or in a header file which can be included in ‘init.c’).

The default value of `character_only` is appropriate when working on a package without any existing registration: `character_only = FALSE` can be used to suggest updates for a package which has been extended since registration. For the default value, if `.NAME` values are found which are not character strings (e.g. names or expressions) this is noted via a comment in the output.

Packages which used the earlier form of creating R objects for native symbols *via* additional arguments in a `useDynLib` directive will probably most easily be updated to use registration with `character_only = FALSE`.

If an entry point is used with different numbers of arguments in the package’s R code, an entry in the table (and optionally, a declaration) is made for each number, and a comment placed in the output. This needs to be resolved: only `.External` calls can have a variable number of arguments, which should be declared as `-1`.

A surprising number of CRAN packages had calls in R code to native routines not included in the package, which will lead to a ‘loading failed’ error during package installation when the registration C code is added.

Calls which do not name a routine such as `.Call(...)` will be silently ignored.

## Value

None: the output is written to the connection `con`.

## Extracting C/C++ prototypes

There are several tools available to extract function declarations from C or C++ code.

For C code one can use `cproto` (<https://invisible-island.net/cproto/cproto.html>; Windows executables are available), for example

```
cproto -I/path/to/R/include -e *.c
```

`ctags` (commonly distributed with the OS) covers C and C++, using something like

```
ctags -x *.c
```

to list all function usages. (The ‘Exuberant’ version allows a lot more control.)

## Extracting Fortran prototypes

gfortran 9.2 and later can extract C prototypes for Fortran subroutines with a special flag:

```
gfortran -c -fc-prototypes-external file.f
```

although ironically not for functions declared `bind(C)`.

## Note

This only examines the 'R' directory: it will not find e.g. `.Call` calls used directly in examples, tests *etc.*

Static code analysis is used to find the `.C` etc calls: it *will* find those in parts of the R code 'commented out' by inclusion in `if (FALSE) { ... }`. On the other hand, it will fail to find the entry points in constructs like

```
.Call(if(int) "rle_i" else "rle_d", i, force)
```

and does not know the value of variables in calls like

```
.Call (cfunction, ...)
.Call(..., PACKAGE="sparseLTSEigen")
```

(but if `character_only` is false, will extract the first as `"cfunction"`). Calls which have not been fully resolved will be noted *via* comments in the output file.

Call to entry points in other packages will be ignored if they have an explicit (character string) `PACKAGE` argument.

## See Also

[package.skeleton](#).

## Examples

```
Not run:
with a completed splines/DESCRIPTION file,
tools::package_native_routine_registration_skeleton('splines',,,FALSE)
produces
#include <R.h>
#include <Rinternals.h>
#include <stdlib.h> // for NULL
#include <R_ext/Rdynload.h>

/* FIXME:
 Check these declarations against the C/Fortran source code.
*/

/* .Call calls */
extern SEXP spline_basis(SEXP, SEXP, SEXP, SEXP);
extern SEXP spline_value(SEXP, SEXP, SEXP, SEXP, SEXP);

static const R_CallMethodDef CallEntries[] = {
```

```

 {"spline_basis", (DL_FUNC) &spline_basis, 4},
 {"spline_value", (DL_FUNC) &spline_value, 5},
 {NULL, NULL, 0}
};

void R_init_splines(DllInfo *dll)
{
 R_registerRoutines(dll, NULL, CallEntries, NULL, NULL);
 R_useDynamicSymbols(dll, FALSE);
}

End(Not run)

```

---

parseLatex

*Experimental Functions to Work with LaTeX Code*

---

## Description

The `parseLatex` function parses LaTeX source, producing a structured object; `deparseLatex` reverses the process. The `latexToUtf8` function takes a LaTeX object, and processes a number of different macros to convert them into the corresponding UTF-8 characters.

## Usage

```

parseLatex(text, filename = deparse1(substitute(text)),
 verbose = FALSE,
 verbatim = c("verbatim", "verbatim*",
 "Sinput", "Soutput"))
deparseLatex(x, dropBraces = FALSE)
latexToUtf8(x)

```

## Arguments

|                         |                                                                                      |
|-------------------------|--------------------------------------------------------------------------------------|
| <code>text</code>       | A character vector containing LaTeX source code.                                     |
| <code>filename</code>   | A filename to use in syntax error messages.                                          |
| <code>verbose</code>    | If TRUE, print debug error messages.                                                 |
| <code>verbatim</code>   | A character vector containing the names of LaTeX environments holding verbatim text. |
| <code>x</code>          | A "LaTeX" object.                                                                    |
| <code>dropBraces</code> | Drop unnecessary braces when displaying a "LaTeX" object.                            |

## Details

The parser does not recognize all legal LaTeX code, only relatively simple examples. It does not associate arguments with macros, that needs to be done after parsing, with knowledge of the definitions of each macro. The main intention for this function is to process simple LaTeX code used in bibliographic references, not fully general LaTeX documents.

Verbose text is allowed in two forms: the `\verb` macro (with single character delimiters), and environments whose names are listed in the `verbatim` argument.

Value

The `parseLatex()` function returns a recursive object of class "LaTeX". Each of the entries in this object will have a "latex\_tag" attribute identifying its syntactic role.

The `deparseLatex()` function returns a single element character vector, possibly containing embedded newlines.

The `latexToUtf8()` function returns a modified version of the "LaTeX" object that was passed to it.

Author(s)

Duncan Murdoch

Examples

```
latex <- parseLatex("fa\\c{c}ile")
deparseLatex(latexToUtf8(latex))
```

---

|          |                         |
|----------|-------------------------|
| parse_Rd | <i>Parse an Rd File</i> |
|----------|-------------------------|

---

Description

This function reads an R documentation (Rd) file and parses it, for processing by other functions.

Usage

```
parse_Rd(file, srcfile = NULL, encoding = "unknown",
 verbose = FALSE, fragment = FALSE, warningCalls = TRUE,
 macros = file.path(R.home("share"), "Rd", "macros", "system.Rd"),
 permissive = FALSE)
S3 method for class 'Rd'
print(x, deparse = FALSE, ...)
S3 method for class 'Rd'
as.character(x, deparse = FALSE, ...)
```

Arguments

|              |                                                                                                                     |
|--------------|---------------------------------------------------------------------------------------------------------------------|
| file         | A filename or text-mode connection. At present filenames work best.                                                 |
| srcfile      | NULL, or a "srcfile" object. See the ‘Details’ section.                                                             |
| encoding     | Encoding to be assumed for input strings.                                                                           |
| verbose      | Logical indicating whether detailed parsing information should be printed.                                          |
| fragment     | Logical indicating whether file represents a complete Rd file, or a fragment.                                       |
| warningCalls | Logical: should parser warnings include the call?                                                                   |
| macros       | Filename or environment from which to load additional macros, or a logical value. See the Details below.            |
| permissive   | Logical indicating that unrecognized macros should be treated as text with no warning.                              |
| x            | An object of class Rd.                                                                                              |
| deparse      | If TRUE, attempt to reinstate the escape characters so that the resulting characters will parse to the same object. |
| ...          | Further arguments to be passed to or from other methods.                                                            |

## Details

This function parses ‘Rd’ files according to the specification given in <https://developer.r-project.org/parseRd.pdf>.

It generates a warning for each parse error and attempts to continue parsing. In order to continue, it is generally necessary to drop some parts of the file, so such warnings should not be ignored.

Files without a marked encoding are by default assumed to be in the native encoding. An alternate default can be set using the `encoding` argument. All text in files is translated to the UTF-8 encoding in the parsed object.

As from R version 3.2.0, User-defined macros may be given in a separate file using ‘`\newcommand`’ or ‘`\renewcommand`’. An environment may also be given: it would be produced by `loadRdMacros`, `loadPkgRdMacros`, or by a previous call to `parse_Rd`. If a logical value is given, only the default built-in macros will be used; `FALSE` indicates that no “macros” attribute will be returned with the result.

The `permissive` argument allows text to be parsed that is not completely in Rd format. Typically it would be LaTeX code, used in an Rd fragment, e.g. in a `bibentry`. With `permissive = TRUE`, this will be passed through as plain text. Since `parse_Rd` doesn’t know how many arguments belong in LaTeX macros, it will guess based on the presence of braces after the macro; this is not infallible.

## Value

`parse_Rd` returns an object of class “Rd”. The internal format of this object is subject to change. The `as.character()` and `print()` methods defined for the class return character vectors and print them, respectively.

Unless `macros = FALSE`, the object will have an attribute named “macros”, which is an environment containing the macros defined in `file`, in a format that can be used for further `parse_Rd` calls in the same session. It is not guaranteed to work if saved to a file and reloaded in a different session.

---

pskill

*Kill a Process*

---

## Description

`pskill` sends a signal to a process, usually to terminate it.

**Usage**

```
pskill(pid, signal = SIGTERM)
```

```
SIGHUP
SIGINT
SIGQUIT
SIGKILL
SIGTERM
SIGSTOP
SIGTSTP
SIGCHLD
SIGUSR1
SIGUSR2
```

**Arguments**

|                     |                                                                                     |
|---------------------|-------------------------------------------------------------------------------------|
| <code>pid</code>    | positive integers: one or more process IDs as returned by <code>Sys.getpid</code> . |
| <code>signal</code> | integer, most often one of the symbolic constants.                                  |

**Details**

Signals are a C99 concept, but only a small number are required to be supported (of those listed, only `SIGINT` and `SIGTERM`). They are much more widely used on POSIX operating systems (which should define all of those listed here), which also support a `kill` system call to send a signal to a process, most often to terminate it. Function `pskill` provides a wrapper: it silently ignores invalid values of its arguments, including zero or negative pids.

In normal use on a Unix-alike, `Ctrl-C` sends `SIGINT`, `Ctrl-\` sends `SIGQUIT` and `Ctrl-Z` sends `SIGTSTP`: that and `SIGSTOP` suspend a process which can be resumed by `SIGCONT`.

The signals are small integers, but the actual numeric values are not standardized (and most do differ between OSes). The `SIG*` objects contain the appropriate integer values for the current platform (or `NA_INTEGER_` if the signal is not defined).

Only `SIGINT` and `SIGKILL` will be defined on Windows, and `pskill` will always use the Windows system call `TerminateProcess`.

**Value**

A logical vector of the same length as `pid`, `TRUE` (for success) or `FALSE`, invisibly.

**See Also**

Package **parallel** has several means to launch child processes which record the process IDs.  
[psnice](#)

**Examples**

```
Not run:
pskill(c(237, 245), SIGKILL)

End(Not run)
```

psnice

*Get or Set the Priority (Niceness) of a Process***Description**

Get or set the ‘niceness’ of the current process, or one or more other processes.

**Usage**

```
psnice(pid = Sys.getpid(), value = NA_integer_)
```

**Arguments**

|                    |                                                                                                 |
|--------------------|-------------------------------------------------------------------------------------------------|
| <code>pid</code>   | positive integers: the process IDs of one or more processes: defaults to the R session process. |
| <code>value</code> | The niceness to be set, or NA for an enquiry.                                                   |

**Details**

POSIX operating systems have a concept of process priorities, usually from 0 to 39 (or 40) with 20 being a normal priority and (somewhat confusingly) larger numeric values denoting lower priority. To add to the confusion, there is a ‘niceness’ value, the amount by which the priority numerically exceeds 20 (which can be negative). Processes with high niceness will receive less CPU time than those with normal priority. On some OSes, processes with niceness +19 are only run when the system would otherwise be idle.

On many OSes utilities such as `top` report the priority and not the niceness. Niceness is used by the utility `/usr/bin/renice`: `/usr/bin/nice` (and `/usr/bin/renice -n`) specifies an *increment* in niceness.

Only privileged users (usually super-users) can lower the niceness.

Windows has a slightly different concept of ‘priority classes’. We have mapped the idle priority to niceness 19, ‘below normal’ to 15, normal to 0, ‘above normal’ to -5 and ‘realtime’ to -10. Unlike Unix-alikes, a non-privileged user can increase the priority class on Windows (but using ‘realtime’ is inadvisable).

**Value**

An integer vector of *previous* niceness values, NA if unknown for any reason.

**See Also**

Various functions in package **parallel** create child processes whose priority may need to be changed. [pskill](#).

## Description

Functions for performing various quality control (QC) checks on R code and documentation, notably on R packages.

## Usage

```
checkDocFiles(package, dir, lib.loc = NULL)
checkDocStyle(package, dir, lib.loc = NULL)
checkReplaceFuns(package, dir, lib.loc = NULL)
checkS3methods(package, dir, lib.loc = NULL)

langElts
nonS3methods(package)
```

## Arguments

|                      |                                                                                                                                                                                                                                             |
|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>package</code> | a character string naming an installed package.                                                                                                                                                                                             |
| <code>dir</code>     | a character string specifying the path to a package's root source directory. This should contain the subdirectories 'R' (for R code) and 'man' with R documentation sources (in Rd format). Only used if <code>package</code> is not given. |
| <code>lib.loc</code> | a character vector of directory names of R libraries, or <code>NULL</code> . The default value of <code>NULL</code> corresponds to all libraries currently known. The specified library trees are used to search for <code>package</code> . |

## Details

`checkDocFiles` checks, for all Rd files in a package, whether all arguments shown in the usage sections of the Rd file are documented in its arguments section. It also reports duplicated entries in the arguments section, and 'over-documented' arguments which are given in the arguments section but not in the usage. Note that the match is for the usage section and not a possibly existing synopsis section, as the usage is what gets displayed.

`checkDocStyle` investigates how (S3) methods are shown in the usages of the Rd files in a package. It reports the methods shown by their full name rather than using the Rd `\method` markup for indicating S3 methods. Earlier versions of R also reported about methods shown along with their generic, which typically caused problems for the documentation of the primary argument in the generic and its methods. With `\method` now being expanded in a way that class information is preserved, joint documentation is no longer necessarily a problem. (The corresponding information is still contained in the object returned by `checkDocStyle`.)

`checkReplaceFuns` checks whether replacement functions or S3/S4 replacement methods in the package R code have their final argument named `value`.

`checkS3methods` checks whether all S3 methods defined in the package R code have all arguments of the corresponding generic, with positional arguments of the generics in the same positions for the method. As an exception, the first argument of a formula method *may* be called `formula` even if this is not the name used by the generic. The rules when `...` is involved are subtle: see the source code. Functions recognized as S3 generics are those with a call to `UseMethod` in their

body, internal S3 generics (see [InternalMethods](#)), and S3 group generics (see [Math](#)). Possible dispatch under a different name is not taken into account. The generics are sought first in the given package, then in the **base** package and (currently) the packages **graphics**, **stats**, and **utils** added in R 1.9.0 by splitting the former **base**, and, if an installed package is tested, also in the loaded namespaces/packages listed in the package's 'DESCRIPTION' Depends field.

`nonS3methods(package)` returns a [character](#) vector with the names of the functions in package which 'look' like S3 methods, but are not. Using `package = NULL` returns all known examples.

`langElts` is a character vector of names of "language elements" of R. These are implemented as "very primitive" functions (no argument list; `print()` ing as `.Primitive("<name>")`).

If using an installed package, the checks needing access to all R objects of the package will load the package (unless it is the **base** package), after possibly detaching an already loaded version of the package.

### Value

The functions return objects of class the same as the respective function names containing the information about problems detected. There are `print` methods for nicely displaying the information contained in such objects.

---

Rcmd

*R CMD Interface*

---

### Description

Invoke R CMD tools from within R.

### Usage

```
Rcmd(args, ...)
```

### Arguments

|                   |                                                     |
|-------------------|-----------------------------------------------------|
| <code>args</code> | a character vector of arguments to R CMD.           |
| <code>...</code>  | arguments to be passed to <a href="#">system2</a> . |

### Details

Provides a portable convenience interface to the R CMD mechanism by invoking the corresponding system commands (using the version of R currently used) via [system2](#).

### Value

See section "Value" in [system2](#).

**Description**

These functions take the output of `parse_Rd()`, an Rd object, and produce a help page from it. As they are mainly intended for internal use, their interfaces are subject to change.

**Usage**

```
Rd2HTML(Rd, out = "", package = "", defines = .Platform$OS.type,
 Links = NULL, Links2 = NULL,
 stages = "render", outputEncoding = "UTF-8",
 dynamic = FALSE, no_links = FALSE, fragment = FALSE,
 stylesheet = "R.css", ...)
```

```
Rd2txt(Rd, out = "", package = "", defines = .Platform$OS.type,
 stages = "render", outputEncoding = "",
 fragment = FALSE, options, ...)
```

```
Rd2latex(Rd, out = "", defines = .Platform$OS.type,
 stages = "render", outputEncoding = "UTF-8",
 fragment = FALSE, ..., writeEncoding = TRUE)
```

```
Rd2ex(Rd, out = "", defines = .Platform$OS.type,
 stages = "render", outputEncoding = "UTF-8",
 commentDontrun = TRUE, commentDonttest = FALSE, ...)
```

**Arguments**

|                             |                                                                                                                                                |
|-----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>Rd</code>             | a filename or Rd object to use as input.                                                                                                       |
| <code>out</code>            | a filename or connection object to which to write the output. The default <code>out = ""</code> is equivalent to <code>out = stdout()</code> . |
| <code>package</code>        | the package to list in the output.                                                                                                             |
| <code>defines</code>        | string(s) to use in <code>#ifdef</code> tests.                                                                                                 |
| <code>stages</code>         | at which stage ("build", "install", or "render") should <code>\Sexpr</code> macros be executed? See the notes below.                           |
| <code>outputEncoding</code> | see the 'Encodings' section below.                                                                                                             |
| <code>dynamic</code>        | logical: set links for render-time resolution by dynamic help system.                                                                          |
| <code>no_links</code>       | logical: suppress hyperlinks to other help topics. Used by R CMD <code>Rdconv</code> .                                                         |
| <code>fragment</code>       | logical: should fragments of Rd files be accepted? See the notes below.                                                                        |
| <code>stylesheet</code>     | character: a URL for a stylesheet to be used in the header of the HTML output page.                                                            |
| <code>Links, Links2</code>  | NULL or a named (by topics) character vector of links, as returned by <code>findHTMLlinks</code> .                                             |
| <code>options</code>        | An optional named list of options to pass to <code>Rd2txt_options</code> .                                                                     |

... additional parameters to pass to `parse_Rd` when `Rd` is a filename.

`writeEncoding` should `\inputencoding` lines be written in the file for non-ASCII encodings?

`commentDontrun` should `\dontrun` sections be commented out?

`commentDonttest` should `\donttest` sections be commented out?

## Details

These functions convert help documents: `Rd2HTML` produces HTML, `Rd2txt` produces plain text, `Rd2latex` produces LaTeX. `Rd2ex` extracts the examples in the format used by `example` and R utilities.

Each of the functions accepts a filename for an Rd file, and will use `parse_Rd` to parse it before applying the conversions or checks.

The difference between arguments `Link` and `Link2` is that links are looked in them in turn, so lazy-evaluation can be used to only do a second-level search for links if required.

Before R 3.6.0, the default for `Rd2latex` was `outputEncoding = "ASCII"`, including using the second option of `\enc` markup, because LaTeX versions did not provide enough coverage of UTF-8 glyphs for a long time.

`Rd2txt` will format text paragraphs to a width determined by `width`, with appropriate margins. The default is to be close to the rendering in versions of R < 2.10.0.

`Rd2txt` will use directional quotes (see `sQuote`) if option `"useFancyQuotes"` is true (the default) and the current encoding is UTF-8.

Various aspects of formatting by `Rd2txt` are controlled by the `options` argument, documented with the `Rd2txt_options` function. Changes made using `options` are temporary, those made with `Rd2txt_options` are persistent.

When `fragment = TRUE`, the Rd file will be rendered with no processing of `\Sexpr` elements or conditional defines using `#ifdef` or `#ifndef`. Normally a fragment represents text within a section, but if the first element of the fragment is a section macro, the whole fragment will be rendered as a series of sections, without the usual sorting.

## Value

These functions are executed mainly for the side effect of writing the converted help page. Their value is the name of the output file (invisibly). For `Rd2latex`, the output name is given an attribute `"latexEncoding"` giving the encoding of the file in a form suitable for use with the LaTeX `'inputenc'` package.

## Encodings

Rd files are normally intended to be rendered on a wide variety of systems, so care must be taken in the encoding of non-ASCII characters. In general, any such encoding should be declared using the `'encoding'` section for there to be any hope of correct rendering.

For output, the `outputEncoding` argument will be used: `outputEncoding = ""` will choose the native encoding for the current system.

If the text cannot be converted to the `outputEncoding`, byte substitution will be used (see `iconv`): `Rd2latex` and `Rd2ex` give a warning.

**Note**

The `\Sexpr` macro is a new addition to Rd files. It includes R code that will be executed at one of three times: *build* time (when a package's source code is built into a tarball), *install* time (when the package is installed or built into a binary package), and *render* time (when the man page is converted to a readable format).

For example, this man page was:

1. built on 2026-08-26 at 11:44:09,
2. installed on 2026-08-26 at 11:44:09, and
3. rendered on 2026-08-26 at 11:48:36.

**Examples**

```
Not run:
Simulate install and rendering of this page in HTML and text format:

Rd <- file.path("src/library/tools/man/Rd2HTML.Rd")

outfile <- tempfile(fileext = ".html")
browseURL(Rd2HTML(Rd, outfile, package = "tools",
 stages = c("install", "render")))

outfile <- tempfile(fileext = ".txt")
file.show(Rd2txt(Rd, outfile, package = "tools",
 stages = c("install", "render")))

checkRd(Rd) # A stricter test than Rd2HTML uses

End(Not run)
```

---

Rd2txt\_options

*Set Formatting Options for Text Help*

---

**Description**

This function sets various options for displaying text help.

**Usage**

```
Rd2txt_options(...)
```

## Arguments

... A list containing named options, or options passed as individual named arguments. See below for currently defined ones.

## Details

This function persistently sets various formatting options for the `Rd2txt` function which is used in displaying text format help. Currently defined options are:

**width** (default 80): The width of the output page.

**minIndent** (default 10): The minimum indent to use in a list.

**extraIndent** (default 4): The extra indent to use in each level of nested lists.

**sectionIndent** (default 5): The indent level for a section.

**sectionExtra** (default 2): The extra indentation for each nested section level.

**itemBullet** (default " \* ", with the asterisk replaced by a Unicode bullet in UTF-8 and most Windows locales): The symbol to use as a bullet in itemized lists.

**enumFormat** : A function to format item numbers in enumerated lists.

**showURLs** (default FALSE): Whether to show URLs when expanding \href tags.

**code\_quote** (default TRUE): Whether to render \code and similar with single quotes.

**underline\_titles** (default TRUE): Whether to render section titles with underlines (via backspacing).

## Value

If called with no arguments, returns all option settings in a list. Otherwise, it changes the named settings and invisibly returns their previous values.

## Author(s)

Duncan Murdoch

[Rd2txt](#)

## Examples

```
The itemBullet is locale-specific
saveOpts <- Rd2txt_options()
saveOpts
Rd2txt_options(minIndent = 4)
Rd2txt_options()
Rd2txt_options(saveOpts)
Rd2txt_options()
```

Rdiff

*Difference R Output Files***Description**

Given two R output files, compute differences ignoring headers, footers and some other differences.

**Usage**

```
Rdiff(from, to, useDiff = FALSE, forEx = FALSE,
 nullPointers = TRUE, Log = FALSE)
```

**Arguments**

|                           |                                                                                             |
|---------------------------|---------------------------------------------------------------------------------------------|
| <code>from, to</code>     | filepaths to be compared                                                                    |
| <code>useDiff</code>      | should diff always be used to compare results?                                              |
| <code>forEx</code>        | logical: extra pruning for ‘-Ex.Rout’ files to exclude the header.                          |
| <code>nullPointers</code> | logical: should the displayed addresses of pointers be set to 0x00000000 before comparison? |
| <code>Log</code>          | logical: should the returned value include a log of differences found?                      |

**Details**

The R startup banner and any timing information from R CMD BATCH are removed from both files, together with lines about loading packages. UTF-8 fancy quotes (see [sQuote](#)) and on Windows, Windows’ so-called ‘smart quotes’, are mapped to a simple quote. Addresses of environments, compiled bytecode and other exotic types expressed as hex addresses (e.g., <environment: 0x12345678>) are mapped to 0x00000000. The files are then compared line-by-line. If there are the same number of lines and `useDiff` is false, a simple `diff -b`-like display of differences is printed (which ignores trailing spaces and differences in numbers of consecutive spaces), otherwise `diff -bw` is called on the edited files. (This tries to ignore all differences in whitespace: note that flag ‘-w’ is not required by POSIX but is supported by GNU, Solaris and FreeBSD versions.)

This can compare uncompressed PDF files, ignoring differences in creation and modification dates.

Mainly for use in examples, text from marker ‘> ## IGNORE\_RDIF\_BEGIN’ up to (but not including) ‘> ## IGNORE\_RDIF\_END’ is ignored.

**Value**

If `Log` is true, a list with components `status` (see below) and `out`, a character vector of descriptions of differences, possibly of zero length.

Otherwise, a status indicator, 0L if and only if no differences were found.

**See Also**

The shell script run as R CMD Rdiff.

---

|         |                                     |
|---------|-------------------------------------|
| Rdindex | <i>Generate Index from Rd Files</i> |
|---------|-------------------------------------|

---

### Description

Print a 2-column index table with names and titles from given R documentation files to a given output file or connection. The titles are nicely formatted between two column positions (typically 25 and 72, respectively).

### Usage

```
Rdindex(RdFiles, outFile = "", type = NULL,
 width = 0.9 * getOption("width"), indent = NULL)
```

### Arguments

|                      |                                                                                                                                                                                                                                                                                                                         |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>RdFiles</code> | a character vector specifying the Rd files to be used for creating the index, either by giving the paths to the files, or the path to a single directory with the sources of a package.                                                                                                                                 |
| <code>outFile</code> | a connection, or a character string naming the output file to print to. "" (the default) indicates output to the console.                                                                                                                                                                                               |
| <code>type</code>    | a character string giving the documentation type of the Rd files to be included in the index, or NULL (the default). The type of an Rd file is typically specified via the <code>\docType</code> tag; if <code>type</code> is "data", Rd files whose <i>only</i> keyword is <code>datasets</code> are included as well. |
| <code>width</code>   | a positive integer giving the target column for wrapping lines in the output.                                                                                                                                                                                                                                           |
| <code>indent</code>  | a positive integer specifying the indentation of the second column. Must not be greater than <code>width/2</code> , and defaults to <code>width/3</code> .                                                                                                                                                              |

### Details

If a name is not a valid alias, the first alias (or the empty string if there is none) is used instead.

---

|              |                                  |
|--------------|----------------------------------|
| RdTextFilter | <i>Select Text in an Rd File</i> |
|--------------|----------------------------------|

---

### Description

This function blanks out all non-text in an Rd file, for spell checking or other uses.

### Usage

```
RdTextFilter(ifile, encoding = "unknown", keepSpacing = TRUE,
 drop = character(), keep = character(),
 macros = file.path(R.home("share"), "Rd", "macros", "system.Rd"))
```

**Arguments**

|                          |                                                                                                        |
|--------------------------|--------------------------------------------------------------------------------------------------------|
| <code>ifile</code>       | An input file specified as a filename or connection, or an "Rd" object from <a href="#">parse_Rd</a> . |
| <code>encoding</code>    | An encoding name to pass to <a href="#">parse_Rd</a> .                                                 |
| <code>keepSpacing</code> | Whether to try to leave the text in the same lines and columns as in the original file.                |
| <code>drop</code>        | Additional sections of the Rd to drop.                                                                 |
| <code>keep</code>        | Sections of the Rd file to keep.                                                                       |
| <code>macros</code>      | Macro definitions to assume when parsing. See <a href="#">parse_Rd</a> .                               |

**Details**

This function parses the Rd file, then walks through it, element by element. Items with tag "TEXT" are kept in the same position as they appeared in the original file, while other parts of the file are replaced with blanks, so a spell checker such as [aspell](#) can check only the text and report the position in the original file. (If `keepSpacing` is `FALSE`, blank filling will not occur, and text will not be output in its original location.)

By default, the tags `\S3method`, `\S4method`, `\command`, `\docType`, `\email`, `\encoding`, `\file`, `\keyword`, `\link`, `\linkS4class`, `\method`, `\pkg`, and `\var` are skipped. Additional tags can be skipped by listing them in the `drop` argument; listing tags in the `keep` argument will stop them from being skipped. It is also possible to `keep` any of the `c("RCODE", "COMMENT", "VERB")` tags, which correspond to R-like code, comments, and verbatim text respectively, or to drop "TEXT".

**Value**

A character vector which if written to a file, one element per line, would duplicate the text elements of the original Rd file.

**Note**

The filter attempts to merge text elements into single words when markup in the Rd file is used to highlight just the start of a word.

**Author(s)**

Duncan Murdoch

**See Also**

[aspell](#), for which this is an acceptable filter.

**Description**

Utilities for computing on the information in Rd objects.

**Usage**

```
Rd_db(package, dir, lib.loc = NULL, stages = "build")
```

**Arguments**

|                      |                                                                                                                                                                                                                                             |
|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>package</code> | a character string naming an installed package.                                                                                                                                                                                             |
| <code>dir</code>     | a character string specifying the path to a package's root source directory. This should contain the subdirectory 'man' with R documentation sources (in Rd format). Only used if <code>package</code> is not given.                        |
| <code>lib.loc</code> | a character vector of directory names of R libraries, or <code>NULL</code> . The default value of <code>NULL</code> corresponds to all libraries currently known. The specified library trees are used to search for <code>package</code> . |
| <code>stages</code>  | if <code>dir</code> is specified and the database is being built from source, which stages of \Sexpr processing should be processed?                                                                                                        |

**Details**

`Rd_db` builds a simple database of all Rd objects in a package, as a list of the results of running [parse\\_Rd](#) on the Rd source files in the package and processing platform conditionals and some \Sexpr macros.

**See Also**

[parse\\_Rd](#)

**Examples**

```
Build the Rd db for the (installed) base package.
db <- Rd_db("base")

Keyword metadata per Rd object.
keywords <- lapply(db, tools:::Rd_get_metadata, "keyword")
Tabulate the keyword entries.
kw_table <- sort(table(unlist(keywords)))
The 5 most frequent ones:
rev(kw_table)[1 : 5]
The "most informative" ones:
kw_table[kw_table == 1]

Concept metadata per Rd file.
concepts <- lapply(db, tools:::Rd_get_metadata, "concept")
How many files already have \concept metadata?
sum(sapply(concepts, length) > 0)
How many concept entries altogether?
length(unlist(concepts))
```

---

|                           |                                 |
|---------------------------|---------------------------------|
| <code>read.00Index</code> | <i>Read 00Index-style Files</i> |
|---------------------------|---------------------------------|

---

**Description**

Read item/description information from ‘00Index’-like files. Such files are description lists rendered in tabular form, and currently used for the ‘INDEX’ and ‘demo/00Index’ files of add-on packages.

**Usage**

```
read.00Index(file)
```

**Arguments**

|                   |                                                                                                                                                                                                                                                                                                                                     |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>file</code> | the name of a file to read data values from. If the specified file is "", then input is taken from the keyboard (in this case input can be terminated by a blank line). Alternatively, <code>file</code> can be a <a href="#">connection</a> , which will be opened if necessary, and if so closed at the end of the function call. |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

**Value**

A character matrix with 2 columns named "Item" and "Description" which hold the items and descriptions.

**See Also**

[formatDL](#) for the inverse operation of creating a 00Index-style file from items and their descriptions.

---

|                           |                                      |
|---------------------------|--------------------------------------|
| <code>showNonASCII</code> | <i>Pick Out Non-ASCII Characters</i> |
|---------------------------|--------------------------------------|

---

**Description**

This function prints elements of a character vector which contain non-ASCII bytes, printing such bytes as a escape like ‘<fc>’.

**Usage**

```
showNonASCII(x)

showNonASCIIfile(file)
```

**Arguments**

|                   |                     |
|-------------------|---------------------|
| <code>x</code>    | a character vector. |
| <code>file</code> | path to a file.     |

**Details**

This was originally written to help detect non-portable text in files in packages.

It prints all element of `x` which contain non-ASCII characters, preceded by the element number and with non-ASCII bytes highlighted *via* `iconv(sub = "byte")`.

**Value**

The elements of `x` containing non-ASCII characters will be returned invisibly.

**Examples**

```
out <- c(
 "fa\xE7ile test of showNonASCII():",
 "\\details{",
 " This is a good line",
 " This has an \xfcm laut in it.",
 " OK again.",
 "}")
f <- tempfile()
cat(out, file = f, sep = "\n")

showNonASCIIfile(f)
unlink(f)
```

---

|                  |                                           |
|------------------|-------------------------------------------|
| startDynamicHelp | <i>Start the Dynamic HTML Help System</i> |
|------------------|-------------------------------------------|

---

**Description**

This function starts the internal help server, so that HTML help pages are rendered when requested.

**Usage**

```
startDynamicHelp(start = TRUE)
```

**Arguments**

|                    |                                                                                                                                    |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------|
| <code>start</code> | logical: whether to start or shut down the dynamic help system. If <code>NA</code> , the server is started if not already running. |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------|

**Details**

This function starts the internal HTTP server, which runs on the loopback interface (127.0.0.1). If `options("help.ports")` is set to a vector of non-zero integer values, `startDynamicHelp` will try those ports in order; otherwise, it tries up to 10 random ports to find one not in use. It can be disabled by setting the environment variable `R_DISABLE_HTTPD` to a non-empty value or `options("help.ports")` to 0.

`startDynamicHelp` is called by functions that need to use the server, so would rarely be called directly by a user.

Note that `options(help_type = "html")` must be set to actually make use of HTML help, although it might be the default for an R installation.

If the server cannot be started or is disabled, `help.start` will be unavailable and requests for HTML help will give text help (with a warning).

The browser in use does need to be able to connect to the loopback interface: occasionally it is set to use a proxy for HTTP on all interfaces, which will not work – the solution is to add an exception for `127.0.0.1`.

### Value

The chosen port number is returned invisibly (which will be 0 if the server has been stopped).

### See Also

`help.start` and `help(help_type = "html")` will attempt to start the HTTP server if required

`Rd2HTML` is used to render the package help pages.

---

SweaveTeXFilter

*Strip R Code out of Sweave File*

---

### Description

This function blanks out code chunks and Noweb markup in an Sweave input file, for spell checking or other uses.

### Usage

```
SweaveTeXFilter(ifile, encoding = "unknown")
```

### Arguments

|                       |                                                   |
|-----------------------|---------------------------------------------------|
| <code>ifile</code>    | Input file or connection.                         |
| <code>encoding</code> | Text encoding to pass to <code>readLines</code> . |

### Details

This function blanks out all Noweb markup and code chunks from an Sweave input file, leaving behind the LaTeX source, so that a LaTeX-aware spelling checker can check it and report errors in their original locations.

### Value

A character vector which if written to a file, one element per line, would duplicate the text elements of the original Sweave input file.

### Author(s)

Duncan Murdoch

### See Also

`aspell`, for which this is used with `filter = "Sweave"`.

---

testInstalledPackage

*Test Installed Packages*

---

## Description

These functions allow an installed package to be tested, or all base and recommended packages.

## Usage

```
testInstalledPackage(pkg, lib.loc = NULL, outDir = ".",
 types = c("examples", "tests", "vignettes"),
 srcdir = NULL, Ropts = "", ...)

testInstalledPackages(outDir = ".", errorsAreFatal = TRUE,
 scope = c("both", "base", "recommended"),
 types = c("examples", "tests", "vignettes"),
 srcdir = NULL, Ropts = "", ...)

testInstalledBasic(scope = c("basic", "devel", "both", "internet"))
```

## Arguments

|                             |                                                                                                                                  |
|-----------------------------|----------------------------------------------------------------------------------------------------------------------------------|
| <code>pkg</code>            | name of an installed package.                                                                                                    |
| <code>lib.loc</code>        | library path(s) in which to look for the package. See <a href="#">library</a> .                                                  |
| <code>outDir</code>         | the directory into which to write the output files: this should already exist.                                                   |
| <code>types</code>          | type(s) of tests to be done.                                                                                                     |
| <code>errorsAreFatal</code> | logical: should testing terminate at the first error?                                                                            |
| <code>srcdir</code>         | Optional directory to look for .save files.                                                                                      |
| <code>Ropts</code>          | Additional options such as ‘-dvalgrind’ to be passed to R CMD BATCH when running examples or tests.                              |
| <code>...</code>            | additional arguments use when preparing the files to be run, e.g. <code>commentDontrun</code> and <code>commentDonttest</code> . |
| <code>scope</code>          | Which set(s) should be tested? Can be abbreviated.                                                                               |

## Details

These tests depend on having the package example files installed (which is the default). If package-specific tests are found in a ‘tests’ directory they can be tested: these are not installed by default, but will be if `R CMD INSTALL --install-tests` was used. Finally, the R code in any vignettes can be extracted and tested.

Package tests are run in a ‘*pkg-tests*’ subdirectory of ‘`outDir`’, and leave their output there.

`testInstalledBasic` runs the basic tests, if installed. This should be run with `LC_COLLATE=C` set: the function tries to set this by it may not work on all OSes. For non-English locales it may be desirable to set environment variables `LANGUAGE` to ‘en’ and `LC_TIME` to ‘C’ to reduce the number of differences from reference results.

Except on Windows, if the environment variable `TEST_MC_CORES` is set to an integer greater than one, `testInstalledPackages` will run the package tests in parallel using its value as the maximum number of parallel processes.

The package-specific tests for the base and recommended packages are not normally installed, but `make install-tests` is provided to do so (as well as the basic tests).

## Value

Invisibly 0L for success, 1L for failure.

---

|          |                            |
|----------|----------------------------|
| texi2dvi | <i>Compile LaTeX Files</i> |
|----------|----------------------------|

---

## Description

Run `latex`/`pdflatex`, `makeindex` and `bibtex` until all cross-references are resolved to create a dvi or a PDF file.

## Usage

```
texi2dvi(file, pdf = FALSE, clean = FALSE, quiet = TRUE,
 texi2dvi = getOption("texi2dvi"),
 texinputs = NULL, index = TRUE)
```

```
texi2pdf(file, clean = FALSE, quiet = TRUE,
 texi2dvi = getOption("texi2dvi"),
 texinputs = NULL, index = TRUE)
```

## Arguments

|                        |                                                                                                                                                                                                                                                                                                                                                   |
|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>file</code>      | character string. Name of the LaTeX source file.                                                                                                                                                                                                                                                                                                  |
| <code>pdf</code>       | logical. If TRUE, a PDF file is produced instead of the default dvi file ( <code>texi2dvi</code> command line option ‘ <code>--pdf</code> ’).                                                                                                                                                                                                     |
| <code>clean</code>     | logical. If TRUE, all auxiliary files created during the conversion are removed.                                                                                                                                                                                                                                                                  |
| <code>quiet</code>     | logical. No output unless an error occurs.                                                                                                                                                                                                                                                                                                        |
| <code>texi2dvi</code>  | character string (or NULL). Script or program used to compile a TeX file to dvi or PDF. The default (selected by "" or "texi2dvi" or NULL) is to look for a program or script named ‘texi2dvi’ on the path and otherwise emulate the script with <code>system2</code> calls (which can be selected by the value "emulation"). See also ‘Details’. |
| <code>texinputs</code> | NULL or a character vector of paths to add to the LaTeX and bibtex input search paths.                                                                                                                                                                                                                                                            |
| <code>index</code>     | logical: should indices be prepared?                                                                                                                                                                                                                                                                                                              |

## Details

`texi2pdf` is a wrapper for the common case of `texi2dvi` (`pdf = TRUE`).

Despite the name, this is used in **R** to compile LaTeX files, specifically those generated from vignettes and by the `Rd2pdf` script (used for package reference manuals). It ensures that the '`R_HOME/share/texmf`' directory is in the `TEXINPUTS` path, so **R** style files such as '`Sweave`' and '`Rd`' will be found. The TeX search path used is first the existing `TEXINPUTS` setting (or the current directory if unset), then elements of argument `texinputs`, then '`R_HOME/share/texmf`' and finally the default path. Analogous changes are made to `BIBINPUTS` and `BSTINPUTS` settings.

The default option for `texi2dvi` is set from environment variable `R_TEXI2DVICMD`, and the default for that is set from environment variable `TEXI2DVI` or if that is unset, from a value chosen when **R** is configured.

A shell script `texi2dvi` is part of GNU's **texinfo**. Several issues have been seen with released versions, so if yours does not work correctly try `R_TEXI2DVICMD=emulation`.

Occasionally indices contain special characters which cause indexing to fail (particularly when using the '`hyperref`' LaTeX package) even on valid input. The argument `index = FALSE` is provided to allow package manuals to be made when this happens: it uses emulation.

## Value

Invisible `NULL`. Used for the side effect of creating a dvi or PDF file in the current working directory (and maybe other files, especially if `clean = FALSE`).

## Note

There are various versions of the `texi2dvi` script on Unix-alikes and quite a number of bugs have been seen, some of which this **R** wrapper works around.

One that was present with `texi2dvi` version 4.8 (as supplied by macOS) is that it will not work correctly for paths which contain spaces, nor if the absolute path to a file would contain spaces.

The three possible approaches all have their quirks. For example the Unix-alike `texi2dvi` script removes ancillary files that already exist but the other two approaches do not (and may get confused by such files).

Where supported (`texi2dvi` 5.0 and later; `texify.exe` from MiKTeX), option '`--max-iterations=20`' is used to avoid infinite retries.

The emulation mode supports `quiet = TRUE` from **R** 3.2.3 only. Currently `clean = TRUE` only cleans up in this mode if the conversion was successful—this gives users a chance to examine log files in the event of error.

All the approaches should respect the values of environment variables `LATEX`, `PDFLATEX`, `MAKEINDEX` and `BIBTEX` for the full paths to the corresponding commands.

## Author(s)

Originally Achim Zeileis but largely rewritten by R-core.

---

`toHTML`*Display an Object in HTML*

---

### Description

This generic function generates a complete HTML page from an object.

### Usage

```
toHTML(x, ...)
S3 method for class 'packageIQR'
toHTML(x, ...)
S3 method for class 'news_db'
toHTML(x, ...)
```

### Arguments

|                  |                                                                                                                    |
|------------------|--------------------------------------------------------------------------------------------------------------------|
| <code>x</code>   | An object to display.                                                                                              |
| <code>...</code> | Optional parameters for methods; the "packageIQR" and "news_db" methods pass these to <a href="#">HTMLheader</a> . |

### Value

A character vector to display the object `x`. The "packageIQR" method is designed to display lists in the R help system.

### See Also

[HTMLheader](#)

### Examples

```
cat(toHTML(demo(package = "base")), sep = "\n")
```

---

`tools-deprecated`*Deprecated Objects in Package **tools***

---

### Description

The functions or variables listed here are provided for compatibility with older versions of R only, and may be defunct as soon as of the next release.

**Usage**

```

package.dependencies(x, check = FALSE,
 depLevel = c("Depends", "Imports", "Suggests"))

getDepList(depMtrx, instPkgs, recursive = TRUE, local = TRUE,
 reduce = TRUE, lib.loc = NULL)

pkgDepends(pkg, recursive = TRUE, local = TRUE, reduce = TRUE,
 lib.loc = NULL)

installFoundDepends(depPkgList, ...)

vignetteDepends(vignette, recursive = TRUE, reduce = TRUE,
 local = TRUE, lib.loc = NULL)

```

**Arguments**

|                         |                                                                                                                                                                                                                                                 |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>          | A matrix of package descriptions as returned by <a href="#">available.packages</a> .                                                                                                                                                            |
| <code>check</code>      | If TRUE, return logical vector of check results. If FALSE, return parsed list of dependencies.                                                                                                                                                  |
| <code>depLevel</code>   | Whether to look for Depends or Suggests level dependencies. Can be abbreviated.                                                                                                                                                                 |
| <code>depMtrx</code>    | a dependency matrix as from <a href="#">package.dependencies()</a> .                                                                                                                                                                            |
| <code>pkg</code>        | the name of the package                                                                                                                                                                                                                         |
| <code>instPkgs</code>   | a matrix specifying all packages installed on the local system, as from <a href="#">installed.packages</a>                                                                                                                                      |
| <code>recursive</code>  | whether or not to include indirect dependencies.                                                                                                                                                                                                |
| <code>local</code>      | whether or not to search only locally                                                                                                                                                                                                           |
| <code>reduce</code>     | whether or not to collapse all sets of dependencies to a minimal value                                                                                                                                                                          |
| <code>lib.loc</code>    | what libraries to use when looking for installed packages. NULL indicates all library directories in the current <a href="#">.libPaths()</a> . Note that <code>lib.loc</code> is not used in <a href="#">getDepList()</a> and deprecated there. |
| <code>depPkgList</code> | A Found element from a <a href="#">pkgDependsList</a> object                                                                                                                                                                                    |
| <code>...</code>        | Arguments to pass on to <a href="#">install.packages</a>                                                                                                                                                                                        |
| <code>vignette</code>   | the path to the vignette source                                                                                                                                                                                                                 |

[Deprecated](#), [Defunct](#)

---

toRd

*Generic Function to Convert Object to a Fragment of Rd Code*

---

### Description

Methods for this function render their associated classes as a fragment of Rd code, which can then be rendered into text, HTML, or LaTeX.

### Usage

```
toRd(obj, ...)
S3 method for class 'bibentry'
toRd(obj, style = NULL, ...)
```

### Arguments

|       |                                                                    |
|-------|--------------------------------------------------------------------|
| obj   | The object to be rendered.                                         |
| style | The style to be used in converting a <code>bibentry</code> object. |
| ...   | Additional arguments used by methods.                              |

### Details

See `bibstyle` for a discussion of styles. The default `style = NULL` value gives the default style.

### Value

Returns a character vector containing a fragment of Rd code that could be parsed and rendered. The default method converts `obj` to mode `character`, then escapes any Rd markup within it. The `bibentry` method converts an object of that class to markup appropriate for use in a bibliography.

---

toTitleCase

*Convert Titles to Title Case*

---

### Description

Convert a character vector to title case, especially package titles.

### Usage

```
toTitleCase(text)
```

### Arguments

|      |                     |
|------|---------------------|
| text | a character vector. |
|------|---------------------|

## Details

This is intended for English text only.

No definition of ‘title case’ is universally accepted: all agree that ‘principal’ words are capitalized and common words like ‘for’ are not, but not which words fall into each category.

Generally words in all capitals are left alone: this implementation knows about conventional mixed-case words such as ‘LaTeX’ and ‘OpenBUGS’ and a few technical terms which are not usually capitalized such as ‘jar’ and ‘xls’. However, unknown technical terms will be capitalized unless they are single words enclosed in single quotes: names of packages and libraries should be quoted in titles.

## Value

A character vector of the same length as `text`, without names.

undoc

*Find Undocumented Objects*

## Description

Finds the objects in a package which are undocumented, in the sense that they are visible to the user (or data objects or S4 classes provided by the package), but no documentation entry exists.

## Usage

```
undoc(package, dir, lib.loc = NULL)
```

## Arguments

|                      |                                                                                                                                                                                                                                                                    |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>package</code> | a character string naming an installed package.                                                                                                                                                                                                                    |
| <code>dir</code>     | a character string specifying the path to a package’s root source directory. This must contain the subdirectory ‘man’ with R documentation sources (in Rd format), and at least one of the ‘R’ or ‘data’ subdirectories with R code or data objects, respectively. |
| <code>lib.loc</code> | a character vector of directory names of R libraries, or <code>NULL</code> . The default value of <code>NULL</code> corresponds to all libraries currently known. The specified library trees are used to search for <code>package</code> .                        |

## Details

This function is useful for package maintainers mostly. In principle, *all* user-level R objects should be documented.

The **base** package is special as it contains the primitives and these do not have definitions available at code level. We provide equivalent closures in environments `.ArgsEnv` and `.GenericArgsEnv` in the **base** package that are used for various purposes: `undoc("base")` checks that all the primitives that are not language constructs are prototyped in those environments and no others are.

## Value

An object of class `"undoc"` which is a list of character vectors containing the names of the undocumented objects split according to documentation type.

There is a `print` method for nicely displaying the information contained in such objects.

See Also

[codoc](#), [QC](#)

Examples

```
undoc("tools") # Undocumented objects in 'tools'
```

---

|                 |                                       |
|-----------------|---------------------------------------|
| update_PACKAGES | <i>Update Existing PACKAGES Files</i> |
|-----------------|---------------------------------------|

---

Description

Update an existing repository by reading the PACKAGES file, retaining entries which are still valid, removing entries which are no longer valid, and only processing built package tarballs which do not match existing entries.

update\_PACKAGES can be much faster than [write\\_PACKAGES](#) for small-moderate changes to large repository indexes, particularly in non-strict mode (see Details).

Usage

```
update_PACKAGES(dir = ".", fields = NULL, type = c("source",
 "mac.binary", "win.binary"), verbose.level = as.integer(dryrun),
 latestOnly = TRUE, addFiles = FALSE, rds_compress = "xz",
 strict = TRUE, dryrun = FALSE)
```

Arguments

|               |                                                                                                                                                                                                  |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| dir           | See <a href="#">write_PACKAGES</a>                                                                                                                                                               |
| fields        | See <a href="#">write_PACKAGES</a>                                                                                                                                                               |
| type          | See <a href="#">write_PACKAGES</a>                                                                                                                                                               |
| verbose.level | (0, 1, 2) What level of informative messages which should be displayed throughout the process. Defaults to 0 if dryrun is FALSE (the default) and 1 otherwise. See details for more information. |
| latestOnly    | See <a href="#">write_PACKAGES</a>                                                                                                                                                               |
| addFiles      | See <a href="#">write_PACKAGES</a>                                                                                                                                                               |
| rds_compress  | See <a href="#">write_PACKAGES</a>                                                                                                                                                               |
| strict        | logical. Should 'strict mode' be used when checking existing PACKAGES entries. See details. Defaults to TRUE.                                                                                    |
| dryrun        | logical. Should the updates to existing PACKAGES files be computed but NOT applied. Defaults to FALSE.                                                                                           |

## Details

Throughout this section, *package tarball* is defined to mean any archive file in `dir` whose name can be interpreted as `<package>_<version>.<ext>` - with `<ext>` the appropriate extension for built packages of type `type` - (or that is pointed to by the `File` field of an existing `PACKAGES` entry). *Novel package tarballs* are those which do not match an existing `PACKAGES` file entry.

`update_PACKAGES` calls directly down to `write_PACKAGES` with a warning (and thus all package tarballs will be processed), if any of the following conditions hold:

- `type` is `win.binary` and `strict` is `TRUE` (no MD5 checksums are included in `win.binary` `PACKAGES` files)
- No `PACKAGES` file exists under `dir`
- A `PACKAGES` file exists under `dir` but is empty
- `fields` is not `NULL` and one or more specified fields are not present in the existing `PACKAGES` file

`update_PACKAGES` avoids (re)processing package tarballs in cases where a `PACKAGES` file entry already exists and appears to remain valid. The logic for detecting still-valid entries is as follows:

Any package tarball which was last modified more recently than the existing `PACKAGES` file is considered novel; existing `PACKAGES` entries appearing to correspond to such tarballs are *always* considered stale and replaced by newly generated ones. Similarly, all `PACKAGES` entries that do not correspond to any package tarball found in `dir` are considered invalid and are excluded from the resulting updated `PACKAGES` files.

When `strict` is `TRUE`, `PACKAGES` entries that match a package tarball (by package name and version) are confirmed via MD5 checksum; only those that pass are retained as valid. All novel package tarballs are fully processed by the standard machinery underlying `write_PACKAGES` and the resulting entries are added. Finally, if `latestOnly` is `TRUE`, package-version pruning is performed across the entries.

When `strict` is `FALSE`, package tarballs are assumed to encode correct metadata in their file-names. `PACKAGES` entries which appear to match a package tarball are retained as valid (No MD5 checksum testing occurs). If `latestOnly` is `TRUE`, package-version pruning is performed across the full set of retained entries and novel package tarballs *before* the processing of the novel tarballs, at significant computational and time savings in some situations. After the optional pruning, any relevant novel package tarballs are processed via the standard machinery and added to the set of retained entries.

In both cases, after the above process concludes, entries are sorted alphabetically by the string concatenation of `Package` and `Version`. This should match the entry order `write_PACKAGES` outputs.

The fields within the entries are ordered as follows: canonical fields - i.e., those appearing as columns when `available.packages` is called on a CRAN mirror - appear first in their canonical order, followed by any non-canonical fields.

After entry and field reordering, the final database of `PACKAGES` entries is written to all three `PACKAGES` files, overwriting the existing versions.

When `verbose.level` is 0, no extra messages are displayed to the user. When it is 1, detailed information about what is happening is conveyed via messages, but underlying machinery from `write_PACKAGES` is invoked with `verbose = FALSE`. Behavior when `verbose.level` is 2 is identical to `verbose.level` 1 with the exception that underlying machinery from `write_PACKAGE` is invoked with `verbose = TRUE`, which will individually list every processed tarball.

**Note**

While both strict and non-strict modes can offer speedups when updating small percentages of large repositories, non-strict mode is *much* faster and is recommended in situations where the assumption it makes about tarballs’ filenames encoding accurate information is safe.

**Note**

Users should expect significantly smaller speedups over `write_PACKAGES` in the `type == "win.binary"` case on at least some operating systems. This is due to `write_PACKAGES` being significantly faster in this context, rather than `update_PACKAGES` being slower.

|               |                                           |
|---------------|-------------------------------------------|
| update_pkg_po | <i>Prepare Translations for a Package</i> |
|---------------|-------------------------------------------|

---

**Description**

Prepare the ‘po’ directory of a package and compile and install the translations.

**Usage**

```
update_pkg_po(pkgdir, pkg = NULL, version = NULL, copyright, bugs)
```

**Arguments**

- `pkgdir` The path to the package directory.
- `pkg` The package name: if `NULL` it is read from the package’s ‘DESCRIPTION’ file.
- `version` The package version: if `NULL` it is read from the package’s ‘DESCRIPTION’ file.
- `copyright, bugs` optional character strings for the ‘Copyright’ and ‘Report-Msgid-Bugs-To’ details in the template files.

## Details

This performs a series of steps to prepare or update messages in the package.

- If the package sources do not already have a ‘po’ directory, one is created.
- `xgettext2pot` is called to create/update a file ‘po/R-*pkgname*.pot’ containing the translatable messages in the package.
- All existing files in directory po with names ‘R-*lang*.po’ are updated from ‘R-*pkgname*.pot’, `checkPoFile` is called on the updated file, and if there are no problems the file is compiled and installed under ‘inst/po’.
- In a UTF-8 locale, a ‘translation’ ‘R-en@quot .po’ is created with UTF-8 directional quotes, compiled and installed under ‘inst/po’.
- The remaining steps are done only if file ‘po/*pkgname*.pot’ already exists. The ‘src/\*.{c,cc,cpp,m,mm}’ files in the package are examined to create a file ‘po/*pkgname*.pot’ containing the translatable messages in the C/C++ files. If there is a src/windows directory, files within it are also examined.
- All existing files in directory po with names ‘*lang*.po’ are updated from ‘*pkgname*.pot’, `checkPoFile` is called on the updated file, and if there are no problems the file is compiled and installed under ‘inst/po’.
- In a UTF-8 locale, a ‘translation’ ‘en@quot .po’ is created with UTF-8 directional quotes, compiled and installed under ‘inst/po’.

Note that C/C++ messages are not automatically prepared for translation as they need to be explicitly marked for translation in the source files. Once that has been done, create an empty file ‘po/*pkgname*.pot’ in the package sources and run this function again.

`pkg = "base"` is special (and for use by R developers only): the C files are not in the package directory but in the main sources.

## System requirements

This function requires the following tools from the GNU `gettext-tools`: `xgettext`, `msgmerge`, `msgfmt`, `msginit` and `msgconv`. These are part of most Linux distributions and easily compiled from the sources on Unix-alikes (including macOS). Pre-compiled versions for Windows are available in <https://www.stats.ox.ac.uk/pub/Rtools/goodies/gettext-tools.zip>.

It will probably not work correctly for en@quot translations except in a UTF-8 locale, so these are skipped elsewhere.

`xgettext2pot`.

## Description

Directories for storing R-related user-specific data, configuration and cache files.

**Usage**

```
R_user_dir(package, which = c("data", "config", "cache"))
```

**Arguments**

|         |                                                                                    |
|---------|------------------------------------------------------------------------------------|
| package | a character string giving the name of an R package                                 |
| which   | a character string indicating the kind of file(s) of interest. Can be abbreviated. |

**Details**

For desktop environments using X Windows, the freedesktop.org project (formerly X Desktop Group, XDG) developed the XDG Base Directory Specification (<https://specifications.freedesktop.org/basedir-spec>) for standardizing the location where certain files should be placed. CRAN package **rappdirs** provides these general locations with appropriate values for all platforms for which R is available.

`R_user_dir` specializes the general mechanism to R package specific locations for user files, by providing package specific subdirectories inside a ‘R’ subdirectory inside the “base” directories appropriate for user-specific data, configuration and cache files (see the examples), with the intent that packages will not interfere if they work within their respective subdirectories.

The locations of these base directories can be customized via the specific environment variables `R_USER_DATA_DIR`, `R_USER_CONFIG_DIR` and `R_USER_CACHE_DIR`. If these are not set, the general XDG-style environment variables `XDG_DATA_HOME`, `XDG_CONFIG_HOME` and `XDG_CACHE_HOME` are used if set, and otherwise, defaults appropriate for the R platform in use are employed.

**Examples**

```
IGNORE_RDIFF_BEGIN
R_user_dir("FOO", "cache")
IGNORE_RDIFF_END
```

---

vignetteEngine

---

*Set or Get a Vignette Processing Engine*

---

**Description**

Vignettes are normally processed by **Sweave**, but package writers may choose to use a different engine (e.g., one provided by the **knitr**, **noweb** or **R.rsp** packages). This function is used by those packages to register their engines, and internally by R to retrieve them.

**Usage**

```
vignetteEngine(name, weave, tangle, pattern = NULL,
 package = NULL, aspell = list())
```

**Arguments**

|                      |                                                                                                                                                                                                             |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>name</code>    | the name of the engine.                                                                                                                                                                                     |
| <code>weave</code>   | a function to convert vignette source files to PDF/HTML or intermediate LaTeX output.                                                                                                                       |
| <code>tangle</code>  | a function to convert vignette source files to R code.                                                                                                                                                      |
| <code>pattern</code> | a regular expression pattern for the filenames handled by this engine, or <code>NULL</code> for the default pattern.                                                                                        |
| <code>package</code> | the package registering the engine. By default, this is the package calling <code>vignetteEngine</code> .                                                                                                   |
| <code>aspell</code>  | a list with element names <code>filter</code> and/or <code>control</code> giving the respective arguments to be used when spell checking the text in the vignette source file with <a href="#">aspell</a> . |

**Details**

If `weave` is missing, `vignetteEngine` will return the currently registered engine matching name and package.

If `weave` is `NULL`, the specified engine will be deleted.

Other settings define a new engine. The `weave` and `tangle` functions must be defined with argument lists compatible with `function(file, ...)`. Currently the `...` arguments may include logical argument `quiet` and character argument `encoding`; others may be added in future. These are described in the documentation for [Sweave](#) and [Stangle](#).

The `weave` and `tangle` functions should return the filename of the output file that has been produced. Currently the `weave` function, when operating on a file named '`<name><pattern>`' must produce a file named '`<name>[.] (tex|pdf|html)`'. The '`.tex`' files will be processed by `pdflatex` to produce '`.pdf`' output for display to the user; the others will be displayed as produced. The `tangle` function must produce a file named '`<name>[.] [rRsS]`' containing the executable R code from the vignette. The `tangle` function may support a `split = TRUE` argument, and then it should produce files named '`<name>.*[.] [rRsS]`'.

The `pattern` argument gives a regular expression to match the extensions of files which are to be processed as vignette input files. If set to `NULL`, the default pattern "`[.] [RrSs] (nw|tex) $"` is used.

**Value**

If the engine is being deleted, `NULL`. Otherwise a list containing components

|                      |                                      |
|----------------------|--------------------------------------|
| <code>name</code>    | The name of the engine               |
| <code>package</code> | The name of its package              |
| <code>pattern</code> | The pattern for vignette input files |
| <code>weave</code>   | The weave function                   |
| <code>tangle</code>  | The tangle function                  |

## Examples

```
str(vignetteEngine("Sweave"))
```

---

vignetteInfo

*Basic Information about a Vignette*

---

## Description

Provide basic information including package and dependency of a vignette from its source file.

## Usage

```
vignetteInfo(file)
```

## Arguments

|      |                            |
|------|----------------------------|
| file | file name of the vignette. |
|------|----------------------------|

## Value

a [list](#) with components, each a possibly empty [character](#):

|          |                                                     |
|----------|-----------------------------------------------------|
| file     | the <a href="#">basename</a> of the file.           |
| title    | the vignette title.                                 |
| depends  | the package dependencies.                           |
| keywords | keywords if provided.                               |
| engine   | the vignette engine such as "Sweave", "knitr", etc. |

## Note

`vignetteInfo(file)$depends` is a substitute for the deprecated `vignetteDepends()` functionality.

|----------------|--------------------------------|
| write_PACKAGES | <i>Generate PACKAGES Files</i> |
|----------------|--------------------------------|

---

## Description

Generate ‘PACKAGES’, ‘PACKAGES.gz’ and ‘PACKAGES.rds’ files for a repository of source or Mac/Windows binary packages.

## Usage

```
write_PACKAGES(dir = ".", fields = NULL,
 type = c("source", "mac.binary", "win.binary"),
 verbose = FALSE, unpacked = FALSE, subdirs = FALSE,
 latestOnly = TRUE, addFiles = FALSE, rds_compress = "xz")
```

## Arguments

|              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|--------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| dir          | Character vector describing the location of the repository (directory including source or binary packages) to generate the ‘PACKAGES’, ‘PACKAGES.gz’ and ‘PACKAGES.rds’ files from and write them to.                                                                                                                                                                                                                                                                                                                                                                |
| fields       | a character vector giving the fields to be used in the ‘PACKAGES’, ‘PACKAGES.gz’ and ‘PACKAGES.rds’ files in addition to the default ones, or NULL (default).<br><br>The default corresponds to the fields needed by <a href="#">available.packages</a> : "Package", "Version", "Priority", "Depends", "Imports", "LinkingTo", "Suggests", "Enhances", "OS_type", "License" and "Archs", and those fields will always be included, plus the file name in field "File" if addFile = TRUE and the path to the subdirectory in field "Path" if subdirectories are used. |
| type         | Type of packages: currently source ‘.tar.{gz,bz2,xz}’ archives, and macOS or Windows binary (‘.tgz’ or ‘.zip’, respectively) packages are supported. Defaults to "win.binary" on Windows and to "source" otherwise.                                                                                                                                                                                                                                                                                                                                                  |
| verbose      | logical. Should packages be listed as they are processed?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| unpacked     | a logical indicating whether the package contents are available in unpacked form or not (default).                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| subdirs      | either logical (to indicate if subdirectories should be included, recursively) or a character vector of names of subdirectories to include (which are not recursed).                                                                                                                                                                                                                                                                                                                                                                                                 |
| latestOnly   | logical: if multiple versions of a package are available should only the latest version be included?                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| addFiles     | logical: should the filenames be included as field ‘File’ in the ‘PACKAGES’ file.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| rds_compress | The type of compression to be used for ‘PACKAGES.rds’: see <a href="#">saveRDS</a> . The default is the one found to give maximal compression, and is as used on CRAN.                                                                                                                                                                                                                                                                                                                                                                                               |

## Details

`write_PACKAGES` scans the named directory for R packages, extracts information from each package's 'DESCRIPTION' file, and writes this information into the 'PACKAGES', 'PACKAGES.gz' and 'PACKAGES.rds' files, where the first two represent the information in DCF format, and the third serializes it via [saveRDS](#).

Including non-latest versions of packages is only useful if they have less constraining version requirements, so for example `latestOnly = FALSE` could be used for a source repository when 'foo\_1.0' depends on 'R >= 2.15.0' but 'foo\_0.9' is available which depends on 'R >= 2.11.0'.

Support for repositories with subdirectories and hence for `subdirs != FALSE` depends on recording a "Path" field in the 'PACKAGES' files.

Support for more general file names (e.g., other types of compression) *via* a "File" field in the 'PACKAGES' files can be used by [download.packages](#). If the file names are not of the standard form, use `addFiles = TRUE`.

`type = "win.binary"` uses [unz](#) connections to read all 'DESCRIPTION' files contained in the (zipped) binary packages for Windows in the given directory `dir`, and builds files 'PACKAGES', 'PACKAGES.gz' and 'PACKAGES.rds' files from this information.

For a remote repository there is a tradeoff between download speed and time spent by [available.packages](#) processing the downloaded file(s). For large repositories it is likely to be beneficial to use `rds_compress = "xz"`.

## Value

Invisibly returns the number of packages described in the resulting 'PACKAGES', 'PACKAGES.gz' and 'PACKAGES.rds' files. If 0, no packages were found and no files were written.

## Note

Processing '.tar.gz' archives to extract the 'DESCRIPTION' files is quite slow.

This function can be useful on other OSes to prepare a repository to be accessed by Windows machines, so `type = "win.binary"` should work on all OSes.

## Author(s)

Uwe Ligges and R-core.

## See Also

See [read.dcf](#) and [write.dcf](#) for reading 'DESCRIPTION' files and writing the 'PACKAGES' and 'PACKAGES.gz' files. See [update\\_PACKAGES](#) for efficiently updating existing 'PACKAGES' and 'PACKAGES.gz' files.

## Examples

```
Not run:
write_PACKAGES("c:/myFolder/myRepository") # on Windows
write_PACKAGES("/pub/RWin/bin/windows/contrib/2.9",
 type = "win.binary") # on Linux

End(Not run)
```

xgettext

*Extract Translatable Messages from R Files in a Package*

## Description

For each file in the ‘R’ directory (including system-specific subdirectories) of a package, extract the unique arguments passed to `stop`, `warning`, `message`, `gettext` and `gettextf`, or to `ngettext`.

## Usage

```
xgettext(dir, verbose = FALSE, asCall = TRUE)

xngettext(dir, verbose = FALSE)

xgettext2pot(dir, potFile, name = "R", version, bugs)
```

## Arguments

|                                  |                                                                                                                                                               |
|----------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>dir</code>                 | the directory of a source package.                                                                                                                            |
| <code>verbose</code>             | logical: should each file be listed as it is processed?                                                                                                       |
| <code>asCall</code>              | logical: if TRUE each argument is returned whole, otherwise the strings within each argument are extracted.                                                   |
| <code>potFile</code>             | name of po template file to be produced. Defaults to ‘R- <i>pkgname</i> .pot’ where <i>pkgname</i> is the basename of ‘dir’.                                  |
| <code>name, version, bugs</code> | as recorded in the template file: <code>version</code> defaults the version number of the currently running R, and <code>bugs</code> to “bugs.r-project.org”. |

## Details

Leading and trailing white space (space, tab and linefeed) is removed for calls to `gettext`, `gettextf`, `stop`, `warning`, and `message`, as it is by the internal code that passes strings for translation.

We look to see if these functions were called with `domain = NA` and if so omit the call if `asCall = TRUE`: note that the call might contain a call to `gettext` which would be visible if `asCall = FALSE`.

`xgettext2pot` calls `xgettext` and then `xngettext`, and writes a PO template file for use with the **GNU Gettext** tools. This ensures that the strings for simple translation are unique in the file (as **GNU Gettext** requires), but does not do so for `ngettext` calls (and the rules are not stated in the Gettext manual, but `msgfmt` complains if there is duplication between the sets.).

If applied to the **base** package, this also looks in the ‘.R’ files in ‘[R\\_HOME](#)/share/R’.

## Value

For `xgettext`, a list of objects of class “xgettext” (which has a `print` method), one per source file that potentially contains translatable strings.

For `xngettext`, a list of objects of class “xngettext”, which are themselves lists of length-2 character strings.

**See Also**

[update\\_pkg\\_po\(\)](#) which calls `xgettext2pot()`.

**Examples**

```
Not run: ## in a source-directory build of R:
xgettext(file.path(R.home(), "src", "library", "splines"))

End(Not run)
```

## Chapter 14

# The `utils` package

---

`utils-package`

*The R Utils Package*

---

### Description

R utility functions

### Details

This package contains a collection of utility functions.

For a complete list, use `library(help = "utils")`.

### Author(s)

R Core Team and contributors worldwide

Maintainer: R Core Team <R-core@r-project.org>

---

`adist`

*Approximate String Distances*

---

### Description

Compute the approximate string distance between character vectors. The distance is a generalized Levenshtein (edit) distance, giving the minimal possibly weighted number of insertions, deletions and substitutions needed to transform one string into another.

### Usage

```
adist(x, y = NULL, costs = NULL, counts = FALSE, fixed = TRUE,
 partial = !fixed, ignore.case = FALSE, useBytes = FALSE)
```

## Arguments

|                          |                                                                                                                                                                                                                                                                                                                    |
|--------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>           | a character vector. <a href="#">Long vectors</a> are not supported.                                                                                                                                                                                                                                                |
| <code>y</code>           | a character vector, or <code>NULL</code> (default) indicating taking <code>x</code> as <code>y</code> .                                                                                                                                                                                                            |
| <code>costs</code>       | a numeric vector or list with names partially matching ‘insertions’, ‘deletions’ and ‘substitutions’ giving the respective costs for computing the Levenshtein distance, or <code>NULL</code> (default) indicating using unit cost for all three possible transformations.                                         |
| <code>counts</code>      | a logical indicating whether to optionally return the transformation counts (numbers of insertions, deletions and substitutions) as the "counts" attribute of the return value.                                                                                                                                    |
| <code>fixed</code>       | a logical. If <code>TRUE</code> (default), the <code>x</code> elements are used as string literals. Otherwise, they are taken as regular expressions and <code>partial = TRUE</code> is implied (corresponding to the approximate string distance used by <a href="#">agrep</a> with <code>fixed = FALSE</code> ). |
| <code>partial</code>     | a logical indicating whether the transformed <code>x</code> elements must exactly match the complete <code>y</code> elements, or only substrings of these. The latter corresponds to the approximate string distance used by <a href="#">agrep</a> (by default).                                                   |
| <code>ignore.case</code> | a logical. If <code>TRUE</code> , case is ignored for computing the distances.                                                                                                                                                                                                                                     |
| <code>useBytes</code>    | a logical. If <code>TRUE</code> distance computations are done byte-by-byte rather than character-by-character.                                                                                                                                                                                                    |

## Details

The (generalized) Levenshtein (or edit) distance between two strings  $s$  and  $t$  is the minimal possibly weighted number of insertions, deletions and substitutions needed to transform  $s$  into  $t$  (so that the transformation exactly matches  $t$ ). This distance is computed for `partial = FALSE`, currently using a dynamic programming algorithm (see, e.g., [https://en.wikipedia.org/wiki/Levenshtein\\_distance](https://en.wikipedia.org/wiki/Levenshtein_distance)) with space and time complexity  $O(mn)$ , where  $m$  and  $n$  are the lengths of  $s$  and  $t$ , respectively. Additionally computing the transformation sequence and counts is  $O(\max(m, n))$ .

The generalized Levenshtein distance can also be used for approximate (fuzzy) string matching, in which case one finds the substring of  $t$  with minimal distance to the pattern  $s$  (which could be taken as a regular expression, in which case the principle of using the leftmost and longest match applies), see, e.g., [https://en.wikipedia.org/wiki/Approximate\\_string\\_matching](https://en.wikipedia.org/wiki/Approximate_string_matching). This distance is computed for `partial = TRUE` using ‘tre’ by Ville Laurikari (<https://laurikari.net/tre/>) and corresponds to the distance used by [agrep](#). In this case, the given cost values are coerced to integer.

Note that the costs for insertions and deletions can be different, in which case the distance between  $s$  and  $t$  can be different from the distance between  $t$  and  $s$ .

## Value

A matrix with the approximate string distances of the elements of `x` and `y`, with rows and columns corresponding to `x` and `y`, respectively.

If `counts` is `TRUE`, the transformation counts are returned as the "counts" attribute of this matrix, as a 3-dimensional array with dimensions corresponding to the elements of `x`, the elements of `y`, and the type of transformation (insertions, deletions and substitutions), respectively. Additionally, if `partial = FALSE`, the transformation sequences are returned as the "trafos" attribute of the return value, as character strings with elements ‘M’, ‘I’, ‘D’ and ‘S’ indicating a match, insertion, deletion and substitution, respectively. If `partial = TRUE`, the offsets (positions of the first

and last element) of the matched substrings are returned as the "offsets" attribute of the return value (with both offsets  $-1$  in case of no match).

### See Also

[agrep](#) for approximate string matching (fuzzy matching) using the generalized Levenshtein distance.

### Examples

```
Cf. https://en.wikipedia.org/wiki/Levenshtein_distance
adist("kitten", "sitting")
To see the transformation counts for the Levenshtein distance:
drop(attr(adist("kitten", "sitting", counts = TRUE), "counts"))
To see the transformation sequences:
attr(adist(c("kitten", "sitting"), counts = TRUE), "trafos")

Cf. the examples for agrep:
adist("lasy", "1 lazy 2")
For a "partial approximate match" (as used for agrep):
adist("lasy", "1 lazy 2", partial = TRUE)
```

---

alarm

*Alert the User*

---

### Description

Gives an audible or visual signal to the user.

### Usage

```
alarm()
```

### Details

`alarm()` works by sending a `"\a"` character to the console. On most platforms this will ring a bell, beep, or give some other signal to the user (unless standard output has been redirected).

It attempts to flush the console (see [flush.console](#)).

### Value

No useful value is returned.

### Examples

```
alarm()
```

---

apropos

*Find Objects by (Partial) Name*

---

## Description

`apropos()` returns a character vector giving the names of objects in the search list matching (as a regular expression) `what`.

`find()` returns where objects of a given name can be found.

## Usage

```
apropos(what, where = FALSE, ignore.case = TRUE, mode = "any")
```

```
find(what, mode = "any", numeric = FALSE, simple.words = TRUE)
```

## Arguments

`what` character string. For `simple.words = FALSE` the name of an object; otherwise a [regular expression](#) to match object names against.

`where, numeric` a logical indicating whether positions in the search list should also be returned

`ignore.case` logical indicating if the search should be case-insensitive, TRUE by default.

`mode` character; if not "any", only objects whose `mode` equals `mode` are searched.

`simple.words` logical; if TRUE, the `what` argument is only searched as a whole word.

## Details

If `mode != "any"` only those objects which are of mode `mode` are considered.

`find` is a different user interface for a similar task to `apropos`. By default (`simple.words == TRUE`), only whole names are matched. Unlike `apropos`, matching is always case-sensitive.

Unlike the default behaviour of [ls](#), names which begin with a `'.'` are included (and these are often 'internal' objects — as from R 3.4.0 most such are excluded).

## Value

For `apropos`, a character vector sorted by name. For `where = TRUE` this has names giving the (numerical) positions on the search path.

For `find`, either a character vector of environment names or (for `numeric = TRUE`) a numerical vector of positions on the search path with names the names of the corresponding environments.

## Author(s)

Originally, Kurt Hornik and Martin Maechler (May 1997).

## See Also

[glob2rx](#) to convert wildcard patterns to regular expressions.

[objects](#) for listing objects from one place, [help.search](#) for searching the help system, [search](#) for the search path.

## Examples

```
require(stats)

Not run: apropos("lm")
apropos("GLM") # several
apropos("GLM", ignore.case = FALSE) # not one
apropos("lq")

cor <- 1:pi
find("cor") #> ".GlobalEnv" "package:stats"
find("cor", numeric = TRUE) # numbers with these names
find("cor", numeric = TRUE, mode = "function") # only the second one
rm(cor)

Not run: apropos(".", mode="list") # a long list

need a DOUBLE backslash '\\' (in case you don't see it anymore)
apropos("\\[")

everything % not diff-able
length(apropos("."))

those starting with 'pr'
apropos("^pr")

the 1-letter things
apropos("^.?$")
the 1-2-letter things
apropos("^..?$")
the 2-to-4 letter things
apropos("^.{2,4}$")

the 8-and-more letter things
apropos("^.{8,}$")
table(nchar(apropos("^.{8,}$")))
```

aregexec

*Approximate String Match Positions*

## Description

Determine positions of approximate string matches.

## Usage

```
aregexec(pattern, text, max.distance = 0.1, costs = NULL,
 ignore.case = FALSE, fixed = FALSE, useBytes = FALSE)
```

## Arguments

|         |                                                                                                                                                                                                      |
|---------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| pattern | a non-empty character string or a character string containing a regular expression (for <code>fixed = FALSE</code> ) to be matched. Coerced by <a href="#">as.character</a> to a string if possible. |
|---------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

|                           |                                                                                                                              |
|---------------------------|------------------------------------------------------------------------------------------------------------------------------|
| <code>text</code>         | character vector where matches are sought. Coerced by <code>as.character</code> to a character vector if possible.           |
| <code>max.distance</code> | maximum distance allowed for a match. See <code>agrep</code> .                                                               |
| <code>costs</code>        | cost of transformations. See <code>agrep</code> .                                                                            |
| <code>ignore.case</code>  | a logical. If <code>TRUE</code> , case is ignored for computing the distances.                                               |
| <code>fixed</code>        | If <code>TRUE</code> , the pattern is matched literally (as is). Otherwise (default), it is matched as a regular expression. |
| <code>useBytes</code>     | a logical. If <code>TRUE</code> comparisons are byte-by-byte rather than character-by-character.                             |

### Details

`aregexec` provides a different interface to approximate string matching than `agrep` (along the lines of the interfaces to exact string matching provided by `regexec` and `grep`).

Note that by default, `agrep` performs literal matches, whereas `aregexec` performs regular expression matches.

See `agrep` and `adist` for more information about approximate string matching and distances.

Comparisons are byte-by-byte if `pattern` or any element of `text` is marked as "bytes".

### Value

A list of the same length as `text`, each element of which is either `-1` if there is no match, or a sequence of integers with the starting positions of the match and all substrings corresponding to parenthesized subexpressions of `pattern`, with attribute `"match.length"` an integer vector giving the lengths of the matches (or `-1` for no match).

### See Also

`regmatches` for extracting the matched substrings.

### Examples

```
Cf. the examples for agrep.
x <- c("1 lazy", "1", "1 LAZY")
aregexec("lasy", x, max.distance = 2)
aregexec("(lay)(sy)", x, max.distance = 2)
aregexec("(lay)(sy)", x, max.distance = 2, ignore.case = TRUE)
m <- aregexec("(lay)(sy)", x, max.distance = 2)
regmatches(x, m)
```

---

arrangeWindows

*Rearrange Windows on MS Windows*

---

### Description

This function allows you to tile or cascade windows, or to minimize or restore them (on Windows, i.e. when `(.Platform$OS.type == "windows")`). This may include windows not “belonging” to R.

## Usage

```
arrangeWindows(action, windows, preserve = TRUE, outer = FALSE)
```

## Arguments

|          |                                                                                                                                                                                                                                                    |
|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| action   | a character string, the action to perform on the windows. The choices are <code>c("vertical", "horizontal", "cascade", "minimize", "restore")</code> with default "vertical"; see the 'Details' for the interpretation. Abbreviations may be used. |
| windows  | a <a href="#">list</a> of window handles, by default produced by <a href="#">getWindowsHandles()</a> .                                                                                                                                             |
| preserve | If TRUE, when tiling preserve the outer boundary of the collection of windows; otherwise make them as large as will fit.                                                                                                                           |
| outer    | This argument is only used in MDI mode. If TRUE, tile the windows on the system desktop. Otherwise, tile them within the MDI frame.                                                                                                                |

## Details

The actions are as follows:

"vertical" Tile vertically.

"horizontal" Tile horizontally.

"cascade" Cascade the windows.

"minimize" Minimize all of the windows.

"restore" Restore all of the windows to normal size (not minimized, not maximized).

The tiling and cascading are done by the standard Windows API functions, but unlike those functions, they will apply to all of the windows in the `windows` list.

By default, `windows` is set to the result of [getWindowsHandles\(\)](#) (with one exception described below). This will select windows belonging to the current R process. However, if the global environment contains a variable named `.arrangeWindowsDefaults`, it will be used as the argument list instead. See the [getWindowsHandles](#) man page for a discussion of the optional arguments to that function.

When `action = "restore"` is used with `windows` unspecified, `minimized = TRUE` is added to the argument list of [getWindowsHandles](#) so that minimized windows will be restored.

In MDI mode, by default tiling and cascading will happen within the R GUI frame. However, if `outer = TRUE`, tiling is done on the system desktop. This will generally not give desirable results if any R child windows are included within `windows`.

## Value

This function is called for the side effect of arranging the windows. The list of window handles is returned invisibly.

## Note

This is only available on Windows.

## Author(s)

Duncan Murdoch

[getWindowsHandles](#)

**Examples**

```
Not run: ## Only available on Windows :
arrangeWindows("v")
This default is useful only in SDI mode: it will tile any Firefox window
along with the R windows
.arrangeWindowsDefaults <- list(c("R", "all"), pattern = c("", "Firefox"))
arrangeWindows("v")

End(Not run)
```

---

askYesNo

*Ask a Yes/No Question*

---

**Description**

askYesNo provides a standard way to ask the user a yes/no question. It provides a way for front-ends to substitute their own dialogs.

**Usage**

```
askYesNo(msg, default = TRUE,
 prompts = getOption("askYesNo", gettext(c("Yes", "No", "Cancel"))),
 ...)
```

**Arguments**

|         |                                                                                                                                                                                                            |
|---------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| msg     | The prompt message for the user.                                                                                                                                                                           |
| default | The default response.                                                                                                                                                                                      |
| prompts | Any of: a character vector containing 3 prompts corresponding to return values of TRUE, FALSE, or NA, or a single character value containing the prompts separated by / characters, or a function to call. |
| ...     | Additional parameters, ignored by the default function.                                                                                                                                                    |

**Details**

askYesNo will accept case-independent partial matches to the prompts. If no response is given the value of default will be returned; if a non-empty string that doesn't match any of the prompts is entered, an error will be raised.

If a function or single character string naming a function is given for prompts, it will be called as `fn(msg=msg, default=default, prompts=prompts, ...)`. On Windows, the GUI uses the unexported `utils::askYesNoWinDialog` function for this purpose.

If strings (or a string such as "Y/N/C") are given as prompts, the choices will be mapped to lowercase for the non-default choices, and left as-is for the default choice.

**Value**

TRUE for yes, FALSE for no, and NA for cancel.

**See Also**

`readline` for more general user input.

**Examples**

```
if (interactive())
 askYesNo("Do you want to use askYesNo?")
```

aspell

*Spell Check Interface***Description**

Spell check given files via Aspell, Hunspell or Ispell.

**Usage**

```
aspell(files, filter, control = list(), encoding = "unknown",
 program = NULL, dictionaries = character())
```

**Arguments**

|                           |                                                                                                                                                                                                                                                                                                                                                                                                                  |
|---------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>files</code>        | a character vector with the names of files to be checked.                                                                                                                                                                                                                                                                                                                                                        |
| <code>filter</code>       | an optional filter for processing the files before spell checking, given as either a function (with formals <code>ifile</code> and <code>encoding</code> ), or a character string specifying a built-in filter, or a list with the name of a built-in filter and additional arguments to be passed to it. See <b>Details</b> for available filters. If missing or <code>NULL</code> , no filtering is performed. |
| <code>control</code>      | a list or character vector of control options for the spell checker.                                                                                                                                                                                                                                                                                                                                             |
| <code>encoding</code>     | the encoding of the files. Recycled as needed.                                                                                                                                                                                                                                                                                                                                                                   |
| <code>program</code>      | a character string giving the name (if on the system path) or full path of the spell check program to be used, or <code>NULL</code> (default). By default, the system path is searched for <code>aspell</code> , <code>hunspell</code> and <code>ispell</code> (in that order), and the first one found is used.                                                                                                 |
| <code>dictionaries</code> | a character vector of names or file paths of additional R level dictionaries to use. Elements with no path separator specify R system dictionaries (in subdirectory ‘share/dictionaries’ of the R home directory). The file extension (currently, only ‘.rds’) can be omitted.                                                                                                                                   |

**Details**

The spell check programs employed must support the so-called Ispell pipe interface activated via command line option ‘-a’. In addition to the programs, suitable dictionaries need to be available. See <http://aspell.net>, <https://hunspell.github.io/> and <https://www.cs.hmc.edu/~geoff/ispell.html>, respectively, for obtaining the Aspell, Hunspell and (International) Ispell programs and dictionaries.

The currently available built-in filters are "Rd" (corresponding to [RdTextFilter](#)), "Sweave" (corresponding to [SweaveTeXFilter](#)), "R", "pot", "dcf" and "md".

Filter "R" is for R code and extracts the message string constants in calls to `message`, `warning`, `stop`, `packageStartupMessage`, `gettext`, `gettextf`, and `ngettext` (the unnamed string constants for the first five, and `fmt` and `msg1/msg2` string constants, respectively, for the latter two).

Filter "pot" is for message string catalog '.pot' files. Both have an argument `ignore` allowing to give regular expressions for parts of message strings to be ignored for spell checking: e.g., using `"[\\t]'[^']*'[\\t[:punct:]]"` ignores all text inside single quotes.

Filter "dcf" is for files in Debian Control File format. The fields to keep can be controlled by argument `keep` (a character vector with the respective field names). By default, 'Title' and 'Description' fields are kept.

Filter "md" is for files in **Markdown** format ('.md' and '.Rmd' files), and needs packages **commonmark** and **xm12** to be available.

The print method for the objects returned by `aspell` has an `indent` argument controlling the indentation of the positions of possibly mis-spelled words. The default is 2; Emacs users may find it useful to use an indentation of 0 and visit output in grep-mode. It also has a `verbose` argument: when this is true, suggestions for replacements are shown as well.

It is possible to employ additional R level dictionaries. Currently, these are files with extension '.rds' obtained by serializing character vectors of word lists using `saveRDS`. If such dictionaries are employed, they are combined into a single word list file which is then used as the spell checker's personal dictionary (option '-p'): hence, the default personal dictionary is not used in this case.

## Value

A data frame inheriting from `aspell` (which has a useful print method) with the information about possibly mis-spelled words.

## Examples

```
Not run:
To check all Rd files in a directory, (additionally) skipping the
\references sections.
files <- Sys.glob("*.Rd")
aspell(files, filter = list("Rd", drop = "\\references"))

To check all Sweave files
files <- Sys.glob(c("*.Rnw", "*.Snw", "*.rnw", "*.snw"))
aspell(files, filter = "Sweave", control = "-t")

To check all Texinfo files (Aspell only)
files <- Sys.glob("*.texi")
aspell(files, control = "--mode=texinfo")

End(Not run)
```

```
List the available R system dictionaries.
Sys.glob(file.path(R.home("share"), "dictionaries", "*.rds"))
```

aspell-utils

*Spell Check Utilities*

## Description

Utilities for spell checking packages via Aspell, Hunspell or Ispell.

## Usage

```
aspell_package_Rd_files(dir, drop = c("\\author", "\\references"),
 control = list(), program = NULL,
 dictionaries = character())
aspell_package_vignettes(dir,
 control = list(), program = NULL,
 dictionaries = character())
aspell_package_R_files(dir, ignore = character(), control = list(),
 program = NULL, dictionaries = character())
aspell_package_C_files(dir, ignore = character(), control = list(),
 program = NULL, dictionaries = character())

aspell_write_personal_dictionary_file(x, out, language = "en",
 program = NULL)
```

## Arguments

|                           |                                                                                                                                                                                                                                                                                                                  |
|---------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>dir</code>          | a character string specifying the path to a package's root directory.                                                                                                                                                                                                                                            |
| <code>drop</code>         | a character vector naming additional Rd sections to drop when selecting text via <a href="#">RdTextFilter</a> .                                                                                                                                                                                                  |
| <code>control</code>      | a list or character vector of control options for the spell checker.                                                                                                                                                                                                                                             |
| <code>program</code>      | a character string giving the name (if on the system path) or full path of the spell check program to be used, or <code>NULL</code> (default). By default, the system path is searched for <code>aspell</code> , <code>hunspell</code> and <code>ispell</code> (in that order), and the first one found is used. |
| <code>dictionaries</code> | a character vector of names or file paths of additional R level dictionaries to use. See <a href="#">aspell</a> .                                                                                                                                                                                                |
| <code>ignore</code>       | a character vector with regular expressions to be replaced by blanks when filtering the message strings.                                                                                                                                                                                                         |
| <code>x</code>            | a character vector, or the result of a call to <a href="#">aspell()</a> .                                                                                                                                                                                                                                        |
| <code>out</code>          | a character string naming the personal dictionary file to write to.                                                                                                                                                                                                                                              |
| <code>language</code>     | a character string indicating a language as used by Aspell.                                                                                                                                                                                                                                                      |

## Details

Functions `aspell_package_Rd_files`, `aspell_package_vignettes`, `aspell_package_R_files` and `aspell_package_C_files` perform spell checking on the Rd files, vignettes, R files, and C-level messages of the package with root directory `dir`. They determine the respective files, apply the appropriate filters, and run the spell checker.

See [aspell](#) for details on filters.

The C-level message string are obtained from the `'po/PACKAGE.pot'` message catalog file, with `PACKAGE` the basename of `dir`. See the section on “C-level messages” in “Writing R Extensions” for more information.

When using Aspell, the vignette checking skips parameters and/or options of commands `\Sexpr`, `\citep`, `\code`, `\pkg`, `\proglang` and `\samp`. Further commands can be skipped by adding `--add-tex-command` options to the `control` argument. E.g., to skip both option and parameter of `\mycmd`, add `--add-tex-command='mycmd op'`.

Suitable values for `control`, `program`, `dictionaries`, `drop` and `ignore` can also be specified using a package defaults file which should go as `'defaults.R'` into the `'.aspell'` subdirectory of `dir`, and provides defaults via assignments of suitable named lists, e.g.,

```
vignettes <- list(control = "--add-tex-command='mycmd op'")
```

for vignettes (when using Aspell) and similarly assigning to `Rd_files`, `R_files` and `C_files` for Rd files, R files and C level message defaults.

Maintainers of packages using both English and American spelling will find it convenient to pass control options `'--master=en_US'` and `'--add-extra-dicts=en_GB'` to Aspell and control options `'-d en_US, en_GB'` to Hunspell (provided that the corresponding dictionaries are installed).

Older versions of R had no support for R level dictionaries, and hence provided the function `aspell_write_personal_dictionary_file` to create (spell check) program-specific personal dictionary files from words to be accepted. The new mechanism is to use R level dictionaries, i.e., `'.rds'` files obtained by serializing character vectors of such words using [saveRDS](#). For such dictionaries specified via the package defaults mechanism, elements with no path separator can be R system dictionaries or dictionaries in the `'.aspell'` subdirectory.

---

available.packages *List Available Packages at CRAN-like Repositories*

---

## Description

`available.packages` returns a matrix of details corresponding to packages currently available at one or more repositories. The current list of packages is downloaded over the internet (or copied from a local mirror).

## Usage

```
available.packages(contriburl = contrib.url(repos, type), method,
 fields = NULL, type = getOption("pkgType"),
 filters = NULL, repos = getOption("repos"),
 ignore_repo_cache = FALSE, max_repo_cache_age,
 quiet = TRUE, ...)
```

## Arguments

|                                 |                                                                                                                                                                                          |
|---------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>contriburl</code>         | URL(s) of the ‘contrib’ sections of the repositories. Specify this argument only if your repository mirror is incomplete, e.g., because you burned only the ‘contrib’ section on a CD.   |
| <code>method</code>             | download method, see <a href="#">download.file</a> .                                                                                                                                     |
| <code>type</code>               | character string, indicate which type of packages: see <a href="#">install.packages</a> . If <code>type = "both"</code> this will use the source repository.                             |
| <code>fields</code>             | a character vector giving the fields to extract from the ‘PACKAGES’ file(s) in addition to the default ones, or <code>NULL</code> (default). Unavailable fields result in NA values.     |
| <code>filters</code>            | a character vector or list or <code>NULL</code> (default). See ‘Details’.                                                                                                                |
| <code>repos</code>              | character vector, the base URL(s) of the repositories to use.                                                                                                                            |
| <code>ignore_repo_cache</code>  | logical. If true, the repository cache is never used (see ‘Details’).                                                                                                                    |
| <code>max_repo_cache_age</code> | any cached values older than this in seconds will be ignored. See ‘Details’.                                                                                                             |
| <code>quiet</code>              | logical, passed to <a href="#">download.file()</a> ; change only if you know what you are doing.                                                                                         |
| <code>...</code>                | allow additional arguments to be passed from callers (which might be arguments to future versions of this function). Currently these are all passed to <a href="#">download.file()</a> . |

## Details

The list of packages is either copied from a local mirror (specified by a ‘file://’ URI) or downloaded. If downloaded and `ignore_repo_cache` is false (the default), the list is cached for the R session in a per-repository file in [tempdir\(\)](#) with a name like

```
repos_http%3a%2f%2fcran.r-project.org%2fsrc%2fcontrib.rds
```

The cached values are renewed when found to be too old, with the age limit controlled *via* argument `max_repo_cache_age`. This defaults to the current value of the environment variable `R_AVAILABLE_PACKAGES_CACHE_CONTROL_MAX_AGE`, or if unset, to 3600 (one hour).

By default, the return value includes only packages whose version and OS requirements are met by the running version of R, and only gives information on the latest versions of packages.

Argument `filters` can be used to select which of the packages on the repositories are reported. It is called with its default value (`NULL`) by functions such as `install.packages`: this value corresponds to `getOption("available_packages_filters")` and to `c("R_version", "OS_type", "subarch", "duplicates")` if that is unset or set to `NULL`.

The built-in filters are

- "R\_version" Exclude packages whose R version requirements are not met.
- "OS\_type" Exclude packages whose OS requirement is incompatible with this version of R: that is exclude Windows-only packages on a Unix-alike platform and *vice versa*.
- "subarch" For binary packages, exclude those with compiled code that is not available for the current sub-architecture, e.g. exclude packages only compiled for 32-bit Windows on a 64-bit Windows R.
- "duplicates" Only report the latest version where more than one version is available, and only report the first-named repository (in `contriburl`) with the latest version if that is in more than one repository.
- "license/FOSS" Include only packages for which installation can proceed solely based on packages which can be verified as Free or Open Source Software (FOSS, e.g., <https://en.wikipedia.org/wiki/FOSS>) employing the available license specifications. Thus both the package and any packages that it depends on to load need to be *known to be* FOSS. Note that this does depend on the repository supplying license information.
- "license/restricts\_use" Include only packages for which installation can proceed solely based on packages which are known not to restrict use.
- "CRAN" Use CRAN versions in preference to versions from other repositories (even if these have a higher version number). This needs to be applied *before* the default "duplicates" filter, so cannot be used with `add = TRUE`.

If all the filters are from this set, then they can be specified as a character vector; otherwise `filters` should be a list with elements which are character strings, user-defined functions or `add = TRUE` (see below).

User-defined filters are functions which take a single argument, a matrix of the form returned by `available.packages`, and return a matrix consisting of a subset of the rows of the argument.

The special 'filter' `add = TRUE` appends the other elements of the filter list to the default filters.

## Value

A matrix with one row per package, row names the package names and column names including "Package", "Version", "Priority", "Depends", "Imports", "LinkingTo", "Suggests", "Enhances", "File" and "Repository". Additional columns can be specified using the `fields` argument.

Where provided by the repository, fields "OS\_type", "License", "License\_is\_FOSS", "License\_restricts\_use", "Archs", "MD5sum" and "NeedsCompilation" are reported for use by the filters and package management tools, including `install.packages`.

## See Also

`install.packages`, `download.packages`, `contrib.url`.

The 'R Installation and Administration' manual for how to set up a repository.

## Examples

```
Not run:
Restrict install.packages() (etc) to known-to-be-FOSS packages
options(available_packages_filters =
 c("R_version", "OS_type", "subarch", "duplicates", "license/FOSS"))
or
options(available_packages_filters = list(add = TRUE, "license/FOSS"))
```

```
Give priority to released versions on CRAN, rather than development
versions on Omegahat, R-Forge etc.
options(available_packages_filters =
 c("R_version", "OS_type", "subarch", "CRAN", "duplicates"))

End(Not run)
```

BATCH

*Batch Execution of R***Description**

Run R non-interactively with input from `infile` and send output (stdout/stderr) to another file.

**Usage**

```
R CMD BATCH [options] infile [outfile]
```

**Arguments**

|                      |                                                                                                                                                                                                                                                                                                   |
|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>infile</code>  | the name of a file with R code to be executed.                                                                                                                                                                                                                                                    |
| <code>options</code> | a list of R command line options, e.g., for setting the amount of memory available and controlling the load/save process. If <code>infile</code> starts with a '-', use '--' as the final option. The default options are '--restore --save --no-readline'. (Without '--no-readline' on Windows.) |
| <code>outfile</code> | the name of a file to which to write output. If not given, the name used is that of <code>infile</code> , with a possible '.R' extension stripped, and '.Rout' appended.                                                                                                                          |

**Details**

Use `R CMD BATCH --help` to be reminded of the usage.

By default, the input commands are printed along with the output. To suppress this behavior, add `options(echo = FALSE)` at the beginning of `infile`, or use option '--no-echo'.

The `infile` can have end of line marked by LF or CRLF (but not just CR), and files with an incomplete last line (missing end of line (EOL) mark) are processed correctly.

A final expression '`proc.time()`' will be executed after the input script unless the latter calls `q(runLast = FALSE)` or is aborted. This can be suppressed by the option '--no-timing'.

Additional options can be set by the environment variable `R_BATCH_OPTIONS`: these come after the default options (see the description of the `options` argument) and before any options given on the command line.

**Note**

On Unix-alikes only: Unlike `Splus BATCH`, this does not run the R process in the background. In most shells,

```
R CMD BATCH [options] infile [outfile] &
```

will do so.

bibentry

*Bibliography Entries***Description**

Functionality for representing and manipulating bibliographic information in enhanced BibTeX style.

**Usage**

```

bibentry(bibtype, textVersion = NULL, header = NULL, footer = NULL,
 key = NULL, ..., other = list(),
 mheader = NULL, mfooter = NULL)

S3 method for class 'bibentry'
print(x, style = "text", .bibstyle, ...)

S3 method for class 'bibentry'
format(x, style = "text", .bibstyle = NULL,
 citation.bibtex.max = getOption("citation.bibtex.max", 1),
 bibtex = length(x) <= citation.bibtex.max,
 sort = FALSE, macros = NULL, ...)

S3 method for class 'bibentry'
sort(x, decreasing = FALSE, .bibstyle = NULL, drop = FALSE, ...)

S3 method for class 'citation'
print(x, style = "citation", ...)
S3 method for class 'citation'
format(x, style = "citation", ...)

```

**Arguments**

|                          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>bibtype</code>     | a character string with a BibTeX entry type. See <b>Entry Types</b> for details.                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <code>textVersion</code> | a character string with a text representation of the reference to optionally be employed for printing. It is recommended to leave this unspecified if <code>format(x, style = "text")</code> works correctly. Only if special LaTeX macros (e.g., math formatting) or special characters (e.g., with accents) are necessary, a <code>textVersion</code> should be provided.                                                                                                                                                                                 |
| <code>header</code>      | a character string with optional header text.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>footer</code>      | a character string with optional footer text.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>key</code>         | a character string giving the citation key for the entry.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>...</code>         | for <code>bibentry</code> : arguments of the form <i>tag=value</i> giving the fields of the entry, with <i>tag</i> and <i>value</i> the name and value of the field, respectively. Arguments with empty values are dropped. See <b>Entry Fields</b> for details.<br><br>For the <code>print()</code> method, extra arguments to pass to the renderer which typically includes the <code>format()</code> method.<br><br>For the <code>citation</code> class methods, arguments passed to the next method, i.e., the corresponding <code>bibentry</code> one. |

|                     |                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| other               | a list of arguments as in ... (useful in particular for fields named the same as <code>formals</code> of <code>bibentry</code> ).                                                                                                                                                                                                                                                                                                     |
| mheader             | a character string with optional “outer” header text.                                                                                                                                                                                                                                                                                                                                                                                 |
| mfooter             | a character string with optional “outer” footer text.                                                                                                                                                                                                                                                                                                                                                                                 |
| x                   | an object inheriting from class <code>"bibentry"</code> .                                                                                                                                                                                                                                                                                                                                                                             |
| style               | an optional character string specifying the print style. If present, must be a unique abbreviation (with case ignored) of the available styles, see <b>Details</b> .                                                                                                                                                                                                                                                                  |
| decreasing          | logical, passed to <code>order</code> indicating the sort direction.                                                                                                                                                                                                                                                                                                                                                                  |
| .bibstyle           | a character string naming a bibliography style.                                                                                                                                                                                                                                                                                                                                                                                       |
| citation.bibtex.max | ( <i>deprecated</i> , use <code>bibtex=T F</code> instead!) a number, say $m$ , indicating that the bibtex code should be given in addition to the formatted text <i>when</i> there are not more than $m$ entries. The default is taken as <code>getOption("citation.bibtex.max", 1)</code> which is 1 typically. For example, to see no bibtex at all, you can change the default by <code>options(citation.bibtex.max = 0)</code> . |
| bibtex              | logical indicating if bibtex code should be given additionally; currently applies only to <code>style = "citation"</code> . The default depends on on the number of (bib) entries and <code>getOption("citation.bibtex.max")</code> .                                                                                                                                                                                                 |
| sort                | logical indicating if bibentries should be sorted, using <code>bibstyle(.bibstyle)\$sortKeys(x)</code> .                                                                                                                                                                                                                                                                                                                              |
| macros              | a character string or an object with already loaded Rd macros, see <b>Details</b> .                                                                                                                                                                                                                                                                                                                                                   |
| drop                | logical used as <code>x[ ..., drop=drop]</code> inside the <code>sort()</code> method.                                                                                                                                                                                                                                                                                                                                                |

## Details

The `bibentry` objects created by `bibentry` can represent an arbitrary positive number of references. One can use `c()` to combine `bibentry` objects, and hence in particular build a multiple reference object from single reference ones. Alternatively, one can use `bibentry` to directly create a multiple reference object by “vectorizing” the given arguments, i.e., use character vectors instead of character strings.

The `print` method for `bibentry` objects provides a choice between seven different styles: plain text (style `"text"`), BibTeX (`"Bibtex"`), a mixture of plain text and BibTeX as traditionally used for citations (`"citation"`), HTML (`"html"`), LaTeX (`"latex"`), R code (`"R"`), and a simple copy of the `textVersion` elements (style `"textVersion"`). The `"text"`, `"html"` and `"latex"` styles make use of the `.bibstyle` argument using the `bibstyle` function. In addition, one can use the `macros` argument to provide additional (otherwise unknown, presumably LaTeX-style) Rd macros, either by giving the path to a file with Rd macros to be loaded via `loadRdMacros`, or an object with macros already loaded.

When printing `bibentry` objects in citation style, a `header/footer` for each item can be displayed as well as a `mheader/mfooter` for the whole vector of references.

The `print` method is based on a `format` method which provides the same styles, and for formatting as R code a choice between giving a character vector with one `bibentry()` call for each `bibentry` (as commonly used in ‘CITATION’ files), or a character string with one collapsed call, obtained by combining the individual calls with `c()` if there is more than one `bibentry`. This can be controlled by setting the option `collapse` to `FALSE` (default) or `TRUE`, respectively. (Printing in R style always collapses to a single call.) Further, for the `"citation"` style, `format()`’s optional argument `citation.bibtex.max` (with default

`getOption("citation.bibtex.max")` which defaults to 1) determines for up to how many citation bibentries text style is shown together with bibtex, automatically.

It is possible to subscript bibentry objects by their keys (which are used for character subscripts if the names are `NULL`).

There is also a `toBibtex` method for direct conversion to BibTeX.

## Value

`bibentry` produces an object of class `"bibentry"`.

## Entry Types

`bibentry` creates `"bibentry"` objects, which are modeled after BibTeX entries. The entry should be a valid BibTeX entry type, e.g.,

**Article:** An article from a journal or magazine.

**Book:** A book with an explicit publisher.

**InBook:** A part of a book, which may be a chapter (or section or whatever) and/or a range of pages.

**InCollection:** A part of a book having its own title.

**InProceedings:** An article in a conference proceedings.

**Manual:** Technical documentation like a software manual.

**MastersThesis:** A Master's thesis.

**Misc:** Use this type when nothing else fits.

**PhdThesis:** A PhD thesis.

**Proceedings:** The proceedings of a conference.

**TechReport:** A report published by a school or other institution, usually numbered within a series.

**Unpublished:** A document having an author and title, but not formally published.

## Entry Fields

The ... argument of `bibentry` can be any number of BibTeX fields, including

**address:** The address of the publisher or other type of institution.

**author:** The name(s) of the author(s), either as a `person` object, or as a character string which `as.person` correctly coerces to such.

**booktitle:** Title of a book, part of which is being cited.

**chapter:** A chapter (or section or whatever) number.

**doi:** The DOI ([https://en.wikipedia.org/wiki/Digital\\_Object\\_Identifier](https://en.wikipedia.org/wiki/Digital_Object_Identifier)) for the reference.

**editor:** Name(s) of editor(s), same format as `author`.

**institution:** The publishing institution of a technical report.

**journal:** A journal name.

**note:** Any additional information that can help the reader. The first word should be capitalized.

**number:** The number of a journal, magazine, technical report, or of a work in a series.

**pages:** One or more page numbers or range of numbers.

**publisher:** The publisher's name.

**school:** The name of the school where a thesis was written.

**series:** The name of a series or set of books.

**title:** The work's title.

**url:** A URL for the reference. (If the URL is an expanded DOI, we recommend to use the 'doi' field with the unexpanded DOI instead.)

**volume:** The volume of a journal or multi-volume book.

**year:** The year of publication.

browseEnv

*Browse Objects in Environment*

---

## Description

The `browseEnv` function opens a browser with list of objects currently in `sys.frame()` environment.

## Usage

```

browseEnv(envir = .GlobalEnv, pattern,
 excludepatt = "^last\\.warning",
 html = .Platform$GUI != "AQUA",
 expanded = TRUE, properties = NULL,
 main = NULL, debugMe = FALSE)

```

## Arguments

|                          |                                                                                                                                                                         |
|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>envir</code>       | an <a href="#">environment</a> the objects of which are to be browsed.                                                                                                  |
| <code>pattern</code>     | a <a href="#">regular expression</a> for object subselection is passed to the internal <code>ls()</code> call.                                                          |
| <code>excludepatt</code> | a regular expression for <i>dropping</i> objects with matching names.                                                                                                   |
| <code>html</code>        | is used to display the workspace on a HTML page in your favorite browser. The default except when running from R.app on macOS.                                          |
| <code>expanded</code>    | whether to show one level of recursion. It can be useful to switch it to FALSE if your workspace is large. This option is ignored if <code>html</code> is set to FALSE. |

|            |                                                                                                                                                                              |
|------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| properties | a named list of global properties (of the objects chosen) to be showed in the browser; when <code>NULL</code> (as per default), user, date, and machine information is used. |
| main       | a title string to be used in the browser; when <code>NULL</code> (as per default) a title is constructed.                                                                    |
| debugMe    | logical switch; if true, some diagnostic output is produced.                                                                                                                 |

### Details

Very experimental code: displays a static HTML page on all platforms except `R.app` on macOS.

Only allows one level of recursion into object structures.

It can be generalized. See sources for details. Most probably, this should rather work through using the **tkWidget** package (from <https://www.bioconductor.org>).

 afl2 <- approxfun(1:2, 1:2, method = "const")
 browseEnv(envir = environment(afl2))
}
```

---

browseURL

*Load URL into an HTML Browser*

---

### Description

Load a given URL into an HTML browser.

### Usage

```
browseURL(url, browser = getOption("browser"),
 encodeIfNeeded = FALSE)
```

## Arguments

|                             |                                                                                                                                                                                                                                                                                                                                                                                    |
|-----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>url</code>            | a non-empty character string giving the URL to be loaded. Some platforms also accept file paths.                                                                                                                                                                                                                                                                                   |
| <code>browser</code>        | a non-empty character string giving the name of the program to be used as the HTML browser. It should be in the PATH, or a full path specified. Alternatively, an R function to be called to invoke the browser.<br>Under Windows <code>NULL</code> is also allowed (and is the default), and implies that the file association mechanism will be used.                            |
| <code>encodeIfNeeded</code> | Should the URL be encoded by <code>URLencode</code> before passing to the browser? This is not needed (and might be harmful) if the <code>browser</code> program/function itself does encoding, and can be harmful for <code>'file:/'</code> URLs on some systems and for <code>'http:/'</code> URLs passed to some CGI applications. Fortunately, most URLs do not need encoding. |

## Details

**On Unix-alikes:** The default browser is set by option `"browser"`, in turn set by the environment variable `R_BROWSER` which is by default set in file `'R_HOME/etc/Renviron'` to a choice made manually or automatically when R was configured. (See [Startup](#) for where to override that default value.) To suppress showing URLs altogether, use the value `"false"`.

On many platforms it is best to set option `"browser"` to a generic program/script and let that invoke the user's choice of browser. For example, on macOS use `open` and on many other Unix-alikes use `xdg-open`.

If `browser` supports remote control and R knows how to perform it, the URL is opened in any already-running browser or a new one if necessary. This mechanism currently is available for browsers which support the `"-remote openURL(. . .)"` interface (which includes Mozilla and Opera), Galeon, KDE konqueror (*via* `kfmclient`) and the GNOME interface to Mozilla. (Firefox has dropped support, but defaults to using an already-running browser.) Note that the type of browser is determined from its name, so this mechanism will only be used if the browser is installed under its canonical name.

Because `"-remote"` will use any browser displaying on the X server (whatever machine it is running on), the remote control mechanism is only used if `DISPLAY` points to the local host. This may not allow displaying more than one URL at a time from a remote host.

It is the caller's responsibility to encode `url` if necessary (see [URLencode](#)).

To suppress showing URLs altogether, set `browser = "false"`.

The behaviour for arguments `url` which are not URLs is platform-dependent. Some platforms accept absolute file paths; fewer accept relative file paths.

**On Windows:** The default browser is set by option `"browser"`, in turn set by the environment variable `R_BROWSER` if that is set, otherwise to `NULL`. To suppress showing URLs altogether, use the value `"false"`.

Some browsers have required `:` be replaced by `|` in file paths: others do not accept that. All seem to accept `\` as a path separator even though the RFC1738 standard requires `/`.

To suppress showing URLs altogether, set `browser = "false"`.

## URL schemes

Which URL schemes are accepted is platform-specific: expect `'http:/'`, `'https:/'` and `'ftp:/'` to work, but `'mailto:'` may or may not (and if it does may not use the user's preferred email client).

For the `'file:/'` scheme the format accepted (if any) can depend on both browser and OS.

**Examples**

```
Not run:
for KDE users who want to open files in a new tab
options(browser = "kfmclient newTab")

browseURL("https://www.r-project.org")

On Windows-only, something like
browseURL("file:///d:/R/R-2.5.1/doc/html/index.html",
 browser = "C:/Program Files/Mozilla Firefox/firefox.exe")

End(Not run)
```

---

|                 |                                          |
|-----------------|------------------------------------------|
| browseVignettes | <i>List Vignettes in an HTML Browser</i> |
|-----------------|------------------------------------------|

---

**Description**

List available vignettes in an HTML browser with links to PDF, LaTeX/noweb source, and (tangled) R code (if available).

**Usage**

```
browseVignettes(package = NULL, lib.loc = NULL, all = TRUE)

S3 method for class 'browseVignettes'
print(x, ...)
```

**Arguments**

|                      |                                                                                                                                                                                 |
|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>package</code> | a character vector with the names of packages to search through, or <code>NULL</code> in which "all" packages (as defined by argument <code>all</code> ) are searched.          |
| <code>lib.loc</code> | a character vector of directory names of R libraries, or <code>NULL</code> . The default value of <code>NULL</code> corresponds to all libraries currently known.               |
| <code>all</code>     | logical; if <code>TRUE</code> search all available packages in the library trees specified by <code>lib.loc</code> , and if <code>FALSE</code> , search only attached packages. |
| <code>x</code>       | Object of class <code>browseVignettes</code> .                                                                                                                                  |
| <code>...</code>     | Further arguments, ignored by the <code>print</code> method.                                                                                                                    |

**Details**

Function `browseVignettes` returns an object of the same class; the `print` method displays it as an HTML page in a browser (using [browseURL](#)).

**See Also**

[browseURL](#), [vignette](#)

**Examples**

```
List vignettes from all *attached* packages
browseVignettes(all = FALSE)

List vignettes from a specific package
browseVignettes("grid")
```

bug.report

*Send a Bug Report***Description**

Invokes an editor or email program to write a bug report or opens a web page for bug submission. Some standard information on the current version and configuration of R are included automatically.

**Usage**

```
bug.report(subject = "", address,
 file = "R.bug.report", package = NULL, lib.loc = NULL,
 ...)
```

**Arguments**

|         |                                                                                                                                                                                    |
|---------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| subject | Subject of the email.                                                                                                                                                              |
| address | Recipient's email address, where applicable: for package bug reports sent by email this defaults to the address of the package maintainer (the first if more than one is listed).  |
| file    | filename to use (if needed) for setting up the email.                                                                                                                              |
| package | Optional character vector naming a single package which is the subject of the bug report.                                                                                          |
| lib.loc | A character vector describing the location of R library trees in which to search for the package, or NULL. The default value of NULL corresponds to all libraries currently known. |
| ...     | additional named arguments such as <code>method</code> and <code>ccaddress</code> to pass to <code>create.post</code> .                                                            |

**Details**

If `package` is NULL or a base package, this opens the R bugs tracker at <https://bugs.r-project.org/>.

If `package` is specified, it is assumed that the bug report is about that package, and parts of its 'DESCRIPTION' file are added to the standard information. If the package has a non-empty `BugReports` field in the 'DESCRIPTION' file specifying the URL of a webpage, that URL will be opened using `browseURL`, otherwise an email directed to the package maintainer will be generated using `create.post`. If there is any other form of `BugReports` field or a `Contact` field, this is examined as it may provide a preferred email address.

**Value**

Nothing useful.

### When is there a bug?

If R executes an illegal instruction, or dies with an operating system error message that indicates a problem in the program (as opposed to something like “disk full”), then it is certainly a bug.

Taking forever to complete a command can be a bug, but you must make certain that it was really R’s fault. Some commands simply take a long time. If the input was such that you KNOW it should have been processed quickly, report a bug. If you don’t know whether the command should take a long time, find out by looking in the manual or by asking for assistance.

If a command you are familiar with causes an R error message in a case where its usual definition ought to be reasonable, it is probably a bug. If a command does the wrong thing, that is a bug. But be sure you know for certain what it ought to have done. If you aren’t familiar with the command, or don’t know for certain how the command is supposed to work, then it might actually be working right. Rather than jumping to conclusions, show the problem to someone who knows for certain.

Finally, a command’s intended definition may not be best for statistical analysis. This is a very important sort of problem, but it is also a matter of judgement. Also, it is easy to come to such a conclusion out of ignorance of some of the existing features. It is probably best not to complain about such a problem until you have checked the documentation in the usual ways, feel confident that you understand it, and know for certain that what you want is not available. The mailing list `r-devel@r-project.org` is a better place for discussions of this sort than the bug list.

If you are not sure what the command is supposed to do after a careful reading of the manual this indicates a bug in the manual. The manual’s job is to make everything clear. It is just as important to report documentation bugs as program bugs.

If the online argument list of a function disagrees with the manual, one of them must be wrong, so report the bug.

### How to report a bug

When you decide that there is a bug, it is important to report it and to report it in a way which is useful. What is most useful is an exact description of what commands you type, from when you start R until the problem happens. Always include the version of R, machine, and operating system that you are using; type `version` in R to print this. To help us keep track of which bugs have been fixed and which are still open please send a separate report for each bug.

The most important principle in reporting a bug is to report FACTS, not hypotheses or categorizations. It is always easier to report the facts, but people seem to prefer to strain to posit explanations and report them instead. If the explanations are based on guesses about how R is implemented, they will be useless; we will have to try to figure out what the facts must have been to lead to such speculations. Sometimes this is impossible. But in any case, it is unnecessary work for us.

For example, suppose that on a data set which you know to be quite large the command `data.frame(x, y, z, monday, tuesday)` never returns. Do not report that `data.frame()` fails for large data sets. Perhaps it fails when a variable name is a day of the week. If this is so then when we got your report we would try out the `data.frame()` command on a large data set, probably with no day of the week variable name, and not see any problem. There is no way in the world that we could guess that we should try a day of the week variable name.

Or perhaps the command fails because the last command you used was a `[` method that had a bug causing R’s internal data structures to be corrupted and making the `data.frame()` command fail from then on. This is why we need to know what other commands you have typed (or read from your startup file).

It is very useful to try and find simple examples that produce apparently the same bug, and somewhat useful to find simple examples that might be expected to produce the bug but actually do not. If you want to debug the problem and find exactly what caused it, that is wonderful. You should still report the facts as well as any explanations or solutions.

Invoking R with the ‘--vanilla’ option may help in isolating a bug. This ensures that the site profile and saved data files are not read.

A bug report can be generated using the function `bug.report()`. For reports on R this will open the Web page at <https://bugs.r-project.org/>: for a contributed package it will open the package’s bug tracker Web page or help you compose an email to the maintainer.

Bug reports on **contributed packages** should not be sent to the R bug tracker: rather make use of the `package` argument.

### Author(s)

This help page is adapted from the Emacs manual and the R FAQ

---

capture.output

*Send Output to a Character String or File*

---

### Description

Evaluates its arguments with the output being returned as a character string or sent to a file. Related to `sink` similarly to how `with` is related to `attach`.

### Usage

```
capture.output(..., file = NULL, append = FALSE,
 type = c("output", "message"), split = FALSE)
```

### Arguments

|                          |                                                                                                                                                                                               |
|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>...</code>         | Expressions to be evaluated.                                                                                                                                                                  |
| <code>file</code>        | A file name or a <a href="#">connection</a> , or <code>NULL</code> to return the output as a character vector. If the connection is not open, it will be opened initially and closed on exit. |
| <code>append</code>      | logical. If <code>file</code> a file name or unopened connection, append or overwrite?                                                                                                        |
| <code>type, split</code> | are passed to <code>sink()</code> , see there.                                                                                                                                                |

### Details

It works via `sink(<file connection>)` and hence the R code in `dots` must *not* interfere with the connection (e.g., by calling `closeAllConnections()`).

An attempt is made to write output as far as possible to `file` if there is an error in evaluating the expressions, but for `file = NULL` all output will be lost.

Messages sent to `stderr()` (including those from `message`, `warning` and `stop`) are captured by `type = "message"`. Note that this can be “unsafe” and should only be used with care.

**Value**

A character string (if `file = NULL`), or invisible `NULL`.

**See Also**

[sink](#), [textConnection](#)

**Examples**

```
require(stats)
glmout <- capture.output(summary(glm(case ~ spontaneous+induced,
 data = infer, family = binomial()))))

glmout[1:5]
capture.output(1+1, 2+2)
capture.output({1+1; 2+2})

Not run: ## on Unix-alike with a2ps available
op <- options(useFancyQuotes=FALSE)
pdf <- pipe("a2ps -o - | ps2pdf - tempout.pdf", "w")
capture.output(example(glm), file = pdf)
close(pdf); options(op) ; system("evince tempout.pdf &")

End(Not run)
```

---

changedFiles

*Detect which Files Have Changed*

---

**Description**

`fileSnapshot` takes a snapshot of a selection of files, recording summary information about each. `changedFiles` compares two snapshots, or compares one snapshot to the current state of the file system. The snapshots need not be the same directory; this could be used to compare two directories.

**Usage**

```
fileSnapshot(path = ".", file.info = TRUE, timestamp = NULL,
 md5sum = FALSE, digest = NULL, full.names = length(path) > 1,
 ...)

changedFiles(before, after, path = before$path, timestamp = before$timestamp,
 check.file.info = c("size", "isdir", "mode", "mtime"),
 md5sum = before$md5sum, digest = before$digest,
 full.names = before$full.names, ...)

S3 method for class 'fileSnapshot'
print(x, verbose = FALSE, ...)

S3 method for class 'changedFiles'
print(x, verbose = FALSE, ...)
```

**Arguments**

|                              |                                                                                                                                                                                                                                                     |
|------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>path</code>            | character vector; the path(s) to record.                                                                                                                                                                                                            |
| <code>file.info</code>       | logical; whether to record <code>file.info</code> values for each file.                                                                                                                                                                             |
| <code>timestamp</code>       | character string or NULL; the name of a file to write at the time the snapshot is taken. This gives a quick test for modification, but may be unreliable; see the Details.                                                                          |
| <code>md5sum</code>          | logical; whether MD5 summaries of each file should be taken as part of the snapshot.                                                                                                                                                                |
| <code>digest</code>          | a function or NULL; a function with header <code>function(filename)</code> which will take a vector of filenames and produce a vector of values of the same length, or a matrix with that number of rows.                                           |
| <code>full.names</code>      | logical; whether full names (as in <code>list.files</code> ) should be recorded. Must be TRUE if <code>length(path) &gt; 1</code> .                                                                                                                 |
| <code>...</code>             | additional parameters to pass to <code>list.files</code> to control the set of files in the snapshots.                                                                                                                                              |
| <code>before, after</code>   | objects produced by <code>fileSnapshot</code> ; two snapshots to compare. If <code>after</code> is missing, a new snapshot of the current file system will be produced for comparison, using arguments recorded in <code>before</code> as defaults. |
| <code>check.file.info</code> | character vector; which columns from <code>file.info</code> should be compared.                                                                                                                                                                     |
| <code>x</code>               | the object to print.                                                                                                                                                                                                                                |
| <code>verbose</code>         | logical; whether to list all data when printing.                                                                                                                                                                                                    |

**Details**

The `fileSnapshot` function uses `list.files` to obtain a list of files, and depending on the `file.info`, `md5sum`, and `digest` arguments, records information about each file.

The `changedFiles` function compares two snapshots.

If the `timestamp` argument to `fileSnapshot` is length 1, a file with that name is created. If it is length 1 in `changedFiles`, the `file_test` function is used to compare the age of all files common to both `before` and `after` to it. This test may be unreliable: it compares the current modification time of the `after` files to the timestamp; that may not be the same as the modification time when the `after` snapshot was taken. It may also give incorrect results if the clock on the file system holding the timestamp differs from the one holding the snapshot files.

If the `check.file.info` argument contains a non-empty character vector, the indicated columns from the result of a call to `file.info` will be compared.

If `md5sum` is TRUE, `fileSnapshot` will call the `tools::md5sum` function to record the 32 byte MD5 checksum for each file, and `changedFiles` will compare the values. The `digest` argument allows users to provide their own digest function.

**Value**

`fileSnapshot` returns an object of class `"fileSnapshot"`. This is a list containing the fields

|                   |                                                                                                      |
|-------------------|------------------------------------------------------------------------------------------------------|
| <code>info</code> | a data frame whose rownames are the filenames, and whose columns contain the requested snapshot data |
| <code>path</code> | the normalized path from the call                                                                    |

timestamp, file.info, md5sum, digest, full.names  
                                           a record of the other arguments from the call

args                                      other arguments passed via . . . to [list.files](#).

changedFiles produces an object of class "changedFiles". This is a list containing

added, deleted, changed, unchanged  
                                           character vectors of filenames from the before and after snapshots, with obvious meanings

changes                                  a logical matrix with a row for each common file, and a column for each comparison test. TRUE indicates a change in that test.

[print](#) methods are defined for each of these types. The [print](#) method for "fileSnapshot" objects displays the arguments used to produce them, while the one for "changedFiles" displays the added, deleted and changed fields if non-empty, and a submatrix of the changes matrix containing all of the TRUE values.

### Author(s)

Duncan Murdoch, using suggestions from Karl Millar and others.

### See Also

[file.info](#), [file\\_test](#), [md5sum](#).

### Examples

```
Create some files in a temporary directory
dir <- tempfile()
dir.create(dir)
writeBin(1L, file.path(dir, "file1"))
writeBin(2L, file.path(dir, "file2"))
dir.create(file.path(dir, "dir"))

Take a snapshot
snapshot <- fileSnapshot(dir, timestamp = tempfile("timestamp"), md5sum=TRUE)

Change one of the files.
writeBin(3L:4L, file.path(dir, "file2"))

Display the detected changes. We may or may not see mtime change...
changedFiles(snapshot)
changedFiles(snapshot)$changes
```

---

choose.dir

*Choose a Folder Interactively on MS Windows*

---

### Description

Use a Windows shell folder widget to choose a folder interactively.

### Usage

```
choose.dir(default = "", caption = "Select folder")
```

**Arguments**

- default            which folder to show initially.
- caption           the caption on the selection dialog.

**Details**

This brings up the Windows shell folder selection widget. With the default `default = ""`, ‘My Computer’ (or similar) is initially selected.

To workaround a bug, on Vista and later only folders under ‘Computer’ are accessible via the widget.

**Value**

A length-one character vector, character NA if ‘Cancel’ was selected.

**Note**

This is only available on Windows.

**See Also**

`choose.files` (on Windows) and `file.choose` (on all platforms).

**Examples**

```
if (interactive() && .Platform$OS.type == "windows")
 choose.dir(getwd(), "Choose a suitable folder")
```

---

|              |                                                           |
|--------------|-----------------------------------------------------------|
| choose.files | <i>Choose a List of Files Interactively on MS Windows</i> |
|--------------|-----------------------------------------------------------|

---

**Description**

Use a Windows file dialog to choose a list of zero or more files interactively.

**Usage**

```
choose.files(default = "", caption = "Select files",
 multi = TRUE, filters = Filters,
 index = nrow(Filters))
```

Filters

**Arguments**

- default            which filename to show initially
- caption           the caption on the file selection dialog
- multi             whether to allow multiple files to be selected
- filters            a matrix of filename filters (see Details)
- index             which row of filters to use by default

## Details

Unlike `file.choose`, `choose.files` will always attempt to return a character vector giving a list of files. If the user cancels the dialog, then zero files are returned, whereas `file.choose` would signal an error. `choose.dir` chooses a directory.

Windows file dialog boxes include a list of ‘filters’, which allow the file selection to be limited to files of specific types. The `filters` argument to `choose.files` allows the list of filters to be set. It should be an `n` by 2 character matrix. The first column gives, for each filter, the description the user will see, while the second column gives the mask(s) to select those files. If more than one mask is used, separate them by semicolons, with no spaces. The `index` argument chooses which filter will be used initially.

`Filters` is a matrix giving the descriptions and masks for the file types that R knows about. Print it to see typical formats for filter specifications. The examples below show how particular filters may be selected.

If you would like to display files in a particular directory, give a fully qualified file mask (e.g., `"c:\\*.*)" in the default argument. If a directory is not given, the dialog will start in the current directory the first time, and remember the last directory used on subsequent invocations.`

There is a buffer limit on the total length of the selected filenames: it is large but this function is not intended to select thousands of files, when the limit might be reached.

## Value

A character vector giving zero or more file paths.

## Note

This is only available on Windows.

## See Also

`file.choose`, `choose.dir`.

`Sys.glob` or `list.files` to select multiple files by pattern.

## Examples

```
if (interactive() && .Platform$OS.type == "windows")
 choose.files(filters = Filters[c("zip", "All"),])
```

---

|------------------|-------------------------------------|
| chooseBioCmirror | <i>Select a Bioconductor Mirror</i> |
|------------------|-------------------------------------|

---

## Description

Interact with the user to choose a Bioconductor mirror.

## Usage

```
chooseBioCmirror(graphics = getOption("menu.graphics"), ind = NULL,
 local.only = FALSE)
```

Arguments

|            |                                                                                                                                                                                                                         |
|------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| graphics   | Logical. If true, use a graphical list: on Windows or the macOS GUI use a list box, and on a Unix-alike use a Tk widget if package <b>tk</b> and an X server are available. Otherwise use a text <a href="#">menu</a> . |
| ind        | Optional numeric value giving which entry to select.                                                                                                                                                                    |
| local.only | Logical, try to get most recent list from the Bioconductor master or use file on local disk only.                                                                                                                       |

Details

This sets the [option](#) "BioC\_mirror": it is used before a call to [setRepositories](#). The out-of-the-box default for that option is NULL, which currently corresponds to the mirror <https://bioconductor.org>.

The 'Bioconductor (World-wide)' 'mirror' is a network of mirrors providing reliable world-wide access; other mirrors may provide faster access on a geographically local scale.

ind chooses a row in '[R\\_HOME](#)/doc/BioC\_mirrors.csv', by number.

Value

None: this function is invoked for its side effect of updating `options("BioC_mirror")`.

See Also

[setRepositories](#), [chooseCRANmirror](#).

Description

Interact with the user to choose a CRAN mirror.

Usage

```
chooseCRANmirror(graphics = getOption("menu.graphics"), ind = NULL,
 local.only = FALSE)

getCRANmirrors(all = FALSE, local.only = FALSE)
```

Arguments

|            |                                                                                                                                                                                                                         |
|------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| graphics   | Logical. If true, use a graphical list: on Windows or the macOS GUI use a list box, and on a Unix-alike use a Tk widget if package <b>tk</b> and an X server are available. Otherwise use a text <a href="#">menu</a> . |
| ind        | Optional numeric value giving which entry to select.                                                                                                                                                                    |
| all        | Logical, get all known mirrors or only the ones flagged as OK.                                                                                                                                                          |
| local.only | Logical, try to get most recent list from the CRAN master or use file on local disk only.                                                                                                                               |

## Details

A list of mirrors is stored in file '[R\\_HOME](#)/doc/CRAN\_mirrors.csv', but first an on-line list of current mirrors is consulted, and the file copy used only if the on-line list is inaccessible.

This function is called by a Windows GUI menu item and by `contrib.url` if it finds the initial dummy value of `options("repos")`.

HTTPS mirrors with mirroring over ssh will be offered in preference to other mirrors (which are listed in a sub-menu).

`ind` chooses a row in the list of current mirrors, by number. It is best used with `local.only = TRUE` and row numbers in '[R\\_HOME](#)/doc/CRAN\_mirrors.csv'.

## Value

None for `chooseCRANmirror()`, this function is invoked for its side effect of updating `options("repos")`.

`getCRANmirrors()` returns a data frame with mirror information.

## See Also

`setRepositories`, `chooseBioCmirror`, `contrib.url`.

citation

*Citing R and R Packages in Publications*

---

## Description

How to cite R and R packages in publications.

## Usage

```
citation(package = "base", lib.loc = NULL, auto = NULL)
readCitationFile(file, meta = NULL)
```

## Arguments

|                      |                                                                                                                                                                                                                                                                                                                      |
|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>package</code> | a character string with the name of a single package. An error occurs if more than one package name is given.                                                                                                                                                                                                        |
| <code>lib.loc</code> | a character vector with path names of R libraries, or the directory containing the source for <code>package</code> , or <code>NULL</code> . The default value of <code>NULL</code> corresponds to all libraries currently known. If the default is used, the loaded packages are searched before the libraries.      |
| <code>auto</code>    | a logical indicating whether the default citation auto-generated from the package 'DESCRIPTION' metadata should be used or not, or <code>NULL</code> (default), indicating that a 'CITATION' file is used if it exists, or an object of class " <code>packageDescription</code> " with package metadata (see below). |
| <code>file</code>    | a file name.                                                                                                                                                                                                                                                                                                         |
| <code>meta</code>    | a list of package metadata as obtained by <code>packageDescription</code> , or <code>NULL</code> (the default).                                                                                                                                                                                                      |

## Details

The R core development team and the very active community of package authors have invested a lot of time and effort in creating R as it is today. Please give credit where credit is due and cite R and R packages when you use them for data analysis.

Execute function `citation()` for information on how to cite the base R system in publications. If the name of a non-base package is given, the function either returns the information contained in the ‘CITATION’ file of the package (using `readCitationFile` with `meta` equal to `packageDescription(package, lib.loc)`) or auto-generates citation information from the ‘DESCRIPTION’ file.

In R  $\geq 2.14.0$ , one can use a ‘Authors@R’ field in ‘DESCRIPTION’ to provide (R code giving) a `person` object with a refined, machine-readable description of the package “authors” (in particular specifying their precise roles). Only those with an author role will be included in the auto-generated citation.

If only one reference is given, the print method for the object returned by `citation()` shows both a text version and a BibTeX entry for it, if a package has more than one reference then only the text versions are shown. The BibTeX versions can be obtained using function `toBibtex()` (see the examples below).

The ‘CITATION’ file of an R package should be placed in the ‘inst’ subdirectory of the package source. The file is an R source file and may contain arbitrary R commands including conditionals and computations. Function `readCitationFile()` is used by `citation()` to extract the information in ‘CITATION’ files. The file is `source()`ed by the R parser in a temporary environment and all resulting bibliographic objects (specifically, of class “`bibentry`”) are collected.

Traditionally, the ‘CITATION’ file contained zero or more calls to `citHeader`, then one or more calls to `citEntry`, and finally zero or more calls to `citFooter`, where in fact `citHeader` and `citFooter` are simply wrappers to `paste`, with their `...` argument passed on to `paste` as is. The “`bibentry`” class makes for improved representation and manipulation of bibliographic information (in fact, the old mechanism is implemented using the new one), and one can write ‘CITATION’ files using the unified `bibentry` interface.

One can include an auto-generated package citation in the ‘CITATION’ file via `citation(auto = meta)`.

`readCitationFile` makes use of the `Encoding` element (if any) of `meta` to determine the encoding of the file.

## Value

An object of class “`citation`”, inheriting from class “`bibentry`”; see there, notably for the `print` and `format` methods.

## See Also

`bibentry`

## Examples

```
the basic R reference
citation()

references for a package -- might not have these installed
if(nchar(system.file(package = "lattice")) > 0) citation("lattice")
if(nchar(system.file(package = "foreign")) > 0) citation("foreign")
```

```
extract the bibtex entry from the return value
x <- citation()
toBibtex(x)

A citation with more than one bibentry:
cm <- tryCatch(citation("mgcv"),
 error = function(e) {
 warning("Recommended package 'mgcv' is not installed properly")
 stop(e$message) })
cm # short entries (2-3 lines each)
print(cm, bibtex = TRUE) # each showing its bibtex code
```

cite

*Cite a Bibliography Entry*

## Description

Cite a bibentry object in text. The `cite()` function uses the `cite()` function from the default `bibstyle` if present, or `citeNatbib()` if not. `citeNatbib()` uses a style similar to that used by the LaTeX package **natbib**.

## Usage

```
cite(keys, bib, ...)
citeNatbib(keys, bib, textual = FALSE, before = NULL, after = NULL,
 mode = c("authoryear", "numbers", "super"),
 abbreviate = TRUE, longnamesfirst = TRUE,
 bibpunct = c("(", ")", ";", "a", "", ",", previous))
```

## Arguments

|                             |                                                                                                                                         |
|-----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| <code>keys</code>           | A character vector of keys of entries to cite. May contain multiple keys in a single entry, separated by commas.                        |
| <code>bib</code>            | A " <a href="#">bibentry</a> " object containing the list of documents in which to find the keys.                                       |
| <code>...</code>            | Additional arguments to pass to the <code>cite()</code> function for the default style.                                                 |
| <code>textual</code>        | Produce a “textual” style of citation, i.e. what <code>\citet</code> would produce in LaTeX.                                            |
| <code>before</code>         | Optional text to display before the citation.                                                                                           |
| <code>after</code>          | Optional text to display after the citation.                                                                                            |
| <code>mode</code>           | The “mode” of citation.                                                                                                                 |
| <code>abbreviate</code>     | Whether to abbreviate long author lists.                                                                                                |
| <code>longnamesfirst</code> | If <code>abbreviate == TRUE</code> , whether to leave the first citation long.                                                          |
| <code>bibpunct</code>       | A vector of punctuation to use in the citation, as used in <b>natbib</b> . See the Details section.                                     |
| <code>previous</code>       | A list of keys that have been previously cited, to be used when <code>abbreviate == TRUE</code> and <code>longnamesfirst == TRUE</code> |

## Details

Argument names are chosen based on the documentation for the LaTeX **natbib** package. See that documentation for the interpretation of the `bibpunct` entries.

The entries in `bibpunct` are as follows:

1. The left delimiter.
2. The right delimiter.
3. The separator between references within a citation.
4. An indicator of the “mode”: “n” for numbers, “s” for superscripts, anything else for author-year.
5. Punctuation to go between the author and year.
6. Punctuation to go between years when authorship is suppressed.

Note that if `mode` is specified, it overrides the mode specification in `bibpunct[4]`. Partial matching is used for `mode`.

The defaults for `citeNatbib` have been chosen to match the JSS style, and by default these are used in `cite`. See [bibstyle](#) for how to set a different default style.

## Value

A single element character string is returned, containing the citation.

## Author(s)

Duncan Murdoch

## Examples

```
R reference
rref <- bibentry(
 bibtype = "Manual",
 title = "R: A Language and Environment for Statistical Computing",
 author = person("R Core Team"),
 organization = "R Foundation for Statistical Computing",
 address = "Vienna, Austria",
 year = 2013,
 url = "https://www.R-project.org/",
 key = "R")

References for boot package and associated book
bref <- c(
 bibentry(
 bibtype = "Manual",
 title = "boot: Bootstrap R (S-PLUS) Functions",
 author = c(
 person("Angelo", "Canty", role = "aut",
 comment = "S original"),
 person(c("Brian", "D."), "Ripley", role = c("aut", "trl", "cre"),
 comment = "R port, author of parallel support",
 email = "ripley@stats.ox.ac.uk")
),
 year = "2012",
 note = "R package version 1.3-4",
```

```

 url = "https://CRAN.R-project.org/package=boot",
 key = "boot-package"
),

 bibentry(
 bibtype = "Book",
 title = "Bootstrap Methods and Their Applications",
 author = as.person("Anthony C. Davison [aut], David V. Hinkley [aut]"),
 year = "1997",
 publisher = "Cambridge University Press",
 address = "Cambridge",
 isbn = "0-521-57391-2",
 url = "http://statwww.epfl.ch/davison/BMA/",
 key = "boot-book"
)
)

Combine and cite
refs <- c(rref, bref)
cite("R, boot-package", refs)

Cite numerically
savestyle <- tools::getBibstyle()
tools::bibstyle("JSSnumbered", .init = TRUE,
 fmtPrefix = function(paper) paste0("[", paper$.index, "]"),
 cite = function(key, bib, ...)
 citeNatbib(key, bib, mode = "numbers",
 bibpunct = c("[", "]", ";", "n", "", ",", "...")
)
)
cite("R, boot-package", refs, textual = TRUE)
refs

restore the old style
tools::bibstyle(savestyle, .default = TRUE)

```

---

citEntry

*Bibliography Entries (Older Interface)*

---

## Description

Functionality for specifying bibliographic information in enhanced BibTeX style.

## Usage

```

citEntry(entry, textVersion, header = NULL, footer = NULL, ...)
citHeader(...)
citFooter(...)

```

## Arguments

|             |                                                                                                                      |
|-------------|----------------------------------------------------------------------------------------------------------------------|
| entry       | a character string with a BibTeX entry type. See section <b>Entry Types</b> in <a href="#">bibentry</a> for details. |
| textVersion | a character string with a text representation of the reference.                                                      |

|        |                                                                                                                                                                                                                                                                                                                                                             |
|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| header | a character string with optional header text.                                                                                                                                                                                                                                                                                                               |
| footer | a character string with optional footer text.                                                                                                                                                                                                                                                                                                               |
| ...    | for <code>citEntry</code> , arguments of the form <code>tag=value</code> giving the fields of the entry, with <code>tag</code> and <code>value</code> the name and value of the field, respectively. See section <b>Entry Fields</b> in <a href="#">bibentry</a> for details.<br>For <code>citHeader</code> and <code>citFooter</code> , character strings. |

### Value

`citEntry` produces an object of class "bibentry".

### See Also

[citation](#) for more information about citing R and R packages and ‘CITATION’ files; [bibentry](#) for the newer functionality for representing and manipulating bibliographic information.

---

|           |                                                       |
|-----------|-------------------------------------------------------|
| clipboard | <i>Read/Write to/from the Clipboard in MS Windows</i> |
|-----------|-------------------------------------------------------|

---

### Description

Transfer text between a character vector and the Windows clipboard in MS Windows (only).

### Usage

```
getClipboardFormats(numeric = FALSE)
readClipboard(format = 1, raw = FALSE)
writeClipboard(str, format = 1)
```

### Arguments

|         |                                                                                    |
|---------|------------------------------------------------------------------------------------|
| numeric | logical: should the result be in human-readable form (the default) or raw numbers? |
| format  | an integer giving the desired format.                                              |
| raw     | should the value be returned as a raw vector rather than as a character vector?    |
| str     | a character vector or a raw vector.                                                |

### Details

The Windows clipboard offers data in a number of formats: see e.g. <https://docs.microsoft.com/en-gb/windows/desktop/dataxchg/clipboard-formats>.

The standard formats include

|                 |   |                              |
|-----------------|---|------------------------------|
| CF_TEXT         | 1 | Text in the machine's locale |
| CF_BITMAP       | 2 |                              |
| CF_METAFILEPICT | 3 | Metafile picture             |
| CF_SYLK         | 4 | Symbolic link                |
| CF_DIF          | 5 | Data Interchange Format      |
| CF_TIFF         | 6 | Tagged-Image File Format     |

|                |    |                                      |
|----------------|----|--------------------------------------|
| CF_OEMTEXT     | 7  | Text in the OEM codepage             |
| CF_DIB         | 8  | Device-Independent Bitmap            |
| CF_PALETTE     | 9  |                                      |
| CF_PENDATA     | 10 |                                      |
| CF_RIFF        | 11 | Audio data                           |
| CF_WAVE        | 12 | Audio data                           |
| CF_UNICODETEXT | 13 | Text in Unicode (UCS-2)              |
| CF_ENHMETAFILE | 14 | Enhanced metafile                    |
| CF_HDROP       | 15 | Drag-and-drop data                   |
| CF_LOCALE      | 16 | Locale for the text on the clipboard |
| CF_MAX         | 17 | Shell-oriented formats               |

Applications normally make data available in one or more of these and possibly additional private formats. Use `raw = TRUE` to read binary formats, `raw = FALSE` (the default) for text formats. The current codepage is used to convert text to Unicode text, and information on that is contained in the `CF_LOCALE` format. (Take care if you are running R in a different locale from Windows.)

The `writeClipboard` function will write a character vector as text or Unicode text with standard CR-LF line terminators. It will copy a raw vector directly to the clipboard without any changes.

### Value

For `getClipboardFormats`, a character or integer vector of available formats, in numeric order. If non human-readable character representation is known, the number is returned.

For `readClipboard`, a character vector by default, a raw vector if `raw` is `TRUE`, or `NULL`, if the format is unavailable.

For `writeClipboard` an invisible logical indicating success or failure.

### Note

This is only available on Windows.

### See Also

[file](#) which can be used to set up a connection to a clipboard.

---

close.socket

*Close a Socket*

---

### Description

Closes the socket and frees the space in the file descriptor table. The port may not be freed immediately.

### Usage

```
close.socket(socket, ...)
```

**Arguments**

|        |                                                    |
|--------|----------------------------------------------------|
| socket | a socket object                                    |
| ...    | further arguments passed to or from other methods. |

**Value**

logical indicating success or failure

**Author(s)**

Thomas Lumley

**See Also**

[make.socket](#), [read.socket](#)

Compiling in support for sockets was optional prior to R 3.3.0: see [capabilities](#)("sockets") to see if it is available.

---

combn

---

*Generate All Combinations of  $n$  Elements, Taken  $m$  at a Time*

---

**Description**

Generate all combinations of the elements of  $x$  taken  $m$  at a time. If  $x$  is a positive integer, returns all combinations of the elements of `seq(x)` taken  $m$  at a time. If argument `FUN` is not `NULL`, applies a function given by the argument to each point. If `simplify` is `FALSE`, returns a list; otherwise returns an [array](#), typically a [matrix](#). ... are passed unchanged to the `FUN` function, if specified.

**Usage**

```
combn(x, m, FUN = NULL, simplify = TRUE, ...)
```

**Arguments**

|                       |                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>        | vector source for combinations, or integer $n$ for <code>x &lt;- seq_len(n)</code> .                                                                                                                                                                                                                                                                                                                                                               |
| <code>m</code>        | number of elements to choose.                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>FUN</code>      | function to be applied to each combination; default <code>NULL</code> means the identity, i.e., to return the combination (vector of length $m$ ).                                                                                                                                                                                                                                                                                                 |
| <code>simplify</code> | logical indicating if the result should be simplified to an <a href="#">array</a> (typically a <a href="#">matrix</a> ); if <code>FALSE</code> , the function returns a <a href="#">list</a> . Note that when <code>simplify = TRUE</code> as by default, the dimension of the result is simply determined from <code>FUN(1st combination)</code> (for efficiency reasons). This will badly fail if <code>FUN(u)</code> is not of constant length. |
| ...                   | optionally, further arguments to <code>FUN</code> .                                                                                                                                                                                                                                                                                                                                                                                                |

**Details**

Factors  $x$  are accepted.

**Value**

A [list](#) or [array](#), see the `simplify` argument above. In the latter case, the identity `dim(combn(n,m)) == c(m, choose(n,m))` holds.

**Author(s)**

Scott Chasalow wrote the original in 1994 for S; R package **combinat** and documentation by Vince Carey <stvjc@channing.harvard.edu>; small changes by the R core team, notably to return an array in all cases of `simplify = TRUE`, e.g., for `combn(5, 5)`.

**References**

Nijenhuis, A. and Wilf, H.S. (1978) *Combinatorial Algorithms for Computers and Calculators*; Academic Press, NY.

**See Also**

[choose](#) for fast computation of the *number* of combinations. [expand.grid](#) for creating a data frame from all combinations of factors or vectors.

**Examples**

```
combn(letters[1:4], 2)
(m <- combn(10, 5, min)) # minimum value in each combination
mm <- combn(15, 6, function(x) matrix(x, 2, 3))
stopifnot(round(choose(10, 5)) == length(m),
 c(2,3, round(choose(15, 6))) == dim(mm))

Different way of encoding points:
combn(c(1,1,1,1,2,2,2,3,3,4), 3, tabulate, nbins = 4)

Compute support points and (scaled) probabilities for a
Multivariate-Hypergeometric(n = 3, N = c(4,3,2,1)) p.f.:
table.mat(t(combn(c(1,1,1,1,2,2,2,3,3,4), 3, tabulate, nbins = 4)))

Assuring the identity
for(n in 1:7)
 for(m in 0:n) stopifnot(is.array(cc <- combn(n, m)),
 dim(cc) == c(m, choose(n, m)))
```

---

compareVersion

---

*Compare Two Package Version Numbers*

---

**Description**

Compare two package version numbers to see which is later.

**Usage**

```
compareVersion(a, b)
```

**Arguments**

`a, b` Character strings representing package version numbers.

Details

R package version numbers are of the form `x.y-z` for integers `x`, `y` and `z`, with components after `x` optionally missing (in which case the version number is older than those with the components present).

Value

0 if the numbers are equal, -1 if `b` is later and 1 if `a` is later (analogous to the C function `strcmp`).

See Also

`package_version`, `library`, `packageStatus`.

Examples

```
compareVersion("1.0", "1.0-1")
compareVersion("7.2-0", "7.1-12")
```

---

|         |                                                    |
|---------|----------------------------------------------------|
| COMPILE | <i>Compile Files for Use with R on Unix-alikes</i> |
|---------|----------------------------------------------------|

---

Description

Compile given source files so that they can subsequently be collected into a shared object using R CMD SHLIB or an executable program using R CMD LINK. Not available on Windows.

Usage

```
R CMD COMPILE [options] srcfiles
```

Arguments

|                       |                                                                                                                                                                                                                                                                                                                                                                                                    |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>srcfiles</code> | A list of the names of source files to be compiled. Currently, C, C++, Objective C, Objective C++ and Fortran are supported; the corresponding files should have the extensions <code>‘.c’</code> , <code>‘.cc’</code> (or <code>‘.cpp’</code> ), <code>‘.m’</code> , <code>‘.mm’</code> (or <code>‘.M’</code> ), <code>‘.f’</code> and <code>‘.f90’</code> or <code>‘.f95’</code> , respectively. |
| <code>options</code>  | A list of compile-relevant settings, or for obtaining information about usage and version of the utility.                                                                                                                                                                                                                                                                                          |

Details

R CMD SHLIB can both compile and link files into a shared object: since it knows what run-time libraries are needed when passed C++, Fortran and Objective C(++) sources, passing source files to R CMD SHLIB is more reliable.

Objective C and Objective C++ support is optional and will work only if the corresponding compilers were available at R configure time: their main usage is on macOS.

Compilation arranges to include the paths to the R public C/C++ headers.

As this compiles code suitable for incorporation into a shared object, it generates PIC code: that might occasionally be undesirable for the main code of an executable program.

This is a make-based facility, so will not compile a source file if a newer corresponding `‘.o’` file is present.

**Note**

Some binary distributions of R have `COMPILE` in a separate bundle, e.g. an R-devel RPM.

This is not available on Windows.

---

`contrib.url`*Find Appropriate Paths in CRAN-like Repositories*

---

**Description**

`contrib.url` adds the appropriate type-specific path within a repository to each URL in `repos`.

**Usage**

```
contrib.url(repos, type = getOption("pkgType"))
```

**Arguments**

|                    |                                                                                             |
|--------------------|---------------------------------------------------------------------------------------------|
| <code>repos</code> | character vector, the base URL(s) of the repositories to use.                               |
| <code>type</code>  | character string, indicating which type of packages: see <a href="#">install.packages</a> . |

**Details**

If `type = "both"` this will use the source repository.

**Value**

A character vector of the same length as `repos`.

**See Also**

[setRepositories](#) to set `options("repos")`, the most common value used for argument `repos`.

[available.packages](#), [download.packages](#), [install.packages](#).

The ‘R Installation and Administration’ manual for how to set up a repository.

count.fields

*Count the Number of Fields per Line***Description**

count.fields counts the number of fields, as separated by sep, in each of the lines of file read.

**Usage**

```
count.fields(file, sep = "", quote = "\"'", skip = 0,
 blank.lines.skip = TRUE, comment.char = "#")
```

**Arguments**

|                  |                                                                                                                                                                      |
|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| file             | a character string naming an ASCII data file, or a <a href="#">connection</a> , which will be opened if necessary, and if so closed at the end of the function call. |
| sep              | the field separator character. Values on each line of the file are separated by this character. By default, arbitrary amounts of whitespace can separate fields.     |
| quote            | the set of quoting characters                                                                                                                                        |
| skip             | the number of lines of the data file to skip before beginning to read data.                                                                                          |
| blank.lines.skip | logical: if TRUE blank lines in the input are ignored.                                                                                                               |
| comment.char     | character: a character vector of length one containing a single character or an empty string.                                                                        |

**Details**

This used to be used by [read.table](#) and can still be useful in discovering problems in reading a file by that function.

For the handling of comments, see [scan](#).

Consistent with [scan](#), count.fields allows quoted strings to contain newline characters. In such a case the starting line will have the field count recorded as NA, and the ending line will include the count of all fields from the beginning of the record.

**Value**

A vector with the numbers of fields found.

**See Also**

[read.table](#)

**Examples**

```
fil <- tempfile()
cat("NAME", "1:John", "2:Paul", file = fil, sep = "\n")
count.fields(fil, sep = ":")
unlink(fil)
```

create.post

*Ancillary Function for Preparing Emails and Postings***Description**

An ancillary function used by [bug.report](#) and [help.request](#) to prepare emails for submission to package maintainers or to R mailing lists.

**Usage**

```
create.post(instructions = character(), description = "post",
 subject = "",
 method = getOption("mailer"),
 address = "the relevant mailing list",
 ccaddress = getOption("ccaddress", ""),
 filename = "R.post", info = character())
```

**Arguments**

|                           |                                                                                                                                                                                   |
|---------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>instructions</code> | Character vector of instructions to put at the top of the template email.                                                                                                         |
| <code>description</code>  | Character string: a description to be incorporated into messages.                                                                                                                 |
| <code>subject</code>      | Subject of the email. Optional except for the "mailx" method.                                                                                                                     |
| <code>method</code>       | Submission method, one of "none", "mailto", "gnudoit", "ess" or (Unix only) "mailx". See 'Details'.                                                                               |
| <code>address</code>      | Recipient's email address, where applicable: for package bug reports sent by email this defaults to the address of the package maintainer (the first if more than one is listed). |
| <code>ccaddress</code>    | Optional email address for copies with the "mailx" and "mailto" methods. Use <code>ccaddress = ""</code> for no copy.                                                             |
| <code>filename</code>     | Filename to use for setting up the email (or storing it when method is "none" or sending mail fails).                                                                             |
| <code>info</code>         | character vector of information to include in the template email below the 'please do not edit the information below' line.                                                       |

**Details**

What this does depends on the `method`. The function first creates a template email body.

`none` A file editor (see [file.edit](#)) is opened with instructions and the template email. When this returns, the completed email is in file `file` ready to be read/pasted into an email program.

`mailto` This opens the default email program with a template email (including address, Cc: address and subject) for you to edit and send.

This works where default mailers are set up (usual on macOS and Windows, and where `xdg-open` is available and configured on other Unix-alikes: if that fails it tries the browser set by `R_BROWSER`).

This is the 'factory-fresh' default method.

`mailx` (Unix-alikes only.) A file editor (see [file.edit](#)) is opened with instructions and the template email. When this returns, it is mailed using a Unix command line mail utility such as `mailx`, to the address (and optionally, the Cc: address) given.

`gnudoit` An (X)emacs mail buffer is opened for the email to be edited and sent: this requires the `gnudoit` program to be available. Currently `subject` is ignored.

`ess` The body of the template email is sent to `stdout`.

**Value**

Invisible `NULL`.

**See Also**

[bug.report](#), [help.request](#).

---

|      |                  |
|------|------------------|
| data | <i>Data Sets</i> |
|------|------------------|

---

**Description**

Loads specified data sets, or list the available data sets.

**Usage**

```
data(..., list = character(), package = NULL, lib.loc = NULL,
 verbose = getOption("verbose"), envir = .GlobalEnv,
 overwrite = TRUE)
```

**Arguments**

|                        |                                                                                                                                                                                                                                |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>...</code>       | literal character strings or names.                                                                                                                                                                                            |
| <code>list</code>      | a character vector.                                                                                                                                                                                                            |
| <code>package</code>   | a character vector giving the package(s) to look in for data sets, or <code>NULL</code> .<br>By default, all packages in the search path are used, then the ‘data’ subdirectory (if present) of the current working directory. |
| <code>lib.loc</code>   | a character vector of directory names of R libraries, or <code>NULL</code> . The default value of <code>NULL</code> corresponds to all libraries currently known.                                                              |
| <code>verbose</code>   | a logical. If <code>TRUE</code> , additional diagnostics are printed.                                                                                                                                                          |
| <code>envir</code>     | the <a href="#">environment</a> where the data should be loaded.                                                                                                                                                               |
| <code>overwrite</code> | logical: should existing objects of the same name in <code>envir</code> be replaced?                                                                                                                                           |

**Details**

Currently, four formats of data files are supported:

1. files ending ‘.R’ or ‘.r’ are `source()`d in, with the R working directory changed temporarily to the directory containing the respective file. (data ensures that the `utils` package is attached, in case it had been run *via* `utils::data`.)
2. files ending ‘.RData’ or ‘.rda’ are `load()`ed.
3. files ending ‘.tab’, ‘.txt’ or ‘.TXT’ are read using `read.table(..., header = TRUE, as.is=FALSE)`, and hence result in a data frame.

4. files ending `‘.csv’` or `‘.CSV’` are read using `read.table(..., header = TRUE, sep = ";", as.is=FALSE)`, and also result in a data frame.

If more than one matching file name is found, the first on this list is used. (Files with extensions `‘.txt’`, `‘.tab’` or `‘.csv’` can be compressed, with or without further extension `‘.gz’`, `‘.bz2’` or `‘.xz’`.)

The data sets to be loaded can be specified as a set of character strings or names, or as the character vector `list`, or as both.

For each given data set, the first two types (`‘.R’` or `‘.r’`, and `‘.RData’` or `‘.rda’` files) can create several variables in the load environment, which might all be named differently from the data set. The third and fourth types will always result in the creation of a single variable with the same name (without extension) as the data set.

If no data sets are specified, `data` lists the available data sets. It looks for a new-style data index in the `‘Meta’` or, if this is not found, an old-style `‘00Index’` file in the `‘data’` directory of each specified package, and uses these files to prepare a listing. If there is a `‘data’` area but no index, available data files for loading are computed and included in the listing, and a warning is given: such packages are incomplete. The information about available data sets is returned in an object of class `"packageIQR"`. The structure of this class is experimental. Where the datasets have a different name from the argument that should be used to retrieve them the index will have an entry like `beaver1 (beavers)` which tells us that dataset `beaver1` can be retrieved by the call `data(beaver)`.

If `lib.loc` and `package` are both `NULL` (the default), the data sets are searched for in all the currently loaded packages then in the `‘data’` directory (if any) of the current working directory.

If `lib.loc = NULL` but `package` is specified as a character vector, the specified package(s) are searched for first amongst loaded packages and then in the default library/ies (see `.libPaths`).

If `lib.loc` is specified (and not `NULL`), packages are searched for in the specified library/ies, even if they are already loaded from another library.

To just look in the `‘data’` directory of the current working directory, set `package = character(0)` (and `lib.loc = NULL`, the default).

## Value

A character vector of all data sets specified (whether found or not), or information about all available data sets in an object of class `"packageIQR"` if none were specified.

## Good practice

There is no requirement for `data(foo)` to create an object named `foo` (nor to create one object), although it much reduces confusion if this convention is followed (and it is enforced if datasets are lazy-loaded).

`data()` was originally intended to allow users to load datasets from packages for use in their examples, and as such it loaded the datasets into the workspace `.GlobalEnv`. This avoided having large datasets in memory when not in use: that need has been almost entirely superseded by lazy-loading of datasets.

The ability to specify a dataset by name (without quotes) is a convenience: in programming the datasets should be specified by character strings (with quotes).

Use of `data` within a function without an `envir` argument has the almost always undesirable side-effect of putting an object in the user’s workspace (and indeed, of replacing any object of that name already there). It would almost always be better to put the object in the current evaluation environment by `data(..., envir = environment())`. However, two alternatives are usually preferable, both described in the `‘Writing R Extensions’` manual.

- For sets of data, set up a package to use lazy-loading of data.
- For objects which are system data, for example lookup tables used in calculations within the function, use a file `'R/sysdata.rda'` in the package sources or create the objects by R code at package installation time.

A sometimes important distinction is that the second approach places objects in the namespace but the first does not. So if it is important that the function sees `mytable` as an object from the package, it is system data and the second approach should be used. In the unusual case that a package uses a lazy-loaded dataset as a default argument to a function, that needs to be specified by `::`, e.g., `survival::survexp.us`.

### Warning

This function creates objects in the `envir` environment (by default the user's workspace) replacing any which already existed. `data("foo")` can silently create objects other than `foo`: there have been instances in published packages where it created/replaced `.Random.seed` and hence change the seed for the session.

### Note

One can take advantage of the search order and the fact that a `'R'` file will change directory. If raw data are stored in `'mydata.txt'` then one can set up `'mydata.R'` to read `'mydata.txt'` and pre-process it, e.g., using `transform()`. For instance one can convert numeric vectors to factors with the appropriate labels. Thus, the `'R'` file can effectively contain a metadata specification for the plaintext formats.

In older versions of R, up to 3.6.x, both `package = "base"` and `package = "stats"` were using `package = "datasets"`, (with a warning), as before 2004, (most of) the datasets in **datasets** were either in **base** or **stats**. For these packages, the result is now empty as they contain no data sets.

The 'Writing R Extensions' for considerations in preparing the 'data' directory of a package.

### Examples

```
require(utils)
data() # list all available data sets
try(data(package = "rpart")) # list the data sets in the rpart package
data(USArrests, "VADeaths") # load the data sets 'USArrests' and 'VADeaths'
Not run: ## Alternatively
ds <- c("USArrests", "VADeaths"); data(list = ds)
End(Not run)
help(USArrests) # give information on data set 'USArrests'
```

## Description

A spreadsheet-like editor for entering or editing data.

## Usage

```
data.entry(..., Modes = NULL, Names = NULL)
dataentry(data, modes)
de(..., Modes = list(), Names = NULL)
```

## Arguments

|                    |                                                                                                                               |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------|
| <code>...</code>   | A list of variables: currently these should be numeric or character vectors or list containing such vectors.                  |
| <code>Modes</code> | The modes to be used for the variables.                                                                                       |
| <code>Names</code> | The names to be used for the variables.                                                                                       |
| <code>data</code>  | A list of numeric and/or character vectors.                                                                                   |
| <code>modes</code> | A list of length up to that of <code>data</code> giving the modes of (some of) the variables. <code>list()</code> is allowed. |

## Details

The data entry editor is only available on some platforms and GUIs. Where available it provides a means to visually edit a matrix or a collection of variables (including a data frame) as described in the Notes section.

`data.entry` has side effects, any changes made in the spreadsheet are reflected in the variables. The functions `de`, `de.ncols`, `de.setup` and `de.restore` are designed to help achieve these side effects. If the user passes in a matrix, `X` say, then the matrix is broken into columns before `dataentry` is called. Then on return the columns are collected and glued back together and the result assigned to the variable `X`. If you don't want this behaviour use `dataentry` directly.

The primitive function is `dataentry`. It takes a list of vectors of possibly different lengths and modes (the second argument) and opens a spreadsheet with these variables being the columns. The columns of the `dataentry` window are returned as vectors in a list when the spreadsheet is closed.

`de.ncols` counts the number of columns which are supplied as arguments to `data.entry`. It attempts to count columns in lists, matrices and vectors. `de.setup` sets things up so that on return the columns can be regrouped and reassigned to the correct name. This is handled by `de.restore`.

## Value

`de` and `dataentry` return the edited value of their arguments. `data.entry` invisibly returns a vector of variable names but its main value is its side effect of assigning new version of those variables in the user's workspace.

## Resources

The data entry window responds to X resources of class `R_dataentry`. Resources `foreground`, `background` and `geometry` are utilized.

## Note

The details of interface to the data grid may differ by platform and GUI. The following description applies to the X11-based implementation under Unix.

You can navigate around the grid using the cursor keys or by clicking with the (left) mouse button on any cell. The active cell is highlighted by thickening the surrounding rectangle. Moving to the right or down will scroll the grid as needed: there is no constraint to the rows or columns currently in use.

There are alternative ways to navigate using the keys. Return and (keypad) Enter and LineFeed all move down. Tab moves right and Shift-Tab move left. Home moves to the top left.

PageDown or Control-F moves down a page, and PageUp or Control-B up by a page. End will show the last used column and the last few rows used (in any column).

Using any other key starts an editing process on the currently selected cell: moving away from that cell enters the edited value whereas Esc cancels the edit and restores the previous value. When the editing process starts the cell is cleared. In numerical columns (the default) only letters making up a valid number (including `- . eE`) are accepted, and entering an invalid edited value (such as blank) enters NA in that cell. The last entered value can be deleted using the BackSpace or Del(ete) key. Only a limited number of characters (currently 29) can be entered in a cell, and if necessary only the start or end of the string will be displayed, with the omissions indicated by `>` or `<`. (The start is shown except when editing.)

Entering a value in a cell further down a column than the last used cell extends the variable and fills the gap (if any) by NAs (not shown on screen).

The column names can only be selected by clicking in them. This gives a popup menu to select the column type (currently Real (numeric) or Character) or to change the name. Changing the type converts the current contents of the column (and converting from Character to Real may generate NAs.) If changing the name is selected the header cell becomes editable (and is cleared). As with all cells, the value is entered by moving away from the cell by clicking elsewhere or by any of the keys for moving down (only).

New columns are created by entering values in them (and not by just assigning a new name). The mode of the column is auto-detected from the first value entered: if this is a valid number it gives a numeric column. Unused columns are ignored, so adding data in `var5` to a three-column grid adds one extra variable, not two.

The Copy button copies the currently selected cell: paste copies the last copied value to the current cell, and right-clicking selects a cell *and* copies in the value. Initially the value is blank, and attempts to paste a blank value will have no effect.

Control-L will refresh the display, recalculating field widths to fit the current entries.

In the default mode the column widths are chosen to fit the contents of each column, with a default of 10 characters for empty columns. you can specify fixed column widths by setting option `de.cellwidth` to the required fixed width (in characters). (set it to zero to return to variable widths). The displayed width of any field is limited to 600 pixels (and by the window width).

## See Also

[vi](#), [edit](#): edit uses dataentry to edit data frames.

**Examples**

```
call data entry with variables x and y
Not run: data.entry(x, y)
```

debugcall

*Debug a Call***Description**

Set or unset debugging flags based on a call to a function. Takes into account S3/S4 method dispatch based on the classes of the arguments in the call.

**Usage**

```
debugcall(call, once = FALSE)
undebugcall(call)
```

**Arguments**

|      |                                                                                                         |
|------|---------------------------------------------------------------------------------------------------------|
| call | An R expression calling a function. The called function will be debugged. See <a href="#">Details</a> . |
| once | logical; if TRUE, debugging only occurs once, as via <a href="#">debugonce</a> . Defaults to FALSE      |

**Details**

`debugcall` debugs the non-generic function, S3 method or S4 method that would be called by evaluating `call`. Thus, the user does not need to specify the signature when debugging methods. Although the call is actually to the generic, it is the method that is debugged, not the generic, except for non-standard S3 generics (see [isS3stdGeneric](#)).

**Value**

`debugcall` invisibly returns the debugged call expression.

**Note**

Non-standard evaluation is used to retrieve the `call` (via [substitute](#)). For this reason, passing a variable containing a call expression, rather than the call expression itself, will not work.

**See Also**

[debug](#) for the primary debugging interface

**Examples**

```
Not run:
Evaluate call after setting debugging
##
f <- factor(1:10)
res <- eval(debugcall(summary(f)))

End(Not run)
```

debugger

*Post-Mortem Debugging***Description**

Functions to dump the evaluation environments (frames) and to examine dumped frames.

**Usage**

```
dump.frames(dumpto = "last.dump", to.file = FALSE,
 include.GlobalEnv = FALSE)
debugger(dump = last.dump)
```

**Arguments**

|                                |                                                                                                                                                                                                        |
|--------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>dumpto</code>            | a character string. The name of the object or file to dump to.                                                                                                                                         |
| <code>to.file</code>           | logical. Should the dump be to an R object or to a file?                                                                                                                                               |
| <code>include.GlobalEnv</code> | logical indicating if a <i>copy</i> of the <code>.GlobalEnv</code> environment should be included in addition to the <code>sys.frames()</code> . Will be particularly useful when used in a batch job. |
| <code>dump</code>              | an R dump object created by <code>dump.frames</code> .                                                                                                                                                 |

**Details**

To use post-mortem debugging, set the option `error` to be a call to `dump.frames`. By default this dumps to an R object `last.dump` in the workspace, but it can be set to dump to a file (a dump of the object produced by a call to `save`). The dumped object contain the call stack, the active environments and the last error message as returned by `geterrmessage`.

When dumping to file, `dumpto` gives the name of the dumped object and the file name has `'.rda'` appended.

A dump object of class `"dump.frames"` can be examined by calling `debugger`. This will give the error message and a list of environments from which to select repeatedly. When an environment is selected, it is copied and the `browser` called from within the copy. Note that not all the information in the original frame will be available, e.g. promises which have not yet been evaluated and the contents of any `...` argument.

If `dump.frames` is installed as the error handler, execution will continue even in non-interactive sessions. See the examples for how to dump and then quit.

**Value**

Invisible `NULL`.

**Note**

Functions such as `sys.parent` and `environment` applied to closures will not work correctly inside `debugger`.

If the error occurred when computing the default value of a formal argument the debugger will report “recursive default argument reference” when trying to examine that environment.

Of course post-mortem debugging will not work if R is too damaged to produce and save the dump, for example if it has run out of workspace.

options(error = quote({dump.frames(to.file = TRUE); q(status = 1)}))

End(Not run)
```

**Description**

`demo` is a user-friendly interface to running some demonstration R scripts. `demo()` gives the list of available topics.

**Usage**

```
demo(topic, package = NULL, lib.loc = NULL,
 character.only = FALSE, verbose = getOption("verbose"),
 echo = TRUE, ask = getOption("demo.ask"),
 encoding = getOption("encoding"))
```

**Arguments**

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>topic</code>          | the topic which should be demonstrated, given as a <a href="#">name</a> or literal character string, or a character string, depending on whether <code>character.only</code> is <code>FALSE</code> (default) or <code>TRUE</code> . If omitted, the list of available topics is displayed.                                                                                                                                                                                                                                                                    |
| <code>package</code>        | a character vector giving the packages to look into for demos, or <code>NULL</code> . By default, all packages in the search path are used.                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>lib.loc</code>        | a character vector of directory names of R libraries, or <code>NULL</code> . The default value of <code>NULL</code> corresponds to all libraries currently known. If the default is used, the loaded packages are searched before the libraries.                                                                                                                                                                                                                                                                                                              |
| <code>character.only</code> | logical; if <code>TRUE</code> , use <code>topic</code> as character string.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>verbose</code>        | a logical. If <code>TRUE</code> , additional diagnostics are printed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>echo</code>           | a logical. If <code>TRUE</code> , show the R input when sourcing.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>ask</code>            | a logical (or "default") indicating if <code>devAskNewPage</code> ( <code>ask = TRUE</code> ) should be called before graphical output happens from the demo code. The value "default" (the factory-fresh default) means to ask if <code>echo == TRUE</code> and the graphics device appears to be interactive. This parameter applies both to any currently opened device and to any devices opened by the demo code. If this is evaluated to <code>TRUE</code> and the session is <a href="#">interactive</a> , the user is asked to press RETURN to start. |
| <code>encoding</code>       | See <a href="#">source</a> . If the package has a declared encoding, that takes preference.                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

**Details**

If no topics are given, `demo` lists the available demos. The corresponding information is returned in an object of class "packageIQR".

**See Also**

[source](#) and [devAskNewPage](#) which are called by `demo`.

**Examples**

```
demo() # for attached packages

All available demos:
demo(package = .packages(all.available = TRUE))

Display a demo, pausing between pages
demo(lm.glm, package = "stats", ask = TRUE)

Display it without pausing
demo(lm.glm, package = "stats", ask = FALSE)

Not run:
ch <- "scoping"
demo(ch, character = TRUE)

End(Not run)

Find the location of a demo
system.file("demo", "lm.glm.R", package = "stats")
```

---

DLL.version

*DLL Version Information on MS Windows*

---

**Description**

On MS Windows only, return the version of the package and the version of R used to build the DLL, if available.

**Usage**

```
DLL.version(path)
```

**Arguments**

path                      character vector of length one giving the complete path to the DLL.

**Value**

If the DLL does not exist, NULL.

A character vector of length two, giving the DLL version and the version of R used to build the DLL. If the information is not available, the corresponding string is empty.

**Note**

This is only available on Windows.

## Examples

```
if(.Platform$OS.type == "windows") withAutoprint({
 DLL.version(file.path(R.home("bin"), "R.dll"))
 DLL.version(file.path(R.home(), "library/stats/libs", .Platform$r_arch, "stats.dll"))
})
```

---

download.file

*Download File from the Internet*

---

## Description

This function can be used to download a file from the Internet.

## Usage

```
download.file(url, destfile, method, quiet = FALSE, mode = "w",
 cacheOK = TRUE,
 extra = getOption("download.file.extra"),
 headers = NULL, ...)
```

## Arguments

|          |                                                                                                                                                                                                                                                                                                              |
|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| url      | a <a href="#">character</a> string (or longer vector e.g., for the "libcurl" method) naming the URL of a resource to be downloaded.                                                                                                                                                                          |
| destfile | a character string (or vector, see url) with the name where the downloaded file is saved. Tilde-expansion is performed.                                                                                                                                                                                      |
| method   | Method to be used for downloading files. Current download methods are "internal", "wininet" (Windows only) "libcurl", "wget" and "curl", and there is a value "auto": see ‘Details’ and ‘Note’.<br><br>The method can also be set through the option "download.file.method": see <a href="#">options()</a> . |
| quiet    | If TRUE, suppress status messages (if any), and the progress bar.                                                                                                                                                                                                                                            |
| mode     | character. The mode with which to write the file. Useful values are "w", "wb" (binary), "a" (append) and "ab". Not used for methods "wget" and "curl". See also ‘Details’, notably about using "wb" for Windows.                                                                                             |
| cacheOK  | logical. Is a server-side cached value acceptable?                                                                                                                                                                                                                                                           |
| extra    | character vector of additional command-line arguments for the "wget" and "curl" methods.                                                                                                                                                                                                                     |
| headers  | named character vector of HTTP headers to use in HTTP requests. It is ignored for non-HTTP URLs. The User-Agent header, coming from the HTTPUserAgent option (see <a href="#">options</a> ) is used as the first header, automatically.                                                                      |
| ...      | allow additional arguments to be passed, unused.                                                                                                                                                                                                                                                             |

## Details

The function `download.file` can be used to download a single file as described by `url` from the internet and store it in `destfile`. The `url` must start with a scheme such as `'http://'`, `'https://'`, `'ftp://'` or `'file://'`.

If `method = "auto"` is chosen (the default), the behavior depends on the platform:

- On a Unix-alike method `"libcurl"` is used except `"internal"` for `'file://'` URLs, where `"libcurl"` uses the library of that name (<https://curl.se/libcurl/>).
- On Windows the `"wininet"` method is used apart from for `'https://'` URLs where `"libcurl"` is tried. The `"wininet"` method uses the WinINet functions (part of the OS). Support for method `"libcurl"` is optional on Windows: use `capabilities("libcurl")` to see if it is supported on your build. It uses an external library of that name (<https://curl.se/libcurl/>) against which R can be compiled.

When method `"libcurl"` is used, it provides (non-blocking) access to `'https://'` and (usually) `'https://'` URLs. There is support for simultaneous downloads, so `url` and `destfile` can be character vectors of the same length greater than one (but the method has to be specified explicitly and not *via* `"auto"`). For a single URL and `quiet = FALSE` a progress bar is shown in interactive use.

For methods `"wget"` and `"curl"` a system call is made to the tool given by `method`, and the respective program must be installed on your system and be in the search path for executables. They will block all other activity on the R process until they complete: this may make a GUI unresponsive.

`cacheOK = FALSE` is useful for `'http://'` and `'https://'` URLs: it will attempt to get a copy directly from the site rather than from an intermediate cache. It is used by [available.packages](#).

The `"libcurl"` and `"wget"` methods follow `'http://'` and `'https://'` redirections to any scheme they support: the `"internal"` method follows `'http://'` to `'http://'` redirections only. (For method `"curl"` use argument `extra = "-L"`. To disable redirection in `wget`, use `extra = "--max-redirect=0"`.) The `"wininet"` method supports some redirections but not all. (For method `"libcurl"`, messages will quote the endpoint of redirections.)

Note that `'https://'` URLs are not supported by the `"internal"` method but are supported by the `"libcurl"` method and the `"wininet"` method on Windows.

See [url](#) for how `'file://'` URLs are interpreted, especially on Windows. The `"internal"` and `"wininet"` methods do not percent-decode `'file://'` URLs, but the `"libcurl"` and `"curl"` methods do: method `"wget"` does not support them.

Most methods do not percent-encode special characters such as spaces in URLs (see [URLencode](#)), but it seems the `"wininet"` method does.

The remaining details apply to the `"internal"`, `"wininet"` and `"libcurl"` methods only.

The timeout for many parts of the transfer can be set by the option `timeout` which defaults to 60 seconds. This is often insufficient for downloads of large files (50MB or more) and so should be increased when `download.file` is used in packages to do so. Note that the user can set the default timeout by the environment variable `R_DEFAULT_INTERNET_TIMEOUT` in recent versions of R, so to ensure that this is not decreased packages should use something like

```
options(timeout = max(300, getOption("timeout")))
```

(It is unrealistic to require download times of less than 1s/MB.)

The level of detail provided during transfer can be set by the `quiet` argument and the `internet.info` option: the details depend on the platform and scheme. For the "internal" method setting option `internet.info` to 0 gives all available details, including all server responses. Using 2 (the default) gives only serious messages, and 3 or more suppresses all messages. For the "libcurl" method values of the option less than 2 give verbose output.

A progress bar tracks the transfer platform specifically:

**On Windows** If the file length is known, the full width of the bar is the known length. Otherwise the initial width represents 100 Kbytes and is doubled whenever the current width is exceeded. (In non-interactive use this uses a text version. If the file length is known, an equals sign represents 2% of the transfer completed: otherwise a dot represents 10Kb.)

**On a unix-alike** If the file length is known, an equals sign represents 2% of the transfer completed: otherwise a dot represents 10Kb.

The choice of binary transfer (`mode = "wb" or "ab"`) is important on Windows, since unlike Unix-alikes it does distinguish between text and binary files and for text transfers changes `\n` line endings to `\r\n` (aka 'CRLF').

On Windows, if `mode` is not supplied (`missing()`) and `url` ends in one of `.gz`, `.bz2`, `.xz`, `.tgz`, `.zip`, `.jar`, `.rda`, `.rds` or `.RData`, `mode = "wb"` is set so that a binary transfer is done to help unwary users.

Code written to download binary files must use `mode = "wb" (or "ab")`, but the problems incurred by a text transfer will only be seen on Windows.

## Value

An (invisible) integer code, 0 for success and non-zero for failure. For the "wget" and "curl" methods this is the status code returned by the external program. The "internal" method can return 1, but will in most cases throw an error.

What happens to the destination file(s) in the case of error depends on the method and R version. Currently the "internal", "wininet" and "libcurl" methods will remove the file if there the URL is unavailable except when `mode` specifies appending when the file should be unchanged.

## Setting Proxies

For the Windows-only method "wininet", the 'Internet Options' of the system are used to choose proxies and so on; these are set in the Control Panel and are those used for system browsers.

The next two paragraphs apply to the internal code only.

Proxies can be specified via environment variables. Setting `no_proxy` to `*` stops any proxy being tried. Otherwise the setting of `http_proxy` or `ftp_proxy` (or failing that, the all upper-case version) is consulted and if non-empty used as a proxy site. For FTP transfers, the username and password on the proxy can be specified by `ftp_proxy_user` and `ftp_proxy_password`. The form of `http_proxy` should be `http://proxy.dom.com/` or `http://proxy.dom.com:8080/` where the port defaults to 80 and the trailing slash may be omitted. For `ftp_proxy` use the form `ftp://proxy.dom.com:3128/` where the default port is 21. These environment variables must be set before the download code is first used: they cannot be altered later by calling `Sys.setenv`.

Usernames and passwords can be set for HTTP proxy transfers via environment variable `http_proxy_user` in the form `user:passwd`. Alternatively, `http_proxy` can be of the form `http://user:pass@proxy.dom.com:8080/` for compatibility with wget. Only the HTTP/1.0 basic authentication scheme is supported.

Under Windows, if `http_proxy_user` is set to ask then a dialog box will come up for the user to enter the username and password. **NB:** you will be given only one opportunity to enter this, but if proxy authentication is required and fails there will be one further prompt per download.

Much the same scheme is supported by `method = "libcurl"`, including `no_proxy`, `http_proxy` and `ftp_proxy`, and for the last two a contents of `[user:password@]machine[:port]` where the parts in brackets are optional. See <https://curl.se/libcurl/c/libcurl-tutorial.html> for details.

## Secure URLs

Methods which access `'https://'` and `'ftps://'` URLs should try to verify the site certificates. This is usually done using the CA root certificates installed by the OS (although we have seen instances in which these got removed rather than updated). For further information see <https://curl.se/docs/sslcerts.html>.

This is an issue for `method = "libcurl"` on Windows, where the OS does not provide a suitable CA certificate bundle, so by default on Windows certificates are not verified. To turn verification on, set environment variable `CURL_CA_BUNDLE` to the path to a certificate bundle file, usually named `'ca-bundle.crt'` or `'curl-ca-bundle.crt'`. (This is normally done for a binary installation of R, which installs `'R_HOME/etc/curl-ca-bundle.crt'` and sets `CURL_CA_BUNDLE` to point to it if that environment variable is not already set.) For an updated certificate bundle, see <https://curl.se/docs/sslcerts.html>. Currently one can download a copy from <https://raw.githubusercontent.com/bagder/ca-bundle/master/ca-bundle.crt> and set `CURL_CA_BUNDLE` to the full path to the downloaded file.

Note that the root certificates used by R may or may not be the same as used in a browser, and indeed different browsers may use different certificate bundles (there is typically a build option to choose either their own or the system ones).

## FTP sites

`'ftp:'` URLs are accessed using the FTP protocol which has a number of variants. One distinction is between `'active'` and `'(extended) passive'` modes: which is used is chosen by the client. The `"internal"` and `"libcurl"` methods use passive mode, and that is almost universally used by browsers. The `"wininet"` method first tries passive and then active.

## Good practice

Setting the `method` should be left to the end user. Neither of the `wget` nor `curl` commands is widely available: you can check if one is available via `Sys.which`, and should do so in a package or script.

If you use `download.file` in a package or script, you must check the return value, since it is possible that the download will fail with a non-zero status but not an R error.

The supported methods do change: `method libcurl` was introduced in R 3.2.0 and is still optional on Windows – use `capabilities("libcurl")` in a program to see if it is available.

## Note

Files of more than 2GB are supported on 64-bit builds of R; they may be truncated on some 32-bit builds.

Methods `"wget"` and `"curl"` are mainly for historical compatibility but provide may provide capabilities not supported by the `"libcurl"` or `"wininet"` methods.

Method "wget" can be used with proxy firewalls which require user/password authentication if proper values are stored in the configuration file for wget.

wget (<https://www.gnu.org/software/wget/>) is commonly installed on Unix-alikes (but not macOS). Windows binaries are available from Cygwin, gnuwin32 and elsewhere.

curl (<https://curl.se/>) is installed on macOS and commonly on Unix-alikes. Windows binaries are available at that URL.

---

download.packages    *Download Packages from CRAN-like Repositories*

---

### Description

These functions can be used to automatically compare the version numbers of installed packages with the newest available version on the repositories and update outdated packages on the fly.

### Usage

```
download.packages(pkgs, destdir, available = NULL,
 repos = getOption("repos"),
 contriburl = contrib.url(repos, type),
 method, type = getOption("pkgType"), ...)
```

### Arguments

|            |                                                                                                                                                                                                            |
|------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| pkgs       | character vector of the names of packages whose latest available versions should be downloaded from the repositories.                                                                                      |
| destdir    | directory where downloaded packages are to be stored.                                                                                                                                                      |
| available  | an object as returned by <a href="#">available.packages</a> listing packages available at the repositories, or NULL which makes an internal call to <a href="#">available.packages</a> .                   |
| repos      | character vector, the base URL(s) of the repositories to use, i.e., the URL of the CRAN master such as "https://cran.r-project.org" or its Statlib mirror, "http://lib.stat.cmu.edu/R/CRAN".               |
| contriburl | URL(s) of the contrib sections of the repositories. Use this argument only if your repository mirror is incomplete, e.g., because you burned only the 'contrib' section on a CD. Overrides argument repos. |
| method     | Download method, see <a href="#">download.file</a> .                                                                                                                                                       |
| type       | character string, indicate which type of packages: see <a href="#">install.packages</a> and 'Details'.                                                                                                     |
| ...        | additional arguments to be passed to <a href="#">download.file</a> and <a href="#">available.packages</a> .                                                                                                |

## Details

`download.packages` takes a list of package names and a destination directory, downloads the newest versions and saves them in `destdir`. If the list of available packages is not given as argument, it is obtained from repositories. If a repository is local, i.e. the URL starts with `"file:"`, then the packages are not downloaded but used directly. Both `"file:"` and `"file://"` are allowed as prefixes to a file path. Use the latter only for URLs: see [url](#) for their interpretation. (Other forms of `'file:/'` URLs are not supported.)

For `download.packages`, `type = "both"` looks at source packages only.

## Value

A two-column matrix of names and destination file names of those packages successfully downloaded. If packages are not available or there is a problem with the download, suitable warnings are given.

## See Also

[available.packages](#), [contrib.url](#).

The main use is by [install.packages](#).

See [download.file](#) for how to handle proxies and other options to monitor file transfers.

---

edit

*Invoke a Text Editor*

---

## Description

Invoke a text editor on an R object.

## Usage

```
Default S3 method:
edit(name = NULL, file = "", title = NULL,
 editor = getOption("editor"), ...)
```

```
vi(name = NULL, file = "")
emacs(name = NULL, file = "")
pico(name = NULL, file = "")
xemacs(name = NULL, file = "")
xedit(name = NULL, file = "")
```

## Arguments

|                    |                                                                                                                                           |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------|
| <code>name</code>  | a named object that you want to edit. If <code>name</code> is missing then the file specified by <code>file</code> is opened for editing. |
| <code>file</code>  | a string naming the file to write the edited version to.                                                                                  |
| <code>title</code> | a display name for the object being edited.                                                                                               |

`editor` usually a character string naming (or giving the path to) the text editor you want to use. On Unix the default is set from the environment variables `EDITOR` or `VISUAL` if either is set, otherwise `vi` is used. On Windows it defaults to `"internal"`, the script editor. On the macOS GUI the argument is ignored and the document editor is always used.

`editor` can also be an R function, in which case it is called with the arguments `name`, `file`, and `title`. Note that such a function will need to independently implement all desired functionality.

... further arguments to be passed to or from methods.

## Details

`edit` invokes the text editor specified by `editor` with the object `name` to be edited. It is a generic function, currently with a default method and one for data frames and matrices.

`data.entry` can be used to edit data, and is used by `edit` to edit matrices and data frames on systems for which `data.entry` is available.

It is important to realize that `edit` does not change the object called `name`. Instead, a copy of `name` is made and it is that copy which is changed. Should you want the changes to apply to the object `name` you must assign the result of `edit` to `name`. (Try `fix` if you want to make permanent changes to an object.)

In the form `edit(name)`, `edit` deparses `name` into a temporary file and invokes the editor `editor` on this file. Quitting from the editor causes `file` to be parsed and that value returned. Should an error occur in parsing, possibly due to incorrect syntax, no value is returned. Calling `edit()`, with no arguments, will result in the temporary file being reopened for further editing.

Note that deparsing is not perfect, and the object recreated after editing can differ in subtle ways from that deparsed: see `dput` and `.deparseOpts`. (The deparse options used are the same as the defaults for `dump`.) Editing a function will preserve its environment. See `edit.data.frame` for further changes that can occur when editing a data frame or matrix.

Currently only the internal editor in Windows makes use of the `title` option; it displays the given `name` in the window header.

## Note

The functions `vi`, `emacs`, `pico`, `xemacs`, `xedit` rely on the corresponding editor being available and being on the path. This is system-dependent.

## See Also

`edit.data.frame`, `data.entry`, `fix`.

## Examples

```
Not run:
use xedit on the function mean and assign the changes
mean <- edit(mean, editor = "xedit")

use vi on mean and write the result to file mean.out
vi(mean, file = "mean.out")

End(Not run)
```

## Description

Use data editor on data frame or matrix contents.

## Usage

```
S3 method for class 'data.frame'
edit(name, factor.mode = c("character", "numeric"),
 edit.row.names = any(row.names(name) != 1:nrow(name)), ...)

S3 method for class 'matrix'
edit(name, edit.row.names = !is.null(dn[[1]]), ...)
```

## Arguments

|                             |                                                                                                                                                                      |
|-----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>name</code>           | A data frame or (numeric, logical or character) matrix.                                                                                                              |
| <code>factor.mode</code>    | How to handle factors (as integers or using character levels) in a data frame. Can be abbreviated.                                                                   |
| <code>edit.row.names</code> | logical. Show the row names (if they exist) be displayed as a separate editable column? It is an error to ask for this on a matrix with <code>NULL</code> row names. |
| <code>...</code>            | further arguments passed to or from other methods.                                                                                                                   |

## Details

At present, this only works on simple data frames containing numeric, logical or character vectors and factors, and numeric, logical or character matrices. Any other mode of matrix will give an error, and a warning is given when the matrix has a class (which will be discarded).

Data frame columns are coerced on input to *character* unless numeric (in the sense of `is.numeric`), logical or factor. A warning is given when classes are discarded. Special characters (tabs, non-printing ASCII, etc.) will be displayed as escape sequences.

Factors columns are represented in the spreadsheet as either numeric vectors (which are more suitable for data entry) or character vectors (better for browsing). After editing, vectors are padded with NA to have the same length and factor attributes are restored. The set of factor levels can not be changed by editing in numeric mode; invalid levels are changed to NA and a warning is issued. If new factor levels are introduced in character mode, they are added at the end of the list of levels in the order in which they encountered.

It is possible to use the data-editor's facilities to select the mode of columns to swap between numerical and factor columns in a data frame. Changing any column in a numerical matrix to character will cause the result to be coerced to a character matrix. Changing the mode of logical columns is not supported.

For a data frame, the row names will be taken from the original object if `edit.row.names = FALSE` and the number of rows is unchanged, and from the edited output if `edit.row.names = TRUE` and there are no duplicates. (If the `row.names` column is incomplete, it is extended by entries like `row223`.) In all other cases the row names are replaced by `seq(length = nrow)`.

For a matrix, colnames will be added (of the form `col17`) if needed. The rownames will be taken from the original object if `edit.row.names = FALSE` and the number of rows is unchanged (otherwise `NULL`), and from the edited output if `edit.row.names = TRUE`. (If the `row.names` column is incomplete, it is extended by entries like `row223`.)

Editing a matrix or data frame will lose all attributes apart from the row and column names.

### Value

The edited data frame or matrix.

### Note

`fix(dataframe)` works for in-place editing by calling this function.

If the data editor is not available, a dump of the object is presented for editing using the default method of `edit`.

At present the data editor is limited to 65535 rows.

*Run an Examples Section from the Online Help*

---

### Description

Run all the R code from the **Examples** part of R's online help topic `topic` with possible exceptions `dontrun`, `dontshow`, and `donttest`, see 'Details' below.

### Usage

```
example(topic, package = NULL, lib.loc = NULL,
 character.only = FALSE, give.lines = FALSE, local = FALSE,
 echo = TRUE, verbose = getOption("verbose"),
 setRNG = FALSE, ask = getOption("example.ask"),
 prompt.prefix = abbreviate(topic, 6),
 run.dontrun = FALSE, run.donttest = interactive())
```

## Arguments

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>topic</code>          | name or literal character string: the online <a href="#">help</a> topic the examples of which should be run.                                                                                                                                                                                                                                                                                                                     |
| <code>package</code>        | a character vector giving the package names to look into for the topic, or <code>NULL</code> (the default), when all packages on the <a href="#">search</a> path are used.                                                                                                                                                                                                                                                       |
| <code>lib.loc</code>        | a character vector of directory names of R libraries, or <code>NULL</code> . The default value of <code>NULL</code> corresponds to all libraries currently known. If the default is used, the loaded packages are searched before the libraries.                                                                                                                                                                                 |
| <code>character.only</code> | a logical indicating whether <code>topic</code> can be assumed to be a character string.                                                                                                                                                                                                                                                                                                                                         |
| <code>give.lines</code>     | logical: if true, the <i>lines</i> of the example source code are returned as a character vector.                                                                                                                                                                                                                                                                                                                                |
| <code>local</code>          | logical: if <code>TRUE</code> evaluate locally, if <code>FALSE</code> evaluate in the workspace.                                                                                                                                                                                                                                                                                                                                 |
| <code>echo</code>           | logical; if <code>TRUE</code> , show the R input when sourcing.                                                                                                                                                                                                                                                                                                                                                                  |
| <code>verbose</code>        | logical; if <code>TRUE</code> , show even more when running example code.                                                                                                                                                                                                                                                                                                                                                        |
| <code>setRNG</code>         | logical or expression; if not <code>FALSE</code> , the random number generator state is saved, then initialized to a specified state, the example is run and the (saved) state is restored. <code>setRNG = TRUE</code> sets the same state as R CMD <a href="#">check</a> does for running a package's examples. This is currently equivalent to <code>setRNG = {RNGkind("default", "default", "default"); set.seed(1)}</code> . |
| <code>ask</code>            | logical (or "default") indicating if <a href="#">devAskNewPage</a> ( <code>ask = TRUE</code> ) should be called before graphical output happens from the example code. The value "default" (the factory-fresh default) means to ask if <code>echo == TRUE</code> and the graphics device appears to be interactive. This parameter applies both to any currently opened device and to any devices opened by the example code.    |
| <code>prompt.prefix</code>  | character; prefixes the prompt to be used if <code>echo = TRUE</code> .                                                                                                                                                                                                                                                                                                                                                          |
| <code>run.dontrun</code>    | logical indicating that <code>\dontrun</code> should be ignored.                                                                                                                                                                                                                                                                                                                                                                 |
| <code>run.donttest</code>   | logical indicating that <code>\donttest</code> should be ignored.                                                                                                                                                                                                                                                                                                                                                                |

## Details

If `lib.loc` is not specified, the packages are searched for amongst those already loaded, then in the libraries given by `.libPaths()`. If `lib.loc` is specified, packages are searched for only in the specified libraries, even if they are already loaded from another library. The search stops at the first package found that has help on the topic.

An attempt is made to load the package before running the examples, but this will not replace a package loaded from another location.

If `local = TRUE` objects are not created in the workspace and so not available for examination after `example` completes: on the other hand they cannot overwrite objects of the same name in the workspace.

As detailed in the manual *Writing R Extensions*, the author of the help page can markup parts of the examples for exception rules

`\dontrun` encloses code that should not be run.

`\dontshow` encloses code that is invisible on help pages, but will be run both by the package checking tools, and the `example()` function. This was previously `testonly`, and that form is still accepted.

`donttest` encloses code that typically should be run, but not during package checking. The default `run.donttest = interactive()` leads `example()` use in other help page examples to skip `\donttest` sections appropriately.

### Value

The value of the last evaluated expression, unless `give.lines` is true, where a [character](#) vector is returned.

### Author(s)

Martin Maechler and others

### Examples

```
example(InsectSprays)
force use of the standard package 'stats':
example("smooth", package = "stats", lib.loc = .Library)

set RNG *before* example as when R CMD check is run:

r1 <- example(quantile, setRNG = TRUE)
x1 <- rnorm(1)
u <- runif(1)
identical random numbers
r2 <- example(quantile, setRNG = TRUE)
x2 <- rnorm(1)
stopifnot(identical(r1, r2))
but x1 and x2 differ since the RNG state from before example()
differs and is restored!
x1; x2

Exploring examples code:
How large are the examples of "lm..." functions?
lmex <- sapply(apropos("^lm", mode = "function"),
 example, character.only = TRUE, give.lines = TRUE)
sapply(lmex, length)
```

---

file.edit

*Edit One or More Files*

---

### Description

Edit one or more files in a text editor.

### Usage

```
file.edit(..., title = file, editor = getOption("editor"),
 fileEncoding = "")
```

**Arguments**

|                           |                                                                                                                                                      |
|---------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>...</code>          | one or more character vectors containing the names of the files to be displayed. These will be tilde-expanded: see <a href="#">path.expand</a> .     |
| <code>title</code>        | the title to use in the editor; defaults to the filename.                                                                                            |
| <code>editor</code>       | the text editor to be used, usually as a character string naming (or giving the path to) the text editor you want to use See ‘Details’.              |
| <code>fileEncoding</code> | the encoding to assume for the file: the default is to assume the native encoding. See the ‘Encoding’ section of the help for <a href="#">file</a> . |

**Details**

The behaviour of this function is very system-dependent. Currently files can be opened only one at a time on Unix; on Windows, the internal editor allows multiple files to be opened, but has a limit of 50 simultaneous edit windows.

The `title` argument is used for the window caption in Windows, and is currently ignored on other platforms.

Any error in re-encoding the files to the native encoding will cause the function to fail.

The default for `editor` is system-dependent. On Windows it defaults to "internal", the script editor, and in the macOS GUI the document editor is used whatever the value of `editor`. On Unix the default is set from the environment variables `EDITOR` or `VISUAL` if either is set, otherwise `vi` is used.

`editor` can also be an R function, in which case it is called with the arguments `name`, `file`, and `title`. Note that such a function will need to independently implement all desired functionality.

On Windows, UTF-8-encoded paths not valid in the current locale can be used.

**Examples**

```
Not run:
open two R scripts for editing
file.edit("script1.R", "script2.R")

End(Not run)
```

---

file\_test

---

*Shell-style Tests on Files*

---

**Description**

Utility for shell-style file tests.

**Usage**

```
file_test(op, x, y)
```

**Arguments**

|                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>op</code>   | a character string specifying the test to be performed. Unary tests (only <code>x</code> is used) are <code>"-f"</code> (existence and not being a directory), <code>"-d"</code> (existence and directory) and <code>"-x"</code> (executable as a file or searchable as a directory). Binary tests are <code>"-nt"</code> (strictly newer than, using the modification dates) and <code>"-ot"</code> (strictly older than): in both cases the test is false unless both files exist. |
| <code>x, y</code> | character vectors giving file paths.                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

**Details**

'Existence' here means being on the file system and accessible by the `stat` system call (or a 64-bit extension) – on a Unix-alike this requires execute permission on all of the directories in the path that leads to the file, but no permissions on the file itself.

For the meaning of `"-x"` on Windows see [file.access](#).

**See Also**

[file.exists](#) which only tests for existence (`test -e` on some systems) but not for not being a directory.

[file.path](#), [file.info](#)

**Examples**

```
dir <- file.path(R.home(), "library", "stats")
file_test("-d", dir)
file_test("-nt", file.path(dir, "R"), file.path(dir, "demo"))
```

---

findLineNum

*Find the Location of a Line of Source Code, or Set a Breakpoint There*

---

**Description**

These functions locate objects containing particular lines of source code, using the information saved when the code was parsed with `keep.source = TRUE`.

**Usage**

```
findLineNum(srcfile, line, nameonly = TRUE,
 envir = parent.frame(), lastenv)

setBreakpoint(srcfile, line, nameonly = TRUE,
 envir = parent.frame(), lastenv, verbose = TRUE,
 tracer, print = FALSE, clear = FALSE, ...)
```

**Arguments**

|                       |                                                                                                                       |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------|
| <code>srcfile</code>  | The name of the file containing the source code.                                                                      |
| <code>line</code>     | The line number within the file. See Details for an alternate way to specify this.                                    |
| <code>nameonly</code> | If <code>TRUE</code> (the default), we require only a match to <code>basename(srcfile)</code> , not to the full path. |

|                      |                                                                                                                                  |
|----------------------|----------------------------------------------------------------------------------------------------------------------------------|
| <code>envir</code>   | Where do we start looking for function objects?                                                                                  |
| <code>lastenv</code> | Where do we stop? See the Details.                                                                                               |
| <code>verbose</code> | Should we print information on where breakpoints were set?                                                                       |
| <code>tracer</code>  | An optional <code>tracer</code> function to pass to <code>trace</code> . By default, a call to <code>browser</code> is inserted. |
| <code>print</code>   | The <code>print</code> argument to pass to <code>trace</code> .                                                                  |
| <code>clear</code>   | If TRUE, call <code>untrace</code> rather than <code>trace</code> .                                                              |
| <code>...</code>     | Additional arguments to pass to <code>trace</code> .                                                                             |

## Details

The `findLineNum` function searches through all objects in environment `envir`, its parent, grandparent, etc., all the way back to `lastenv`.

`lastenv` defaults to the global environment if `envir` is not specified, and to the root environment `emptyenv()` if `envir` is specified. (The first default tends to be quite fast, and will usually find all user code other than S4 methods; the second one is quite slow, as it will typically search all attached system libraries.)

For convenience, `envir` may be specified indirectly: if it is not an environment, it will be replaced with `environment(envir)`.

`setBreakpoint` is a simple wrapper function for `trace` and `untrace`. It will set or clear breakpoints at the locations found by `findLineNum`.

The `srcfile` is normally a filename entered as a character string, but it may be a "`srcfile`" object, or it may include a suffix like "`filename.R#nn`", in which case the number `nn` will be used as a default value for `line`.

As described in the description of the `where` argument on the man page for `trace`, the R package system uses a complicated scheme that may include more than one copy of a function in a package. The user will typically see the public one on the search path, while code in the package will see a private one in the package namespace. If you set `envir` to the environment of a function in the package, by default `findLineNum` will find both versions, and `setBreakpoint` will set the breakpoint in both. (This can be controlled using `lastenv`; e.g., `envir = environment(foo)`, `lastenv = globalenv()` will find only the private copy, as the search is stopped before seeing the public copy.)

S version 4 methods are also somewhat tricky to find. They are stored with the generic function, which may be in the **base** or other package, so it is usually necessary to have `lastenv = emptyenv()` in order to find them. In some cases transformations are done by R when storing them and `findLineNum` may not be able to find the original code. Many special cases, e.g. methods on primitive generics, are not yet supported.

## Value

`findLineNum` returns a list of objects containing location information. A `print` method is defined for them.

`setBreakpoint` has no useful return value; it is called for the side effect of calling `trace` or `untrace`.

## Author(s)

Duncan Murdoch

**See Also**[trace](#)**Examples**

```
Not run:
Find what function was defined in the file mysource.R at line 100:
findLineNum("mysource.R#100")

Set a breakpoint in both copies of that function, assuming one is in the
same namespace as myfunction and the other is on the search path
setBreakpoint("mysource.R#100", envir = myfunction)

End(Not run)
```

---

fix*Fix an Object*

---

**Description**

`fix` invokes [edit](#) on `x` and then assigns the new (edited) version of `x` in the user's workspace.

**Usage**

```
fix(x, ...)
```

**Arguments**

|                  |                                                           |
|------------------|-----------------------------------------------------------|
| <code>x</code>   | the name of an R object, as a name or a character string. |
| <code>...</code> | arguments to pass to editor: see <a href="#">edit</a> .   |

**Details**

The name supplied as `x` need not exist as an R object, in which case a function with no arguments and an empty body is supplied for editing.

Editing an R object may change it in ways other than are obvious: see the comment under [edit](#). See [edit.data.frame](#) for changes that can occur when editing a data frame or matrix.

**See Also**[edit](#), [edit.data.frame](#)**Examples**

```
Not run:
Assume 'my.fun' is a user defined function :
fix(my.fun)
now my.fun is changed
Also,
fix(my.data.frame) # calls up data editor
fix(my.data.frame, factor.mode="char") # use of ...

End(Not run)
```

---

|               |                                  |
|---------------|----------------------------------|
| flush.console | <i>Flush Output to a Console</i> |
|---------------|----------------------------------|

---

**Description**

This does nothing except on console-based versions of R. On the macOS and Windows GUIs, it ensures that the display of output in the console is current, even if output buffering is on.

**Usage**

```
flush.console()
```

---

|        |                                           |
|--------|-------------------------------------------|
| format | <i>Format Unordered and Ordered Lists</i> |
|--------|-------------------------------------------|

---

**Description**

Format unordered (itemize) and ordered (enumerate) lists.

**Usage**

```
formatUL(x, label = "*", offset = 0,
 width = 0.9 * getOption("width"))
formatOL(x, type = "arabic", offset = 0, start = 1,
 width = 0.9 * getOption("width"))
```

**Arguments**

|        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x      | a character vector of list items.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| label  | a character string used for labelling the items.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| offset | a non-negative integer giving the offset (indentation) of the list.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| width  | a positive integer giving the target column for wrapping lines in the output.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| type   | a character string specifying the ‘type’ of the labels in the ordered list. If "arabic" (default), arabic numerals are used. For "Alph" or "alph", single upper or lower case letters are employed (in this case, the number of the last item must not exceed 26). Finally, for "Roman" or "roman", the labels are given as upper or lower case roman numerals (with the number of the last item maximally 3899). type can be given as a unique abbreviation of the above, or as one of the HTML style tokens "1" (arabic), "A"/"a" (alphabetic), or "I"/"i" (roman), respectively. |
| start  | a positive integer specifying the starting number of the first item in an ordered list.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

**Value**

A character vector with the formatted entries.

**See Also**

[formatDL](#) for formatting description lists.

**Examples**

```
A simpler recipe.
x <- c("Mix dry ingredients thoroughly.",
 "Pour in wet ingredients.",
 "Mix for 10 minutes.",
 "Bake for one hour at 300 degrees.")
Format and output as an unordered list.
writeLines(formatUL(x))
Format and output as an ordered list.
writeLines(formatOL(x))
Ordered list using lower case roman numerals.
writeLines(formatOL(x, type = "i"))
Ordered list using upper case letters and some offset.
writeLines(formatOL(x, type = "A", offset = 5))
```

---

getAnywhere

---

*Retrieve an R Object, Including from a Namespace*

---

**Description**

These functions locate all objects with name matching their argument, whether visible on the search path, registered as an S3 method or in a namespace but not exported. `getAnywhere()` returns the objects and `argsAnywhere()` returns the arguments of any objects that are functions.

**Usage**

```
getAnywhere(x)
argsAnywhere(x)
```

**Arguments**

`x` a character string or name.

**Details**

These functions look at all loaded namespaces, whether or not they are associated with a package on the search list.

They do not search literally “anywhere”: for example, local evaluation frames and namespaces that are not loaded will not be searched.

Where functions are found as registered S3 methods, an attempt is made to find which namespace registered them. This may not be correct, especially if namespaces have been unloaded.

**Value**

For `getAnywhere()` an object of class "getAnywhere". This is a list with components

|                      |                                                              |
|----------------------|--------------------------------------------------------------|
| <code>name</code>    | the name searched for                                        |
| <code>objs</code>    | a list of objects found                                      |
| <code>where</code>   | a character vector explaining where the object(s) were found |
| <code>visible</code> | logical: is the object visible                               |
| <code>dups</code>    | logical: is the object identical to one earlier in the list. |

In computing whether objects are identical, their environments are ignored.

Normally the structure will be hidden by the `print` method. There is a `[` method to extract one or more of the objects found.

For `argsAnywhere()` one or more argument lists as returned by `args`.

**See Also**

`getS3method` to find the method which would be used: this might not be the one of those returned by `getAnywhere` since it might have come from a namespace which was unloaded or be registered under another name.

`get`, `getFromNamespace`, `args`

**Examples**

```
getAnywhere("format.dist")
getAnywhere("simpleLoess") # not exported from stats
argsAnywhere(format.dist)
```

---

`getFromNamespace`      *Utility Functions for Developing Namespaces*

---

**Description**

Utility functions to access and replace the non-exported functions in a namespace, for use in developing packages with namespaces.

They should not be used in production code (except perhaps `assignInMyNamespace`, but see the 'Note').

**Usage**

```
getFromNamespace(x, ns, pos = -1, envir = as.environment(pos))

assignInNamespace(x, value, ns, pos = -1,
 envir = as.environment(pos))

assignInMyNamespace(x, value)

fixInNamespace(x, ns, pos = -1, envir = as.environment(pos), ...)
```

## Arguments

|                    |                                                             |
|--------------------|-------------------------------------------------------------|
| <code>x</code>     | an object name (given as a character string).               |
| <code>value</code> | an R object.                                                |
| <code>ns</code>    | a namespace, or character string giving the namespace.      |
| <code>pos</code>   | where to look for the object: see <a href="#">get</a> .     |
| <code>envir</code> | an alternative way to specify an environment to look in.    |
| <code>...</code>   | arguments to pass to the editor: see <a href="#">edit</a> . |

## Details

`assignInMyNamespace` is intended to be called from functions within a package, and chooses the namespace as the environment of the function calling it.

The namespace can be specified in several ways. Using, for example, `ns = "stats"` is the most direct, but a loaded package can be specified via any of the methods used for [get](#): `ns` can also be the environment printed as `<namespace:foo>`.

`getFromNamespace` is similar to (but predates) the `:::` operator: it is more flexible in how the namespace is specified.

`fixInNamespace` invokes [edit](#) on the object named `x` and assigns the revised object in place of the original object. For compatibility with `fix`, `x` can be unquoted.

## Value

`getFromNamespace` returns the object found (or gives an error).

`assignInNamespace`, `assignInMyNamespace` and `fixInNamespace` are invoked for their side effect of changing the object in the namespace.

## Warning

`assignInNamespace` should not be used in final code, and will in future throw an error if called from a package. Already certain uses are disallowed.

## Note

`assignInNamespace`, `assignInMyNamespace` and `fixInNamespace` change the copy in the namespace, but not any copies already exported from the namespace, in particular an object of that name in the package (if already attached) and any copies already imported into other namespaces. They are really intended to be used *only* for objects which are not exported from the namespace. They do attempt to alter a copy registered as an S3 method if one is found.

They can only be used to change the values of objects in the namespace, not to create new objects.

## See Also

[get](#), [fix](#), [getS3method](#)

## Examples

```
getFromNamespace("findGeneric", "utils")
Not run:
fixInNamespace("predict.ppr", "stats")
stats::predict.ppr
getS3method("predict", "ppr")
alternatively
fixInNamespace("predict.ppr", pos = 3)
fixInNamespace("predict.ppr", pos = "package:stats")

End(Not run)
```

getParseData

*Get Detailed Parse Information from Object*

## Description

If the "keep.source" option is TRUE, R's parser will attach detailed information on the object it has parsed. These functions retrieve that information.

## Usage

```
getParseData(x, includeText = NA)
getParseText(parseData, id)
```

## Arguments

|             |                                                                                                                     |
|-------------|---------------------------------------------------------------------------------------------------------------------|
| x           | an expression returned from <a href="#">parse</a> , or a function or other object with source reference information |
| includeText | logical; whether to include the text of parsed items in the result                                                  |
| parseData   | a data frame returned from <code>getParseData</code>                                                                |
| id          | a vector of item identifiers whose text is to be retrieved                                                          |

## Details

In version 3.0.0, the R parser was modified to include code written by Romain Francois in his **parser** package. This constructs a detailed table of information about every token and higher level construct in parsed code. This table is stored in the [srcfile](#) record associated with source references in the parsed code, and retrieved by the `getParseData` function.

## Value

For `getParseData`:

If parse data is not present, NULL. Otherwise a data frame is returned, containing the following columns:

|       |                                                                                                                                                                   |
|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| line1 | integer. The line number where the item starts. This is the parsed line number called "parse" in <a href="#">getSrcLocation</a> , which ignores #line directives. |
| col1  | integer. The column number where the item starts. The first character is column 1. This corresponds to "column" in <a href="#">getSrcLocation</a> .               |
| line2 | integer. The line number where the item ends.                                                                                                                     |

|                       |                                                                                                                                                                                                                                                                                                                                                                                            |
|-----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>col2</code>     | integer. The column number where the item ends.                                                                                                                                                                                                                                                                                                                                            |
| <code>id</code>       | integer. An identifier associated with this item.                                                                                                                                                                                                                                                                                                                                          |
| <code>parent</code>   | integer. The <code>id</code> of the parent of this item.                                                                                                                                                                                                                                                                                                                                   |
| <code>token</code>    | character string. The type of the token.                                                                                                                                                                                                                                                                                                                                                   |
| <code>terminal</code> | logical. Whether the token is “terminal”, i.e. a leaf in the parse tree.                                                                                                                                                                                                                                                                                                                   |
| <code>text</code>     | character string. If <code>includeText</code> is <code>TRUE</code> , the text of all tokens; if it is <code>NA</code> (the default), the text of terminal tokens. If <code>includeText == FALSE</code> , this column is not included. Very long strings (with source of 1000 characters or more) will not be stored; a message giving their length and delimiter will be included instead. |

The rownames of the data frame will be equal to the `id` values, and the data frame will have a `"srcfile"` attribute containing the `srcfile` record which was used. The rows will be ordered by starting position within the source file, with parent items occurring before their children.

For `getParseText`:

A character vector of the same length as `id` containing the associated text items. If they are not included in `parseData`, they will be retrieved from the original file.

### Note

There are a number of differences in the results returned by `getParseData` relative to those in the original **parser** code:

- Fewer columns are kept.
- The internal token number is not returned.
- `col1` starts counting at 1, not 0.
- The `id` values are not attached to the elements of the parse tree, they are only retained in the table returned by `getParseData`.
- `#line` directives are identified, but other comment markup (e.g., **roxygen** comments) are not.

### Examples

```
fn <- function(x) {
 x + 1 # A comment, kept as part of the source
}

d <- getParseData(fn)
if (!is.null(d)) {
 plus <- which(d$token == "'+'")
}
```

```
sum <- d$parent[plus]
print(d[as.character(sum),])
print(getParseText(d, sum))
}
```

---

`getS3method`*Get an S3 Method*

---

## Description

Get a method for an S3 generic, possibly from a namespace or the generic's registry.

## Usage

```
getS3method(f, class, optional = FALSE, envir = parent.frame())
```

## Arguments

|                       |                                                                                         |
|-----------------------|-----------------------------------------------------------------------------------------|
| <code>f</code>        | a character string giving the name of the generic.                                      |
| <code>class</code>    | a character string giving the name of the class.                                        |
| <code>optional</code> | logical: should failure to find the generic or a method be allowed?                     |
| <code>envir</code>    | the <a href="#">environment</a> in which the method and its generic are searched first. |

## Details

S3 methods may be hidden in namespaces, and will not then be found by [get](#): this function can retrieve such functions, primarily for debugging purposes.

Further, S3 methods can be registered on the generic when a namespace is loaded, and the registered method will be used if none is visible (using namespace scoping rules).

It is possible that which S3 method will be used may depend on where the generic `f` is called from: `getS3method` returns the method found if `f` were called from the same environment.

## Value

The function found, or `NULL` if no function is found and `optional = TRUE`.

## Examples

```
require(stats)
exists("predict.ppr") # false
getS3method("predict", "ppr")
```

---

getWindowsHandle     *Get a Windows Handle*

---

### Description

Get the Windows handle of a window or of the R process in MS Windows.

### Usage

```
getWindowsHandle(which = "Console")
```

### Arguments

`which`                a string (see below), or the number of a graphics device window (which must be a [windows](#) one).

### Details

`getWindowsHandle` gets the Windows handle. Possible choices for `which` are:

|                 |                                        |
|-----------------|----------------------------------------|
| "Console"       | The console window handle.             |
| "Frame"         | The MDI frame window handle.           |
| "Process"       | The process pseudo-handle.             |
| A device number | The window handle of a graphics device |

These values are not normally useful to users, but may be used by developers making add-ons to R.

NULL is returned for the Frame handle if not running in MDI mode, for the Console handle when running Rterm, for any unrecognized string for `which`, or for a graphics device with no corresponding window.

Other windows (help browsers, etc.) are not accessible through this function.

### Value

An external pointer holding the Windows handle, or NULL.

### Note

This is only available on Windows.

### See Also

[getIdentification](#), [getWindowsHandles](#)

### Examples

```
if(.Platform$OS.type == "windows")
 print(getWindowsHandle())
```

---

getWindowsHandles    *Get handles of Windows in the MS Windows RGui*

---

### Description

This function gets the Windows handles of visible top level windows or windows within the R MDI frame (when using the Rgui).

### Usage

```
getWindowsHandles(which = "R", pattern = "", minimized = FALSE)
```

### Arguments

|                        |                                                                                        |
|------------------------|----------------------------------------------------------------------------------------|
| <code>which</code>     | A vector of strings "R" or "all" (possibly with repetitions). See the Details section. |
| <code>pattern</code>   | A vector of patterns that the titles of the windows must match.                        |
| <code>minimized</code> | A logical vector indicating whether minimized windows should be considered.            |

### Details

This function will search for Windows handles, for passing to external GUIs or to the [arrangeWindows](#) function. Each of the arguments may be a vector of values. These will be treated as follows:

- The arguments will all be recycled to the same length.
- The corresponding elements of each argument will be applied in separate searches.
- The final result will be the union of the windows identified in each of the searches.

If an element of `which` is "R", only windows belonging to the current R process will be returned. In MDI mode, those will be the child windows within the R GUI (Rgui) frame. In SDI mode, all windows belonging to the process will be included.

If the element is "all", then top level windows will be returned.

The elements of `pattern` will be used to make a subset of windows whose title text matches (according to [grep](#)) the pattern.

If `minimized = FALSE`, minimized windows will be ignored.

### Value

A list of external pointers containing the window handles.

### Note

This is only available on Windows.

 getWindowsHandles()
 getWindowsHandles("all")
})
```

---

 glob2rx

---

*Change Wildcard or Globbing Pattern into Regular Expression*

---

**Description**

Change *wildcard* aka *globbing* patterns into the corresponding regular expressions ([regex](#)).

**Usage**

```
glob2rx(pattern, trim.head = FALSE, trim.tail = TRUE)
```

**Arguments**

|                        |                                                                                         |
|------------------------|-----------------------------------------------------------------------------------------|
| <code>pattern</code>   | character vector                                                                        |
| <code>trim.head</code> | logical specifying if leading " <code>^.*</code> " should be trimmed from the result.   |
| <code>trim.tail</code> | logical specifying if trailing " <code>.*\$</code> " should be trimmed from the result. |

**Details**

This takes a wildcard as used by most shells and returns an equivalent regular expression. `?` is mapped to `.` (match a single character), `*` to `.*` (match any string, including an empty one), and the pattern is anchored (it must start at the beginning and end at the end). Optionally, the resulting `regex` is simplified.

Note that now even `(`, `[` and `{` can be used in `pattern`, but `glob2rx()` may not work correctly with arbitrary characters in `pattern`.

**Value**

A character vector of the same length as the input `pattern` where each wildcard is translated to the corresponding regular expression.

[regex](#) about regular expression, [sub](#), etc about substitutions using `regex`s.

## Examples

```
stopifnot(glob2rx("abc.*") == "^abc\\.\"",
 glob2rx("a?b.*") == "^a.b\\.\"",
 glob2rx("a?b.*", trim.tail = FALSE) == "^a.b\\.\\.\\.*$",
 glob2rx("*.doc") == "^.*\\.\\.doc$",
 glob2rx("*.doc", trim.head = TRUE) == "\\\\.doc$",
 glob2rx("*.t*") == "^.*\\.\\.t",
 glob2rx("*.t??") == "^.*\\.\\.t\\.\\.*$",
 glob2rx("[*]") == "^.*\\["
)
```

---

globalVariables      *Declarations Used in Checking a Package*

---

## Description

For `globalVariables`, the names supplied are of functions or other objects that should be regarded as defined globally when the `check` tool is applied to this package. The call to `globalVariables` will be included in the package's source. Repeated calls in the same package accumulate the names of the global variables.

Typical examples are the fields and methods in reference classes, which appear to be global objects to `codetools`. (This case is handled automatically by `setRefClass()` and friends, using the supplied field and method names.)

For `suppressForeignCheck`, the names supplied are of variables used as `.NAME` in foreign function calls which should not be checked by `checkFF(registration = TRUE)`. Without this declaration, expressions other than simple character strings are assumed to evaluate to registered native symbol objects. The type of call (`.Call`, `.External`, etc.) and argument counts will be checked. With this declaration, checks on those names will usually be suppressed. (If the code uses an expression that should only be evaluated at runtime, the message can be suppressed by wrapping it in a `dontCheck` function call, or by saving it to a local variable, and suppressing messages about that variable. See the example below.)

## Usage

```
globalVariables(names, package, add = TRUE)
suppressForeignCheck(names, package, add = TRUE)
```

## Arguments

|         |                                                                                                                                                                                                                                                                                                                         |
|---------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| names   | The character vector of object names. If omitted, the current list of global variables declared in the package will be returned, unchanged.                                                                                                                                                                             |
| package | The relevant package, usually the character string name of the package but optionally its corresponding namespace environment.<br><br>When the call to <code>globalVariables</code> or <code>suppressForeignCheck</code> comes in the package's source file, the argument is normally omitted, as in the example below. |
| add     | Should the contents of <code>names</code> be added to the current global variables or replace it?                                                                                                                                                                                                                       |

**Details**

The lists of declared global variables and native symbol objects are stored in a metadata object in the package's namespace, assuming the `globalVariables` or `suppressForeignCheck` call(s) occur as top-level calls in the package's source code.

The check command, as implemented in package `tools`, queries the list before checking the R source code in the package for possible problems.

`globalVariables` was introduced in R 2.15.1 and `suppressForeignCheck` was introduced in R 3.1.0 so both should be used conditionally: see the example.

**Value**

`globalVariables` returns the current list of declared global variables, possibly modified by this call.

`suppressForeignCheck` returns the current list of native symbol objects which are not to be checked.

**Note**

The global variables list really belongs to a restricted scope (a function or a group of method definitions, for example) rather than the package as a whole. However, implementing finer control would require changes in `check` and/or in `codetools`, so in this version the information is stored at the package level.

**Author(s)**

John Chambers and Duncan Murdoch

**See Also**

`dontCheck`.

**Examples**

```
Not run:
assume your package has some code that assigns ".obj1" and ".obj2"
but not in a way that codetools can find.
In the same source file (to remind you that you did it) add:
if(getRversion() >= "2.15.1") utils::globalVariables(c(".obj1", ".obj2"))

To suppress messages about a run-time calculated native symbol,
save it to a local variable.

At top level, put this:
if(getRversion() >= "3.1.0") utils::suppressForeignCheck("localvariable")

Within your function, do the call like this:
localvariable <- if (condition) entry1 else entry2
.Call(localvariable, 1, 2, 3)

HOWEVER, it is much better practice to write code
that can be checked thoroughly, e.g.
if(condition) .Call(entry1, 1, 2, 3) else .Call(entry2, 1, 2, 3)

End(Not run)
```

---

hasName*Check for Name*

---

### Description

hasName is a convenient way to test for one or more names in an R object.

### Usage

```
hasName(x, name)
```

### Arguments

|      |                                           |
|------|-------------------------------------------|
| x    | Any object.                               |
| name | One or more character values to look for. |

### Details

hasName(x, name) is defined to be equivalent to name %in% names(x), though it will evaluate slightly more quickly. It is intended to replace the common idiom !is.null(x\$name). The latter can be unreliable due to partial name matching; see the example below.

### Value

A logical vector of the same length as name containing TRUE if the corresponding entry is in names(x).

### See Also

`%in%, exists`

### Examples

```
x <- list(abc = 1, def = 2)
!is.null(x$abc) # correct
!is.null(x$a) # this is the wrong test!
hasName(x, "abc")
hasName(x, "a")
```

---

head*Return the First or Last Parts of an Object*

---

### Description

Returns the first or last parts of a vector, matrix, table, data frame or function. Since head() and tail() are generic functions, they may also have been extended to other classes.

**Usage**

```

head(x, ...)
Default S3 method:
head(x, n = 6L, ...)

S3 method for class 'matrix'
head(x, n = 6L, ...) # is exported as head.matrix()
NB: The methods for 'data.frame' and 'array' are identical to the 'matrix' one

S3 method for class 'ftable'
head(x, n = 6L, ...)
S3 method for class 'function'
head(x, n = 6L, ...)

tail(x, ...)
Default S3 method:
tail(x, n = 6L, keepnums = FALSE, addrownums, ...)
S3 method for class 'matrix'
tail(x, n = 6L, keepnums = TRUE, addrownums, ...) # exported as tail.matrix()
NB: The methods for 'data.frame', 'array', and 'table'
are identical to the 'matrix' one

S3 method for class 'ftable'
tail(x, n = 6L, keepnums = FALSE, addrownums, ...)
S3 method for class 'function'
tail(x, n = 6L, ...)

```

**Arguments**

|                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>          | an object                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>n</code>          | an integer vector of length up to <code>dim(x)</code> (or 1, for non-dimensioned objects). Values specify the indices to be selected in the corresponding dimension (or along the length) of the object. A positive value of <code>n[i]</code> includes the first/last <code>n[i]</code> indices in that dimension, while a negative value excludes the last/first <code>abs(n[i])</code> , including all remaining indices. NA or non-specified values (when <code>length(n) &lt; length(dim(x))</code> ) select all indices in that dimension. Must contain at least one non-missing value. |
| <code>keepnums</code>   | in each dimension, if no names in that dimension are present, create them using the indices included in that dimension. Ignored if <code>dim(x)</code> is NULL or its length 1.                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>addrownums</code> | deprecated - <code>keepnums</code> should be used instead. Taken as the value of <code>keepnums</code> if it is explicitly set when <code>keepnums</code> is not.                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>...</code>        | arguments to be passed to or from other methods.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

**Details**

For vector/array based objects, `head()` (`tail()`) returns a subset of the same dimensionality as `x`, usually of the same class. For historical reasons, by default they select the first (last) 6 indices in the first dimension ("rows") or along the length of a non-dimensioned vector, and the full extent (all indices) in any remaining dimensions. `head.matrix()` and `tail.matrix()` are exported.

The default and array(/matrix) methods for `head()` and `tail()` are quite general. They will work as is for any class which has a `dim()` method, a `length()` method (only required if `dim()` returns `NULL`), and a `[]` method (that accepts the `drop` argument and can subset in all dimensions in the dimensioned case).

For functions, the lines of the deparsed function are returned as character strings.

When `x` is an array(/matrix) of dimensionality two and more, `tail()` will add `dimnames` similar to how they would appear in a full printing of `x` for all dimensions `k` where `n[k]` is specified and non-missing and `dimnames(x)[[k]]` (or `dimnames(x)` itself) is `NULL`. Specifically, the form of the added `dimnames` will vary for different dimensions as follows:

`k=1 (rows):` " `[n, ]` " (right justified with whitespace padding)

`k=2 (columns):` " `[, n]` " (with *no* whitespace padding)

`k>2 (higher dims):` "n", i.e., the indices as *character* values

Setting `keepnums = FALSE` suppresses this behaviour.

As `data.frame` subsetting ('indexing') keeps `attributes`, so do the `head()` and `tail()` methods for data frames.

### Value

An object (usually) like `x` but generally smaller. Hence, for `arrays`, the result corresponds to `x[. . , drop=FALSE]`. For `ftable` objects `x`, a transformed `format(x)`.

### Note

For array inputs the output of `tail` when `keepnums` is `TRUE`, any `dimnames` vectors added for dimensions `>2` are the original numeric indices in that dimension *as character vectors*. This means that, e.g., for 3-dimensional array `arr`, `tail(arr, c(2, 2, -1))[, , 2]` and `tail(arr, c(2, 2, -1))[, , "2"]` may both be valid but have completely different meanings.

### Author(s)

Patrick Burns, improved and corrected by R-Core. Negative argument added by Vincent Goulet. Multi-dimension support added by Gabriel Becker.

### Examples

```
head(letters)
head(letters, n = -6L)

head(freeny.x, n = 10L)
head(freeny.y)

head(iris3)
head(iris3, c(6L, 2L))
head(iris3, c(6L, -1L, 2L))

tail(letters)
tail(letters, n = -6L)

tail(freeny.x)
the bottom-right "corner" :
tail(freeny.x, n = c(4, 2))
tail(freeny.y)
```

```

tail(iris3)
tail(iris3, c(6L, 2L))
tail(iris3, c(6L, -1L, 2L))

iris with dimnames stripped
a3d <- iris3 ; dimnames(a3d) <- NULL
tail(a3d, c(6, -1, 2)) # keepnums = TRUE is default here!
tail(a3d, c(6, -1, 2), keepnums = FALSE)

data frame w/ a (non-standard) attribute:
treeS <- structure(trees, foo = "bar")
(n <- nrow(treeS))
stopifnot(exprs = { # attribute is kept
 identical(htS <- head(treeS), treeS[1:6,])
 identical(attr(htS, "foo"), "bar")
 identical(tlS <- tail(treeS), treeS[(n-5):n,])
 ## BUT if I use "useAttrib(.)", this is *not* ok, when n is of length 2:
 ## --- because [i,j]-indexing of data frames *also* drops "other" attributes ..
 identical(tail(treeS, 3:2), treeS[(n-2):n, 2:3])
})

tail(library) # last lines of function

head(stats::ftable(Titanic))

1d-array (with named dim) :
a1 <- array(1:7, 7); names(dim(a1)) <- "O2"
stopifnot(exprs = {
 identical(tail(a1, 10), a1)
 identical(head(a1, 10), a1)
 identical(head(a1, 1), a1 [1 , drop=FALSE]) # was a1[1] in R <= 3.6.x
 identical(tail(a1, 2), a1[6:7])
 identical(tail(a1, 1), a1 [7 , drop=FALSE]) # was a1[7] in R <= 3.6.x
})

```

help

Documentation

---

## Description

help is the primary interface to the help systems.

## Usage

```

help(topic, package = NULL, lib.loc = NULL,
 verbose = getOption("verbose"),
 try.all.packages = getOption("help.try.all.packages"),
 help_type = getOption("help_type"))

```

## Arguments

|       |                                                                                                                                                                                                         |
|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| topic | usually, a <a href="#">name</a> or character string specifying the topic for which help is sought. A character string (enclosed in explicit single or double quotes) is always taken as naming a topic. |
|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

|                               |                                                                                                                                                                                                                                                                                                                           |
|-------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                               | <p>If the value of <code>topic</code> is a length-one character vector the topic is taken to be the value of the only element. Otherwise <code>topic</code> must be a name or a <a href="#">reserved</a> word (if syntactically valid) or character string.</p> <p>See ‘Details’ for what happens if this is omitted.</p> |
| <code>package</code>          | a name or character vector giving the packages to look into for documentation, or <code>NULL</code> . By default, all packages whose namespaces are loaded are used. To avoid a name being deparsed use e.g. <code>(pkg_ref)</code> (see the examples).                                                                   |
| <code>lib.loc</code>          | a character vector of directory names of R libraries, or <code>NULL</code> . The default value of <code>NULL</code> corresponds to all libraries currently known. If the default is used, the loaded packages are searched before the libraries. This is not used for HTML help (see ‘Details’).                          |
| <code>verbose</code>          | logical; if <code>TRUE</code> , the file name is reported.                                                                                                                                                                                                                                                                |
| <code>try.all.packages</code> | logical; see Note.                                                                                                                                                                                                                                                                                                        |
| <code>help_type</code>        | character string: the type of help required. Possible values are <code>"text"</code> , <code>"html"</code> and <code>"pdf"</code> . Case is ignored, and partial matching is allowed.                                                                                                                                     |

## Details

The following types of help are available:

- Plain text help
- HTML help pages with hyperlinks to other topics, shown in a browser by [browseURL](#). (On Unix-alikes, where possible an existing browser window is re-used: the macOS GUI uses its own browser window.)  
If for some reason HTML help is unavailable (see [startDynamicHelp](#)), plain text help will be used instead.
- For help only, typeset as PDF – see the section on ‘Offline help’.

**On Unix-alikes:** The ‘factory-fresh’ default is text help except from the macOS GUI, which uses HTML help displayed in its own browser window.

**On Windows:** The default for the type of help is selected when R is installed – the ‘factory-fresh’ default is HTML help.

The rendering of text help will use directional quotes in suitable locales (UTF-8 and single-byte Windows locales): sometimes the fonts used do not support these quotes so this can be turned off by setting [options](#) (`useFancyQuotes = FALSE`).

`topic` is not optional: if it is omitted R will give

- If a package is specified, (text or, in interactive use only, HTML) information on the package, including hints/links to suitable help topics.
- If `lib.loc` only is specified, a (text) list of available packages.
- Help on help itself if none of the first three arguments is specified.

Some topics need to be quoted (by [backticks](#)) or given as a character string. These include those which cannot syntactically appear on their own such as unary and binary operators, `function` and control-flow [reserved](#) words (including `if`, `else`, `for`, `in`, `repeat`, `while`, `break` and `next`). The other reserved words can be used as if they were names, for example `TRUE`, `NA` and `Inf`.

If multiple help files matching `topic` are found, in interactive use a menu is presented for the user to choose one: in batch use the first on the search path is used. (For HTML help the menu will be

an HTML page, otherwise a graphical menu if possible if `getOption("menu.graphics")` is true, the default.)

Note that HTML help does not make use of `lib.loc`: it will always look first in the loaded packages and then along `.libPaths()`.

### Offline help

Typeset documentation is produced by running the LaTeX version of the help page through `pdflatex`: this will produce a PDF file.

The appearance of the output can be customized through a file ‘`Rhelp.cfg`’ somewhere in your LaTeX search path: this will be input as a LaTeX style file after `Rd.sty`. Some [environment variables](#) are consulted, notably `R_PAPERSIZE` (via `getOption("papersize")`) and `R_RD4PDF` (see ‘Making manuals’ in the ‘R Installation and Administration’ manual).

If there is a function `offline_help_helper` in the workspace or further down the search path it is used to do the typesetting, otherwise the function of that name in the `utils` namespace (to which the first paragraph applies). It should accept at least two arguments, the name of the LaTeX file to be typeset and the type (which is nowadays ignored). It accepts a third argument, `texinputs`, which will give the graphics path when the help document contains figures, and will otherwise not be supplied.

### Note

Unless `lib.loc` is specified explicitly, the loaded packages are searched before those in the specified libraries. This ensures that if a library is loaded from a library not in the known library trees, then the help from the loaded library is used. If `lib.loc` is specified explicitly, the loaded packages are *not* searched.

If this search fails and argument `try.all.packages` is TRUE and neither packages nor `lib.loc` is specified, then all the packages in the known library trees are searched for help on `topic` and a list of (any) packages where help may be found is displayed (with hyperlinks for `help_type = "html"`). **NB:** searching all packages can be slow, especially the first time (caching of files by the OS can expedite subsequent searches dramatically).

### See Also

[?](#) for shortcuts to help topics.

[help.search\(\)](#) or [??](#) for finding help pages on a vague topic; [help.start\(\)](#) which opens the HTML version of the R help pages; [library\(\)](#) for listing available packages and the help objects they contain; [data\(\)](#) for listing available data sets; [methods\(\)](#).

Use [prompt\(\)](#) to get a prototype for writing help pages of your own package.

### Examples

```
help()
help(help) # the same

help(lapply)
```

```

help("for") # or ?"for", but quotes/backticks are needed

try({# requires working TeX installation:
 help(dgamma, help_type = "pdf")
 ## -> nicely formatted pdf -- including math formula -- for help(dgamma):
 system2(getOption("pdfviewer"), "dgamma.pdf", wait = FALSE)
})

help(package = "splines") # get help even when package is not loaded

topi <- "women"
help(topi)

try(help("bs", try.all.packages = FALSE)) # reports not found (an error)
help("bs", try.all.packages = TRUE) # reports can be found
 # in package 'splines'

For programmatic use:
topic <- "family"; pkg_ref <- "stats"
help((topic), (pkg_ref))

```

|--------------|------------------------------|
| help.request | <i>Send a Post to R-help</i> |
|--------------|------------------------------|

---

## Description

Prompts the user to check they have done all that is expected of them before sending a post to the R-help mailing list, provides a template for the post with session information included and optionally sends the email (on Unix systems).

## Usage

```

help.request(subject = "",
 address = "r-help@R-project.org",
 file = "R.help.request", ...)

```

## Arguments

|         |                                                                                                                             |
|---------|-----------------------------------------------------------------------------------------------------------------------------|
| subject | subject of the email. Please do not use single quotes (') in the subject! Post separate help requests for multiple queries. |
| address | recipient's email address.                                                                                                  |
| file    | filename to use (if needed) for setting up the email.                                                                       |
| ...     | additional named arguments such as method and ccaddress to pass to <a href="#">create.post</a> .                            |

## Details

This function is not intended to replace the posting guide. Please read the guide before posting to R-help or using this function (see <https://www.r-project.org/posting-guide.html>).

The `help.request` function:

- asks whether the user has consulted relevant resources, stopping and opening the relevant URL if a negative response if given.

- checks whether the current version of R is being used and whether the add-on packages are up-to-date, giving the option of updating where necessary.
- asks whether the user has prepared appropriate (minimal, reproducible, self-contained, commented) example code ready to paste into the post.

Once this checklist has been completed a template post is prepared including current session information, and passed to `create.post`.

### Value

Nothing useful.

### Author(s)

Heather Turner, based on the then current code and help page of `bug.report()`.

### See Also

The posting guide (<https://www.r-project.org/posting-guide.html>), also `sessionInfo()` from which you may add to the help request.

`create.post`.

---

help.search

*Search the Help System*

---

### Description

Allows for searching the help system for documentation matching a given character string in the (file) name, alias, title, concept or keyword entries (or any combination thereof), using either [fuzzy matching](#) or [regular expression](#) matching. Names and titles of the matched help entries are displayed nicely formatted.

Vignette names, titles and keywords and demo names and titles may also be searched.

### Usage

```
help.search(pattern, fields = c("alias", "concept", "title"),
 apropos, keyword, whatis, ignore.case = TRUE,
 package = NULL, lib.loc = NULL,
 help.db = getOption("help.db"),
 verbose = getOption("verbose"),
 rebuild = FALSE, agrep = NULL, use_UTF8 = FALSE,
 types = getOption("help.search.types"))
??pattern
field??pattern
```

**Arguments**

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| pattern     | a character string to be matched in the specified fields. If this is given, the arguments <code>apropos</code> , <code>keyword</code> , and <code>what is</code> are ignored.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| fields      | a character vector specifying the fields of the help database to be searched. The entries must be abbreviations of "name", "title", "alias", "concept", and "keyword", corresponding to the help page's (file) name, its title, the topics and concepts it provides documentation for, and the keywords it can be classified to. See below for details and how vignettes and demos are searched.                                                                                                                                                                                                                                                                     |
| apropos     | a character string to be matched in the help page topics and title.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| keyword     | a character string to be matched in the help page 'keywords'. 'Keywords' are really categories: the standard categories are listed in file <code>'R.home("doc")/KEYWORDS'</code> (see also the example) and some package writers have defined their own. If <code>keyword</code> is specified, <code>agrep</code> defaults to <code>FALSE</code> .                                                                                                                                                                                                                                                                                                                   |
| what is     | a character string to be matched in the help page topics.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| ignore.case | a logical. If <code>TRUE</code> , case is ignored during matching; if <code>FALSE</code> , pattern matching is case sensitive.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| package     | a character vector with the names of packages to search through, or <code>NULL</code> in which case <i>all</i> available packages in the library trees specified by <code>lib.loc</code> are searched.                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| lib.loc     | a character vector describing the location of R library trees to search through, or <code>NULL</code> . The default value of <code>NULL</code> corresponds to all libraries currently known.                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| help.db     | a character string giving the file path to a previously built and saved help database, or <code>NULL</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| verbose     | logical; if <code>TRUE</code> , the search process is traced. Integer values are also accepted, with <code>TRUE</code> being equivalent to 2, and 1 being less verbose. On Windows a progress bar is shown during rebuilding, and on Unix a heartbeat is shown for <code>verbose = 1</code> and a package-by-package list for <code>verbose &gt;= 2</code> .                                                                                                                                                                                                                                                                                                         |
| rebuild     | a logical indicating whether the help database should be rebuilt. This will be done automatically if <code>lib.loc</code> or the search path is changed, or if <code>package</code> is used and a value is not found.                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| agrep       | if <code>NULL</code> (the default unless <code>keyword</code> is used) and the character string to be matched consists of alphanumeric characters, whitespace or a dash only, approximate (fuzzy) matching via <a href="#">agrep</a> is used unless the string has fewer than 5 characters; otherwise, it is taken to contain a <a href="#">regular expression</a> to be matched via <a href="#">grep</a> . If <code>FALSE</code> , approximate matching is not used. Otherwise, one can give a numeric or a list specifying the maximal distance for the approximate match, see argument <code>max.distance</code> in the documentation for <a href="#">agrep</a> . |
| use_UTF8    | logical: should results be given in UTF-8 encoding? Also changes the meaning of regexps in <code>agrep</code> to be Perl regexps.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| types       | a character vector listing the types of documentation to search. The entries must be abbreviations of "vignette" "help" or "demo". Results will be presented in the order specified.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| field       | a single value of <code>fields</code> to search.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

## Details

Upon installation of a package, a pre-built help.search index is serialized as 'hsearch.rds' in the 'Meta' directory (provided the package has any help pages). Vignettes are also indexed in the 'Meta/vignette.rds' file. These files are used to create the help search database via [hsearch\\_db](#).

The arguments `apropos` and `whatIs` play a role similar to the Unix commands with the same names.

Searching with `agrep = FALSE` will be several times faster than the default (once the database is built). However, approximate searches should be fast enough (around a second with 5000 packages installed).

If possible, the help database is saved in memory for use by subsequent calls in the session.

Note that currently the aliases in the matching help files are not displayed.

As with `?`, in `??` the pattern may be prefixed with a package name followed by `::` or `:::` to limit the search to that package.

For help files, '`\keyword`' entries which are not among the standard keywords as listed in file '`KEYWORDS`' in the R documentation directory are taken as concepts. For standard keyword entries different from '`internal`', the corresponding descriptions from file '`KEYWORDS`' are additionally taken as concepts. All '`\concept`' entries used as concepts.

Vignettes are searched as follows. The "`name`" and "`alias`" are both the base of the vignette filename, and the "`concept`" entries are taken from the `\VignetteKeyword` entries. Vignettes are not classified using the help system "`keyword`" classifications. Demos are handled similarly to vignettes, without the "`concept`" search.

## Value

The results are returned in a list object of class "`hsearch`", which has a print method for nicely formatting the results of the query. This mechanism is experimental, and may change in future versions of R.

In R.app on macOS, this will show up a browser with selectable items. On exiting this browser, the help pages for the selected items will be shown in separate help windows.

The internal format of the class is undocumented and subject to change.

## See Also

[hsearch\\_db](#) for more information on the help search database employed, and for utilities to inspect available concepts and keywords.

[help](#); [help.start](#) for starting the hypertext (currently HTML) version of R's online documentation, which offers a similar search mechanism.

[RSiteSearch](#) to access an on-line search of R resources.

[apropos](#) uses regexps and has nice examples.

## Examples

```
help.search("linear models") # In case you forgot how to fit linear
 # models
help.search("non-existent topic")

??utils::help # All the topics matching "help" in the utils package
```

```

help.search("print") # All help pages with topics or title
 # matching 'print'
help.search(apropos = "print") # The same

help.search(keyword = "hplot") # All help pages documenting high-level
 # plots.
file.show(file.path(R.home("doc"), "KEYWORDS")) # show all keywords

Help pages with documented topics starting with 'try'.
help.search("\\btry", fields = "alias")

```

---

## Description

Start the hypertext (currently HTML) version of R's online documentation.

## Usage

```

help.start(update = FALSE, gui = "irrelevant",
 browser = getOption("browser"), remote = NULL)

```

## Arguments

|         |                                                                                                                                                                                                                                                                                                       |
|---------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| update  | logical: should this attempt to update the package index to reflect the currently available packages. (Not attempted if remote is non-NULL.)                                                                                                                                                          |
| gui     | just for compatibility with S-PLUS.                                                                                                                                                                                                                                                                   |
| browser | the name of the program to be used as hypertext browser. It should be in the PATH, or a full path specified. Alternatively, it can be an R function which will be called with a URL as its only argument. This option is normally unset on Windows, when the file-association mechanism will be used. |
| remote  | A character string giving a valid URL for the ' <a href="#">R_HOME</a> ' directory on a remote location.                                                                                                                                                                                              |

## Details

Unless remote is specified this requires the HTTP server to be available (it will be started if possible: see [startDynamicHelp](#)).

One of the links on the index page is the HTML package index, '[R.home\("docs"\)/html/packages.html](#)', which can be remade by [make.packages.html\(\)](#). For local operation, the HTTP server will remake a temporary version of this list when the link is first clicked, and each time thereafter check if updating is needed (if [.libPaths](#) has changed or any of the directories has been changed). This can be slow, and using update = TRUE will ensure that the packages list is updated before launching the index page.

Argument remote can be used to point to HTML help published by another R installation: it will typically only show packages from the main library of that installation.

**See Also**

[help\(\)](#) for on- and off-line help in other formats.  
[browseURL](#) for how the help file is displayed.  
[RSiteSearch](#) to access an on-line search of R resources.

**Examples**

```
help.start()
Not run:
if(.Platform$OS.type == "unix") # includes Mac
 ## the 'remote' arg can be tested by
 help.start(remote = paste0("file://", R.home()))

End(Not run)
```

hsearch-utils

*Help Search Utilities***Description**

Utilities for searching the help system.

**Usage**

```
hsearch_db(package = NULL, lib.loc = NULL,
 types = getOption("help.search.types"),
 verbose = getOption("verbose"),
 rebuild = FALSE, use_UTF8 = FALSE)
hsearch_db_concepts(db = hsearch_db())
hsearch_db_keywords(db = hsearch_db())
```

**Arguments**

|          |                                                                                                                                                                                                        |
|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| package  | a character vector with the names of packages to search through, or <code>NULL</code> in which case <i>all</i> available packages in the library trees specified by <code>lib.loc</code> are searched. |
| lib.loc  | a character vector describing the location of R library trees to search through, or <code>NULL</code> . The default value of <code>NULL</code> corresponds to all libraries currently known.           |
| types    | a character vector listing the types of documentation to search. See <a href="#">help.search</a> for details.                                                                                          |
| verbose  | a logical controlling the verbosity of building the help search database. See <a href="#">help.search</a> for details.                                                                                 |
| rebuild  | a logical indicating whether the help search database should be rebuilt. See <a href="#">help.search</a> for details.                                                                                  |
| use_UTF8 | logical: should results be given in UTF-8 encoding?                                                                                                                                                    |
| db       | a help search database as obtained by calls to <code>hsearch_db()</code> .                                                                                                                             |

## Details

`hsearch_db()` builds and caches the help search database for subsequent use by [help.search](#). (In fact, re-builds only when forced (`rebuild = TRUE`) or “necessary”.)

The format of the help search database is still experimental, and may change in future versions. Currently, it consists of four tables: one with base information about all documentation objects found, including their names and titles and unique ids; three more tables contain the individual aliases, concepts and keywords together with the ids of the documentation objects they belong to. Separating out the latter three tables accounts for the fact that a single documentation object may provide several of these entries, and allows for efficient searching.

See the details in [help.search](#) for how searchable entries are interpreted according to help type.

`hsearch_db_concepts()` and `hsearch_db_keywords()` extract all concepts or keywords, respectively, from a help search database, and return these in a data frame together with their total frequencies and the numbers of packages they are used in, with entries sorted in decreasing total frequency.

## Examples

```
db <- hsearch_db()
Total numbers of documentation objects, aliases, keywords and
concepts (using the current format):
sapply(db, NROW)
Can also be obtained from print method:
db
10 most frequent concepts:
head(hsearch_db_concepts(), 10)
10 most frequent keywords:
head(hsearch_db_keywords(), 10)
```

---

 INSTALL

*Install Add-on Packages*

---

## Description

Utility for installing add-on packages.

## Usage

```
R CMD INSTALL [options] [-l lib] pkgs
```

## Arguments

|                      |                                                                                                                                                                                                      |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>pkgs</code>    | a space-separated list with the path names of the packages to be installed. See ‘Details’.                                                                                                           |
| <code>lib</code>     | the path name of the R library tree to install to. Also accepted in the form ‘ <code>--library=lib</code> ’. Paths including spaces should be quoted, using the conventions for the shell in use.    |
| <code>options</code> | a space-separated list of options through which in particular the process for building the help files can be controlled. Use <code>R CMD INSTALL --help</code> for the full current list of options. |

## Details

This will stop at the first error, so if you want all the `pkgs` to be tried, call this via a shell loop.

If used as `R CMD INSTALL pkgs` without explicitly specifying `lib`, packages are installed into the library tree rooted at the first directory in the library path which would be used by R run in the current environment.

To install into the library tree `lib`, use `R CMD INSTALL -l lib pkgs`. This prepends `lib` to the library path for duration of the install, so required packages in the installation directory will be found (and used in preference to those in other libraries).

Both `lib` and the elements of `pkgs` may be absolute or relative path names of directories. `pkgs` may also contain names of package archive files: these are then extracted to a temporary directory. These are tarballs containing a single directory, optionally compressed by `gzip`, `bzip2`, `xz` or `compress`. Finally, binary package archive files (as created by `R CMD INSTALL --build`) can be supplied.

Tarballs are by default unpackaged by the internal `untar` function: if needed an external `tar` command can be specified by the environment variable `R_INSTALL_TAR`: please ensure that it can handle the type of compression used on the tarball. (This is sometimes needed for tarballs containing invalid or unsupported sections, and can be faster on very large tarballs. Setting `R_INSTALL_TAR` to `'tar.exe'` has been needed to overcome permissions issues on some Windows systems.)

The package sources can be cleaned up prior to installation by `'--preclean'` or after by `'--clean'`: cleaning is essential if the sources are to be used with more than one architecture or platform.

Some package sources contain a `'configure'` script that can be passed arguments or variables via the option `'--configure-args'` and `'--configure-vars'`, respectively, if necessary. The latter is useful in particular if libraries or header files needed for the package are in non-system directories. In this case, one can use the configure variables `LIBS` and `CPPFLAGS` to specify these locations (and set these via `'--configure-vars'`), see section “Configuration variables” in “R Installation and Administration” for more information. (If these are used more than once on the command line they are concatenated.) The configure mechanism can be bypassed using the option `'--no-configure'`.

If the attempt to install the package fails, leftovers are removed. If the package was already installed, the old version is restored. This happens either if a command encounters an error or if the install is interrupted from the keyboard: after cleaning up the script terminates.

For details of the locking which is done, see the section ‘Locking’ in the help for [install.packages](#).

Option `'--build'` can be used to tar up the installed package for distribution as a binary package (as used on macOS). This is done by `utils::tar` unless environment variable `R_INSTALL_TAR` is set.

By default a package is installed with static HTML help pages if and only if R was: use options `'--html'` and `'--no-html'` to override this.

Packages are not by default installed keeping the source formatting (see the `keep.source` argument to [source](#)): this can be enabled by the option `'--with-keep.source'` or by setting environment variable `R_KEEP_PKG_SOURCE` to `yes`.

Specifying the `'--install-tests'` option copies the contents of the `'tests'` directory into the package installation. If the `R_ALWAYS_INSTALL_TESTS` environment variable is set to a true value, the tests will be installed even if `'--install-tests'` is omitted.

Use `R CMD INSTALL --help` for concise usage information, including all the available options.

## Sub-architectures

An R installation can support more than one sub-architecture: currently this is most commonly used for 32- and 64-bit builds on Windows.

For such installations, the default behaviour is to try to install source packages for all installed sub-architectures unless the package has a configure script or a 'src/Makefile' (or 'src/Makefile.win' on Windows), when only compiled code for the sub-architecture running R CMD INSTALL is installed.

To install a source package with compiled code only for the sub-architecture used by R CMD INSTALL, use '--no-multiarch'. To install just the compiled code for another sub-architecture, use '--libs-only'.

There are two ways to install for all available sub-architectures. If the configure script is known to work for both Windows architectures, use flag '--force-biarch' (and packages can specify this *via* a 'Biarch: yes' field in their DESCRIPTION files). Second, a single tarball can be installed with

```
R CMD INSTALL --merge-multiarch mypkg_version.tar.gz
```

## Staged installation

The default way to install source packages changed in R 3.6.0, so packages are first installed to a temporary location and then (if successful) moved to the destination library directory. Some older packages were written in ways that assume direct installation to the destination library.

Staged installation can currently be overridden by having a line 'StagedInstall: no' in the package's 'DESCRIPTION' file, *via* flag '--no-staged-install' or by setting environment variable R\_INSTALL\_STAGED to a false value (e.g. 'false' or 'no').

Staged installation requires either '--pkglock' or '--lock', one of which is used by default.

## Note

The options do not have to precede 'pkgs' on the command line, although it will be more legible if they do. All the options are processed before any packages, and where options have conflicting effects the last one will win.

Some parts of the operation of INSTALL depend on the R temporary directory (see [tempdir](#), usually under '/tmp') having both write and execution access to the account running R. This is usually the case, but if '/tmp' has been mounted as `noexec`, environment variable TMPDIR may need to be set to a directory from which execution is allowed.

---

install.packages     *Install Packages from Repositories or Local Files*

---

## Description

Download and install packages from CRAN-like repositories or from local files.

## Usage

```
install.packages(pkgs, lib, repos = getOption("repos"),
 contriburl = contrib.url(repos, type),
 method, available = NULL, destdir = NULL,
 dependencies = NA, type = getOption("pkgType"),
 configure.args = getOption("configure.args"),
 configure.vars = getOption("configure.vars"),
 clean = FALSE, Ncpus = getOption("Ncpus", 1L),
 verbose = getOption("verbose"),
 libs_only = FALSE, INSTALL_opts, quiet = FALSE,
 keep_outputs = FALSE, ...)
```

## Arguments

|            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| pkgs       | <p>character vector of the names of packages whose current versions should be downloaded from the repositories.</p> <p>If <code>repos = NULL</code>, a character vector of file paths,</p> <p><b>on windows</b>, file paths of ‘.zip’ files containing binary builds of packages. (<code>http://</code> and <code>file://</code> URLs are also accepted and the files will be downloaded and installed from local copies.) Source directories or file paths or URLs of archives may be specified with <code>type = "source"</code>, but some packages need suitable tools installed (see the ‘Details’ section).</p> <p><b>On Unix-alikes</b>, these file paths can be source directories or archives or binary package archive files (as created by <code>R CMD build --binary</code>). (<code>http://</code> and <code>file://</code> URLs are also accepted and the files will be downloaded and installed from local copies.) On a CRAN build of R for macOS these can be ‘.tgz’ files containing binary package archives. Tilde-expansion will be done on file paths.</p> <p>If this is missing, a listbox of available packages is presented where possible in an interactive R session.</p> |
| lib        | <p>character vector giving the library directories where to install the packages. Recycled as needed. If missing, defaults to the first element of <code>.libPaths()</code>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| repos      | <p>character vector, the base URL(s) of the repositories to use, e.g., the URL of a CRAN mirror such as <code>"https://cloud.r-project.org"</code>. For more details on supported URL schemes see <a href="#">url</a>.</p> <p>Can be <code>NULL</code> to install from local files, directories or URLs: this will be inferred by extension from <code>pkgs</code> if of length one.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| contriburl | <p>URL(s) of the contrib sections of the repositories. Use this argument if your repository mirror is incomplete, e.g., because you burned only the ‘contrib’ section on a CD, or only have binary packages. Overrides argument <code>repos</code>. Incompatible with <code>type = "both"</code>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| method         | download method, see <a href="#">download.file</a> . Unused if a non-NULL available is supplied.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| available      | a matrix as returned by <a href="#">available.packages</a> listing packages available at the repositories, or NULL when the function makes an internal call to <a href="#">available.packages</a> . Incompatible with <code>type = "both"</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| destdir        | directory where downloaded packages are stored. If it is NULL (the default) a subdirectory <code>downloaded_packages</code> of the session temporary directory will be used (and the files will be deleted at the end of the session).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| dependencies   | logical indicating whether to also install uninstalled packages which these packages depend on/link to/import/suggest (and so on recursively). Not used if <code>repos = NULL</code> . Can also be a character vector, a subset of <code>c("Depends", "Imports", "LinkingTo", "Suggests", "Enhances")</code> . Only supported if <code>lib</code> is of length one (or missing), so it is unambiguous where to install the dependent packages. If this is not the case it is ignored, with a warning.<br>The default, NA, means <code>c("Depends", "Imports", "LinkingTo")</code> .<br>TRUE means to use <code>c("Depends", "Imports", "LinkingTo", "Suggests")</code> for <code>pkgs</code> and <code>c("Depends", "Imports", "LinkingTo")</code> for added dependencies: this installs all the packages needed to run <code>pkgs</code> , their examples, tests and vignettes (if the package author specified them correctly).<br>In all of these, "LinkingTo" is omitted for binary packages. |
| type           | character, indicating the type of package to download and install. Will be "source" except on Windows and some macOS builds: see the section on 'Binary packages' for those.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| configure.args | (Used only for source installs.) A character vector or a named list. If a character vector with no names is supplied, the elements are concatenated into a single string (separated by a space) and used as the value for the ' <code>--configure-args</code> ' flag in the call to <code>R CMD INSTALL</code> . If the character vector has names these are assumed to identify values for ' <code>--configure-args</code> ' for individual packages. This allows one to specify settings for an entire collection of packages which will be used if any of those packages are to be installed. (These settings can therefore be re-used and act as default settings.)<br>A named list can be used also to the same effect, and that allows multi-element character strings for each package which are concatenated to a single string to be used as the value for ' <code>--configure-args</code> '.                                                                                            |
| configure.vars | (Used only for source installs.) Analogous to <code>configure.args</code> for flag ' <code>--configure-vars</code> ', which is used to set environment variables for the <code>configure</code> run.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| clean          | a logical value indicating whether to add the ' <code>--clean</code> ' flag to the call to <code>R CMD INSTALL</code> . This is sometimes used to perform additional operations at the end of the package installation in addition to removing intermediate files.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Ncpus          | the number of parallel processes to use for a parallel install of more than one source package. Values greater than one are supported if the <code>make</code> command specified by <code>Sys.getenv("MAKE", "make")</code> accepts argument <code>-k -j Ncpus</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| verbose        | a logical indicating if some "progress report" should be given.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

|                           |                                                                                                                                                                                                                                                                                                                                |
|---------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>libs_only</code>    | a logical value: should the ‘ <code>--libs-only</code> ’ option be used to install only additional sub-architectures for source installs? (See also <code>INSTALL_opts</code> .) This can also be used on Windows to install just the DLL(s) from a binary package, e.g. to add 64-bit DLLs to a 32-bit install.               |
| <code>INSTALL_opts</code> | an optional character vector of additional option(s) to be passed to <code>R CMD INSTALL</code> for a source package install. E.g., <code>c("--html", "--no-multiarch", "--no-test-load")</code> .<br>Can also be a named list of character vectors to be used as additional options, with names the respective package names. |
| <code>quiet</code>        | logical: if true, reduce the amount of output. This is <i>not</i> passed to <code>available.packages()</code> in case that is called, on purpose.                                                                                                                                                                              |
| <code>keep_outputs</code> | a logical: if true, keep the outputs from installing source packages in the current working directory, with the names of the output files the package names with ‘.out’ appended. Alternatively, a character string giving the directory in which to save the outputs. Ignored when installing from local files.               |
| <code>...</code>          | Arguments to be passed to <code>download.file</code> , <code>available.packages</code> , or to the functions for binary installs on macOS and Windows (which accept an argument <code>"lock"</code> : see the section on ‘Locking’).                                                                                           |

## Details

This is the main function to install packages. It takes a vector of names and a destination library, downloads the packages from the repositories and installs them. (If the library is omitted it defaults to the first directory in `.libPaths()`, with a message if there is more than one.) If `lib` is omitted or is of length one and is not a (group) writable directory, in interactive use the code offers to create a personal library tree (the first element of `Sys.getenv("R_LIBS_USER")`) and install there.

Detection of a writable directory is problematic on Windows: see the ‘Note’ section.

For installs from a repository an attempt is made to install the packages in an order that respects their dependencies. This does assume that all the entries in `lib` are on the default library path for installs (set by environment variable `R_LIBS`).

You are advised to run `update.packages` before `install.packages` to ensure that any already installed dependencies have their latest versions.

## Value

Invisible `NULL`.

## Binary packages

This section applies only to platforms where binary packages are available: Windows and CRAN builds for macOS.

R packages are primarily distributed as *source* packages, but *binary* packages (a packaging up of the installed package) are also supported, and the type most commonly used on Windows and by the CRAN builds for macOS. This function can install either type, either by downloading a file from a repository or from a local file.

Possible values of `type` are (currently) `"source"`, `"mac.binary"`, and `"win.binary"`: the appropriate binary type where supported can also be selected as `"binary"`.

For a binary install from a repository, the function checks for the availability of a source package on the same repository, and reports if the source package has a later version, or is available but no binary version is. This check can be suppressed by using

```
options(install.packages.check.source = "no")
```

and should be if there is a partial repository containing only binary files.

An alternative (and the current default) is "both" which means 'use binary if available and current, otherwise try source'. The action if there are source packages which are preferred but may contain code which needs to be compiled is controlled by `getOption("install.packages.compile.from.source")`. `type = "both"` will be silently changed to "binary" if either `contriburl` or `available` is specified.

Using packages with `type = "source"` always works provided the package contains no C/C++/Fortran code that needs compilation. Otherwise,

**on Windows** you will need to have installed the Rtools collection as described in the 'R for Windows FAQ' and you must have the `PATH` environment variable set up as required by Rtools.

For a 32/64-bit installation of R on Windows, a small minority of packages with compiled code need either `INSTALL_opts = "--force-biarch"` or `INSTALL_opts = "--merge-multiarch"` for a source installation. (It is safe to always set the latter when installing from a repository or tarballs, although it will be a little slower.)

When installing a package on Windows, `install.packages` will abort the install if it detects that the package is already installed and is currently in use. In some circumstances (e.g., multiple instances of R running at the same time and sharing a library) it will not detect a problem, but the installation may fail as Windows locks files in use.

**On Unix-alikes**, when the package contains C/C++/Fortran code that needs compilation, on macOS you need to have installed the 'Command-line tools for Xcode' (see the 'R Installation and Administration' manual) and if needed by the package a Fortran compiler, and have them in your path.

## Locking

There are various options for locking: these differ between source and binary installs.

By default for a source install, the library directory is 'locked' by creating a directory '00LOCK' within it. This has two purposes: it prevents any other process installing into that library concurrently, and is used to store any previous version of the package to restore on error. A finer-grained locking is provided by the option '`--pkglock`' which creates a separate lock for each package: this allows enough freedom for parallel installation. Per-package locking is the default when installing a single package, and for multiple packages when `Ncpus > 1L`. Finally locking (and restoration on error) can be suppressed by '`--no-lock`'.

For a macOS binary install, no locking is done by default. Setting argument `lock` to `TRUE` (it defaults to the value of `getOption("install.lock", FALSE)`) will use per-directory locking as described for source installs. For Windows binary install, per-directory locking is used by default (`lock` defaults to the value of `getOption("install.lock", TRUE)`). If the value is "pkglock" per-package locking will be used.

If package locking is used on Windows with `libs_only = TRUE` and the installation fails, the package will be restored to its previous state.

Note that it is possible for the package installation to fail so badly that the lock directory is not removed: this inhibits any further installs to the library directory (or for `--pkglock`, of the package) until the lock directory is removed manually.

## Parallel installs

Parallel installs are attempted if `pkgs` has length greater than one and `Ncpus > 1`. It makes use of a parallel make, so the make specified (default make) when R was built must be capable of

supporting `make -j n`: GNU `make`, `dmake` and `pmake` do, but Solaris `make` and older FreeBSD `make` do not: if necessary environment variable `MAKE` can be set for the current session to select a suitable `make`.

`install.packages` needs to be able to compute all the dependencies of `pkgs` from available, including if one element of `pkgs` depends indirectly on another. This means that if for example you are installing CRAN packages which depend on Bioconductor packages which in turn depend on CRAN packages, `available` needs to cover both CRAN and Bioconductor packages.

### Timeouts

A limit on the elapsed time for each call to R CMD `INSTALL` (so for source installs) can be set *via* environment variable `_R_INSTALL_PACKAGES_ELAPSED_TIMEOUT_`: in seconds (or in minutes or hours with optional suffix ‘m’ or ‘h’, suffix ‘s’ being allowed for the default seconds) with 0 meaning no limit.

For non-parallel installs this is implemented *via* the `timeout` argument of `system2`: for parallel installs *via* the OS’s `timeout` command. (The one tested is from GNU **coreutils**, commonly available on Linux but not other Unix-alikes. If no such command is available the timeout request is ignored, with a warning.) For parallel installs a ‘Error 124’ message from `make` indicates that timeout occurred.

Timeouts during installation might leave lock directories behind and not restore previous versions.

### Version requirements on source installs

If you are not running an up-to-date version of R you may see a message like

```
package 'RODBC' is not available (for R version 3.5.3)
```

One possibility is that the package is not available in any of the selected repositories; another is that it is available but only for current or recent versions of R. For CRAN packages take a look at the package’s CRAN page (e.g., <https://cran.r-project.org/package=RODBC>). If that indicates in the ‘Depends’ field a dependence on a later version of R you will need to look in the ‘Old sources’ section and select the URL of a version of comparable age to your R. Then you can supply that URL as the first argument of `install.packages()`: you may need to first manually install its dependencies.

For other repositories, using `available.packages(filters = "OS_type") [pkgname, ]` will show if the package is available for any R version (for your OS).

### Note

**On Unix-alikes:** Some binary distributions of R have `INSTALL` in a separate bundle, e.g. an R-devel RPM. `install.packages` will give an error if called with `type = "source"` on such a system.

Some binary Linux distributions of R can be installed on a machine without the tools needed to install packages: a possible remedy is to do a complete install of R which should bring in all those tools as dependencies.

**On Windows:** `install.packages` tries to detect if you have write permission on the library directories specified, but Windows reports unreliably. If there is only one library directory (the default), R tries to find out by creating a test directory, but even this need not be the whole story: you may have permission to write in a library directory but lack permission to write binary files (such as ‘.dll’ files) there. See the ‘R for Windows FAQ’ for workarounds.

**Examples**

```
Not run:
A Linux example for Fedora's layout of udunits2 headers.
install.packages(c("ncdf4", "RNetCDF"),
 configure.args = c(RNetCDF = "--with-netcdf-include=/usr/include/udunits2"))

End(Not run)
```

---

`installed.packages` *Find Installed Packages*

---

**Description**

Find (or retrieve) details of all packages installed in the specified libraries.

**Usage**

```
installed.packages(lib.loc = NULL, priority = NULL,
 noCache = FALSE, fields = NULL,
 subarch = .Platform$r_arch, ...)
```

**Arguments**

|                       |                                                                                                                                                                                                                                  |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>lib.loc</code>  | character vector describing the location of R library trees to search through, or NULL for all known trees (see <a href="#">.libPaths</a> ).                                                                                     |
| <code>priority</code> | character vector or NULL (default). If non-null, used to select packages; "high" is equivalent to <code>c("base", "recommended")</code> . To select all packages without an assigned priority use <code>priority = "NA"</code> . |
| <code>noCache</code>  | Do not use cached information, nor cache it.                                                                                                                                                                                     |
| <code>fields</code>   | a character vector giving the fields to extract from each package's DESCRIPTION file in addition to the default ones, or NULL (default). Unavailable fields result in NA values.                                                 |
| <code>subarch</code>  | character string or NULL. If non-null and non-empty, used to select packages which are installed for that sub-architecture.                                                                                                      |
| <code>...</code>      | allows unused arguments to be passed down from other functions.                                                                                                                                                                  |

## Details

`installed.packages` scans the ‘DESCRIPTION’ files of each package found along `lib.loc` and returns a matrix of package names, library paths and version numbers.

The information found is cached (by library) for the R session and specified `fields` argument, and updated only if the top-level library directory has been altered, for example by installing or removing a package. If the cached information becomes confused, it can be avoided by specifying `noCache = TRUE`.

## Value

A matrix with one row per package, row names the package names and column names (currently) "Package", "LibPath", "Version", "Priority", "Depends", "Imports", "LinkingTo", "Suggests", "Enhances", "OS\_type", "License" and "Built" (the R version the package was built under). Additional columns can be specified using the `fields` argument.

## Note

This needs to read several files per installed package, which will be slow on Windows and on some network-mounted file systems.

It will be slow when thousands of packages are installed, so do not use it to find out if a named package is installed (use `find.package` or `system.file`) nor to find out if a package is usable (call `requireNamespace` or `require` and check the return value) nor to find details of a small number of packages (use `packageDescription`).

## See Also

`update.packages`, `install.packages`, `INSTALL`, `REMOVE`.

## Examples

```
confine search to .Library for speed
str(ip <- installed.packages(.Library, priority = "high"))
ip[, c(1,3:5)]
plic <- installed.packages(.Library, priority = "high", fields = "License")
what licenses are there:
table(plic[, "License"])
```

---

isS3method

*Is 'method' the Name of an S3 Method?*

---

## Description

Checks if `method` is the name of a valid / registered S3 method. Alternatively, when `f` and `class` are specified, it is checked if `f` is the name of an S3 generic function and `paste(f, class, sep=". ")` is a valid S3 method.

## Usage

```
isS3method(method, f, class, envir = parent.frame())
```

**Arguments**

|        |                                                                                                                                           |
|--------|-------------------------------------------------------------------------------------------------------------------------------------------|
| method | a character string, typically of the form "<fn>.<class>". If omitted, <code>f</code> and <code>class</code> have to be specified instead. |
| f      | optional character string, typically specifying an S3 generic function. Used, when <code>method</code> is not specified.                  |
| class  | optional character string, typically specifying an S3 class name. Used, when <code>method</code> is not specified.                        |
| envir  | the <code>environment</code> in which the method and its generic are searched first, as in <code>getS3method()</code> .                   |

**Value**

logical TRUE or FALSE

**See Also**

`methods`, `getS3method`.

**Examples**

```
isS3method("t") # FALSE - it is an S3 generic
isS3method("t.default") # TRUE
isS3method("t.ts") # TRUE
isS3method("t.test") # FALSE
isS3method("t.data.frame") # TRUE
isS3method("t.lm") # FALSE - not existing
isS3method("t.foo.bar") # FALSE - not existing

S3 methods with "4 parts" in their name:
ff <- c("as.list", "as.matrix", "is.na", "row.names", "row.names<-")
for(m in ff) if(isS3method(m)) stop("wrongly declared an S3 method: ", m)
(m4 <- paste(ff, "data.frame", sep="."))
for(m in m4) if(!isS3method(m)) stop("not an S3 method: ", m)
```

---

isS3stdGeneric

---

*Check if a Function Acts as an S3 Generic*

---

**Description**

Determines whether `f` acts as a standard S3-style generic function.

**Usage**

```
isS3stdGeneric(f)
```

**Arguments**

`f` a function object

**Details**

A closure is considered a standard S3 generic if the first expression in its body calls [UseMethod](#). Functions which perform operations before calling `UseMethod` will not be considered “standard” S3 generics.

If `f` is currently being traced, i.e., inheriting from class `"traceable"`, the definition of the original untraced version of the function is used instead.

**Value**

If `f` is an S3 generic, a logical containing `TRUE` with the name of the S3 generic (the string passed to `UseMethod`). Otherwise, `FALSE` (unnamed).

---

 LINK

---

*Create Executable Programs on Unix-alikes*

---

**Description**

Front-end for creating executable programs on unix-alikes, i.e., not on Windows.

**Usage**

```
R CMD LINK [options] linkcmd
```

**Arguments**

|                      |                                                                                                                       |
|----------------------|-----------------------------------------------------------------------------------------------------------------------|
| <code>linkcmd</code> | a list of commands to link together suitable object files (include library objects) to create the executable program. |
| <code>options</code> | further options to control the linking, or for obtaining information about usage and version.                         |

**Details**

The linker front-end is useful in particular when linking against the R shared or static library: see the examples.

The actual linking command is constructed by the version of `libtool` installed at `'R_HOME/bin'`.

`R CMD LINK --help` gives usage information.

**Note**

Some binary distributions of R have `LINK` in a separate bundle, e.g. an R-devel RPM.

This is not available on Windows.

**See Also**

[COMPILE](#).

## Examples

```
Not run: ## examples of front-ends linked against R.
First a C program
CC=`R CMD config CC`
R CMD LINK $CC -o foo foo.o `R CMD config --ldflags`

if Fortran code has been compiled into ForFoo.o
FLIBS=`R CMD config FLIBS`
R CMD LINK $CC -o foo foo.o ForFoo.o `R CMD config --ldflags` $FLIBS

And for a C++ front-end
CXX=`R CMD config CXX`
R CMD COMPILE foo.cc
R CMD LINK $CXX -o foo foo.o `R CMD config --ldflags`

End(Not run)
```

---

|                 |                                                           |
|-----------------|-----------------------------------------------------------|
| localeToCharset | <i>Select a Suitable Encoding Name from a Locale Name</i> |
|-----------------|-----------------------------------------------------------|

---

## Description

This functions aims to find a suitable coding for the locale named, by default the current locale, and if it is a UTF-8 locale a suitable single-byte encoding.

## Usage

```
localeToCharset(locale = Sys.getlocale("LC_CTYPE"))
```

## Arguments

locale                      character string naming a locale.

## Details

The operation differs by OS.

**On Windows,** a locale is specified like "English\_United Kingdom.1252". The final component gives the codepage, and this defines the encoding.

**On Unix-alikes:** Locale names are normally like es\_MX.iso88591. If final component indicates an encoding and it is not utf8 we just need to look up the equivalent encoding name. Otherwise, the language (here es) is used to choose a primary or fallback encoding.

In the C locale the answer will be "ASCII".

## Value

A character vector naming an encoding and possibly a fallback single-encoding, NA if unknown.

## Note

The encoding names are those used by libiconv, and ought also to work with glibc but maybe not with commercial Unixen.

**See Also**

[Sys.getlocale](#), [iconv](#).

**Examples**

```
localeToCharset()
```

---

ls.str

---

*List Objects and their Structure*

---

**Description**

ls.str and lsf.str are variations of [ls](#) applying [str\(\)](#) to each matched name: see section [Value](#).

**Usage**

```
ls.str(pos = -1, name, envir, all.names = FALSE,
 pattern, mode = "any")

lsf.str(pos = -1, envir, ...)

S3 method for class 'ls_str'
print(x, max.level = 1, give.attr = FALSE, ...,
 digits = max(1, getOption("str")$digits.d))
```

**Arguments**

|           |                                                                                                                                                                                         |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| pos       | integer indicating <a href="#">search</a> path position, or -1 for the current environment.                                                                                             |
| name      | optional name indicating <a href="#">search</a> path position, see <a href="#">ls</a> .                                                                                                 |
| envir     | environment to use, see <a href="#">ls</a> .                                                                                                                                            |
| all.names | logical indicating if names which begin with a . are omitted; see <a href="#">ls</a> .                                                                                                  |
| pattern   | a <a href="#">regular expression</a> passed to <a href="#">ls</a> . Only names matching pattern are considered.                                                                         |
| max.level | maximal level of nesting which is applied for displaying nested structures, e.g., a list containing sub lists. Default 1: Display only the first nested level.                          |
| give.attr | logical; if TRUE (default), show attributes as sub structures.                                                                                                                          |
| mode      | character specifying the <a href="#">mode</a> of objects to consider. Passed to <a href="#">exists</a> and <a href="#">get</a> .                                                        |
| x         | an object of class "ls_str".                                                                                                                                                            |
| ...       | further arguments to pass. lsf.str passes them to ls.str which passes them on to <a href="#">ls</a> . The (non-exported) print method print.ls_str passes them to <a href="#">str</a> . |
| digits    | the number of significant digits to use for printing.                                                                                                                                   |

**Value**

ls.str and lsf.str return an object of class "ls\_str", basically the character vector of matching names (functions only for lsf.str), similarly to [ls](#), with a print() method that calls [str\(\)](#) on each object.

**Author(s)**

Martin Maechler

**See Also**

[str](#), [summary](#), [args](#).

**Examples**

```
require(stats)

lsf.str() #- how do the functions look like which I am using?
ls.str(mode = "list") #- what are the structured objects I have defined?

create a few objects
example(glm, echo = FALSE)
ll <- as.list(LETTERS)
print(ls.str(), max.level = 0) # don't show details

which base functions have "file" in their name ?
lsf.str(pos = length(search()), pattern = "file")

demonstrating that ls.str() works inside functions
["browser/debug mode"]:
tt <- function(x, y = 1) { aa <- 7; r <- x + y; ls.str() }
(nms <- sapply(strsplit(capture.output(tt(2)), " *: *"), `[`, 1))
stopifnot(nms == c("aa", "r", "x", "y"))
```

---

`maintainer`

*Show Package Maintainer*

---

**Description**

Show the name and email address of the maintainer of a package.

**Usage**

```
maintainer(pkg)
```

**Arguments**

`pkg`                      Character string. The name of a single package.

**Details**

Accesses the package description to return the name and email address of the maintainer.

Questions about contributed packages should often be addressed to the package maintainer; questions about base packages should usually be addressed to the R-help or R-devel mailing lists. Bug reports should be submitted using the [bug.report](#) function.

**Value**

A character string giving the name and email address of the maintainer of the package, or `NA` if no such package is installed.

**Author(s)**

David Scott <d.scott@auckland.ac.nz> from code on R-help originally due to Charlie Sharpsteen <source@sharpsteen.net>; multiple corrections by R-core.

**References**

<https://stat.ethz.ch/pipermail/r-help/2010-February/230027.html>

**See Also**

[packageDescription](#), [bug.report](#)

**Examples**

```
maintainer("MASS")
```

---

make.packages.html *Update HTML Package List*

---

**Description**

Re-create the HTML list of packages.

**Usage**

```
make.packages.html(lib.loc = .libPaths(), temp = FALSE,
 verbose = TRUE, docdir = R.home("doc"))
```

**Arguments**

|                      |                                                                                                                       |
|----------------------|-----------------------------------------------------------------------------------------------------------------------|
| <code>lib.loc</code> | character vector. List of libraries to be included.                                                                   |
| <code>temp</code>    | logical: should the package indices be created in a temporary location for use by the HTTP server?                    |
| <code>verbose</code> | logical. If true, print out a message.                                                                                |
| <code>docdir</code>  | If <code>temp</code> is false, directory in whose ‘html’ directory the ‘packages.html’ file is to be created/updated. |

**Details**

This creates the ‘packages.html’ file, either a temporary copy for use by [help.start](#), or the copy in ‘R.home("doc")/html’ (for which you will need write permission).

It can be very slow, as all the package ‘DESCRIPTION’ files in all the library trees are read.

For `temp = TRUE` there is some caching of information, so the file will only be re-created if `lib.loc` or any of the directories it lists have been changed.

**Value**

Invisible logical, with FALSE indicating a failure to create the file, probably due to lack of suitable permissions.

**See Also**[help.start](#)**Examples**

```
Not run:
make.packages.html()
this can be slow for large numbers of installed packages.

End(Not run)
```

make.socket

*Create a Socket Connection***Description**

With `server = FALSE` attempts to open a client socket to the specified port and host. With `server = TRUE` the R process listens on the specified port for a connection and then returns a server socket. It is a good idea to use [on.exit](#) to ensure that a socket is closed, as you only get 64 of them.

**Usage**

```
make.socket(host = "localhost", port, fail = TRUE, server = FALSE)
```

**Arguments**

|                     |                                 |
|---------------------|---------------------------------|
| <code>host</code>   | name of remote host             |
| <code>port</code>   | port to connect to/listen on    |
| <code>fail</code>   | failure to connect is an error? |
| <code>server</code> | a server socket?                |

**Value**

An object of class `"socket"`, a list with components:

|                     |                                                                                   |
|---------------------|-----------------------------------------------------------------------------------|
| <code>socket</code> | socket number. This is for internal use. On a Unix-alike it is a file descriptor. |
| <code>port</code>   | port number of the connection.                                                    |
| <code>host</code>   | name of remote computer.                                                          |

**Warning**

I don't know if the connecting host name returned when `server = TRUE` can be trusted. I suspect not.

**Author(s)**

Thomas Lumley

## References

Adapted from Luke Tierney's code for XLISP-Stat, in turn based on code from Robbins and Robbins "Practical UNIX Programming".

## See Also

`close.socket`, `read.socket`.

Compiling in support for sockets was optional prior to R 3.3.0: see `capabilities("sockets")` to see if it is available.

## Examples

```
daytime <- function(host = "localhost"){
 a <- make.socket(host, 13)
 on.exit(close.socket(a))
 read.socket(a)
}
Official time (UTC) from US Naval Observatory
Not run: daytime("tick.usno.navy.mil")
```

---

memory.size

*Report on Memory Allocation (on Windows)*

---

## Description

**On MS Windows**, `memory.size()` reports the current or maximum memory allocation of the `malloc` function used in this version of R.

`memory.limit()` reports or increases the limit in force on the total allocation.

**On non-Windows platforms** these are stubs which report infinity (`Inf`) with a warning.

## Usage

```
memory.size(max = FALSE)
```

```
memory.limit(size = NA)
```

## Arguments

|                   |                                                                                                                                                            |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>max</code>  | logical. If TRUE the maximum amount of memory obtained from the OS is reported, if FALSE the amount currently in use, if NA the memory limit.              |
| <code>size</code> | numeric. If NA report the memory limit, otherwise request a new limit, in Mb. Only values of up to 4095 are allowed on 32-bit R builds, but see 'Details'. |

## Details

Command-line flag '`--max-mem-size`' sets the maximum value of obtainable memory (including a very small amount of housekeeping overhead). This cannot exceed 3Gb on 32-bit Windows, and most versions are limited to 2Gb. The minimum is currently 32Mb.

If 32-bit R is run on most 64-bit versions of Windows the maximum value of obtainable memory is just under 4Gb. For a 64-bit versions of R under 64-bit Windows the limit is currently 8Tb.

Memory limits can only be increased.

Environment variable `R_MAX_MEM_SIZE` provides another way to specify the initial limit.

**Value**

A number: On Windows, size in Mb (1048576 bytes), rounded to 0.01 Mb for `memory.size` and rounded down for `memory.limit`.  
 On other platforms: `Inf` always.

**Note**

These functions exist on all platforms, but on non-Windows always report infinity as R does itself provide limits on memory allocation—the OS's own facilities can be used.

**See Also**

[Memory-limits](#) for other limits.

On Windows: The `rw-FAQ` for more details and references.

**Examples**

```
if(.Platform$OS.type == "windows") withAutoprint({
 memory.size()
 memory.size(TRUE)
 memory.limit()
})
```

---

 menu

---

*Menu Interaction Function*

---

**Description**

`menu` presents the user with a menu of choices labelled from 1 to the number of choices. To exit without choosing an item one can select '0'.

**Usage**

```
menu(choices, graphics = FALSE, title = NULL)
```

**Arguments**

|                       |                                                                                             |
|-----------------------|---------------------------------------------------------------------------------------------|
| <code>choices</code>  | a character vector of choices                                                               |
| <code>graphics</code> | a logical indicating whether a graphics menu should be used if available.                   |
| <code>title</code>    | a character string to be used as the title of the menu. <code>NULL</code> is also accepted. |

**Details**

If `graphics = TRUE` and a windowing system is available (Windows, macOS or X11 *via* Tcl/Tk) a listbox widget is used, otherwise a text menu. It is an error to use `menu` in a non-interactive session.

Ten or fewer items will be displayed in a single column, more in multiple columns if possible within the current display width.

No title is displayed if `title` is `NULL` or `" "`.

**Value**

The number corresponding to the selected item, or 0 if no choice was made.

**References**

Becker, R. A., Chambers, J. M. and Wilks, A. R. (1988) *The New S Language*. Wadsworth & Brooks/Cole.

**See Also**

`select.list`, which is used to implement the graphical menu, and allows multiple selections.

**Examples**

```
Not run:
switch(menu(c("List letters", "List LETTERS")) + 1,
 cat("Nothing done\n"), letters, LETTERS)

End(Not run)
```

---

 methods

---

*List Methods for S3 Generic Functions or Classes*

---

**Description**

List all available methods for a S3 and S4 generic function, or all methods for an S3 or S4 class.

**Usage**

```
methods(generic.function, class)
.S3methods(generic.function, class, envir=parent.frame())

S3 method for class 'MethodsFunction'
format(x, byclass = attr(x, "byclass"), ...)
S3 method for class 'MethodsFunction'
print(x, byclass = attr(x, "byclass"), ...)
```

**Arguments**

|                               |                                                                                                                                         |
|-------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| <code>generic.function</code> | a generic function, or a character string naming a generic function.                                                                    |
| <code>class</code>            | a symbol or character string naming a class: only used if <code>generic.function</code> is not supplied.                                |
| <code>envir</code>            | the environment in which to look for the definition of the generic function, when the generic function is passed as a character string. |
| <code>x</code>                | typically the result of <code>methods(..)</code> , an R object of S3 class "MethodsFunction", see 'Value' below.                        |
| <code>byclass</code>          | an optional <a href="#">logical</a> allowing to override the "byclass" attribute determining how the result is printed, see 'Details'.  |
| <code>...</code>              | potentially further arguments passed to and from <code>methods</code> ; unused currently.                                               |

## Details

`methods()` finds S3 and S4 methods associated with either the `generic.function` or `class` argument. Methods are found in all packages on the current `search()` path. `.S3methods()` finds only S3 methods, `.S4methods()` finds only S4 methods.

When invoked with the `generic.function` argument, the `"byclass"` attribute (see Details) is `FALSE`, and the `print` method by default displays the signatures (full names) of S3 and S4 methods. S3 methods are printed by pasting the generic function and class together, separated by a `'.'`, as `generic.class`. The S3 method name is followed by an asterisk `*` if the method definition is not exported from the package namespace in which the method is defined. S4 method signatures are printed as `generic, class-method`; S4 allows for multiple dispatch, so there may be several classes in the signature `generic, A, B-method`.

When invoked with the `class` argument, `"byclass"` is `TRUE`, and the `print` method by default displays the names of the generic functions associated with the class, `generic`.

The source code for all functions is available. For S3 functions exported from the namespace, enter the method at the command line as `generic.class`. For S3 functions not exported from the namespace, see `getAnywhere` or `getS3method`. For S4 methods, see `getMethod`.

Help is available for each method, in addition to each generic. For interactive help, use the documentation shortcut `?` with the name of the generic and tab completion, `?"generic<tab>"` to select the method for which help is desired.

The S3 functions listed are those which *are named like methods* and may not actually be methods (known exceptions are discarded in the code).

## Value

An object of class `"MethodsFunction"`, a character vector of method names with `"byclass"` and `"info"` attributes. The `"byclass"` attribute is a `logical` indicating if the results were obtained with argument `class` defined. The `"info"` attribute is a data frame with columns:

**generic** `character` vector of the names of the generic.

**visible** `logical()`, is the method exported from the namespace of the package in which it is defined?

**isS4** `logical()`, true when the method is an S4 method.

**from** a `factor`, the location or package name where the method was found.

## Note

The original `methods` function was written by Martin Maechler.

## Examples

```

methods(class = "MethodsFunction") # format and print

require(stats)

methods(summary)
methods(class = "aov") # S3 class
The same, with more details and more difficult to read:
print(methods(class = "aov"), byclass=FALSE)
methods("[") # uses C-internal dispatching
methods("$")
methods("$<-") # replacement function
methods("+") # binary operator
methods("Math") # group generic
require(graphics)
methods(axis) # looks like a generic, but is not

mf <- methods(format) # quite a few; ... the last few :
tail(cbind(meth = format(mf)))

if(require(Matrix)) {
 print(methods(class = "Matrix")) # S4 class
 m <- methods(dim) # S3 and S4 methods
 print(m)
 print(attr(m, "info")) # more extensive information

 mirrorAdmin

*Managing Repository Mirrors*

---

## Description

Functions helping to maintain CRAN, some of them may also be useful for administrators of other repository networks.

## Usage

```

mirror2html(mirrors = NULL, file = "mirrors.html",
 head = "mirrors-head.html", foot = "mirrors-foot.html")
checkCRAN(method)

```

## Arguments

|                      |                                                            |
|----------------------|------------------------------------------------------------|
| <code>mirrors</code> | A data frame, by default the CRAN list of mirrors is used. |
| <code>file</code>    | A <a href="#">connection</a> or a character string.        |
| <code>head</code>    | Name of optional header file.                              |
| <code>foot</code>    | Name of optional footer file.                              |
| <code>method</code>  | Download method, see <code>download.file</code> .          |

## Details

`mirror2html` creates the HTML file for the CRAN list of mirrors and invisibly returns the HTML text.

`checkCRAN` performs a sanity checks on all CRAN mirrors.

---

`modifyList`*Recursively Modify Elements of a List*

---

## Description

Modifies a possibly nested list recursively by changing a subset of elements at each level to match a second list.

## Usage

```
modifyList(x, val, keep.null = FALSE)
```

## Arguments

|                        |                                                                                                                                                                                                                |
|------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>         | A named <code>list</code> , possibly empty.                                                                                                                                                                    |
| <code>val</code>       | A named list with components to replace corresponding components in <code>x</code> .                                                                                                                           |
| <code>keep.null</code> | If <code>TRUE</code> , <code>NULL</code> elements in <code>val</code> become <code>NULL</code> elements in <code>x</code> . Otherwise, the corresponding element, if present, is deleted from <code>x</code> . |

## Value

A modified version of `x`, with the modifications determined as follows (here, list elements are identified by their names). Elements in `val` which are missing from `x` are added to `x`. For elements that are common to both but are not both lists themselves, the component in `x` is replaced (or possibly deleted, depending on the value of `keep.null`) by the one in `val`. For common elements that are in both lists, `x[[name]]` is replaced by `modifyList(x[[name]], val[[name]])`.

## Author(s)

Deepayan Sarkar <Deepayan.Sarkar@R-project.org>

## Examples

```
foo <- list(a = 1, b = list(c = "a", d = FALSE))
bar <- modifyList(foo, list(e = 2, b = list(d = TRUE)))
str(foo)
str(bar)
```

**Description**

Build and query the news data base for R or add-on packages.

**Usage**

```
news(query, package = "R", lib.loc = NULL, format = NULL,
 reader = NULL, db = NULL)

S3 method for class 'news_db'
print(x, doBrowse = interactive(),
 browser = getOption("browser"), ...)
```

**Arguments**

|                       |                                                                                                                                                                                    |
|-----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>query</code>    | an expression for selecting news entries                                                                                                                                           |
| <code>package</code>  | a character string giving the name of an installed add-on package, or "R" or "R-3" or "R-2".                                                                                       |
| <code>lib.loc</code>  | a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known.                                             |
| <code>format</code>   | Not yet used.                                                                                                                                                                      |
| <code>reader</code>   | Not yet used.                                                                                                                                                                      |
| <code>db, x</code>    | a news db obtained from <code>news()</code> .                                                                                                                                      |
| <code>doBrowse</code> | logical specifying that the news should be opened in the browser (by <a href="#">browseURL</a> , accessible as via <a href="#">help.start</a> ) instead of printed to the console. |
| <code>browser</code>  | the browser to be used, see <a href="#">browseURL</a> .                                                                                                                            |
| <code>...</code>      | potentially further arguments passed to <code>print()</code> .                                                                                                                     |

**Details**

If `package` is "R" (default), a news db is built with the news since the 4.0.0 release of R (corresponding to R's top-level 'NEWS' file). For "R-3" or "R-2". news for R 3.x.y or R 2.x.y respectively. Otherwise, if the given add-on package can be found in the given libraries, it is attempted to read its news in structured form from files 'inst/NEWS.Rd', 'NEWS.md' (since R version 3.6.0, needs packages **commonmark** and **xml2** to be available), 'NEWS' or 'inst/NEWS' (in that order).

File 'inst/NEWS.Rd' should be an Rd file given the entries as Rd \itemize lists, grouped according to version using section elements with names starting with a suitable prefix (e.g. "Changes in version") followed by a space and the version number, and optionally followed by a space and a parenthesized ISO 8601 (%Y-%m-%d, see [strptime](#)) format date, and possibly further grouped according to categories using \subsection elements named as the categories. At the very end of \section{...}, the date may also be specified as (%Y-%m-%d, <note>), i.e., including parentheses.

File 'NEWS.md' should contain the news in Markdown (following the CommonMark (<https://commonmark.org/>) specification), with the primary heading level giving the version number

after a prefix followed by a space, and optionally followed by a space and a parenthesized ISO 8601 format date. Where available, secondary heading are taken to indicate categories. To accommodate for common practice, news entries are only split down to the category level.

The plain text 'NEWS' files in add-on packages use a variety of different formats; the default news reader should be capable to extract individual news entries from a majority of packages from the standard repositories, which use (slight variations of) the following format:

- Entries are grouped according to version, with version header "Changes in version" at the beginning of a line, followed by a version number, optionally followed by an ISO 8601 format date, possibly parenthesized.
- Entries may be grouped according to category, with a category header (different from a version header) starting at the beginning of a line.
- Entries are written as itemize-type lists, using one of 'o', '\*', '-' or '+' as item tag. Entries must be indented, and ideally use a common indentation for the item texts.

Additional formats and readers may be supported in the future.

Package **tools** provides an (internal) utility function `news2Rd` to convert plain text 'NEWS' files to Rd. For 'NEWS' files in a format which can successfully be handled by the default reader, package maintainers can use `tools::news2Rd(dir, "NEWS.Rd")`, possibly with additional argument `codify = TRUE`, with `dir` a character string specifying the path to a package's root directory. Upon success, the 'NEWS.Rd' file can further be improved and then be moved to the 'inst' subdirectory of the package source directory.

The news db built is a character data frame inheriting from "news\_db" with variables `Version`, `Category`, `Date` and `Text`, where the last contains the entry texts read, and the other variables may be NA if they were missing or could not be determined.

Using `query`, one can select news entries from the db. If missing or NULL, the complete db is returned. Otherwise, `query` should be an expression involving (a subset of) the variables `Version`, `Category`, `Date` and `Text`, and when evaluated within the db returning a logical vector with length the number of entries in the db. The entries for which evaluation gave TRUE are selected. When evaluating, `Version` and `Date` are coerced to `numeric_version` and `Date` objects, respectively, so that the comparison operators for these classes can be employed.

## Value

A data frame inheriting from class "news\_db", with `attributes` "package" (and "subset" if the query lead to proper subsetting).

## Examples

```
Build a db of all R news entries.
db <- news()

Bug fixes with PR number in 4.0.0.
db4 <- news(Version == "4.0.0" & grepl("^BUG", Category) & grepl("PR#", Text),
 db = db)
nrow(db4)

print db4 to show in an HTML browser.

News from a date range ('Matrix' is there in a regular R installation):
if(length(iM <- find.package("Matrix", quiet = TRUE)) && nzchar(iM)) {
```

```

dM <- news(package="Matrix")
stopifnot(identical(dM, news(db=dM)))
dM2014 <- news("2014-01-01" <= Date & Date <= "2014-12-31", db = dM)
stopifnot(paste0("1.1-", 2:4) %in% dM2014[, "Version"])
}

Which categories have been in use? % R-core maybe should standardize a bit more
sort(table(db[, "Category"]), decreasing = TRUE)
Entries with version >= 4.0.0
table(news(Version >= "4.0.0", db = db)$Version)

do the same for R 3.x.y, more slowly
db3 <- news(package = "R-3")
sort(table(db3[, "Category"]), decreasing = TRUE)
Entries with version >= 3.6.0
table(news(Version >= "3.6.0", db = db3)$Version)

```

---

nsl

---

*Look up the IP Address by Hostname (on Unix-alikes)*

---

## Description

Interface to the system `gethostbyname`, currently available only on unix-alikes, i.e., not on Windows.

## Usage

```
nsl(hostname)
```

## Arguments

`hostname`      the name of the host.

## Details

This was included as a test of internet connectivity, to fail if the node running R is not connected. It will also return `NULL` if BSD networking is not supported, including the header file `'arpa/inet.h'`.

This function is not available on Windows.

## Value

The IP address, as a character string, or `NULL` if the call fails.

## Examples

```

if(.Platform$OS.type == "unix") # includes Mac
 print(nsl("www.r-project.org"))

```

object.size

*Report the Space Allocated for an Object***Description**

Provides an estimate of the memory that is being used to store an R object.

**Usage**

```
object.size(x)

S3 method for class 'object_size'
format(x, units = "b", standard = "auto", digits = 1L, ...)
S3 method for class 'object_size'
print(x, quote = FALSE, units = "b", standard = "auto",
 digits = 1L, ...)
```

**Arguments**

|          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x        | an R object.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| quote    | logical, indicating whether or not the result should be printed with surrounding quotes.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| units    | <p>the units to be used in formatting and printing the size. Allowed values for the different standards are</p> <p>standard = "legacy": "b", "Kb", "Mb", "Gb", "Tb", "Pb", "B", "KB", "MB", "GB", "TB" and "PB".</p> <p>standard = "IEC": "B", "KiB", "MiB", "GiB", "TiB", "PiB", "EiB", "ZiB" and "YiB".</p> <p>standard = "SI": "B", "kB", "MB", "GB", "TB", "PB", "EB", "ZB" and "YB".</p> <p>For all standards, unit = "auto" is also allowed. If standard = "auto", any of the "legacy" and IEC units are allowed. See ‘Formatting and printing object sizes’ for details.</p> |
| standard | the byte-size unit standard to be used. A character string, possibly abbreviated from "legacy", "IEC", "SI" and "auto". See ‘Formatting and printing object sizes’ for details.                                                                                                                                                                                                                                                                                                                                                                                                     |
| digits   | the number of digits after the decimal point, passed to <a href="#">round</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| ...      | arguments to be passed to or from other methods.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

**Details**

Exactly which parts of the memory allocation should be attributed to which object is not clear-cut. This function merely provides a rough indication: it should be reasonably accurate for atomic vectors, but does not detect if elements of a list are shared, for example. (Sharing amongst elements of a character vector is taken into account, but not that between character vectors in a single object.)

The calculation is of the size of the object, and excludes the space needed to store its name in the symbol table.

Associated space (e.g., the environment of a function and what the pointer in a `EXTPTRSXP` points to) is not included in the calculation.

Object sizes are larger on 64-bit builds than 32-bit ones, but will very likely be the same on different platforms with the same word length and pointer size.

Sizes of objects using a compact internal representation may be over-estimated.

### Value

An object of class `"object_size"` with a length-one double value, an estimate of the memory allocation attributable to the object in bytes.

### Formatting and printing object sizes

Object sizes can be formatted using byte-size units from R's legacy standard, the IEC standard, or the SI standard. As illustrated by below tables, the legacy and IEC standards use *binary* units (multiples of 1024), whereas the SI standard uses *decimal* units (multiples of 1000).

For methods `format` and `print`, argument `standard` specifies which standard to use and argument `units` specifies which byte-size unit to use. `units = "auto"` chooses the largest units in which the result is one or more (before rounding). Byte sizes are rounded to `digits` decimal places. `standard = "auto"` chooses the standard based on `units`, if possible, otherwise, the legacy standard is used.

Summary of R's legacy and IEC units:

| object size | legacy  | IEC   |
|-------------|---------|-------|
| 1           | 1 bytes | 1 B   |
| 1024        | 1 Kb    | 1 KiB |
| 1024^2      | 1 Mb    | 1 MiB |
| 1024^3      | 1 Gb    | 1 GiB |
| 1024^4      | 1 Tb    | 1 TiB |
| 1024^5      | 1 Pb    | 1 PiB |
| 1024^6      |         | 1 EiB |
| 1024^7      |         | 1 ZiB |
| 1024^8      |         | 1 YiB |

Summary of SI units:

| object size | SI   |
|-------------|------|
| 1           | 1 B  |
| 1000        | 1 kB |
| 1000^2      | 1 MB |
| 1000^3      | 1 GB |
| 1000^4      | 1 TB |
| 1000^5      | 1 PB |
| 1000^6      | 1 EB |
| 1000^7      | 1 ZB |
| 1000^8      | 1 YB |

### Author(s)

R Core; Henrik Bengtsson for the non-legacy standards.

## References

## Examples

```
object.size(letters)
object.size(ls)
format(object.size(library), units = "auto")

sl <- object.size(rep(letters, 1000))

print(sl) ## 209288 bytes
print(sl, units = "auto") ## 204.4 Kb
print(sl, units = "auto", standard = "IEC") ## 204.4 KiB
print(sl, units = "auto", standard = "SI") ## 209.3 kB

(fsl <- sapply(c("Kb", "KB", "KiB"),
 function(u) format(sl, units = u)))
stopifnot(identical(## assert that all three are the same :
 unique(substr(as.vector(fsl), 1,5)),
 format(round(as.vector(sl)/1024, 1))))

find the 10 largest objects in the base package
z <- sapply(ls("package:base"), function(x)
 object.size(get(x, envir = baseenv())))
if(interactive()) {
 as.matrix(rev(sort(z))[1:10])
} else # (more constant over time):
 names(rev(sort(z))[1:10])
```

---

package.skeleton     *Create a Skeleton for a New Source Package*

---

## Description

`package.skeleton` automates some of the setup for a new source package. It creates directories, saves functions, data, and R code files to appropriate places, and creates skeleton help files and a ‘Read-and-delete-me’ file describing further steps in packaging.

## Usage

```
package.skeleton(name = "anRpackage", list,
 environment = .GlobalEnv,
 path = ".", force = FALSE,
 code_files = character(), encoding = "unknown")
```

## Arguments

|                          |                                                                                                                                                                                                                                                                                    |
|--------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>name</code>        | character string: the package name and directory name for your package. Must be a valid package name.                                                                                                                                                                              |
| <code>list</code>        | character vector naming the R objects to put in the package. Usually, at most one of <code>list</code> , <code>environment</code> , or <code>code_files</code> will be supplied. See ‘Details’.                                                                                    |
| <code>environment</code> | an environment where objects are looked for. See ‘Details’.                                                                                                                                                                                                                        |
| <code>path</code>        | path to put the package directory in.                                                                                                                                                                                                                                              |
| <code>force</code>       | If <code>FALSE</code> will not overwrite an existing directory.                                                                                                                                                                                                                    |
| <code>code_files</code>  | a character vector with the paths to R code files to build the package around. See ‘Details’.                                                                                                                                                                                      |
| <code>encoding</code>    | optionally a <a href="#">character</a> string with an encoding for an optional <code>Encoding:</code> line in ‘DESCRIPTION’ when non-ASCII characters will be used; typically one of <code>"latin1"</code> , <code>"latin2"</code> , or <code>"UTF-8"</code> ; see the WRE manual. |

## Details

The arguments `list`, `environment`, and `code_files` provide alternative ways to initialize the package. If `code_files` is supplied, the files so named will be sourced to form the environment, then used to generate the package skeleton. Otherwise `list` defaults to the objects in `environment` (including those whose names start with `.`), but can be supplied to select a subset of the objects in that environment.

Stubs of help files are generated for functions, data objects, and S4 classes and methods, using the [prompt](#), [promptClass](#), and [promptMethods](#) functions. If an object from another package is intended to be imported and re-exported without changes, the [promptImport](#) function should be used after `package.skeleton` to generate a simple help file linking to the original one.

The package sources are placed in subdirectory `name` of `path`. If `code_files` is supplied, these files are copied; otherwise, objects will be dumped into individual source files. The file names in `code_files` should have suffix `".R"` and be in the current working directory.

The filenames created for source and documentation try to be valid for all OSes known to run R. Invalid characters are replaced by `'_'`, invalid names are preceded by `'zz'`, names are converted to lower case (to avoid case collisions on case-insensitive file systems) and finally the converted names are made unique by [make.unique](#) (`sep = "_"`). This can be done for code and help files but not data files (which are looked for by name). Also, the code and help files should have names starting with an ASCII letter or digit, and this is checked and if necessary `z` prepended.

Functions with names starting with a dot are placed in file `'R/name-internal.R'`.

When you are done, delete the `'Read-and-delete-me'` file, as it should not be distributed.

## Value

Used for its side-effects.

## References

Read the ‘Writing R Extensions’ manual for more details.

Once you have created a *source* package you need to install it: see the ‘R Installation and Administration’ manual, [INSTALL](#) and [install.packages](#).

**See Also**

[prompt](#), [promptClass](#), and [promptMethods](#).

**Examples**

```
require(stats)
two functions and two "data sets" :
f <- function(x, y) x+y
g <- function(x, y) x-y
d <- data.frame(a = 1, b = 2)
e <- rnorm(1000)

package.skeleton(list = c("f", "g", "d", "e"), name = "mypkg")
```

---

packageDescription *Package Description*

---

**Description**

Parses and returns the ‘DESCRIPTION’ file of a package as a "packageDescription".

Utility functions return (transformed) parts of that.

**Usage**

```
packageDescription(pkg, lib.loc = NULL, fields = NULL,
 drop = TRUE, encoding = "")
packageVersion(pkg, lib.loc = NULL)
packageDate(pkg, lib.loc = NULL,
 date.fields = c("Date", "Packaged", "Date/Publication", "Built"),
 tryFormats = c("%Y-%m-%d", "%Y/%m/%d", "%D", "%m/%d/%Y"),
 desc = packageDescription(pkg, lib.loc=lib.loc, fields=date.fields))
asDateBuilt(built)
```

**Arguments**

|                       |                                                                                                                                                                                                                                                                 |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>pkg</code>      | a character string with the package name.                                                                                                                                                                                                                       |
| <code>lib.loc</code>  | a character vector of directory names of R libraries, or <code>NULL</code> . The default value of <code>NULL</code> corresponds to all libraries currently known. If the default is used, the loaded packages and namespaces are searched before the libraries. |
| <code>fields</code>   | a character vector giving the tags of fields to return (if other fields occur in the file they are ignored).                                                                                                                                                    |
| <code>drop</code>     | If <code>TRUE</code> and the length of <code>fields</code> is 1, then a single character string with the value of the respective field is returned instead of an object of class "packageDescription".                                                          |
| <code>encoding</code> | If there is an <code>Encoding</code> field, to what encoding should re-encoding be attempted? If <code>NA</code> , no re-encoding. The other values are as used by <a href="#">iconv</a> , so the default "" indicates the encoding of the current locale.      |

|                          |                                                                                                                                                                                                            |
|--------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>date.fields</code> | character vector of field tags to be tried. The first for which <code>as.Date(.)</code> is not <code>NA</code> will be returned. (Partly experimental, see <i>Note</i> .)                                  |
| <code>tryFormats</code>  | date formats to try, see <code>as.Date.character()</code> .                                                                                                                                                |
| <code>desc</code>        | optionally, a named <code>list</code> with components named from <code>date.fields</code> ; where the default is <code>fine</code> , a complete <code>packageDescription()</code> maybe specified as well. |
| <code>built</code>       | for <code>asDateBuilt()</code> , a <code>character</code> string as from <code>packageDescription(*, fields="Built")</code> .                                                                              |

## Details

A package will not be ‘found’ unless it has a ‘DESCRIPTION’ file which contains a valid `Version` field. Different warnings are given when no package directory is found and when there is a suitable directory but no valid ‘DESCRIPTION’ file.

An [attached](#) environment named to look like a package (e.g., `package:utils2`) will be ignored. `packageVersion()` is a convenience shortcut, allowing things like `if (packageVersion("MASS") < "7.3") { do.things }`.

For `packageDate()`, if `desc` is valid, both `pkg` and `lib.loc` are not made use of.

## Value

If a ‘DESCRIPTION’ file for the given package is found and can successfully be read, `packageDescription` returns an object of class `"packageDescription"`, which is a named list with the values of the (given) fields as elements and the tags as names, unless `drop = TRUE`.

If parsing the ‘DESCRIPTION’ file was not successful, it returns a named list of `NA`s with the field tags as names if `fields` is not null, and `NA` otherwise.

`packageVersion()` returns a (length-one) object of class `"package_version"`.

`packageDate()` will return a `"Date"` object from `as.Date()` or `NA`.

`asDateBuilt(built)` returns a `"Date"` object or signals an error if `built` is invalid.

## Note

The default behavior of `packageDate()`, notably for `date.fields`, is somewhat experimental and may change. Using `date.fields = <string> single`

## See Also

## Examples

```
packageDescription("stats")
packageDescription("stats", fields = c("Package", "Version"))

packageDescription("stats", fields = "Version")
packageDescription("stats", fields = "Version", drop = FALSE)

if (packageVersion("MASS") < "7.3.29")
 message("you need to update 'MASS'")
```

```
pu <- packageDate("utils")
str(pu)
stopifnot(identical(pu, packageDate(desc = packageDescription("utils"))),
 identical(pu, packageDate("stats"))) # as "utils" and "stats" are
 # both 'base R' and "Built" at same time
```

---

packageName

*Find Package Associated with an Environment*

---

## Description

Many environments are associated with a package; this function attempts to determine that package.

## Usage

```
packageName(env = parent.frame())
```

## Arguments

env                      The environment whose name we seek.

## Details

Environment `env` would be associated with a package if `topenv(env)` is the namespace environment for that package. Thus when `env` is the environment associated with functions inside a package, or local functions defined within them, `packageName` will normally return the package name.

Not all environments are associated with a package: for example, the global environment, or the evaluation frames of functions defined there. `packageName` will return `NULL` in these cases.

## Value

A length one character vector containing the name of the package, or `NULL` if there is no name.

## See Also

[getPackageName](#) is a more elaborate function that can construct a name if none is found.

## Examples

```
packageName()
packageName(environment(mean))
```

packageStatus

*Package Management Tools***Description**

Summarize information about installed packages and packages available at various repositories, and automatically upgrade outdated packages.

**Usage**

```
packageStatus(lib.loc = NULL, repositories = NULL, method,
 type = getOption("pkgType"), ...)

S3 method for class 'packageStatus'
summary(object, ...)

S3 method for class 'packageStatus'
update(object, lib.loc = levels(object$inst$LibPath),
 repositories = levels(object$avail$Repository), ...)

S3 method for class 'packageStatus'
upgrade(object, ask = TRUE, ...)
```

**Arguments**

|                           |                                                                                                                                                                                                                                                                                  |
|---------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>lib.loc</code>      | a character vector describing the location of R library trees to search through, or NULL. The default value of NULL corresponds to all libraries currently known.                                                                                                                |
| <code>repositories</code> | a character vector of URLs describing the location of R package repositories on the Internet or on the local machine. If specified as NULL, derive appropriate URLs from <a href="#">option</a> "repos".                                                                         |
| <code>method</code>       | Download method, see <a href="#">download.file</a> .                                                                                                                                                                                                                             |
| <code>type</code>         | type of package distribution: see <a href="#">install.packages</a> .                                                                                                                                                                                                             |
| <code>object</code>       | an object of class "packageStatus" as returned by <code>packageStatus</code> .                                                                                                                                                                                                   |
| <code>ask</code>          | if TRUE, the user is prompted which packages should be upgraded and which not.                                                                                                                                                                                                   |
| <code>...</code>          | for <code>packageStatus</code> : arguments to be passed to <a href="#">available.packages</a> and <a href="#">installed.packages</a> .<br>for the <code>upgrade</code> method, arguments to be passed to <a href="#">install.packages</a> for other methods: currently not used. |

**Details**

The URLs in `repositories` should be full paths to the appropriate contrib sections of the repositories. The default is `contrib.url(getOption("repos"))`.

There are `print` and `summary` methods for the "packageStatus" objects: the `print` method gives a brief tabular summary and the `summary` method prints the results.

The `update` method updates the "packageStatus" object. The `upgrade` method is similar to [update.packages](#): it offers to install the current versions of those packages which are not currently up-to-date.

**Value**

An object of class "packageStatus". This is a list with two components

|       |                                                                                                                                                                                                                                                                                   |
|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| inst  | a data frame with columns as the <i>matrix</i> returned by <code>installed.packages</code> plus "Status", a factor with levels <code>c("ok", "upgrade", "unavailable")</code> . Only the newest version of each package is reported, in the first repository in which it appears. |
| avail | a data frame with columns as the <i>matrix</i> returned by <code>available.packages</code> plus "Status", a factor with levels <code>c("installed", "not installed")</code> .                                                                                                     |

For the `summary` method the result is also of class "summary.packageStatus" with additional components

|       |                                             |
|-------|---------------------------------------------|
| Libs  | a list with one element for each library    |
| Repos | a list with one element for each repository |

with the elements being lists of character vectors of package name for each status.

**See Also**

`installed.packages`, `available.packages`

**Examples**

```
Not run:
x <- packageStatus()
print(x)
summary(x)
upgrade(x)
x <- update(x)
print(x)

End(Not run)
```

---

page

---

*Invoke a Pager on an R Object*

---

**Description**

Displays a representation of the object named by `x` in a pager via `file.show`.

**Usage**

```
page(x, method = c("dput", "print"), ...)
```

**Arguments**

|                     |                                                                                                                                                                                   |
|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>      | An R object, or a character string naming an object.                                                                                                                              |
| <code>method</code> | The default method is to dump the object via <code>dput</code> . An alternative is to use <code>print</code> and capture the output to be shown in the pager. Can be abbreviated. |
| <code>...</code>    | additional arguments for <code>dput</code> , <code>print</code> or <code>file.show</code> (such as <code>title</code> ).                                                          |

## Details

If `x` is a length-one character vector, it is used as the name of an object to look up in the environment from which `page` is called. All other objects are displayed directly.

A default value of `title` is passed to `file.show` if one is not supplied in . . .

## See Also

`file.show`, `edit`, `fix`.

To go to a new page when graphing, see `frame`.

## Examples

```
Not run: ## four ways to look at the code of 'page'
page(page) # as an object
page("page") # a character string
v <- "page"; page(v) # a length-one character vector
page(utils::page) # a call

End(Not run)
```

---

person

*Persons*

---

## Description

A class and utility methods for holding information about persons like name and email address.

## Usage

```
person(given = NULL, family = NULL, middle = NULL,
 email = NULL, role = NULL, comment = NULL,
 first = NULL, last = NULL)
Default S3 method:
as.person(x)
S3 method for class 'person'
format(x,
 include = c("given", "family", "email", "role", "comment"),
 braces = list(given = "", family = "", email = c("<", ">"),
 role = c("[", "]"), comment = c("(", ")")),
 collapse = list(given = " ", family = " ", email = " ",
 role = " ", comment = " "),
 ...,
 style = c("text", "R")
)
```

## Arguments

|                     |                                                                                        |
|---------------------|----------------------------------------------------------------------------------------|
| <code>given</code>  | a character vector with the <i>given</i> names, or a list thereof.                     |
| <code>family</code> | a character string with the <i>family</i> name, or a list thereof.                     |
| <code>middle</code> | a character string with the collapsed middle name(s). Deprecated, see <b>Details</b> . |

|          |                                                                                                          |
|----------|----------------------------------------------------------------------------------------------------------|
| email    | a character string (or vector) giving an e-mail address (each), or a list thereof.                       |
| role     | a character vector specifying the role(s) of the person (see <b>Details</b> ), or a list thereof.        |
| comment  | a character string (or vector) providing comments, or a list thereof.                                    |
| first    | a character string giving the first name. Deprecated, see <b>Details</b> .                               |
| last     | a character string giving the last name. Deprecated, see <b>Details</b> .                                |
| x        | a character string for the <code>as.person</code> default method; an object of class "person" otherwise. |
| include  | a character vector giving the fields to be included when formatting.                                     |
| braces   | a list of characters (see <b>Details</b> ).                                                              |
| collapse | a list of characters (see <b>Details</b> ).                                                              |
| ...      | currently not used.                                                                                      |
| style    | a character string specifying the print style, with "R" yielding formatting as R code.                   |

## Details

Objects of class "person" can hold information about an arbitrary positive number of persons. These can be obtained by one call to `person()` with list arguments, or by first creating objects representing single persons and combining these via `c()`.

The `format()` method collapses information about persons into character vectors (one string for each person): the fields in `include` are selected, each collapsed to a string using the respective element of `collapse` and subsequently "embraced" using the respective element of `braces`, and finally collapsed into one string separated by white space. If `braces` and/or `collapse` do not specify characters for all fields, the defaults shown in the usage are imputed. If `collapse` is `FALSE` or `NA` the corresponding field is not collapsed but only the first element is used. The `print()` method calls the `format()` method and prints the result, the `toBibtex()` method creates a suitable BibTeX representation.

Person objects can be subscripted by fields (using `$`) or by position (using `[]`).

`as.person()` is a generic function. Its default method tries to reverse the default person formatting, and can also handle formatted person entries collapsed by comma or "and" (with appropriate white space).

Personal names are rather tricky, e.g., [https://en.wikipedia.org/wiki/Personal\\_name](https://en.wikipedia.org/wiki/Personal_name).

The current implementation (starting from R 2.12.0) of the "person" class uses the notions of *given* (including middle names) and *family* names, as specified by `given` and `family` respectively. Earlier versions used a scheme based on first, middle and last names, as appropriate for most of Western culture where the given name precedes the family name, but not universal, as some other cultures place it after the family name, or use no family name. To smooth the transition to the new scheme, arguments `first`, `middle` and `last` are still supported, but their use is deprecated and they must not be given in combination with the corresponding new style arguments. For persons which are not natural persons (e.g., institutions, companies, etc.) it is appropriate to use `given` (but not `family`) for the name, e.g., `person("R Core Team", role = "aut")`.

The new scheme also adds the possibility of specifying *roles* based on a subset of the MARC Code List for Relators (<https://www.loc.gov/marc/relators/relaterm.html>). When giving the roles of persons in the context of authoring R packages, the following usage is suggested.

"aut" (Author) Use for full authors who have made substantial contributions to the package and should show up in the package citation.

"com" (Compiler) Use for persons who collected code (potentially in other languages) but did not make further substantial contributions to the package.

"cph" (Copyright holder) Use for all copyright holders. This is a legal concept so should use the legal name of an institution or corporate body.

"cre" (Creator) Use for the package maintainer.

"ctb" (Contributor) Use for authors who have made smaller contributions (such as code patches etc.) but should not show up in the package citation.

"ctr" (Contractor) Use for authors who have been contracted to write (parts of) the package and hence do not own intellectual property.

"dte" (Data contributor) Use for persons who contributed data sets for the package.

"fnd" (Funder) Use for persons or organizations that furnished financial support for the development of the package.

"rev" (Reviewer) Use for persons or organizations responsible for reviewing (parts of) the package.

"ths" (Thesis advisor) If the package is part of a thesis, use for the thesis advisor.

"trl" (Translator) If the R code is a translation from another language (typically S), use for the translator to R.

In the old scheme, person objects were used for single persons, and a separate "personList" class with corresponding creator `personList()` for collections of these. The new scheme employs a single class for information about an arbitrary positive number of persons, eliminating the need for the `personList` mechanism.

The `comment` field can be used for "arbitrary" additional information about persons. Elements named "ORCID" will be taken to give ORCID identifiers (see <https://orcid.org/> for more information), and be displayed as the corresponding URIs by the `print()` and `format()` methods (see **Examples** below).

## Value

`person()` and `as.person()` return objects of class "person".

## See Also

[citation](#)

## Examples

```
Create a person object directly ...
p1 <- person("Karl", "Pearson", email = "pearson@stats.heaven")

... or convert a string.
p2 <- as.person("Ronald Aylmer Fisher")

Combining and subsetting.
p <- c(p1, p2)
p[1]
p[-1]

Extracting fields.
p$family
p$email
p[1]$email
```

```
Specifying package authors, example from "boot":
AC is the first author [aut] who wrote the S original.
BR is the second author [aut], who translated the code to R [trl],
and maintains the package [cre].
b <- c(person("Angelo", "Canty", role = "aut", comment =
 "S original, <http://statwww.epfl.ch/davison/BMA/library.html>"),
 person(c("Brian", "D."), "Ripley", role = c("aut", "trl", "cre"),
 comment = "R port", email = "ripley@stats.ox.ac.uk")
)
b

Formatting.
format(b)
format(b, include = c("family", "given", "role"),
 braces = list(family = c("", ","), role = c("Role(s): ", "")))

Conversion to BibTeX author field.
paste(format(b, include = c("given", "family")), collapse = " and ")
toBibtex(b)

ORCID identifiers.
(p3 <- person("Achim", "Zeileis",
 comment = c(ORCID = "0000-0003-0918-3766")))
```

PkgUtils

*Utilities for Building and Checking Add-on Packages*

## Description

Utilities for checking whether the sources of an R add-on package work correctly, and for building a source package from them.

## Usage

```
R CMD check [options] pkgdirs
R CMD build [options] pkgdirs
```

## Arguments

|         |                                                                                                                                                                                                                                                          |
|---------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| pkgdirs | a list of names of directories with sources of R add-on packages. For check these can also be the filenames of compressed tar archives with extension <code>‘.tar.gz’</code> , <code>‘.tgz’</code> , <code>‘.tar.bz2’</code> or <code>‘.tar.xz’</code> . |
| options | further options to control the processing, or for obtaining information about usage and version of the utility.                                                                                                                                          |

## Details

R CMD check checks R add-on packages from their sources, performing a wide variety of diagnostic checks.

R CMD build builds R source tarballs. The name(s) of the packages are taken from the `‘DESCRIPTION’` files and not from the directory names. This works entirely on a copy of the supplied source directories.

Use R CMD *foo --help* to obtain usage information on utility *foo*.

The defaults for some of the options to R CMD *build* can be set by environment variables `_R_BUILD_RESAVE_DATA_` and `_R_BUILD_COMPACT_VIGNETTES_`: see ‘Writing R Extensions’. Many of the checks in R CMD *check* can be turned off or on by environment variables: see Chapter 6 of the ‘R Internals’ manual.

By default R CMD *build* uses the “internal” option to `tar` to prepare the tarball. An external `tar` program can be specified by the `R_BUILD_TAR` environment variable. This may be substantially faster for very large packages, and can be needed for packages with long path names (over 100 bytes) or very large files (over 8GB): however, the resulting tarball may not be portable.

R CMD *check* by default unpacks tarballs by the internal `untar` function: if needed an external `tar` command can be specified by the environment variable `R_INSTALL_TAR`: please ensure that it can handle the type of compression used on the tarball. (This is sometimes needed for tarballs containing invalid or unsupported sections, and can be faster on very large tarballs. Setting `R_INSTALL_TAR` to ‘`tar.exe`’ has been needed to overcome permissions issues on some Windows systems.)

### Note

Only on Windows: They make use of a temporary directory specified by the environment variable `TMPDIR` and defaulting to ‘`c:/TEMP`’. Do ensure that if set forward slashes are used.

### See Also

The sections on “Checking and building packages” and “Processing Rd format” in “Writing R Extensions” (see on Unix-alikes the ‘`doc/manual`’ subdirectory of the R source tree, on Windows, see the Manuals sub-menu of the Help menu on the console).

---

process.events

*Trigger Event Handling*

---

### Description

R front ends like the Windows GUI handle key presses and mouse clicks through “events” generated by the OS. These are processed automatically by R at intervals during computations, but in some cases it may be desirable to trigger immediate event handling. The `process.events` function does that.

### Usage

```
process.events()
```

### Details

This is a simple wrapper for the C API function `R_ProcessEvents`. As such, it is possible that it will not return if the user has signalled to interrupt the calculation.

### Value

NULL is returned invisibly.

**Author(s)**

Duncan Murdoch

**See Also**

See ‘Writing R Extensions’ and the ‘R for Windows FAQ’ for more discussion of the `R_ProcessEvents` function.

---

prompt

*Produce Prototype of an R Documentation File*

---

**Description**

Facilitate the constructing of files documenting R objects.

**Usage**

```
prompt(object, filename = NULL, name = NULL, ...)

Default S3 method:
prompt(object, filename = NULL, name = NULL,
 force.function = FALSE, ...)

S3 method for class 'data.frame'
prompt(object, filename = NULL, name = NULL, ...)

promptImport(object, filename = NULL, name = NULL,
 importedFrom = NULL, importPage = name, ...)
```

**Arguments**

|                             |                                                                                                                                                                                                                                                                                         |
|-----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code>         | an R object, typically a function for the default method. Can be <a href="#">missing</a> when name is specified.                                                                                                                                                                        |
| <code>filename</code>       | usually, a <a href="#">connection</a> or a character string giving the name of the file to which the documentation shell should be written. The default corresponds to a file whose name is <code>name</code> followed by <code>".Rd"</code> . Can also be <code>NA</code> (see below). |
| <code>name</code>           | a character string specifying the name of the object.                                                                                                                                                                                                                                   |
| <code>force.function</code> | a logical. If <code>TRUE</code> , treat <code>object</code> as function in any case.                                                                                                                                                                                                    |
| <code>...</code>            | further arguments passed to or from other methods.                                                                                                                                                                                                                                      |
| <code>importedFrom</code>   | a character string naming the package from which <code>object</code> was imported. Defaults to the environment of <code>object</code> if <code>object</code> is a function.                                                                                                             |
| <code>importPage</code>     | a character string naming the help page in the package from which <code>object</code> was imported.                                                                                                                                                                                     |

## Details

Unless `filename` is `NA`, a documentation shell for `object` is written to the file specified by `filename`, and a message about this is given. For function objects, this shell contains the proper function and argument names. R documentation files thus created still need to be edited and moved into the ‘man’ subdirectory of the package containing the object to be documented.

If `filename` is `NA`, a list-style representation of the documentation shell is created and returned. Writing the shell to a file amounts to `cat(unlist(x), file = filename, sep = "\n")`, where `x` is the list-style representation.

When `prompt` is used in `for` loops or scripts, the explicit name specification will be useful.

The `importPage` argument for `promptImport` needs to give the base of the name of the help file of the original help page. For example, the `approx` function is documented in ‘`approxfun.Rd`’ in the `stats` package, so if it were imported and re-exported it should have `importPage = "approxfun"`. Objects that are imported from other packages are not normally documented unless re-exported.

## Value

If `filename` is `NA`, a list-style representation of the documentation shell. Otherwise, the name of the file written to is returned invisibly.

## Warning

The default `filename` may not be a valid filename under limited file systems (e.g., those on Windows).

Currently, calling `prompt` on a non-function object assumes that the object is in fact a data set and hence documents it as such. This may change in future versions of R. Use `promptData` to create documentation skeletons for data sets.

## Note

The documentation file produced by `prompt.data.frame` does not have the same format as many of the data frame documentation files in the `base` package. We are trying to settle on a preferred format for the documentation.

## Author(s)

Douglas Bates for `prompt.data.frame`

## References

Becker, R. A., Chambers, J. M. and Wilks, A. R. (1988) *The New S Language*. Wadsworth & Brooks/Cole.

## See Also

For creation of many help pages (for a package), see `package.skeleton`.

To prompt the user for input, see `readline`.

**Examples**

```
require(graphics)

prompt(plot.default)
prompt(interactive, force.function = TRUE)
unlink("plot.default.Rd")
unlink("interactive.Rd")

prompt(women) # data.frame
unlink("women.Rd")

prompt(sunspots) # non-data.frame data
unlink("sunspots.Rd")

Not run:
Create a help file for each function in the .GlobalEnv:
for(f in ls()) if(is.function(get(f))) prompt(name = f)

End(Not run)
```

promptData

*Generate Outline Documentation for a Data Set***Description**

Generates a shell of documentation for a data set.

**Usage**

```
promptData(object, filename = NULL, name = NULL)
```

**Arguments**

|          |                                                                                                                                                                                                                                                 |
|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object   | an R object to be documented as a data set.                                                                                                                                                                                                     |
| filename | usually, a <a href="#">connection</a> or a character string giving the name of the file to which the documentation shell should be written. The default corresponds to a file whose name is name followed by ".Rd". Can also be NA (see below). |
| name     | a character string specifying the name of the object.                                                                                                                                                                                           |

**Details**

Unless filename is NA, a documentation shell for object is written to the file specified by filename, and a message about this is given.

If filename is NA, a list-style representation of the documentation shell is created and returned. Writing the shell to a file amounts to `cat(unlist(x), file = filename, sep = "\n")`, where x is the list-style representation.

Currently, only data frames are handled explicitly by the code.

**Value**

If `filename` is `NA`, a list-style representation of the documentation shell. Otherwise, the name of the file written to is returned invisibly.

promptPackage

*Generate a Shell for Documentation of a Package*

---

**Description**

Generates a shell of documentation for an installed or source package.

**Usage**

```
promptPackage(package, lib.loc = NULL, filename = NULL,
 name = NULL, final = FALSE)
```

**Arguments**

|                       |                                                                                                                                                                                                                                                                                         |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>package</code>  | a <a href="#">character</a> string with the name of an <i>installed</i> or <i>source</i> package to be documented.                                                                                                                                                                      |
| <code>lib.loc</code>  | a character vector describing the location of R library trees to search through, or <code>NULL</code> . The default value of <code>NULL</code> corresponds to all libraries currently known. For a source package this should specify the parent directory of the package's sources.    |
| <code>filename</code> | usually, a <a href="#">connection</a> or a character string giving the name of the file to which the documentation shell should be written. The default corresponds to a file whose name is <code>name</code> followed by <code>".Rd"</code> . Can also be <code>NA</code> (see below). |
| <code>name</code>     | a character string specifying the name of the help topic, typically of the form <code>'&lt;pkg&gt;-package'</code> .                                                                                                                                                                    |
| <code>final</code>    | a logical value indicating whether to attempt to create a usable version of the help topic, rather than just a shell.                                                                                                                                                                   |

**Details**

Unless `filename` is `NA`, a documentation shell for package is written to the file specified by `filename`, and a message about this is given.

If `filename` is `NA`, a list-style representation of the documentation shell is created and returned. Writing the shell to a file amounts to `cat(unlist(x), file = filename, sep = "\n")`, where `x` is the list-style representation.

If `final` is `TRUE`, the generated documentation will not include the place-holder slots for manual editing, it will be usable as-is. In most cases a manually edited file is preferable (but `final = TRUE` is certainly less work).

**Value**

If `filename` is `NA`, a list-style representation of the documentation shell. Otherwise, the name of the file written to is returned invisibly.

**See Also**

**Examples**

```
filename <- tempfile()
promptPackage("utils", filename = filename)
file.show(filename)
unlink(filename)
```

---

 Question

---

*Documentation Shortcuts*

---

**Description**

These functions provide access to documentation. Documentation on a topic with name `name` (typically, an R object or a data set) can be displayed by either `help("name")` or `?name`.

**Usage**

```
?topic
```

```
type?topic
```

**Arguments**

|                    |                                                                                                                                                                                                                                                                                                                                                                                                  |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>topic</code> | Usually, a <a href="#">name</a> or character string specifying the topic for which help is sought. Alternatively, a function call to ask for documentation on a corresponding S4 method: see the section on S4 method documentation. The calls <code>pkg::topic</code> and <code>pkg:::topic</code> are treated specially, and look for help on <code>topic</code> in package <code>pkg</code> . |
| <code>type</code>  | the special type of documentation to use for this topic; for example, if the type is <code>class</code> , documentation is provided for the class with name <code>topic</code> . See the Section ‘S4 Method Documentation’ for the uses of <code>type</code> to get help on formal methods, including <code>methods?function</code> and <code>method?call</code> .                               |

**Details**

This is a shortcut to [help](#) and uses its default type of help.

Some topics need to be quoted (by [backticks](#)) or given as a character string. There include those which cannot syntactically appear on their own such as unary and binary operators, `function` and control-flow [reserved](#) words (including `if`, `else`, `for`, `in`, `repeat`, `while`, `break` and `next`). The other reserved words can be used as if they were names, for example `TRUE`, `NA` and `Inf`.

## S4 Method Documentation

Authors of formal ('S4') methods can provide documentation on specific methods, as well as overall documentation on the methods of a particular function. The "?" operator allows access to this documentation in three ways.

The expression `methods?f` will look for the overall documentation methods for the function *f*. Currently, this means the documentation file containing the alias *f-methods*.

There are two different ways to look for documentation on a particular method. The first is to supply the `topic` argument in the form of a function call, omitting the `type` argument. The effect is to look for documentation on the method that would be used if this function call were actually evaluated. See the examples below. If the function is not a generic (no S4 methods are defined for it), the help reverts to documentation on the function name.

The "?" operator can also be called with `doc_type` supplied as `method`; in this case also, the `topic` argument is a function call, but the arguments are now interpreted as specifying the class of the argument, not the actual expression that will appear in a real call to the function. See the examples below.

The first approach will be tedious if the actual call involves complicated expressions, and may be slow if the arguments take a long time to evaluate. The second approach avoids these issues, but you do have to know what the classes of the actual arguments will be when they are evaluated.

Both approaches make use of any inherited methods; the signature of the method to be looked up is found by using `selectMethod` (see the documentation for `getMethod`). A limitation is that methods in packages (as opposed to regular functions) will only be found if the package exporting them is on the search list, even if it is specified explicitly using the `?package::generic()` notation.

rcompgen

*A Completion Generator for R*

---

## Description

This page documents a mechanism to generate relevant completions from a partially completed command line. It is not intended to be useful by itself, but rather in conjunction with other mechanisms that use it as a backend. The functions listed in the usage section provide a simple control and query mechanism. The actual interface consists of a few unexported functions described further down.

## Usage

```
rc.settings(ops, ns, args, dots, func, ipck, S3, data, help,
 argdb, fuzzy, quotes, files)

rc.status()
rc.getOption(name)
rc.options(...)

.DollarNames(x, pattern)

Default S3 method:
.DollarNames(x, pattern = "")
S3 method for class 'list'
.DollarNames(x, pattern = "")
S3 method for class 'environment'
.DollarNames(x, pattern = "")
```

## Arguments

`ops`, `ns`, `args`, `dots`, `func`, `ipck`, `S3`, `data`, `help`, `argdb`, `fuzzy`, `quotes`, `files`  
logical, turning some optional completion features on and off.

`ops`: Activates completion after the `$` and `@` operators.

`ns`: Controls namespace related completions.

`args`: Enables completion of function arguments.

**dots:** If disabled, drops `...` from list of function arguments. Relevant only if `args` is enabled.

**func:** Enables detection of functions. If enabled, a customizable extension (`" "` by default) is appended to function names. The process of determining whether a potential completion is a function requires evaluation, including for lazy loaded symbols. This is undesirable for large objects, because of potentially wasteful use of memory in addition to the time overhead associated with loading. For this reason, this feature is disabled by default.

**S3:** When `args = TRUE`, activates completion on arguments of all S3 methods (otherwise just the generic, which usually has very few arguments).

**ipck:** Enables completion of installed package names inside `library` and `require`.

**data:** Enables completion of data sets (including those already visible) inside `data`.

**help:** Enables completion of help requests starting with a question mark, by looking inside help index files.

**argdb:** When `args = TRUE`, completion is attempted on function arguments. Generally, the list of valid arguments is determined by dynamic calls to `args`. While this gives results that are technically correct, the use of the `...` argument often hides some useful arguments. To give more flexibility in this regard, an optional table of valid arguments names for specific functions is retained internally. Setting `argdb = TRUE` enables preferential lookup in this internal data base for functions with an entry in it. Of course, this is useful only when the data base contains information about the function of interest. Some functions are already included, and more can be added by the user through the unexported function `.addFunctionInfo` (see below).

**fuzzy:** Enables fuzzy matching, where close but non-exact matches (e.g., with different case) are considered if no exact matches are found. This feature is experimental and the details can change.

**quotes:** Enables completion in R code when inside quotes. This normally leads to filename completion, but can be otherwise depending on context (for example, when the open quote is preceded by `?`), help completion is invoked. Setting this to `FALSE` relegates completion to the underlying completion front-end, which may do its own processing (for example, readline on Unix-alikes will do filename completion).

**files:** Deprecated. Use `quotes` instead.

All settings are turned on by default except `ipck`, `func`, and `fuzzy`. Turn more off if your CPU cycles are valuable; you will still retain basic completion on names of objects in the search list. See below for additional details.

`name, ...` user-settable options. Currently valid names are

`function.suffix:` default `" ("`

`funarg.suffix:` default `" = "`

`package.suffix` default `" : : "`

Usage is similar to that of `options`.

`x` An R object for which valid names after `"$"` are computed and returned.

`pattern` A regular expression. Only matching names are returned.

## Details

There are several types of completion, some of which can be disabled using `rc.settings`. The most basic level, which can not be turned off once the completion functionality is activated, provides completion on names visible on the search path, along with a few special keywords (e.g., `TRUE`). This type of completion is not attempted if the partial ‘word’ (a.k.a. token) being completed is empty (since there would be too many completions). The more advanced types of completion are described below.

**Completion after extractors `$` and `@`:** When the `ops` setting is turned on, completion after `$` and `@` is attempted. This requires the prefix to be evaluated, which is attempted unless it involves an explicit function call (implicit function calls involving the use of `[`, `$`, etc *do not* inhibit evaluation).

Valid completions after the `$` extractor are determined by the generic function `.DollarNames`. Some basic methods are provided, and more can be written for custom classes.

**Completion inside namespaces:** When the `ns` setting is turned on, completion inside namespaces is attempted when a token is preceded by the `::` or `:::` operators. Additionally, the basic completion mechanism is extended to include all loaded namespaces, i.e., `foopkg::` becomes a valid completion of `foo` if `"foopkg"` is a loaded namespace.

The completion of package namespaces applies only to already loaded namespaces, i.e. if `MASS` is not loaded, `MAS` will not complete to `MASS::`. However, attempted completion *inside* an apparent namespace will attempt to load the namespace if it is not already loaded, e.g. trying to complete on `MASS::fr` will load `MASS` if it is not already loaded.

**Completion for help items:** When the `help` setting is turned on, completion on help topics is attempted when a token is preceded by `?`. Prefixes (such as `class`, `method`) are supported, as well as quoted help topics containing special characters.

**Completion of function arguments:** When the `args` setting is turned on, completion on function arguments is attempted whenever deemed appropriate. The mechanism used will currently fail if the relevant function (at the point where completion is requested) was entered on a previous prompt (which implies in particular that the current line is being typed in response to a continuation prompt, usually `+`). Note that separation by newlines is fine.

The list of possible argument completions that is generated can be misleading. There is no problem for non-generic functions (except that `...` is listed as a completion; this is intentional as it signals the fact that the function can accept further arguments). However, for generic functions, it is practically impossible to give a reliable argument list without evaluating arguments (and not even then, in some cases), which is risky (in addition to being difficult to code, which is the real reason it hasn’t even been tried), especially when that argument is itself an inline function call. Our compromise is to consider arguments of *all* currently available methods of that generic. This has two drawbacks. First, not all listed completions may be appropriate in the call currently being constructed. Second, for generics with many methods (like `print` and `plot`), many matches will need to be considered, which may take a noticeable amount of time. Despite these drawbacks, we believe this behaviour to be more useful than the only other practical alternative, which is to list arguments of the generic only.

Only S3 methods are currently supported in this fashion, and that can be turned off using the `S3` setting.

Since arguments can be unnamed in R function calls, other types of completion are also appropriate whenever argument completion is. Since there are usually many many more visible objects than formal arguments of any particular function, possible argument completions are often buried in a bunch of other possibilities. However, recall that basic completion is suppressed for blank tokens. This can be useful to list possible arguments of a function. For example, trying to complete `seq([TAB]` and `seq(from = 1, [TAB])` will both list only the

arguments of `seq` (or any of its methods), whereas trying to complete `seq(length[TAB]` will list both the `length.out` argument and the `length(` function as possible completions. Note that no attempt is made to remove arguments already supplied, as that would incur a further speed penalty.

**Special functions:** For a few special functions (`library`, `data`, etc), the first argument is treated specially, in the sense that normal completion is suppressed, and some function specific completions are enabled if so requested by the settings. The `ipck` setting, which controls whether `library` and `require` will complete on *installed packages*, is disabled by default because the first call to `installed.packages` is potentially time consuming (e.g., when packages are installed on a remote network file server). Note, however, that the results of a call to `installed.packages` is cached, so subsequent calls are usually fast, so turning this option on is not particularly onerous even in such situations.

## Value

If `rc.settings` is called without any arguments, it returns the current settings as a named logical vector. Otherwise, it returns `NULL` invisibly.

`rc.status` returns, as a list, the contents of an internal (unexported) environment that is used to record the results of the last completion attempt. This can be useful for debugging. For such use, one must resist the temptation to use completion when typing the call to `rc.status` itself, as that then becomes the last attempt by the time the call is executed.

The items of primary interest in the returned list are:

|                         |                                                                                                                                                                  |
|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>comps</code>      | The possible completions generated by the last call to <code>.completeToken</code> , as a character vector.                                                      |
| <code>token</code>      | The token that was (or, is to be) completed, as set by the last call to <code>.assignToken</code> (possibly inside a call to <code>.guessTokenFromLine</code> ). |
| <code>linebuffer</code> | The full line, as set by the last call to <code>.assignLinebuffer</code> .                                                                                       |
| <code>start</code>      | The start position of the token in the line buffer, as set by the last call to <code>.assignStart</code> .                                                       |
| <code>end</code>        | The end position of the token in the line buffer, as set by the last call to <code>.assignEnd</code> .                                                           |
| <code>fileName</code>   | Logical, indicating whether the cursor is currently inside quotes.                                                                                               |
| <code>fguess</code>     | The name of the function the cursor is currently inside.                                                                                                         |
| <code>isFirstArg</code> | Logical. If cursor is inside a function, is it the first argument?                                                                                               |

In addition, the components `settings` and `options` give the current values of settings and options respectively.

`rc.getOption` and `rc.options` behave much like `getOption` and `options` respectively.

## Unexported API

There are several unexported functions in the package. Of these, a few are special because they provide the API through which other mechanisms can make use of the facilities provided by this package (they are unexported because they are not meant to be called directly by users). The usage of these functions are:

```
.assignToken(text)
.assignLinebuffer(line)
.assignStart(start)
```

```

.assignEnd(end)

.completeToken()
.retrieveCompletions()
.getFileComp()

.guessTokenFromLine()
.win32consoleCompletion(linebuffer, cursorPosition,
 check.repeat = TRUE,
 minlength = -1)

.addFunctionInfo(...)

```

The first four functions set up a completion attempt by specifying the token to be completed (`text`), and indicating where (`start` and `end`, which should be integers) the token is placed within the complete line typed so far (`line`).

Potential completions of the token are generated by `.completeToken`, and the completions can be retrieved as an R character vector using `.retrieveCompletions`. It is possible for the user to specify a replacement for this function by setting `rc.options("custom.completer")`; if not `NULL`, this function is called to compute potential completions. This facility is meant to help in situations where completing as R code is not appropriate. See source code for more details.

If the cursor is inside quotes, completion may be suppressed. The function `.getFileComp` can be used after a call to `.completeToken` to determine if this is the case (returns `TRUE`), and alternative completions generated as deemed useful. In most cases, filename completion is a reasonable fallback.

The `.guessTokenFromLine` function is provided for use with backends that do not already break a line into tokens. It requires the `linebuffer` and endpoint (cursor position) to be already set, and itself sets the token and the start position. It returns the token as a character string.

The `.win32consoleCompletion` is similar in spirit, but is more geared towards the Windows GUI (or rather, any front-end that has no completion facilities of its own). It requires the `linebuffer` and cursor position as arguments, and returns a list with three components, `addition`, `possible` and `comps`. If there is an unambiguous extension at the current position, `addition` contains the additional text that should be inserted at the cursor. If there is more than one possibility, these are available either as a character vector of preformatted strings in `possible`, or as a single string in `comps`. `possible` consists of lines formatted using the current `width` option, so that printing them on the console one line at a time will be a reasonable way to list them. `comps` is a space separated (collapsed) list of the same completions, in case the front-end wishes to display it in some other fashion.

The `minlength` argument can be used to suppress completion when the token is too short (which can be useful if the front-end is set up to try completion on every keypress). If `check.repeat` is `TRUE`, it is detected if the same completion is being requested more than once in a row, and ambiguous completions are returned only in that case. This is an attempt to emulate GNU Readline behaviour, where a single TAB completes up to any unambiguous part, and multiple possibilities are reported only on two consecutive TABs.

As the various front-end interfaces evolve, the details of these functions are likely to change as well.

The function `.addFunctionInfo` can be used to add information about the permitted argument names for specific functions. Multiple named arguments are allowed in calls to it, where the tags are names of functions and values are character vectors representing valid arguments. When the `argdb` setting is `TRUE`, these are used as a source of valid argument names for the relevant functions.

**Note**

If you are uncomfortable with unsolicited evaluation of pieces of code, you should set `ops = FALSE`. Otherwise, trying to complete `foo@ba` will evaluate `foo`, trying to complete `foo[i, 1:10]$ba` will evaluate `foo[i, 1:10]`, etc. This should not be too bad, as explicit function calls (involving parentheses) are not evaluated in this manner. However, this *will* affect promises and lazy loaded symbols.

---

read.DIF

*Data Input from Spreadsheet*

---

**Description**

Reads a file in Data Interchange Format (DIF) and creates a data frame from it. DIF is a format for data matrices such as single spreadsheets.

**Usage**

```
read.DIF(file, header = FALSE,
 dec = ".", numerals = c("allow.loss", "warn.loss", "no.loss"),
 row.names, col.names, as.is = !stringsAsFactors,
 na.strings = "NA", colClasses = NA, nrow = -1,
 skip = 0, check.names = TRUE, blank.lines.skip = TRUE,
 stringsAsFactors = default.stringsAsFactors(),
 transpose = FALSE, fileEncoding = "")
```

**Arguments**

|                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>file</code>      | the name of the file which the data are to be read from, or a <a href="#">connection</a> , or a complete URL.<br>The name "clipboard" may also be used on Windows, in which case <code>read.DIF("clipboard")</code> will look for a DIF format entry in the Windows clipboard.                                                                                                                                                                                                                                                      |
| <code>header</code>    | a logical value indicating whether the spreadsheet contains the names of the variables as its first line. If missing, the value is determined from the file format: <code>header</code> is set to <code>TRUE</code> if and only if the first row contains only character values and the top left cell is empty.                                                                                                                                                                                                                     |
| <code>dec</code>       | the character used in the file for decimal points.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <code>numerals</code>  | string indicating how to convert numbers whose conversion to double precision would lose accuracy, see <a href="#">type.convert</a> .                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>row.names</code> | a vector of row names. This can be a vector giving the actual row names, or a single number giving the column of the table which contains the row names, or character string giving the name of the table column containing the row names. If there is a header and the first row contains one fewer field than the number of columns, the first column in the input is used for the row names. Otherwise if <code>row.names</code> is missing, the rows are numbered.<br>Using <code>row.names = NULL</code> forces row numbering. |

|                               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>col.names</code>        | a vector of optional names for the variables. The default is to use "V" followed by the column number.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>as.is</code>            | <p>controls conversion of character variables (insofar as they are not converted to logical, numeric or complex) to factors, if not otherwise specified by <code>colClasses</code>. Its value is either a vector of logicals (values are recycled if necessary), or a vector of numeric or character indices which specify which columns should not be converted to factors.</p> <p>Note: In releases prior to R 2.12.1, cells marked as being of character type were converted to logical, numeric or complex using <code>type.convert</code> as in <code>read.table</code>.</p> <p>Note: to suppress all conversions including those of numeric columns, set <code>colClasses = "character"</code>.</p> <p>Note that <code>as.is</code> is specified per column (not per variable) and so includes the column of row names (if any) and any columns to be skipped.</p> |
| <code>na.strings</code>       | a character vector of strings which are to be interpreted as NA values. Blank fields are also considered to be missing values in logical, integer, numeric and complex fields.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>colClasses</code>       | <p>character. A vector of classes to be assumed for the columns. Recycled as necessary, or if the character vector is named, unspecified values are taken to be NA.</p> <p>Possible values are NA (when <code>type.convert</code> is used), "NULL" (when the column is skipped), one of the atomic vector classes (logical, integer, numeric, complex, character, raw), or "factor", "Date" or "POSIXct". Otherwise there needs to be an <code>as</code> method (from package <b>methods</b>) for conversion from "character" to the specified formal class.</p> <p>Note that <code>colClasses</code> is specified per column (not per variable) and so includes the column of row names (if any).</p>                                                                                                                                                                   |
| <code>nrows</code>            | the maximum number of rows to read in. Negative values are ignored.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>skip</code>             | the number of lines of the data file to skip before beginning to read data.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <code>check.names</code>      | logical. If TRUE then the names of the variables in the data frame are checked to ensure that they are syntactically valid variable names. If necessary they are adjusted (by <code>make.names</code> ) so that they are, and also to ensure that there are no duplicates.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>blank.lines.skip</code> | logical: if TRUE blank lines in the input are ignored.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>stringsAsFactors</code> | logical: should character vectors be converted to factors?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>transpose</code>        | logical, indicating if the row and column interpretation should be transposed. Microsoft's Excel has been known to produce (non-standard conforming) DIF files which would need <code>transpose = TRUE</code> to be read correctly.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>fileEncoding</code>     | character string: if non-empty declares the encoding used on a file (not a connection or clipboard) so the character data can be re-encoded. See the 'Encoding' section of the help for <code>file</code> , the 'R Data Import/Export Manual' and 'Note'.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

## Value

A data frame (`data.frame`) containing a representation of the data in the file. Empty input is an error unless `col.names` is specified, when a 0-row data frame is returned: similarly giving just a header line if `header = TRUE` results in a 0-row data frame.

**Note**

The columns referred to in `as.is` and `colClasses` include the column of row names (if any).  
 Less memory will be used if `colClasses` is specified as one of the six atomic vector classes.

**Author(s)**

R Core; `transpose` option by Christoph Buser, ETH Zurich

**References**

The DIF format specification can be found by searching on <http://www.wotsit.org/>; the optional header fields are ignored. See also [https://en.wikipedia.org/wiki/Data\\_Interchange\\_Format](https://en.wikipedia.org/wiki/Data_Interchange_Format).

The term is likely to lead to confusion: Windows will have a ‘Windows Data Interchange Format (DIF) data format’ as part of its WinFX system, which may or may not be compatible.

**See Also**

The *R Data Import/Export* manual.

`scan`, `type.convert`, `read.fwf` for reading *fixed width formatted* input; `read.table`; `data.frame`.

**Examples**

```
read.DIF() may need transpose = TRUE for a file exported from Excel
udir <- system.file("misc", package = "utils")
dd <- read.DIF(file.path(udir, "exDIF.dif"), header = TRUE, transpose = TRUE)
dc <- read.csv(file.path(udir, "exDIF.csv"), header = TRUE)
stopifnot(identical(dd, dc), dim(dd) == c(4,2))
```

---

read.fortran

*Read Fixed-Format Data in a Fortran-like Style*

---

**Description**

Read fixed-format data files using Fortran-style format specifications.

**Usage**

```
read.fortran(file, format, ..., as.is = TRUE, colClasses = NA)
```

**Arguments**

|                         |                                                                                 |
|-------------------------|---------------------------------------------------------------------------------|
| <code>file</code>       | File or <a href="#">connection</a> to read from.                                |
| <code>format</code>     | Character vector or list of vectors. See ‘Details’ below.                       |
| <code>...</code>        | Other arguments for <code>read.fwf</code> .                                     |
| <code>as.is</code>      | Keep characters as characters?                                                  |
| <code>colClasses</code> | Variable classes to override defaults. See <code>read.table</code> for details. |

## Details

The format for a field is of one of the following forms: `rF $l$ .d`, `rD $l$ .d`, `rX $l$` , `rA $l$` , `rI $l$` , where  $l$  is the number of columns,  $d$  is the number of decimal places, and  $r$  is the number of repeats. `F` and `D` are numeric formats, `A` is character, `I` is integer, and `X` indicates columns to be skipped. The repeat code  $r$  and decimal place code  $d$  are always optional. The length code  $l$  is required except for `X` formats when  $r$  is present.

For a single-line record, `format` should be a character vector. For a multiline record it should be a list with a character vector for each line.

Skipped (`X`) columns are not passed to `read.fwf`, so `colClasses`, `col.names`, and similar arguments passed to `read.fwf` should not reference these columns.

## Value

A data frame

## Note

`read.fortran` does not use actual Fortran input routines, so the formats are at best rough approximations to the Fortran ones. In particular, specifying  $d > 0$  in the `F` or `D` format will shift the decimal  $d$  places to the left, even if it is explicitly specified in the input file.

## See Also

[read.fwf](#), [read.table](#), [read.csv](#)

## Examples

```
ff <- tempfile()
cat(file = ff, "123456", "987654", sep = "\n")
read.fortran(ff, c("F2.1", "F2.0", "I2"))
read.fortran(ff, c("2F1.0", "2X", "2A1"))
unlink(ff)
cat(file = ff, "123456AB", "987654CD", sep = "\n")
read.fortran(ff, list(c("2F3.1", "A2"), c("3I2", "2X")))
unlink(ff)
Note that the first number is read differently than Fortran would
read it:
cat(file = ff, "12.3456", "1234567", sep = "\n")
read.fortran(ff, "F7.4")
unlink(ff)
```

---

read.fwf

*Read Fixed Width Format Files*

---

## Description

Read a table of fixed width formatted data into a [data.frame](#).

## Usage

```
read.fwf(file, widths, header = FALSE, sep = "\t",
 skip = 0, row.names, col.names, n = -1,
 buffersize = 2000, fileEncoding = "", ...)
```

**Arguments**

|                           |                                                                                                                                                                                                                                                 |
|---------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>file</code>         | the name of the file which the data are to be read from.<br>Alternatively, <code>file</code> can be a <a href="#">connection</a> , which will be opened if necessary, and if so closed at the end of the function call.                         |
| <code>widths</code>       | integer vector, giving the widths of the fixed-width fields (of one line), or list of integer vectors giving widths for multiline records.                                                                                                      |
| <code>header</code>       | a logical value indicating whether the file contains the names of the variables as its first line. If present, the names must be delimited by <code>sep</code> .                                                                                |
| <code>sep</code>          | character; the separator used internally; should be a character that does not occur in the file (except in the header).                                                                                                                         |
| <code>skip</code>         | number of initial lines to skip; see <a href="#">read.table</a> .                                                                                                                                                                               |
| <code>row.names</code>    | see <a href="#">read.table</a> .                                                                                                                                                                                                                |
| <code>col.names</code>    | see <a href="#">read.table</a> .                                                                                                                                                                                                                |
| <code>n</code>            | the maximum number of records (lines) to be read, defaulting to no limit.                                                                                                                                                                       |
| <code>buffer size</code>  | Maximum number of lines to read at one time                                                                                                                                                                                                     |
| <code>fileEncoding</code> | character string: if non-empty declares the encoding used on a file (not a connection) so the character data can be re-encoded. See the ‘Encoding’ section of the help for <a href="#">file</a> , the ‘R Data Import/Export’ manual and ‘Note’. |
| <code>...</code>          | further arguments to be passed to <a href="#">read.table</a> . Useful such arguments include <code>as.is</code> , <code>na.strings</code> , <code>colClasses</code> and <code>strip.white</code> .                                              |

**Details**

Multiline records are concatenated to a single line before processing. Fields that are of zero-width or are wholly beyond the end of the line in `file` are replaced by NA.

Negative-width fields are used to indicate columns to be skipped, e.g., `-5` to skip 5 columns. These fields are not seen by `read.table` and so should not be included in a `col.names` or `colClasses` argument (nor in the header line, if present).

Reducing the `buffer size` argument may reduce memory use when reading large files with long lines. Increasing `buffer size` may result in faster processing when enough memory is available.

Note that `read.fwf` (not `read.table`) reads the supplied file, so the latter’s argument `encoding` will not be useful.

**Value**

A [data.frame](#) as produced by [read.table](#) which is called internally.

**Author(s)**

Brian Ripley for R version: originally in Perl by Kurt Hornik.

**See Also**

[scan](#) and [read.table](#).

[read.fortran](#) for another style of fixed-format files.

**Examples**

```
ff <- tempfile()
cat(file = ff, "123456", "987654", sep = "\n")
read.fwf(ff, widths = c(1,2,3)) #> 1 23 456 \ 9 87 654
read.fwf(ff, widths = c(1,-2,3)) #> 1 456 \ 9 654
unlink(ff)
cat(file = ff, "123", "987654", sep = "\n")
read.fwf(ff, widths = c(1,0, 2,3)) #> 1 NA 23 NA \ 9 NA 87 654
unlink(ff)
cat(file = ff, "123456", "987654", sep = "\n")
read.fwf(ff, widths = list(c(1,0, 2,3), c(2,2,2))) #> 1 NA 23 456 98 76 54
unlink(ff)
```

read.socket

*Read from or Write to a Socket***Description**

`read.socket` reads a string from the specified socket, `write.socket` writes to the specified socket. There is very little error checking done by either.

**Usage**

```
read.socket(socket, maxlen = 256L, loop = FALSE)
write.socket(socket, string)
```

**Arguments**

|                     |                                              |
|---------------------|----------------------------------------------|
| <code>socket</code> | a socket object.                             |
| <code>maxlen</code> | maximum length (in bytes) of string to read. |
| <code>loop</code>   | wait for ever if there is nothing to read?   |
| <code>string</code> | string to write to socket.                   |

**Value**

`read.socket` returns the string read as a length-one character vector.

`write.socket` returns the number of bytes written.

**Author(s)**

Thomas Lumley

## Examples

```
finger <- function(user, host = "localhost", port = 79, print = TRUE)
{
 if (!is.character(user))
 stop("user name must be a string")
 user <- paste(user, "\r\n")
 socket <- make.socket(host, port)
 on.exit(close.socket(socket))
 write.socket(socket, user)
 output <- character(0)
 repeat{
 ss <- read.socket(socket)
 if (ss == "") break
 output <- paste(output, ss)
 }
 close.socket(socket)
 if (print) cat(output)
 invisible(output)
}
Not run:
finger("root") ## only works if your site provides a finger daemon
End(Not run)
```

---

read.table

*Data Input*

---

## Description

Reads a file in table format and creates a data frame from it, with cases corresponding to lines and variables to fields in the file.

## Usage

```
read.table(file, header = FALSE, sep = "", quote = "\"",
 dec = ".", numerals = c("allow.loss", "warn.loss", "no.loss"),
 row.names, col.names, as.is = !stringsAsFactors,
 na.strings = "NA", colClasses = NA, nrows = -1,
 skip = 0, check.names = TRUE, fill = !blank.lines.skip,
 strip.white = FALSE, blank.lines.skip = TRUE,
 comment.char = "#",
 allowEscapes = FALSE, flush = FALSE,
 stringsAsFactors = default.stringsAsFactors(),
 fileEncoding = "", encoding = "unknown", text, skipNul = FALSE)

read.csv(file, header = TRUE, sep = ",", quote = "\"",
 dec = ".", fill = TRUE, comment.char = "", ...)

read.csv2(file, header = TRUE, sep = ";", quote = "\"",
 dec = ",", fill = TRUE, comment.char = "", ...)

read.delim(file, header = TRUE, sep = "\t", quote = "\"",
 dec = ".", fill = TRUE, comment.char = "", ...)
```

```
read.delim2(file, header = TRUE, sep = "\t", quote = "\"",
 dec = ",", fill = TRUE, comment.char = "", ...)
```

## Arguments

|           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| file      | <p>the name of the file which the data are to be read from. Each row of the table appears as one line of the file. If it does not contain an <i>absolute</i> path, the file name is <i>relative</i> to the current working directory, <code>getwd()</code>. Tilde-expansion is performed where supported. This can be a compressed file (see <a href="#">file</a>).</p> <p>Alternatively, <code>file</code> can be a readable text-mode <a href="#">connection</a> (which will be opened for reading if necessary, and if so <code>closed</code> (and hence destroyed) at the end of the function call). (If <code>stdin()</code> is used, the prompts for lines may be somewhat confusing. Terminate input with a blank line or an EOF signal, Ctrl-D on Unix and Ctrl-Z on Windows. Any pushback on <code>stdin()</code> will be cleared before return.)</p> <p><code>file</code> can also be a complete URL. (For the supported URL schemes, see the ‘URLs’ section of the help for <a href="#">url</a>.)</p> |
| header    | a logical value indicating whether the file contains the names of the variables as its first line. If missing, the value is determined from the file format: <code>header</code> is set to <code>TRUE</code> if and only if the first row contains one fewer field than the number of columns.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| sep       | the field separator character. Values on each line of the file are separated by this character. If <code>sep = ""</code> (the default for <code>read.table</code> ) the separator is ‘white space’, that is one or more spaces, tabs, newlines or carriage returns.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| quote     | the set of quoting characters. To disable quoting altogether, use <code>quote = ""</code> . See <a href="#">scan</a> for the behaviour on quotes embedded in quotes. Quoting is only considered for columns read as character, which is all of them unless <code>colClasses</code> is specified.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| dec       | the character used in the file for decimal points.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| numerals  | string indicating how to convert numbers whose conversion to double precision would lose accuracy, see <a href="#">type.convert</a> . Can be abbreviated. (Applies also to complex-number inputs.)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| row.names | <p>a vector of row names. This can be a vector giving the actual row names, or a single number giving the column of the table which contains the row names, or character string giving the name of the table column containing the row names.</p> <p>If there is a header and the first row contains one fewer field than the number of columns, the first column in the input is used for the row names. Otherwise if <code>row.names</code> is missing, the rows are numbered.</p> <p>Using <code>row.names = NULL</code> forces row numbering. Missing or <code>NULL</code> <code>row.names</code> generate row names that are considered to be ‘automatic’ (and not preserved by <a href="#">as.matrix</a>).</p>                                                                                                                                                                                                                                                                                             |
| col.names | a vector of optional names for the variables. The default is to use "V" followed by the column number.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| as.is     | controls conversion of character variables (insofar as they are not converted to logical, numeric or complex) to factors, if not otherwise specified by <code>colClasses</code> . Its value is either a vector of logicals (values are recycled if necessary), or a vector of numeric or character indices which specify which columns should not be converted to factors.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

|                               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                               | <p>Note: to suppress all conversions including those of numeric columns, set <code>colClasses = "character"</code>.</p> <p>Note that <code>as.is</code> is specified per column (not per variable) and so includes the column of row names (if any) and any columns to be skipped.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>na.strings</code>       | a character vector of strings which are to be interpreted as <a href="#">NA</a> values. Blank fields are also considered to be missing values in logical, integer, numeric and complex fields. Note that the test happens <i>after</i> white space is stripped from the input, so <code>na.strings</code> values may need their own white space stripped in advance.                                                                                                                                                                                                                                                                                                                                                             |
| <code>colClasses</code>       | <p>character. A vector of classes to be assumed for the columns. If unnamed, recycled as necessary. If named, names are matched with unspecified values being taken to be NA.</p> <p>Possible values are NA (the default, when <a href="#">type.convert</a> is used), "NULL" (when the column is skipped), one of the atomic vector classes (logical, integer, numeric, complex, character, raw), or "factor", "Date" or "POSIXct". Otherwise there needs to be an <code>as</code> method (from package <b>methods</b>) for conversion from "character" to the specified formal class.</p> <p>Note that <code>colClasses</code> is specified per column (not per variable) and so includes the column of row names (if any).</p> |
| <code>nrows</code>            | integer: the maximum number of rows to read in. Negative and other invalid values are ignored.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>skip</code>             | integer: the number of lines of the data file to skip before beginning to read data.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>check.names</code>      | logical. If TRUE then the names of the variables in the data frame are checked to ensure that they are syntactically valid variable names. If necessary they are adjusted (by <a href="#">make.names</a> ) so that they are, and also to ensure that there are no duplicates.                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>fill</code>             | logical. If TRUE then in case the rows have unequal length, blank fields are implicitly added. See ‘Details’.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>strip.white</code>      | logical. Used only when <code>sep</code> has been specified, and allows the stripping of leading and trailing white space from unquoted character fields (numeric fields are always stripped). See <a href="#">scan</a> for further details (including the exact meaning of ‘white space’), remembering that the columns may include the row names.                                                                                                                                                                                                                                                                                                                                                                              |
| <code>blank.lines.skip</code> | logical: if TRUE blank lines in the input are ignored.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>comment.char</code>     | character: a character vector of length one containing a single character or an empty string. Use "" to turn off the interpretation of comments altogether.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>allowEscapes</code>     | logical. Should C-style escapes such as ‘\n’ be processed or read verbatim (the default)? Note that if not within quotes these could be interpreted as a delimiter (but not as a comment character). For more details see <a href="#">scan</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <code>flush</code>            | logical: if TRUE, <code>scan</code> will flush to the end of the line after reading the last of the fields requested. This allows putting comments after the last field.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>stringsAsFactors</code> | logical: should character vectors be converted to factors? Note that this is overridden by <code>as.is</code> and <code>colClasses</code> , both of which allow finer control.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>fileEncoding</code>     | character string: if non-empty declares the encoding used on a file (not a connection) so the character data can be re-encoded. See the ‘Encoding’ section of the help for <a href="#">file</a> , the ‘R Data Import/Export Manual’ and ‘Note’.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

|          |                                                                                                                                                                                                                                                                                                          |
|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| encoding | encoding to be assumed for input strings. It is used to mark character strings as known to be in Latin-1 or UTF-8 (see <a href="#">Encoding</a> ): it is not used to re-encode the input, but allows R to handle encoded strings in their native encoding (if one of those two). See ‘Value’ and ‘Note’. |
| text     | character string: if file is not supplied and this is, then data are read from the value of text via a text connection. Notice that a literal string can be used to include (small) data sets within R code.                                                                                             |
| skipNul  | logical: should nuls be skipped?                                                                                                                                                                                                                                                                         |
| ...      | Further arguments to be passed to read.table.                                                                                                                                                                                                                                                            |

## Details

This function is the principal means of reading tabular data into R.

Unless `colClasses` is specified, all columns are read as character columns and then converted using `type.convert` to logical, integer, numeric, complex or (depending on `as.is`) factor as appropriate. Quotes are (by default) interpreted in all fields, so a column of values like "42" will result in an integer column.

A field or line is ‘blank’ if it contains nothing (except whitespace if no separator is specified) before a comment character or the end of the field or line.

If `row.names` is not specified and the header line has one less entry than the number of columns, the first column is taken to be the row names. This allows data frames to be read in from the format in which they are printed. If `row.names` is specified and does not refer to the first column, that column is discarded from such files.

The number of data columns is determined by looking at the first five lines of input (or the whole input if it has less than five lines), or from the length of `col.names` if it is specified and is longer. This could conceivably be wrong if `fill` or `blank.lines.skip` are true, so specify `col.names` if necessary (as in the ‘Examples’).

`read.csv` and `read.csv2` are identical to `read.table` except for the defaults. They are intended for reading ‘comma separated value’ files (`.csv`) or (`read.csv2`) the variant used in countries that use a comma as decimal point and a semicolon as field separator. Similarly, `read.delim` and `read.delim2` are for reading delimited files, defaulting to the TAB character for the delimiter. Notice that `header = TRUE` and `fill = TRUE` in these variants, and that the comment character is disabled.

The rest of the line after a comment character is skipped; quotes are not processed in comments. Complete comment lines are allowed provided `blank.lines.skip = TRUE`; however, comment lines prior to the header must have the comment character in the first non-blank column.

Quoted fields with embedded newlines are supported except after a comment character. Embedded nuls are unsupported: skipping them (with `skipNul = TRUE`) may work.

## Value

A data frame (`data.frame`) containing a representation of the data in the file.

Empty input is an error unless `col.names` is specified, when a 0-row data frame is returned: similarly giving just a header line if `header = TRUE` results in a 0-row data frame. Note that in either case the columns will be logical unless `colClasses` was supplied.

Character strings in the result (including factor levels) will have a declared encoding if `encoding` is "latin1" or "UTF-8".

## Memory usage

These functions can use a surprising amount of memory when reading large files. There is extensive discussion in the ‘R Data Import/Export’ manual, supplementing the notes here.

Less memory will be used if `colClasses` is specified as one of the six [atomic](#) vector classes. This can be particularly so when reading a column that takes many distinct numeric values, as storing each distinct value as a character string can take up to 14 times as much memory as storing it as an integer.

Using `nrows`, even as a mild over-estimate, will help memory usage.

Using `comment.char = ""` will be appreciably faster than the `read.table` default.

`read.table` is not the right tool for reading large matrices, especially those with many columns: it is designed to read *data frames* which may have columns of very different classes. Use [scan](#) instead for matrices.

## Note

The columns referred to in `as.is` and `colClasses` include the column of row names (if any).

There are two approaches for reading input that is not in the local encoding. If the input is known to be UTF-8 or Latin1, use the `encoding` argument to declare that. If the input is in some other encoding, then it may be translated on input. The `fileEncoding` argument achieves this by setting up a connection to do the re-encoding into the current locale. Note that on Windows or other systems not running in a UTF-8 locale, this may not be possible.

The ‘R Data Import/Export’ manual.

[scan](#), [type.convert](#), [read.fwf](#) for reading fixed width formatted input; [write.table](#); [data.frame](#).

[count.fields](#) can be useful to determine problems with reading files which result in reports of incorrect record lengths (see the ‘Examples’ below).

<https://tools.ietf.org/html/rfc4180> for the IANA definition of CSV files (which requires comma as separator and CRLF line endings).

## Examples

```
using count.fields to handle unknown maximum number of fields
when fill = TRUE
test1 <- c(1:5, "6,7", "8,9,10")
tf <- tempfile()
writeLines(test1, tf)

read.csv(tf, fill = TRUE) # 1 column
ncol <- max(count.fields(tf, sep = ","))
read.csv(tf, fill = TRUE, header = FALSE,
 col.names = paste0("V", seq_len(ncol)))
unlink(tf)
```

```
"Inline" data set, using text=
Notice that leading and trailing empty lines are auto-trimmed

read.table(header = TRUE, text = "
a b
1 2
3 4
")
```

readRegistry

*Read a Windows Registry Hive*

## Description

On Windows, read values of keys in the Windows Registry, and optionally whole hives.

## Usage

```
readRegistry(key, hive = c("HLM", "HCR", "HCU", "HU", "HCC", "HPD"),
 maxdepth = 1, view = c("default", "32-bit", "64-bit"))
```

## Arguments

|          |                                                                                                                                                                              |
|----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| key      | character string, the path to the key in the Windows Registry.                                                                                                               |
| hive     | The 'hive' containing the key. The abbreviations are for HKEY_LOCAL_MACHINE, HKEY_CLASSES_ROOT, HKEY_CURRENT_USER, HKEY_USERS, HKEY_CURRENT_CONFIG and HKEY_PERFORMANCE_DATA |
| maxdepth | How far to recurse into the subkeys of the key. By default only the values of the key and the names of subkeys are returned.                                                 |
| view     | On 64-bit Windows, the view of the Registry to be used: see 'Details'.                                                                                                       |

## Details

Registry access is done using the security settings of the current R session: this means that some Registry keys may not be accessible even if they exist. This may result in NULL values in the object returned, and, possibly, empty element names.

On 64-bit Windows, this will by default read the 32-bit view of the Registry when run from 32-bit R, and the 64-bit view when run from 64-bit R: see <https://docs.microsoft.com/en-us/windows/win32/winprog64/registry-redirector>.

## Value

A named list of values and subkeys (which may themselves be named lists). The default value (if any) precedes named values which precede subkeys, and both the latter sets are sorted alphabetically.

## Note

This is only available on Windows.

## Examples

```
if(.Platform$OS.type == "windows") withAutoprint({
 ## only in HLM if set in an admin-mode install.
 try(readRegistry("SOFTWARE\\R-core", maxdepth = 3))

 gmt <- file.path("SOFTWARE", "Microsoft", "Windows NT",
 "CurrentVersion", "Time Zones",
 "GMT Standard Time", fsep = "\\")
 readRegistry(gmt, "HLM")
})
Not run: ## on a 64-bit R need this to find 32-bit JAGS
readRegistry("SOFTWARE\\JAGS", maxdepth = 3, view = "32")

See if there is a 64-bit user install
readRegistry("SOFTWARE\\R-core\\R64", "HCU", maxdepth = 2)

End(Not run)
```

---

recover

*Browsing after an Error*

---

## Description

This function allows the user to browse directly on any of the currently active function calls, and is suitable as an error option. The expression `options(error = recover)` will make this the error option.

## Usage

```
recover()
```

## Details

When called, `recover` prints the list of current calls, and prompts the user to select one of them. The standard R `browser` is then invoked from the corresponding environment; the user can type ordinary R language expressions to be evaluated in that environment.

When finished browsing in this call, type `c` to return to `recover` from the browser. Type another frame number to browse some more, or type `0` to exit `recover`.

The use of `recover` largely supersedes `dump.frames` as an error option, unless you really want to wait to look at the error. If `recover` is called in non-interactive mode, it behaves like `dump.frames`. For computations involving large amounts of data, `recover` has the advantage that it does not need to copy out all the environments in order to browse in them. If you do decide to quit interactive debugging, call `dump.frames` directly while browsing in any frame (see the examples).

## Value

Nothing useful is returned. However, you *can* invoke `recover` directly from a function, rather than through the error option shown in the examples. In this case, execution continues after you type `0` to exit `recover`.

## Compatibility Note

The `R recover` function can be used in the same way as the S function of the same name; therefore, the `error` option shown is a compatible way to specify the error action. However, the actual functions are essentially unrelated and interact quite differently with the user. The navigating commands `up` and `down` do not exist in the R version; instead, exit the browser and select another frame.

## References

See the compatibility note above, however.

## See Also

[browser](#) for details about the interactive computations; [options](#) for setting the error option; [dump.frames](#) to save the current environments for later debugging.

## Examples

```
Not run:

options(error = recover) # setting the error option

Example of interaction

> myFit <- lm(y ~ x, data = xy, weights = w)
Error in lm.wfit(x, y, w, offset = offset, ...) :
 missing or negative weights not allowed

Enter a frame number, or 0 to exit
1:lm(y ~ x, data = xy, weights = w)
2:lm.wfit(x, y, w, offset = offset, ...)
Selection: 2
Called from: eval(expr, envir, enclos)
Browse[1]> objects() # all the objects in this frame
[1] "method" "n" "ny" "offset" "tol" "w"
[7] "x" "y"
Browse[1]> w
[1] -0.5013844 1.3112515 0.2939348 -0.8983705 -0.1538642
[6] -0.9772989 0.7888790 -0.1919154 -0.3026882
Browse[1]> dump.frames() # save for offline debugging
Browse[1]> c # exit the browser

Enter a frame number, or 0 to exit
1:lm(y ~ x, data = xy, weights = w)
2:lm.wfit(x, y, w, offset = offset, ...)
Selection: 0 # exit recover
>

End(Not run)
```

relist

*Allow Re-Listing an unlist()ed Object***Description**

`relist()` is an S3 generic function with a few methods in order to allow easy inversion of `unlist(obj)` when that is used with an object `obj` of (S3) class "relistable".

**Usage**

```
relist(flesh, skeleton)
Default S3 method:
relist(flesh, skeleton = attr(flesh, "skeleton"))
S3 method for class 'factor'
relist(flesh, skeleton = attr(flesh, "skeleton"))
S3 method for class 'list'
relist(flesh, skeleton = attr(flesh, "skeleton"))
S3 method for class 'matrix'
relist(flesh, skeleton = attr(flesh, "skeleton"))

as.relistable(x)
is.relistable(x)

S3 method for class 'relistable'
unlist(x, recursive = TRUE, use.names = TRUE)
```

**Arguments**

|                        |                                                                             |
|------------------------|-----------------------------------------------------------------------------|
| <code>flesh</code>     | a vector to be relisted                                                     |
| <code>skeleton</code>  | a list, the structure of which determines the structure of the result       |
| <code>x</code>         | an R object, typically a list (or vector).                                  |
| <code>recursive</code> | logical. Should unlisting be applied to list components of <code>x</code> ? |
| <code>use.names</code> | logical. Should names be preserved?                                         |

**Details**

Some functions need many parameters, which are most easily represented in complex structures, e.g., nested lists. Unfortunately, many mathematical functions in R, including `optim` and `nlm` can only operate on functions whose domain is a vector. R has `unlist()` to convert nested list objects into a vector representation. `relist()`, its methods and the functionality mentioned here provide the inverse operation to convert vectors back to the convenient structural representation. This allows structured functions (such as `optim()`) to have simple mathematical interfaces.

For example, a likelihood function for a multivariate normal model needs a variance-covariance matrix and a mean vector. It would be most convenient to represent it as a list containing a vector and a matrix. A typical parameter might look like

```
list(mean = c(0, 1), vcov = cbind(c(1, 1), c(1, 0)))
```

However, `optim` cannot operate on functions that take lists as input; it only likes numeric vectors. The solution is conversion. Given a function `mvdnorm(x, mean, vcov, log = FALSE)` which computes the required probability density, then

```

ipar <- list(mean = c(0, 1), vcov = c bind(c(1, 1), c(1, 0)))
initial.param <- as.relistable(ipar)

ll <- function(param.vector)
{
 param <- relist(param.vector, skeleton = ipar)
 -sum(mvdnorm(x, mean = param$mean, vcov = param$vcov,
 log = TRUE))
}

optim(unlist(initial.param), ll)

```

`relist` takes two parameters: `skeleton` and `flesh`. `Skeleton` is a sample object that has the right shape but the wrong content. `flesh` is a vector with the right content but the wrong shape. Invoking

```
relist(flesh, skeleton)
```

will put the content of `flesh` on the `skeleton`. You don't need to specify `skeleton` explicitly if the `skeleton` is stored as an attribute inside `flesh`. In particular, if `flesh` was created from some object `obj` with `unlist(as.relistable(obj))` then the `skeleton` attribute is automatically set. (Note that this does not apply to the example here, as `optim` is creating a new vector to pass to `ll` and not its `par` argument.)

As long as `skeleton` has the right shape, it should be a precise inverse of `unlist`. These equalities hold:

```

relist(unlist(x), x) == x
unlist(relist(y, skeleton)) == y

x <- as.relistable(x)
relist(unlist(x)) == x

```

### Value

an object of (S3) class "relistable" (and "list").

### Author(s)

R Core, based on a code proposal by Andrew Clausen.

### See Also

[unlist](#)

### Examples

```

ipar <- list(mean = c(0, 1), vcov = cbind(c(1, 1), c(1, 0)))
initial.param <- as.relistable(ipar)
ul <- unlist(initial.param)
relist(ul)
stopifnot(identical(relist(ul), initial.param))

```

---

|        |                               |
|--------|-------------------------------|
| REMOVE | <i>Remove Add-on Packages</i> |
|--------|-------------------------------|

---

### Description

Utility for removing add-on packages.

### Usage

```
R CMD REMOVE [options] [-l lib] pkgs
```

### Arguments

|         |                                                                                                                             |
|---------|-----------------------------------------------------------------------------------------------------------------------------|
| pkgs    | a space-separated list with the names of the packages to be removed.                                                        |
| lib     | the path name of the R library tree to remove from. May be absolute or relative. Also accepted in the form '--library=lib'. |
| options | further options for help or version.                                                                                        |

### Details

If used as `R CMD REMOVE pkgs` without explicitly specifying `lib`, packages are removed from the library tree rooted at the first directory in the library path which would be used by R run in the current environment.

To remove from the library tree *lib* instead of the default one, use `R CMD REMOVE -l lib pkgs`.

Use `R CMD REMOVE --help` for more usage information.

### Note

Some binary distributions of R have REMOVE in a separate bundle, e.g. an R-devel RPM.

---

removeSource

---

*Remove Stored Source from a Function or Language Object*

---

**Description**

When `options("keep.source")` is `TRUE`, a copy of the original source code to a function is stored with it. Similarly, `parse()` may keep formatted source for an expression. Such source reference attributes are removed from the object by `removeSource()`.

**Usage**

```
removeSource(fn)
```

**Arguments**

`fn` a [function](#) or another language object (fulfilling [is.language](#)) from which to remove the source.

**Details**

This removes the `"srcref"` and related attributes, via *recursive* cleaning of `body(fn)` in the case of a function or the recursive language parts, otherwise.

**Value**

A copy of the `fn` object with the source removed.

**See Also**

[is.language](#) about language objects.  
[srcref](#) for a description of source reference records, [deparse](#) for a description of how functions are deparsed.

**Examples**

```
to make this act independently of the global 'options()' setting:
op <- options(keep.source = TRUE)
fn <- function(x) {
 x + 1 # A comment, kept as part of the source
}
fn
names(attributes(fn)) # "srcref" (only)
names(attributes(body(fn))) # "srcref" "srcfile" "wholeSrcref"
f2 <- removeSource(fn)
f2
stopifnot(length(attributes(fn)) > 0,
 is.null(attributes(f2)),
 is.null(attributes(body(f2))))
```

```
Source attribute of parse()d expressions,
have {"srcref", "srcfile", "wholeSrcref"} :
E <- parse(text ="a <- x^y # power") ; names(attributes(E))
E. <- removeSource(E) ; names(attributes(E.))
stopifnot (length(attributes(E)) > 0,
 is.null(attributes(E.)))
options(op) # reset to previous state
```

---

|       |                         |
|-------|-------------------------|
| RHOME | <i>R Home Directory</i> |
|-------|-------------------------|

---

**Description**

Returns the location of the R home directory, which is the root of the installed R tree.

**Usage**

```
R RHOME
```

---

|       |                       |
|-------|-----------------------|
| roman | <i>Roman Numerals</i> |
|-------|-----------------------|

---

**Description**

Simple manipulation of (a small set of) integer numbers as roman numerals.

**Usage**

```
as.roman(x)
.romans

r1 + r2
r1 <= r2
max(r1)
sum(r2)
```

**Arguments**

- x                    a numeric or character vector of arabic or roman numerals.
- r1, r2              a roman number vector, i.e., of `class "roman"`.

## Details

`as.roman` creates objects of class "roman" which are internally represented as integers, and have suitable methods for printing, formatting, subsetting, coercion, etc, see `methods(class = "roman")`.

Arithmetic ("[Arith](#)"), Comparison ("[Compare](#)") and ("[Logic](#)"), i.e., all "[Ops](#)" group operations work as for regular numbers via R's integer functionality.

Only numbers between 1 and 3899 have a unique representation as roman numbers, and hence others result in `as.roman(NA)`.

`.romans` is the basic dictionary, a named [character](#) vector.

## References

## Examples

```
First five roman 'numbers'.
(y <- as.roman(1 : 5))
Middle one.
y[3]
Current year as a roman number.
(y <- as.roman(format(Sys.Date(), "%Y")))
Today, and 10, 20, 30, and 100 years ago ...
y - 10*c(0:3,10)

mixture of arabic and roman numbers :
as.roman(c(NA, 1:3, "", strrep("I", 1:6))) # + NA with a warning for "IIIIII"
cc <- c(NA, 1:3, strrep("I", 0:5))
(rc <- as.roman(cc)) # two NAs: 0 is not "roman"
(ic <- as.integer(rc)) # works automatically [without an explicit method]
rNA <- as.roman(NA)
simple consistency checks -- arithmetic when result is in {1,2,...,3899} :
stopifnot(identical(rc, as.roman(rc)), # as.roman(.) is "idempotent"
 identical(rc + rc + (3*rc), rc*5),
 identical(ic, c(NA, 1:3, NA, 1:5)),
 identical(as.integer(5*rc), 5L*ic),
 identical(as.numeric(rc), as.numeric(ic)),
 identical(rc[1], rNA),
 identical(as.roman(0), rNA),
 identical(as.roman(NA_character_), rNA),
 identical(as.list(rc), as.list(ic)))
Non-Arithmetic 'Ops' :
stopifnot(exprs = {
 # Comparisons :
 identical(ic < 1:5, rc < 1:5)
 identical(ic < 1:5, rc < as.roman(1:5))
 # Logic [integers |-> logical] :
 identical(rc & TRUE , ic & TRUE)
 identical(rc & FALSE, ic & FALSE)
 identical(rc | FALSE, ic | FALSE)
 identical(rc | NA , ic | NA)
})
```

```
'Summary' group functions (and comparison):
(rc. <- rc[!is.na(rc)])
stopifnot(exprs = {
 identical(min(rc), as.roman(NA))
 identical(min(rc, na.rm=TRUE),
 as.roman(min(ic, na.rm=TRUE)))
 identical(range(rc.),
 as.roman(range(as.integer(rc))))
 identical(sum(rc, na.rm=TRUE), as.roman("XXI"))
 identical(format(prod(rc, na.rm=TRUE)), "DCCXX")
 format(prod(rc.)) == "DCCXX"
})
```

Rprof

*Enable Profiling of R's Execution*

## Description

Enable or disable profiling of the execution of R expressions.

## Usage

```
Rprof(filename = "Rprof.out", append = FALSE, interval = 0.02,
 memory.profiling = FALSE, gc.profiling = FALSE,
 line.profiling = FALSE, filter.callframes = FALSE,
 numfiles = 100L, bufsize = 10000L)
```

## Arguments

|                   |                                                                                                          |
|-------------------|----------------------------------------------------------------------------------------------------------|
| filename          | The file to be used for recording the profiling results. Set to NULL or "" to disable profiling.         |
| append            | logical: should the file be over-written or appended to?                                                 |
| interval          | real: time interval between samples.                                                                     |
| memory.profiling  | logical: write memory use information to the file?                                                       |
| gc.profiling      | logical: record whether GC is running?                                                                   |
| line.profiling    | logical: write line locations to the file?                                                               |
| filter.callframes | logical: filter out intervening call frames of the call tree. See the filtering out call frames section. |
| numfiles, bufsize | integers: line profiling memory allocation                                                               |

## Details

Enabling profiling automatically disables any existing profiling to another or the same file.

Profiling works by writing out the call stack every `interval` seconds, to the file specified. Either the [summaryRprof](#) function or the wrapper script `R CMD Rprof` can be used to process the output file to produce a summary of the usage; use `R CMD Rprof --help` for usage information.

How time is measured varies by platform:

**On Windows:** Exactly what the time interval measures is subtle: it is time that the R process is running and executing an R command. It is not however just CPU time, for if `readline()` is waiting for input, that counts (on Windows, but not on a Unix-alike).

Note that the timing interval cannot be too small, for the time spent in each profiling step is added to the interval. What is feasible is machine-dependent, but 10ms seemed as small as advisable on a 1GHz machine.

**On Unix-alikes** it is the CPU time of the R process, so for example excludes time when R is waiting for input or for processes run by `system` to return.

Note that the timing interval cannot usefully be too small: once the timer goes off, the information is not recorded until the next timing click (probably in the range 1–10 ms).

Functions will only be recorded in the profile log if they put a context on the call stack (see `sys.calls`). Some `primitive` functions do not do so: specifically those which are of `type "special"` (see the ‘R Internals’ manual for more details).

Individual statements will be recorded in the profile log if `line.profiling` is `TRUE`, and if the code being executed was parsed with source references. See `parse` for a discussion of source references. By default the statement locations are not shown in `summaryRprof`, but see that help page for options to enable the display.

### Filtering Out Call Frames

Lazy evaluation makes the call stack more complex because intervening call frames are created between the time arguments are applied to a function, and the time they are effectively evaluated. When the call stack is represented as a tree, these intervening frames appear as sibling nodes. For instance, evaluating `try(EXPR)` produces the following call tree, at the time `EXPR` gets evaluated:

```
1. +-base::try(EXPR)
2. | \-base::tryCatch(...)
3. | \-base::tryCatchList(expr, classes, parentenv, handlers)
4. | \-base::tryCatchOne(expr, names, parentenv, handlers[[1L]])
5. | \-base::doTryCatch(return(expr), name, parentenv, handler)
6. \-EXPR
```

Lines 2 to 5 are intervening call frames, the last of which finally triggered evaluation of `EXPR`. Setting `filter.callframes` to `TRUE` simplifies the profiler output by removing all sibling nodes of intervening frames.

The same kind of call frame filtering is applied with `eval()` frames. When you call `eval()`, two frames are pushed on the stack to ensure a continuity between frames. Say we have these definitions:

```
calling <- function() evaluator(quote(called()), environment())
evaluator <- function(expr, env) eval(expr, env)
called <- function() EXPR()
```

`calling()` calls `called()` in its own environment, via `eval()`. The latter is called indirectly through `evaluator()`. The net effect of this code is identical to just calling `called()` directly, without the intermediaries. However, the full call stack looks like this:

```
1. calling()
2. \-evaluator(quote(called()), environment())
3. \-base::eval(expr, env)
```

```

4. \-base::eval(expr, env)
5. \-called()
6. \-EXPR()

```

When call frame filtering is turned on, the true calling environment of `called()` is looked up, and the filtered call stack looks like this:

```

1. calling()
5. \-called()
6. \-EXPR()

```

If the calling environment is not on the stack, the function called by `eval()` becomes a root node. Say we have:

```
calling <- function() evaluator(quote(called()), new.env())
```

With call frame filtering we then get the following filtered call stack:

```

5. called()
6. \-EXPR()

```

## Note

**On Unix-alikes:** Profiling is not available on all platforms. By default, support for profiling is compiled in if possible – configure R with ‘`--disable-R-profiling`’ to change this.

As R profiling uses the same mechanisms as C profiling, the two cannot be used together, so do not use `Rprof` in an executable built for C-level profiling.

**On Windows:** `filename` can be a UTF-8-encoded filepath that cannot be translated to the current locale.

The profiler interrupts R asynchronously, and it cannot allocate memory to store results as it runs. This affects line profiling, which needs to store an unknown number of file pathnames. The `numfiles` and `bufsize` arguments control the size of pre-allocated buffers to hold these results: the former counts the maximum number of paths, the latter counts the numbers of bytes in them. If the profiler runs out of space it will skip recording the line information for new files, and issue a warning when `Rprof(NULL)` is called to finish profiling.

## See Also

The chapter on “Tidying and profiling R code” in “Writing R Extensions” (see the ‘`doc/manual`’ subdirectory of the R source tree).

[summaryRprof](#) to analyse the output file.

[tracemem](#), [Rprofmem](#) for other ways to track memory use.

## Examples

```

Not run: Rprof()
some code to be profiled
Rprof(NULL)
some code NOT to be profiled
Rprof(append = TRUE)
some code to be profiled
Rprof(NULL)

```

```
...
Now post-process the output as described in Details

End(Not run)
```

Rprofmem

*Enable Profiling of R's Memory Use***Description**

Enable or disable reporting of memory allocation in R.

**Usage**

```
Rprofmem(filename = "Rprofmem.out", append = FALSE, threshold = 0)
```

**Arguments**

|           |                                                                                                                              |
|-----------|------------------------------------------------------------------------------------------------------------------------------|
| filename  | The file to be used for recording the memory allocations. Set to <code>NULL</code> or <code>" "</code> to disable reporting. |
| append    | logical: should the file be over-written or appended to?                                                                     |
| threshold | numeric: allocations on R's "large vector" heap larger than this number of bytes will be reported.                           |

**Details**

Enabling profiling automatically disables any existing profiling to another or the same file.

Profiling writes the call stack to the specified file every time `malloc` is called to allocate a large vector object or to allocate a page of memory for small objects. The size of a page of memory and the size above which `malloc` is used for vectors are compile-time constants, by default 2000 and 128 bytes respectively.

The profiler tracks allocations, some of which will be to previously used memory and will not increase the total memory use of R.

**Value**

None

**Note**

The memory profiler slows down R even when not in use, and so is a compile-time option. (It is enabled in a standard Windows build of R.)

The memory profiler can be used at the same time as other R and C profilers.

**See Also**

The R sampling profiler, [Rprof](#) also collects memory information.

[tracemem](#) traces duplications of specific objects.

The "Writing R Extensions" manual section on "Tidying and profiling R code"

## Examples

```
Not run:
not supported unless R is compiled to support it.
Rprofmem("Rprofmem.out", threshold = 1000)
example(glm)
Rprofmem(NULL)
noquote(readLines("Rprofmem.out", n = 5))

End(Not run)
```

---

Rscript

*Scripting Front-End for R*

---

## Description

This is an alternative front end for use in ‘#!’ scripts and other scripting applications.

## Usage

```
Rscript [options] [-e expr [-e expr2 ...] | file] [args]
```

## Arguments

|             |                                                                                                                                                   |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------|
| options     | a list of options, all beginning with ‘--’. These can be any of the options of the standard R front-end, and also those described in the details. |
| expr, expr2 | R expression(s), properly quoted.                                                                                                                 |
| file        | the name of a file containing R commands. ‘-’ indicates ‘stdin’.                                                                                  |
| args        | arguments to be passed to the script in file.                                                                                                     |

## Details

Rscript --help gives details of usage, and Rscript --version gives the version of Rscript.

Other invocations invoke the R front-end with selected options. This front-end is convenient for writing ‘#!’ scripts since it is an executable and takes *file* directly as an argument. Options ‘--no-echo --no-restore’ are always supplied: these imply ‘--no-save’. Arguments that contain spaces cannot be specified directly on the ‘#!’ line, because spaces and tabs are interpreted as delimiters and there is no way to protect them from this interpretation on the ‘#!’ line. (The standard Windows command line has no concept of ‘#!’ scripts, but Cygwin shells do.)

*Either* one or more ‘-e’ options or *file* should be supplied. When using ‘-e’ options be aware of the quoting rules in the shell used: see the examples.

Additional options accepted (before *file* or *args*) are

‘-verbose’ gives details of what Rscript is doing. Also passed on to R.

‘-default-packages=list’ where *list* is a comma-separated list of package names or NULL. Sets the environment variable R\_DEFAULT\_PACKAGES which determines the packages loaded on startup.

Spaces are allowed in expression and file (but will need to be protected from the shell in use, if any, for example by enclosing the argument in quotes).

If ‘--default-packages’ is not used, then `Rscript` checks the environment variable `R_SCRIPT_DEFAULT_PACKAGES`. If this is set, then it takes precedence over `R_DEFAULT_PACKAGES`.

Normally the version of R is determined at installation, but this can be overridden by setting the environment variable `RHOME`.

`stdin()` refers to the input file, and `file("stdin")` to the `stdin` file stream of the process.

## Note

`Rscript` is only supported on systems with the `execv` system call.

## Examples

```
Not run:
Rscript -e 'date()' -e 'format(Sys.time(), "%a %b %d %X %Y")'

Get the same initial packages in the same order as default R:
Rscript --default-packages=methods,datasets,utils,grDevices,graphics,stats -e 'sessionInfo()'

example #! script for a Unix-alike

#! /path/to/Rscript --vanilla --default-packages=utils
args <- commandArgs(TRUE)
res <- try(install.packages(args))
if(inherits(res, "try-error")) q(status=1) else q()

End(Not run)
```

## Description

Utility function to find and display R documentation.

## Usage

```
RShowDoc(what, type = c("pdf", "html", "txt"), package)
```

## Arguments

|                      |                                                                                                       |
|----------------------|-------------------------------------------------------------------------------------------------------|
| <code>what</code>    | a character string: see ‘Details’.                                                                    |
| <code>type</code>    | an optional character string giving the preferred format. Can be abbreviated.                         |
| <code>package</code> | an optional character string specifying the name of a package within which to look for documentation. |

## Details

what can specify one of several different sources of documentation, including the R manuals (R-admin, R-data, R-exts, R-intro, R-ints, R-lang), NEWS, COPYING (the GPL licence), any of the licenses in 'share/licenses', FAQ (also available as R-FAQ), and the files in '[R\\_HOME](#)/doc'.

Only on Windows, the R for Windows FAQ is specified by `rw-FAQ`.

If `package` is supplied, documentation is looked for in the 'doc' and top-level directories of an installed package of that name.

If `what` is missing a brief usage message is printed.

The documentation types are tried in turn starting with the first specified in `type` (or "pdf" if none is specified).

## Value

A invisible character string given the path to the file found.

## See Also

For displaying regular help files, [help](#) (or [?](#)) and [help.start](#).

For `type = "txt"`, [file.show](#) is used. [vignettes](#) are nicely viewed via `RShowDoc(*, package= .)`.

## Examples

```
RShowDoc("R-lang")
RShowDoc("FAQ", type = "html")
RShowDoc("frame", package = "grid")
RShowDoc("changes.txt", package = "grid")
RShowDoc("NEWS", package = "MASS")
```

---

RSiteSearch

---

*Search for Key Words or Phrases in Documentation*

---

## Description

Search for key words or phrases in help pages, vignettes or task views, using the search engine at <http://search.r-project.org> and view them in a web browser.

## Usage

```
RSiteSearch(string,
 restrict = c("functions", "vignettes", "views"),
 format = c("normal", "short"),
 sortby = c("score", "date:late", "date:early",
 "subject", "subject:descending",
 "from", "from:descending",
 "size", "size:descending"),
 matchesPerPage = 20)
```

**Arguments**

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>string</code>         | A character string specifying word(s) or a phrase to search. If the words are to be searched as one entity, enclose all words in braces (see the first example).                                                                                                                                                                                                                                                                                                                |
| <code>restrict</code>       | a character vector, typically of length greater than one. Values can be abbreviated. Possible areas to search in: <code>functions</code> for help pages, <code>views</code> for task views and <code>vignettes</code> for package vignettes.                                                                                                                                                                                                                                    |
| <code>format</code>         | <code>normal</code> or <code>short</code> (no excerpts); can be abbreviated.                                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>sortby</code>         | character string (can be abbreviated) indicating how to sort the search results: <code>(score, date:late</code> for sorting by date with latest results first, <code>date:early</code> for earliest first, <code>subject</code> for subject in alphabetical order, <code>subject:descending</code> for reverse alphabetical order, <code>from</code> or <code>from:descending</code> for sender (when applicable), <code>size</code> or <code>size:descending</code> for size.) |
| <code>matchesPerPage</code> | How many items to show per page.                                                                                                                                                                                                                                                                                                                                                                                                                                                |

**Details**

This function is designed to work with the search site at <http://search.r-project.org>, and depends on that site continuing to be made available (thanks to Jonathan Baron and the School of Arts and Sciences of the University of Pennsylvania).

Unique partial matches will work for all arguments. Each new browser window will stay open unless you close it.

**Value**

(Invisibly) the complete URL passed to the browser, including the query string.

**Author(s)**

Andy Liaw and Jonathan Baron

**See Also**

[help.search](#), [help.start](#) for local searches.

[browseURL](#) for how the help file is displayed.

**Examples**

```
need Internet connection
RSiteSearch("{logistic regression}") # matches exact phrase
Sys.sleep(5) # allow browser to open, take a quick look
Search in vignettes and store the query-string:
fullquery <- RSiteSearch("lattice", restrict = "vignettes")
fullquery # a string of ~ 110 characters
```

**Description**

`rtags` provides etags-like indexing capabilities for R code, using R's own parser.

**Usage**

```
rtags(path = ".", pattern = "\\.[RrSs]$",
 recursive = FALSE,
 src = list.files(path = path, pattern = pattern,
 full.names = TRUE,
 recursive = recursive),
 keep.re = NULL,
 ofile = "", append = FALSE,
 verbose = getOption("verbose"))
```

**Arguments**

|                                                                   |                                                                                                                                                                                                                                                                                                      |
|-------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>path</code> , <code>pattern</code> , <code>recursive</code> | Arguments passed on to <code>list.files</code> to determine the files to be tagged. By default, these are all files with extension <code>.R</code> , <code>.r</code> , <code>.S</code> , and <code>.s</code> in the current directory. These arguments are ignored if <code>src</code> is specified. |
| <code>src</code>                                                  | A vector of file names to be indexed.                                                                                                                                                                                                                                                                |
| <code>keep.re</code>                                              | A regular expression further restricting <code>src</code> (the files to be indexed). For example, specifying <code>keep.re = "/R/[^/]*\\.R\$"</code> will only retain files with extension <code>.R</code> inside a directory named <code>R</code> .                                                 |
| <code>ofile</code>                                                | Passed on to <code>cat</code> as the <code>file</code> argument; typically the output file where the tags will be written (" <code>TAGS</code> " by convention). By default, the output is written to the R console (unless redirected).                                                             |
| <code>append</code>                                               | Logical, indicating whether the output should overwrite an existing file, or append to it.                                                                                                                                                                                                           |
| <code>verbose</code>                                              | Logical. If <code>TRUE</code> , file names are echoed to the R console as they are processed.                                                                                                                                                                                                        |

**Details**

Many text editors allow definitions of functions and other language objects to be quickly and easily located in source files through a tagging utility. This functionality requires the relevant source files to be preprocessed, producing an index (or tag) file containing the names and their corresponding locations. There are multiple tag file formats, the most popular being the vi-style `ctags` format and the emacs-style `etags` format. Tag files in these formats are usually generated by the `ctags` and `etags` utilities respectively. Unfortunately, these programs do not recognize R code syntax. They do allow tagging of arbitrary language files through regular expressions, but this too is insufficient.

The `rtags` function is intended to be a tagging utility for R code. It parses R code files (using R's parser) and produces tags in Emacs' `etags` format. Support for vi-style tags is currently absent, but should not be difficult to add.

Rtangle

*R Driver for Stangle*

---

**Description**

A driver for [Stangle](#) that extracts R code chunks. Notably all `RtangleSetup()` arguments may be used as arguments in the `Stangle()` call.

**Usage**

```
Rtangle()
RtangleSetup(file, syntax, output = NULL, annotate = TRUE,
 split = FALSE, quiet = FALSE, drop.evalFALSE = FALSE, ...)
```

**Arguments**

|                       |                                                                                                                                                                                                                                                                                                              |
|-----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>file</code>     | name of Sweave source file. See the description of the corresponding argument of <a href="#">Sweave</a> .                                                                                                                                                                                                    |
| <code>syntax</code>   | an object of class <code>SweaveSyntax</code> .                                                                                                                                                                                                                                                               |
| <code>output</code>   | name of output file used unless <code>split = TRUE</code> : see ‘Details’.                                                                                                                                                                                                                                   |
| <code>annotate</code> | a logical or <a href="#">function</a> . When true, as by default, code chunks are separated by comment lines specifying the names and line numbers of the code chunks. If FALSE the decorating comments are omitted. Alternatively, <code>annotate</code> may be a function, see section ‘Chunk annotation’. |
| <code>split</code>    | split output into a file for each code chunk?                                                                                                                                                                                                                                                                |

`quiet` logical to suppress all progress messages.

`drop.evalFALSE` logical; When false, as by default, all chunks with option `eval = FALSE` are *commented out* in the output; otherwise (`drop.evalFALSE = TRUE`) they are omitted entirely.

... additional named arguments setting defaults for further options listed in ‘Supported Options’.

## Details

Unless `split = TRUE`, the default name of the output file is `basename(file)` with an extension corresponding to the Sweave syntax (e.g., ‘Rnw’, ‘Stex’) replaced by ‘R’. File names “`stdout`” and “`stderr`” are interpreted as the output and message connection respectively.

If splitting is selected (including by the options in the file), each chunk is written to a separate file with extension the name of the ‘engine’ (default ‘.R’).

Note that this driver does more than simply extract the code chunks verbatim, because chunks may re-use earlier chunks.

## Chunk annotation (annotate)

By default `annotate = TRUE`, the annotation is of one of the forms

```
#####
code chunk number 3: viewport
#####

#####
code chunk number 18: grid.Rnw:647-648
#####

#####
code chunk number 19: trellisdata (eval = FALSE)
#####
```

using either the chunk label (if present, i.e., when specified in the source) or the file name and line numbers.

`annotate` may be a function with formal arguments (`options, chunk, output`), e.g. to produce less dominant chunk annotations; see `Rtangle()$runcode` how it is called instead of the default.

## Supported Options

`Rtangle` supports the following options for code chunks (the values in parentheses show the default values):

**engine:** character string (“R”). Only chunks with `engine` equal to “R” or “S” are processed.

**keep.source:** logical (TRUE). If `keep.source == TRUE` the original source is copied to the file. Otherwise, deparsed source is output.

**eval:** logical (TRUE). If FALSE, the code chunk is copied across but commented out.

**prefix** Used if `split = TRUE`. See `prefix.string`.

**prefix.string:** a character string, default is the name of the source file (without extension). Used if `split = TRUE` as the prefix for the filename if the chunk has no label, or if it has a label and `prefix = TRUE`. Note that this is used as part of filenames, so needs to be portable.

**show.line.nos** logical (FALSE). Should the output be annotated with comments showing the line number of the first code line of the chunk?

### Author(s)

Friedrich Leisch and R-core.

### Examples

```
nmRnw <- "example-1.Rnw"
exfile <- system.file("Sweave", nmRnw, package = "utils")
Create R source file
Stangle(exfile)
nmR <- sub("Rnw$", "R", nmRnw) # the (default) R output file name
if(interactive()) file.show("example-1.R")

Smaller R source file with custom annotation:
my.Ann <- function(options, chunk, output) {
 cat("### chunk #", options$chunknr, ": ",
 if(!is.null(ol <- options$label)) ol else .RtangleCodeLabel(chunk),
 if(!options$eval) " (eval = FALSE)", "\n",
 file = output, sep = "")
}
Stangle(exfile, annotate = my.Ann)
if(interactive()) file.show("example-1.R")

Stangle(exfile, annotate = my.Ann, drop.evalFALSE=TRUE)
if(interactive()) file.show("example-1.R")
```

---

RweaveLatex

*R/LaTeX Driver for Sweave*

---

### Description

A driver for [Sweave](#) that translates R code chunks in  $\text{\LaTeX}$  files by “running them”, i.e., [parse\(\)](#) and [eval\(\)](#) each.

### Usage

```
RweaveLatex()
```

```
RweaveLatexSetup(file, syntax, output = NULL, quiet = FALSE,
 debug = FALSE, stylepath, ...)
```

## Arguments

|                        |                                                                                                                                                                                                                                                                                                |
|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>file</code>      | Name of Sweave source file. See the description of the corresponding argument of <a href="#">Sweave</a> .                                                                                                                                                                                      |
| <code>syntax</code>    | An object of class <code>SweaveSyntax</code> .                                                                                                                                                                                                                                                 |
| <code>output</code>    | Name of output file. The default is to remove extension <code>‘.nw’</code> , <code>‘.Rnw’</code> or <code>‘.Snw’</code> and to add extension <code>‘.tex’</code> . Any directory paths in <code>file</code> are also removed such that the output is created in the current working directory. |
| <code>quiet</code>     | If <code>TRUE</code> all progress messages are suppressed.                                                                                                                                                                                                                                     |
| <code>debug</code>     | If <code>TRUE</code> , input and output of all code chunks is copied to the console.                                                                                                                                                                                                           |
| <code>stylepath</code> | See ‘Details’.                                                                                                                                                                                                                                                                                 |
| <code>...</code>       | named values for the options listed in ‘Supported Options’.                                                                                                                                                                                                                                    |

## Details

The  $\LaTeX$  file generated needs to contain the line `‘\usepackage{Sweave}’`, and if this is not present in the Sweave source file (possibly in a comment), it is inserted by the `RweaveLatex` driver. If `stylepath = TRUE`, a hard-coded path to the file `‘Sweave.sty’` in the R installation is set in place of `Sweave`. The hard-coded path makes the  $\LaTeX$  file less portable, but avoids the problem of installing the current version of `‘Sweave.sty’` to some place in your TeX input path. However, TeX may not be able to process the hard-coded path if it contains spaces (as it often will under Windows) or TeX special characters.

The default for `stylepath` is now taken from the environment variable `SWEAVE_STYLEPATH_DEFAULT`, or is `FALSE` if that is unset or empty. If set, it should be exactly `TRUE` or `FALSE`; any other values are taken as `FALSE`.

The simplest way for frequent Sweave users to ensure that `‘Sweave.sty’` is in the TeX input path is to add `‘R_HOME/share/texmf’` as a `‘texmf tree’` (`‘root directory’` in the parlance of the `‘MiKTeX settings’` utility).

By default, `‘Sweave.sty’` sets the width of all included graphics to:

```
‘\setkeys{Gin}{width=0.8\textwidth}’.
```

This setting affects the `width` size option passed to the `‘\includegraphics{...}’` directive for each plot file and in turn impacts the scaling of your plot files as they will appear in your final document.

Thus, for example, you may set `width=3` in your figure chunk and the generated graphics files will be set to 3 inches in width. However, the width of your graphic in your final document will be set to `‘0.8\textwidth’` and the height dimension will be scaled accordingly. Fonts and symbols will be similarly scaled in the final document.

You can adjust the default value by including the `‘\setkeys{Gin}{width=...}’` directive in your `‘.Rnw’` file after the `‘\begin{document}’` directive and changing the `width` option value as you prefer, using standard  $\LaTeX$  measurement values.

If you wish to override this default behavior entirely, you can add a `‘\usepackage[nogin]{Sweave}’` directive in your preamble. In this case, no size/scaling options will be passed to the `‘\includegraphics{...}’` directive and the `height` and `width` options will determine both the runtime generated graphic file sizes and the size of the graphics in your final document.

`‘Sweave.sty’` also supports the `‘[noae]’` option, which suppresses the use of the `‘ae’` package, the use of which may interfere with certain encoding and typeface selections. If you have problems in the rendering of certain character sets, try this option.

It also supports the `'[inconsolata]'` option, to render monospaced text in `inconsolata`, the font used by default for R help pages.

The use of fancy quotes (see [sQuote](#)) can cause problems when setting R output. Either set `options(useFancyQuotes = FALSE)` or arrange that  $\text{\LaTeX}$  is aware of the encoding used (by a `'\usepackage[utf8]{inputenc}'` declaration: Windows users of Sweave from `Rgui.exe` will need to replace `'utf8'` by `'cp1252'` or similar) and ensure that typewriter fonts containing directional quotes are used.

Some  $\text{\LaTeX}$  graphics drivers do not include `'.png'` or `'.jpg'` in the list of known extensions. To enable them, add something like `'\DeclareGraphicsExtensions{.png, .pdf, .jpg}'` to the preamble of your document or check the behavior of your graphics driver. When both `pdf` and `png` are `TRUE` both files will be produced by Sweave, and their order in the `'DeclareGraphicsExtensions'` list determines which will be used by `pdflatex`.

## Supported Options

RweaveLatex supports the following options for code chunks (the values in parentheses show the default values). Character string values should be quoted when passed from Sweave through `...` but not when use in the header of a code chunk.

**engine:** character string (`"R"`). Only chunks with `engine` equal to `"R"` or `"S"` are processed.

**echo:** logical (`TRUE`). Include R code in the output file?

**keep.source:** logical (`TRUE`). When echoing, if `TRUE` the original source is copied to the file. Otherwise, deparsed source is echoed.

**eval:** logical (`TRUE`). If `FALSE`, the code chunk is not evaluated, and hence no text nor graphical output produced.

**results:** character string (`"verbatim"`). If `"verbatim"`, the output of R commands is included in the verbatim-like `'Soutput'` environment. If `"tex"`, the output is taken to be already proper  $\text{\LaTeX}$  markup and included as is. If `"hide"` then all output is completely suppressed (but the code executed during the weave). Values can be abbreviated.

**print:** logical (`FALSE`). If `TRUE`, this forces auto-printing of all expressions.

**term:** logical (`TRUE`). If `TRUE`, visibility of values emulates an interactive R session: values of assignments are not printed, values of single objects are printed. If `FALSE`, output comes only from explicit `print` or similar statements.

**split:** logical (`FALSE`). If `TRUE`, text output is written to separate files for each code chunk.

**strip.white:** character string (`"true"`). If `"true"`, blank lines at the beginning and end of output are removed. If `"all"`, then all blank lines are removed from the output. If `"false"` then blank lines are retained.

A 'blank line' is one that is empty or includes only whitespace (spaces and tabs).

Note that blank lines in a code chunk will usually produce a prompt string rather than a blank line on output.

**prefix:** logical (`TRUE`). If `TRUE` generated filenames of figures and output all have the common prefix given by the `prefix.string` option: otherwise only unlabelled chunks use the prefix.

**prefix.string:** a character string, default is the name of the source file (without extension). Note that this is used as part of filenames, so needs to be portable.

**include:** logical (`TRUE`), indicating whether input statements for text output (if `split = TRUE`) and `'\includegraphics'` statements for figures should be auto-generated. Use `include = FALSE` if the output should appear in a different place than the code chunk (by placing the input line manually).

**fig:** logical (FALSE), indicating whether the code chunk produces graphical output. Note that only one figure per code chunk can be processed this way. The labels for figure chunks are used as part of the file names, so should preferably be alphanumeric.

**eps:** logical (FALSE), indicating whether EPS figures should be generated. Ignored if `fig = FALSE`.

**pdf:** logical (TRUE), indicating whether PDF figures should be generated. Ignored if `fig = FALSE`.

**pdf.version, pdf.encoding, pdf.compress:** passed to `pdf` to set the version, encoding and compression (or not). Defaults taken from `pdf.options()`.

**png:** logical (FALSE), indicating whether PNG figures should be generated. Ignored if `fig = FALSE`. Only available in  $R \geq 2.13.0$ .

**jpeg:** logical (FALSE), indicating whether JPEG figures should be generated. Ignored if `fig = FALSE`. Only available in  $R \geq 2.13.0$ .

**grdevice:** character (NULL): see section ‘Custom Graphics Devices’. Ignored if `fig = FALSE`. Only available in  $R \geq 2.13.0$ .

**width:** numeric (6), width of figures in inches. See ‘Details’.

**height:** numeric (6), height of figures in inches. See ‘Details’.

**resolution:** numeric (300), resolution in pixels per inch: used for PNG and JPEG graphics. Note that the default is a fairly high value, appropriate for high-quality plots. Something like 100 is a better choice for package vignettes.

**concordance:** logical (FALSE). Write a concordance file to link the input line numbers to the output line numbers. This is an experimental feature; see the source code for the output format, which is subject to change in future releases.

**figs.only:** logical (FALSE). By default each figure chunk is run once, then re-run for each selected type of graphics. That will open a default graphics device for the first figure chunk and use that device for the first evaluation of all subsequent chunks. If this option is true, the figure chunk is run only for each selected type of graphics, for which a new graphics device is opened and then closed.

In addition, users can specify further options, either in the header of an individual code section or in a ‘`\SweaveOpts{}`’ line in the document. For unknown options, their type is set at first use.

### Custom Graphics Devices

If option `grdevice` is supplied for a code chunk with both `fig` and `eval` true, the following call is made

```
get(options$grdevice, envir = .GlobalEnv)(name=, width=,
 height=, options)
```

which should open a graphics device. The chunk’s code is then evaluated and `dev.off` is called. Normally a function of the name given will have been defined earlier in the Sweave document, e.g.

```
<<results=hide>>=
my.Swd <- function(name, width, height, ...)
 grDevices::png(filename = paste(name, "png", sep = "."),
 width = width, height = height, res = 100,
 units = "in", type = "quartz", bg = "transparent")
@
```

Alternatively for `R >= 3.4.0`, if the function exists in a package (rather than the `.GlobalEnv`) it can be used by setting `grdevice = "pkg:my.Swd"` (or with `'::'` instead of `':'` if the function is not exported).

Currently only one custom device can be used for each chunk, but different devices can be used for different chunks.

A replacement for `dev.off` can be provided as a function with suffix `.off`, e.g. `my.Swd.off()` or `pkg:my.Swd.off()`, respectively.

## Hook Functions

Before each code chunk is evaluated, zero or more hook functions can be executed. If `getOption("SweaveHooks")` is set, it is taken to be a named list of hook functions. For each *logical* option of a code chunk (`echo`, `print`, ...) a hook can be specified, which is executed if and only if the respective option is `TRUE`. Hooks must be named elements of the list returned by `getOption("SweaveHooks")` and be functions taking no arguments. E.g., if option `"SweaveHooks"` is defined as `list(fig = foo)`, and `foo` is a function, then it would be executed before the code in each figure chunk. This is especially useful to set defaults for the graphical parameters in a series of figure chunks.

Note that the user is free to define new Sweave logical options and associate arbitrary hooks with them. E.g., one could define a hook function for a new option called `clean` that removes all objects in the workspace. Then all code chunks specified with `clean = TRUE` would start operating on an empty workspace.

Rwin configuration *R for Windows Configuration*

---

## Description

The file `‘Rconsole’` configures the R GUI (`Rgui`) console under MS Windows and `loadRconsole(*)` loads a new configuration.

The file `‘Rdevga’` configures the graphics devices `windows`, `win.graph`, `win.metafile` and `win.print`, as well as the bitmap devices `bmp`, `jpeg`, `png` and `tiff` (which use for type `"windows"` use `windows` internally).

## Usage

```
loadRconsole(file)
```

## Arguments

|                   |                                                                                                                             |
|-------------------|-----------------------------------------------------------------------------------------------------------------------------|
| <code>file</code> | The file from which to load a new <code>‘Rconsole’</code> configuration. By default a file dialog is used to select a file. |
|-------------------|-----------------------------------------------------------------------------------------------------------------------------|

## Details

There are system copies of these files in '*R\_HOME*\etc'. Users can have personal copies of the files: these are looked for in the location given by the environment variable *R\_USER*. The system files are read only if a corresponding personal file is not found.

If the environment variable *R\_USER* is not set, the *R* system sets it to *HOME* if that is set (stripping any trailing slash), otherwise to the Windows 'personal' directory, otherwise to *{HOMEDRIVE}{HOMEPATH}* if *HOMEDRIVE* and *HOMEDRIVE* are both set otherwise to the working directory. This is as described in the file '*rw-FAQ*'.

## Value

Each of the files contains details in its comments of how to set the values.

At the time of writing '*Rdevga*' configured the mapping of font numbers to fonts, and '*Rconsole*' configured the appearance (single or multiple document interface, toolbar, status-bar on MDI), size, font and colours of the GUI console, and whether resizing the console sets *options*("width").

The file '*Rconsole*' also configures the internal pager. This shares the font and colours of the console, but can be sized separately.

'*Rconsole*' can also set the initial positions of the console and the graphics device, as well as the size and position of the MDI workspace in MDI mode.

*loadRconsole* is called for its side effect of loading new defaults. It returns no useful value.

## Chinese/Japanese/Korean

Users of these languages will need to select a suitable font for the console (perhaps MS Mincho) and for the graphics device (although the default *Arial* has many East Asian characters). It is essential that the font selected for the console has double-width East Asian characters – many monospaced fonts do not.

## Note

The GUI preferences item on the Edit menu brings up an dialog box which can be used to edit the console settings, and to save them to a file.

This is only available on Windows.

```

## Arguments

|                       |                                                                                                                                     |
|-----------------------|-------------------------------------------------------------------------------------------------------------------------------------|
| <code>file</code>     | The name of the file in which to save the history, or from which to load it. The path is relative to the current working directory. |
| <code>max.show</code> | The maximum number of lines to show. <code>Inf</code> will give all of the currently available history.                             |
| <code>reverse</code>  | logical. If true, the lines are shown in reverse order. Note: this is not useful when there are continuation lines.                 |
| <code>pattern</code>  | A character string to be matched against the lines of the history. When supplied, only <i>unique</i> matching lines are shown.      |
| <code>...</code>      | Arguments to be passed to <code>grep</code> when doing the matching.                                                                |
| <code>stamp</code>    | A value or vector of values to be written into the history.                                                                         |
| <code>prefix</code>   | A prefix to apply to each line.                                                                                                     |
| <code>suffix</code>   | A suffix to apply to each line.                                                                                                     |
| <code>quiet</code>    | If TRUE, suppress printing timestamp to the console.                                                                                |

## Details

There are several history mechanisms available for the different R consoles, which work in similar but not identical ways. Notably, there are different implementations for Unix and Windows.

**Windows:** The functions described here work in Rgui and interactive Rterm but not in batch use of Rterm nor in embedded/DCOM versions.

**Unix-alikes:** The functions described here work under the readline command-line interface but may not otherwise (for example, in batch use or in an embedded application). Note that R can be built without readline.

R.app, the console on macOS, has a separate and largely incompatible history mechanism, which by default uses a file `‘.Rapp.history’` and saves up to 250 entries. These functions are not currently implemented there.

The (readline on Unix-alikes) history mechanism is controlled by two environment variables: `R_HISTSIZE` controls the number of lines that are saved (default 512), and `R_HISTFILE` (default `‘.Rhistory’`) sets the filename used for the loading/saving of history if requested at the beginning/end of a session (but not the default for `loadhistory/savehistory`). There is no limit on the number of lines of history retained during a session, so setting `R_HISTSIZE` to a large value has no penalty unless a large file is actually generated.

These environment variables are read at the time of saving, so can be altered within a session by the use of [Sys.setenv](#).

On Unix-alikes: Note that readline history library saves files with permission 0600, that is with read/write permission for the user and not even read permission for any other account.

The `timestamp` function writes a timestamp (or other message) into the history and echos it to the console. On platforms that do not support a history mechanism only the console message is printed.

## Note

If you want to save the history at the end of (almost) every interactive session (even those in which you do not save the workspace), you can put a call to `savehistory()` in `.Last`. See the examples.

## Examples

```
Not run:
Save the history in the home directory: note that it is not
(by default) read from there but from the current directory
.Last <- function()
 if(interactive()) try(savehistory("~/Rhistory"))

End(Not run)
```

---

select.list

---

*Select Items from a List*

---

## Description

Select item(s) from a character vector.

**Usage**

```
select.list(choices, preselect = NULL, multiple = FALSE,
 title = NULL, graphics = getOption("menu.graphics"))
```

**Arguments**

|                        |                                                                                                                                     |
|------------------------|-------------------------------------------------------------------------------------------------------------------------------------|
| <code>choices</code>   | a character vector of items.                                                                                                        |
| <code>preselect</code> | a character vector, or <code>NULL</code> . If non-null and if the string(s) appear in the list, the item(s) are selected initially. |
| <code>multiple</code>  | logical: can more than one item be selected?                                                                                        |
| <code>title</code>     | optional character string for window title, or <code>NULL</code> for no title.                                                      |
| <code>graphics</code>  | logical: should a graphical widget be used?                                                                                         |

**Details**

The normal default is `graphics = TRUE`.

**On Windows**, this brings up a modal dialog box with a (scrollable) list of items, which can be selected by the mouse. If `multiple` is true, further items can be selected or deselected by holding the control key down whilst selecting, and shift-clicking can be used to select ranges. Normal termination is via the ‘OK’ button or by hitting Enter or double-clicking an item. Selection can be aborted via the ‘Cancel’ button or pressing Escape.

**Under the macOS GUI**, this brings up a modal dialog box with a (scrollable) list of items, which can be selected by the mouse.

**On other Unix-like platforms** it will use a Tcl/Tk listbox widget if possible.

If `graphics` is `FALSE` or no graphical widget is available it displays a text list from which the user can choose by number(s). The `multiple = FALSE` case uses [menu](#). Preselection is only supported for `multiple = TRUE`, where it is indicated by a "+" preceding the item.

It is an error to use `select.list` in a non-interactive session.

**Value**

A character vector of selected items. If `multiple` is false and no item was selected (or Cancel was used), "" is returned. If `multiple` is true and no item was selected (or Cancel was used) then a character vector of length 0 is returned.

**See Also**

[menu](#), [tk\\_select.list](#) for a graphical version using Tcl/Tk.

**Examples**

```
Not run:
select.list(sort(.packages(all.available = TRUE)))

End(Not run)
```

---

sessionInfo

Collect Information About the Current R Session

---

## Description

Print version information about R, the OS and attached or loaded packages.

## Usage

```
sessionInfo(package = NULL)
S3 method for class 'sessionInfo'
print(x, locale = TRUE,
 RNG = !identical(x$RNGkind, .RNGdefaults), ...)
S3 method for class 'sessionInfo'
toLatex(object, locale = TRUE,
 RNG = !identical(object$RNGkind, .RNGdefaults), ...)
osVersion
```

## Arguments

|         |                                                                                                                                               |
|---------|-----------------------------------------------------------------------------------------------------------------------------------------------|
| package | a character vector naming installed packages, or NULL (the default) meaning all attached packages.                                            |
| x       | an object of class "sessionInfo".                                                                                                             |
| object  | an object of class "sessionInfo".                                                                                                             |
| locale  | show locale and code page information?                                                                                                        |
| RNG     | show information on <code>RNGkind()</code> ? Defaults to true iff it differs from the R version's default, i.e., <code>RNGversion(*)</code> . |
| ...     | currently not used.                                                                                                                           |

## Value

`sessionInfo()` returns an object of class "sessionInfo" which has `print` and `toLatex` methods. This is a list with components

|            |                                                                                                                                                                                                                                                                           |         |                                                                                        |
|------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------|----------------------------------------------------------------------------------------|
| R.version  | a list, the result of calling <code>R.Version()</code> .                                                                                                                                                                                                                  |         |                                                                                        |
| platform   | a character string describing the platform R was built under. Where sub-architectures are in use this is of the form 'platform/sub-arch (nn-bit)'.<br><br><td>running</td> <td>a character string (or possibly NULL), the same as <code>osVersion</code>, see below.</td> | running | a character string (or possibly NULL), the same as <code>osVersion</code> , see below. |
| RNGkind    | a character vector, the result of calling <code>RNGkind()</code> .                                                                                                                                                                                                        |         |                                                                                        |
| matprod    | a character string, the result of calling <code>getOption("matprod")</code> .                                                                                                                                                                                             |         |                                                                                        |
| BLAS       | a character string, the result of calling <code>extSoftVersion()["BLAS"]</code> .                                                                                                                                                                                         |         |                                                                                        |
| LAPACK     | a character string, the result of calling <code>La_library()</code> .                                                                                                                                                                                                     |         |                                                                                        |
| locale     | a character string, the result of calling <code>Sys.getlocale()</code> .                                                                                                                                                                                                  |         |                                                                                        |
| basePkgs   | a character vector of base packages which are attached.                                                                                                                                                                                                                   |         |                                                                                        |
| otherPkgs  | (not always present): a character vector of other attached packages.                                                                                                                                                                                                      |         |                                                                                        |
| loadedOnly | (not always present): a named list of the results of calling <code>packageDescription</code> on packages whose namespaces are loaded but are not attached.                                                                                                                |         |                                                                                        |

osVersion

osVersion is a character string (or possibly NULL on bizarre platforms) describing the OS and version which it is running under (as distinct from built under). This attempts to name a Linux distribution and give the OS name on an Apple Mac.

It is the same as `sessionInfo()$running` and created when loading the **utils** package.

Windows may report unexpected versions: see the help for `win.version`.

How OSes identify themselves and their versions can be arcane: where possible `osVersion` (and hence `sessionInfo()$running`) uses a human-readable form.

Where R is compiled under an earlier version of macOS (as the CRAN distribution has been) but running under ‘Big Sur’, macOS reports itself as ‘10.16’ (which R recognizes as ‘Big Sur’) and not ‘11.x’.

### Note

The information on ‘loaded’ packages and namespaces is the *current* version installed at the location the package was loaded from: it can be wrong if another process has been changing packages during the session.

### See Also

[R.version](#)

### Examples

```
sI <- sessionInfo()
sI
The same, showing the RNGkind, but not the locale :
print(sI, RNG = TRUE, locale = FALSE)
toLatex(sI, locale = FALSE) # shortest; possibly desirable at end of report
```

---

|                 |                                    |
|-----------------|------------------------------------|
| setRepositories | <i>Select Package Repositories</i> |
|-----------------|------------------------------------|

---

### Description

Interact with the user to choose the package repositories to be used.

### Usage

```
setRepositories(graphics = getOption("menu.graphics"),
 ind = NULL, addURLs = character())
```

### Arguments

|          |                                                                                                                                                                                                            |
|----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| graphics | Logical. If true, use a graphical list: on Windows or macOS GUI use a list box, and on a Unix-alike if <b>tk</b> and an X server are available, use Tk widget. Otherwise use a text <a href="#">menu</a> . |
| ind      | NULL or a vector of integer indices, which have the same effect as if they were entered at the prompt for <code>graphics = FALSE</code> .                                                                  |
| addURLs  | A character vector of additional URLs: it is often helpful to use a named vector.                                                                                                                          |

## Details

The default list of known repositories is stored in the file ‘[R\\_HOME](#)/etc/repositories’. That file can be edited for a site, or a user can have a personal copy in the file pointed to by the environment variable `R_REPOSITORIES`, or if this is unset or does not exist, in ‘`HOME/.R/repositories`’, which will take precedence.

A Bioconductor mirror can be selected by setting `options("BioC_mirror")`, e.g. via `chooseBioCmirror` — the default value is ‘`"https://bioconductor.org"`’.

The items that are preselected are those that are currently in `options("repos")` plus those marked as default in the list of known repositories.

The list of repositories offered depends on the setting of option `"pkgType"` as some repositories only offer a subset of types (e.g., only source packages or not macOS binary packages). Further, for binary packages some repositories (notably R-Forge) only offer packages for the current or recent versions of R. (Type `"both"` is equivalent to `"source"`.)

Repository ‘CRAN’ is treated specially: the value is taken from the current setting of `getOption("repos")` if this has an element `"CRAN"`: this ensures mirror selection is sticky.

This function requires the R session to be interactive unless `ind` is supplied.

## Value

This function is invoked mainly for its side effect of updating `options("repos")`. It returns (invisibly) the previous `repos` options setting (as a `list` with component `repos`) or `NULL` if no changes were applied.

## Note

This does **not** set the list of repositories at startup: to do so set `options(repos =)` in a start up file (see help topic [Startup](#)).

## See Also

[chooseCRANmirror](#), [chooseBioCmirror](#), [install.packages](#).

## Examples

```
Not run:
setRepositories(addURLs =
 c(CRANxtras = "http://www.stats.ox.ac.uk/pub/RWin"))

End(Not run)
```

---

setWindowTitle

*Set the Window Title or the Statusbar of the RGui in Windows*

---

## Description

Set or get the title of the R (i.e. RGui) window which will appear in the task bar, or set the statusbar (if in use).

**Usage**

```
setWindowTitle(suffix, title = paste(getIdentification(), suffix))

getWindowTitle()

getIdentification()

setStatusBar(text)
```

**Arguments**

|                     |                                                                                |
|---------------------|--------------------------------------------------------------------------------|
| <code>suffix</code> | a character string to form part of the title                                   |
| <code>title</code>  | a character string forming the complete new title                              |
| <code>text</code>   | a character string of up to 255 characters, to be displayed in the status bar. |

**Details**

`setWindowTitle` appends `suffix` to the normal window identification (RGui, R Console or Rterm). Use `suffix = ""` to reset the title.

`getWindowTitle` gets the current title.

This sets the title of the frame in MDI mode, the title of the console for RGui `--sdi`, and the title of the window from which it was launched for Rterm. It has no effect in embedded uses of R.

`getIdentification` returns the normal window identification.

`setStatusBar` sets the text in the statusbar of an MDI frame: if this is not currently shown it is selected and shown.

**Value**

The first three functions return a length 1 character vector.

`setWindowTitle` returns the previous window title (invisibly).

`getWindowTitle` and `getIdentification` return the current window title and the normal window identification, respectively.

**Note**

These functions are only available on Windows and only make sense when using the Rgui. E.g., in Rterm (and hence in ESS) the title is not visible (but can be set and gotten), and in a version of RStudio it has been "", invariably.

**Examples**

```
if(.Platform$OS.type == "windows") withAutoprint({
 ## show the current working directory in the title, saving the old one
 oldtitle <- setWindowTitle(getwd())
 Sys.sleep(0.5)
 ## reset the title
 setWindowTitle("")
 Sys.sleep(0.5)
 ## restore the original title
 setWindowTitle(title = oldtitle)
})
```

SHLIB

*Build Shared Object/DLL for Dynamic Loading***Description**

Compile the given source files and then link all specified object files into a shared object aka DLL which can be loaded into R using `dyn.load` or `library.dynam`.

**Usage**

```
R CMD SHLIB [options] [-o dllname] files
```

**Arguments**

|                      |                                                                                                                                                                                                                                                        |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>files</code>   | a list specifying the object files to be included in the shared object/DLL. You can also include the name of source files (for which the object files are automatically made from their sources) and library linking commands.                         |
| <code>dllname</code> | the full name of the shared object/DLL to be built, including the extension (typically <code>.so</code> on Unix systems, and <code>.dll</code> on Windows). If not given, the basename of the object/DLL is taken from the basename of the first file. |
| <code>options</code> | Further options to control the processing. Use <code>R CMD SHLIB --help</code> for a current list.                                                                                                                                                     |

**Details**

`R CMD SHLIB` is the mechanism used by [INSTALL](#) to compile source code in packages. It will generate suitable compilation commands for C, C++, Objective C(++) and Fortran sources: Fortran 90/95 sources can also be used but it may not be possible to mix these with other languages (on most platforms it is possible to mix with C, but mixing with C++ rarely works).

Please consult section ‘Creating shared objects’ in the manual ‘Writing R Extensions’ for how to customize it (for example to add `cpp` flags and to add libraries to the link step) and for details of some of its quirks.

Items in `files` with extensions `.c`, `.cpp`, `.cc`, `.C`, `.f`, `.f90`, `.f95`, `.m` (ObjC), `.M` and `.mm` (ObjC++) are regarded as source files, and those with extension `.o` as object files. All other items are passed to the linker.

Objective C(++) support is optional when R was configured: their main usage is on macOS.

Note that the appropriate run-time libraries will be used when linking if C++, Fortran or Objective C(++) sources are supplied, but not for compiled object files from these languages.

Option `-n` (also known as `--dry-run`) will show the commands that would be run without actually executing them.

**Note**

Some binary distributions of R have SHLIB in a separate bundle, e.g., an R-devel RPM.

**See Also**

[COMPILE](#), `dyn.load`, `library.dynam`.

The ‘R Installation and Administration’ and ‘Writing R Extensions’ manuals, including the section on “Customizing compilation” in the former.

**Examples**

```
Not run:
To link against a library not on the system library paths:
R CMD SHLIB -o mylib.so a.f b.f -L/opt/acml3.5.0/gnu64/lib -lacml

End(Not run)
```

---

shortPathName

*Express File Paths in Short Form on Windows*

---

**Description**

Convert file paths to the short form. This is an interface to the Windows API call GetShortPathNameW.

**Usage**

```
shortPathName(path)
```

**Arguments**

path                      character vector of file paths.

**Details**

For most file systems, the short form is the ‘DOS’ form with 8+3 path components and no spaces, and this used to be guaranteed. But some file systems on recent versions of Windows do not have short path names when the long-name path will be returned instead.

**Value**

A character vector. The path separator will be \. If a file path does not exist, the supplied path will be returned with slashes replaced by backslashes.

**Note**

This is only available on Windows.

**See Also**

[normalizePath](#).

**Examples**

```
if(.Platform$OS.type == "windows") withAutoprint({
 cat(shortPathName(c(R.home(), tempdir())), sep = "\n")
})
```

sourceutils

*Source Reference Utilities*

---

## Description

These functions extract information from source references.

## Usage

```
getSrcFilename(x, full.names = FALSE, unique = TRUE)
getSrcDirectory(x, unique = TRUE)
getSrcref(x)
getSrcLocation(x, which = c("line", "column", "byte", "parse"),
 first = TRUE)
```

## Arguments

|                         |                                                                  |
|-------------------------|------------------------------------------------------------------|
| <code>x</code>          | An object (typically a function) containing source references.   |
| <code>full.names</code> | Whether to include the full path in the filename result.         |
| <code>unique</code>     | Whether to list only unique filenames/directories.               |
| <code>which</code>      | Which part of a source reference to extract. Can be abbreviated. |
| <code>first</code>      | Whether to show the first (or last) location of the object.      |

## Details

Each statement of a function will have its own source reference if the `"keep.source"` option is `TRUE`. These functions retrieve all of them.

The components are as follows:

**line** The line number where the object starts or ends.

**column** The column number where the object starts or ends.

**byte** As for `"column"`, but counting bytes, which may differ in case of multibyte characters.

**parse** As for `"line"`, but this ignores `#line` directives.

## Value

`getSrcFilename` and `getSrcDirectory` return character vectors holding the filename/directory.

`getSrcref` returns a list of `"srcref"` objects or `NULL` if there are none.

`getSrcLocation` returns an integer vector of the requested type of locations.

## See Also

[srcref](#), [getParseData](#)

## Examples

```
fn <- function(x) {
 x + 1 # A comment, kept as part of the source
}

Show the temporary file directory
where the example was saved

getSrcDirectory(fn)
getSrcLocation(fn, "line")
```

---

stack

---

*Stack or Unstack Vectors from a Data Frame or List*

---

## Description

Stacking vectors concatenates multiple vectors into a single vector along with a factor indicating where each observation originated. Unstacking reverses this operation.

## Usage

```
stack(x, ...)
Default S3 method:
stack(x, drop=FALSE, ...)
S3 method for class 'data.frame'
stack(x, select, drop=FALSE, ...)

unstack(x, ...)
Default S3 method:
unstack(x, form, ...)
S3 method for class 'data.frame'
unstack(x, form, ...)
```

## Arguments

|        |                                                                                                                                                                                                                                              |
|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x      | a list or data frame to be stacked or unstacked.                                                                                                                                                                                             |
| select | an expression, indicating which variable(s) to select from a data frame.                                                                                                                                                                     |
| form   | a two-sided formula whose left side evaluates to the vector to be unstacked and whose right side evaluates to the indicator of the groups to create. Defaults to <code>formula(x)</code> in the data frame method for <code>unstack</code> . |
| drop   | Whether to drop the unused levels from the “ind” column of the return value.                                                                                                                                                                 |
| ...    | further arguments passed to or from other methods.                                                                                                                                                                                           |

## Details

The `stack` function is used to transform data available as separate columns in a data frame or list into a single column that can be used in an analysis of variance model or other linear model. The `unstack` function reverses this operation.

Note that `stack` applies to *vectors* (as determined by `is.vector`): non-vector columns (e.g., factors) will be ignored with a warning. Where vectors of different types are selected they are concatenated by `unlist` whose help page explains how the type of the result is chosen.

These functions are generic: the supplied methods handle data frames and objects coercible to lists by `as.list`.

### Value

`unstack` produces a list of columns according to the formula `form`. If all the columns have the same length, the resulting list is coerced to a data frame.

`stack` produces a data frame with two columns:

|                     |                                                                                     |
|---------------------|-------------------------------------------------------------------------------------|
| <code>values</code> | the result of concatenating the selected vectors in <code>x</code> .                |
| <code>ind</code>    | a factor indicating from which vector in <code>x</code> the observation originated. |

`lm`, `reshape`

### Examples

```
require(stats)
formula(PlantGrowth) # check the default formula
pg <- unstack(PlantGrowth) # unstack according to this formula
pg
stack(pg) # now put it back together
stack(pg, select = -ctrl) # omitting one vector
```

---

str

*Compactly Display the Structure of an Arbitrary R Object*

---

### Description

Compactly display the internal **structure** of an R object, a diagnostic function and an alternative to `summary` (and to some extent, `dput`). Ideally, only one line for each ‘basic’ structure is displayed. It is especially well suited to compactly display the (abbreviated) contents of (possibly nested) lists. The idea is to give reasonable output for **any** R object. It calls `args` for (non-primitive) function objects.

`strOptions()` is a convenience function for setting `options(str = .)`, see the examples.

### Usage

```
str(object, ...)
```

## S3 method for class 'data.frame'

```
str(object, ...)
```

## Default S3 method:

```
str(object, max.level = NA,
 vec.len = strO$vec.len, digits.d = strO$digits.d,
 nchar.max = 128, give.attr = TRUE,
```

```

drop.deparse.attr = strO$drop.deparse.attr,
give.head = TRUE, give.length = give.head,
width = getOption("width"), nest.lev = 0,
indent.str = paste(rep.int(" ", max(0, nest.lev + 1)),
 collapse = "..."),
comp.str = "$ ", no.list = FALSE, envir = baseenv(),
strict.width = strO$strict.width,
formatNum = strO$formatNum, list.len = strO$list.len,
deparse.lines = strO$deparse.lines, ...)

strOptions(strict.width = "no", digits.d = 3, vec.len = 4,
 list.len = 99, deparse.lines = NULL,
 drop.deparse.attr = TRUE,
 formatNum = function(x, ...)
 format(x, trim = TRUE, drop0trailing = TRUE, ...))

```

## Arguments

|                                |                                                                                                                                                                                                                                                                                                              |
|--------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code>            | any R object about which you want to have some information.                                                                                                                                                                                                                                                  |
| <code>max.level</code>         | maximal level of nesting which is applied for displaying nested structures, e.g., a list containing sub lists. Default NA: Display all nesting levels.                                                                                                                                                       |
| <code>vec.len</code>           | numeric ( $\geq 0$ ) indicating how many ‘first few’ elements are displayed of each vector. The number is multiplied by different factors (from .5 to 3) depending on the kind of vector. Defaults to the <code>vec.len</code> component of option "str" (see <a href="#">options</a> ) which defaults to 4. |
| <code>digits.d</code>          | number of digits for numerical components (as for <a href="#">print</a> ). Defaults to the <code>digits.d</code> component of option "str" which defaults to 3.                                                                                                                                              |
| <code>nchar.max</code>         | maximal number of characters to show for <a href="#">character</a> strings. Longer strings are truncated, see longch example below.                                                                                                                                                                          |
| <code>give.attr</code>         | logical; if TRUE (default), show attributes as sub structures.                                                                                                                                                                                                                                               |
| <code>drop.deparse.attr</code> | logical; if TRUE (default), <a href="#">deparse</a> ( <code>control = &lt;S&gt;</code> ) will not have "showAttributes" in <code>&lt;S&gt;</code> . Used to be hard coded to FALSE and hence can be set via <code>strOptions()</code> for back compatibility.                                                |
| <code>give.length</code>       | logical; if TRUE (default), indicate length (as <code>[1:...] </code> ).                                                                                                                                                                                                                                     |
| <code>give.head</code>         | logical; if TRUE (default), give (possibly abbreviated) mode/class and length (as <code>&lt;type&gt;[1:...] </code> ).                                                                                                                                                                                       |
| <code>width</code>             | the page width to be used. The default is the currently active <a href="#">options</a> ("width"); note that this has only a weak effect, unless <code>strict.width</code> is not "no".                                                                                                                       |
| <code>nest.lev</code>          | current nesting level in the recursive calls to <code>str</code> .                                                                                                                                                                                                                                           |
| <code>indent.str</code>        | the indentation string to use.                                                                                                                                                                                                                                                                               |
| <code>comp.str</code>          | string to be used for separating list components.                                                                                                                                                                                                                                                            |
| <code>no.list</code>           | logical; if true, no ‘list of ...’ nor the class are printed.                                                                                                                                                                                                                                                |
| <code>envir</code>             | the environment to be used for <i>promise</i> (see <a href="#">delayedAssign</a> ) objects only.                                                                                                                                                                                                             |
| <code>strict.width</code>      | string indicating if the <code>width</code> argument’s specification should be followed strictly, one of the values <code>c("no", "cut", "wrap")</code> , which can be abbreviated. Defaults to the <code>strict.width</code> component of option "str" (see                                                 |

|                            |                                                                                                                                                                                                                                                                                                        |
|----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                            | <code>options</code> ) which defaults to "no" for back compatibility reasons; "wrap" uses <code>strwrap</code> (*, width = width) whereas "cut" cuts directly to width. Note that a small <code>vec.length</code> may be better than setting <code>strict.width = "wrap"</code> .                      |
| <code>formatNum</code>     | a function such as <code>format</code> for formatting numeric vectors. It defaults to the <code>formatNum</code> component of option "str", see "Usage" of <code>strOptions()</code> above, which is almost back compatible to R <= 2.7.x, however, using <code>formatC</code> may be slightly better. |
| <code>list.len</code>      | numeric; maximum number of list elements to display within a level.                                                                                                                                                                                                                                    |
| <code>deparse.lines</code> | numeric or NULL as by default, determining the <code>nlines</code> argument to <code>deparse()</code> when object is a <code>call</code> . When NULL, the <code>nchar.max</code> and <code>width</code> arguments are used to determine a smart default.                                               |
| <code>...</code>           | potential further arguments (required for Method/Generic reasons).                                                                                                                                                                                                                                     |

### Value

`str` does not return anything, for efficiency reasons. The obvious side effect is output to the terminal.

### Author(s)

Martin Maechler <maechler@stat.math.ethz.ch> since 1990.

### See Also

`ls.str` for *listing* objects with their structure; `summary`, `args`.

### Examples

```
require(stats); require(grDevices); require(graphics)
The following examples show some of 'str' capabilities
str(1:12)
str(ls)
str(args) #- more useful than args(args) !
str(freeny)
str(str)
str(.Machine, digits.d = 20) # extra digits for identification of binary numbers
str(lsfit(1:9, 1:9))
str(lsfit(1:9, 1:9), max.level = 1)
str(lsfit(1:9, 1:9), width = 60, strict.width = "cut")
str(lsfit(1:9, 1:9), width = 60, strict.width = "wrap")
op <- options(); str(op) # save first;
 # otherwise internal options() is used.

need.dev <-
 !exists(".Device") || is.null(.Device) || .Device == "null device"
{ if(need.dev) postscript()
 str(par())
 if(need.dev) graphics.off()
}

ch <- letters[1:12]; is.na(ch) <- 3:5
str(ch) # character NA's

str(list(a = "A", L = as.list(1:100)), list.len = 9)
```

```

" .. [list output truncated] "

Long strings, 'nchar.max'; 'strict.width' :
nchar(longch <- paste(rep(letters,100), collapse = ""))
str(longch)
str(longch, nchar.max = 52)
str(longch, strict.width = "wrap")

Multibyte characters in strings (in multibyte locales):
oloc <- Sys.getlocale("LC_CTYPE")
mbyte.lc <- if(.Platform$OS.type == "windows")
 "English_United States.28605" else "en_GB.UTF-8"
try(Sys.setlocale("LC_CTYPE", mbyte.lc))
Truncation behavior (<-> correct width measurement) for "long" non-ASCII:
idx <- c(65313:65338, 65345:65350)
fwch <- intToUtf8(idx) # full width character string: each has width 2
ch <- strtrim(paste(LETTERS, collapse="._"), 64)
(ncc <- c(c.ch = nchar(ch), w.ch = nchar(ch, "w"),
 c.fw = nchar(fwch), w.fw = nchar(fwch, "w")))
stopifnot(unname(ncc) == c(64,64, 32, 64))
nchar.max: 1st line needs an increase of 2 in order to see 1 (in UTF-8!):
invisible(lapply(60:66, function(N) str(fwch, nchar.max = N)))
invisible(lapply(60:66, function(N) str(ch, nchar.max = N))) # "1 is 1" here
revert locale to previous:
Sys.setlocale("LC_CTYPE", oloc)

Settings for narrow transcript :
op <- options(width = 60,
 str = strOptions(strict.width = "wrap"))
str(lsf1(1:9,1:9))
str(options())
reset to previous:
options(op)

str(quote({ A+B; list(C, D) }))

S4 classes :
require(stats4)
x <- 0:10; y <- c(26, 17, 13, 12, 20, 5, 9, 8, 5, 4, 8)
ll <- function(ymax = 15, xh = 6)
 -sum(dpois(y, lambda=ymax/(1+x/xh), log=TRUE))
fit <- mle(ll)
str(fit)
```

**Description**

Given a character vector and a regular expression containing capture expressions, `strcapture` will extract the captured tokens into a tabular data structure, such as a `data.frame`, the type and structure of which is specified by a prototype object. The assumption is that the same number of tokens are captured from every input string.

**Usage**

```
strcapture(pattern, x, proto, perl = FALSE, useBytes = FALSE)
```

**Arguments**

|                             |                                                                            |
|-----------------------------|----------------------------------------------------------------------------|
| <code>pattern</code>        | The regular expression with the capture expressions.                       |
| <code>x</code>              | A character vector in which to capture the tokens.                         |
| <code>proto</code>          | A <code>data.frame</code> or S4 object that behaves like one. See details. |
| <code>perl, useBytes</code> | Arguments passed to <a href="#">regexec</a> .                              |

**Details**

The `proto` argument is typically a `data.frame`, with a column corresponding to each capture expression, in order. The captured character vector is coerced to the type of the column, and the column names are carried over to the return value. Any data in the prototype are ignored. See the examples.

**Value**

A tabular data structure of the same type as `proto`, so typically a `data.frame`, containing a column for each capture expression. The column types and names are inherited from `proto`. Cases in `x` that do not match `pattern` have NA in every column.

**See Also**

[regexec](#) and [regmatches](#) for related low-level utilities.

**Examples**

```
x <- "chr1:1-1000"
pattern <- "(.*?):([[:digit:]]+)-([[:digit:]]+)"
proto <- data.frame(chr=character(), start=integer(), end=integer())
strcapture(pattern, x, proto)
```

**Description**

Summarise the output of the [Rprof](#) function to show the amount of time used by different R functions.

**Usage**

```
summaryRprof(filename = "Rprof.out", chunksize = 5000,
 memory = c("none", "both", "tseries", "stats"),
 lines = c("hide", "show", "both"),
 index = 2, diff = TRUE, exclude = NULL,
 basenames = 1)
```

**Arguments**

|           |                                                                                        |
|-----------|----------------------------------------------------------------------------------------|
| filename  | Name of a file produced by <code>Rprof()</code> .                                      |
| chunksize | Number of lines to read at a time.                                                     |
| memory    | Summaries for memory information. See ‘Memory profiling’ below. Can be abbreviated.    |
| lines     | Summaries for line information. See ‘Line profiling’ below. Can be abbreviated.        |
| index     | How to summarize the stack trace for memory information. See ‘Details’ below.          |
| diff      | If <code>TRUE</code> memory summaries use change in memory rather than current memory. |
| exclude   | Functions to exclude when summarizing the stack trace for memory summaries.            |
| basenames | Number of components of the path to filenames to display.                              |

**Details**

This function provides the analysis code for [Rprof](#) files used by R CMD `Rprof`.

As the profiling output file could be larger than available memory, it is read in blocks of `chunksize` lines. Increasing `chunksize` will make the function run faster if sufficient memory is available.

**Value**

If `memory = "none"` and `lines = "hide"`, a list with components

|                              |                                                 |
|------------------------------|-------------------------------------------------|
| <code>by.self</code>         | A data frame of timings sorted by ‘self’ time.  |
| <code>by.total</code>        | A data frame of timings sorted by ‘total’ time. |
| <code>sample.interval</code> | The sampling interval.                          |
| <code>sampling.time</code>   | Total time of profiling run.                    |

The first two components have columns ‘`self.time`’, ‘`self.pct`’, ‘`total.time`’ and ‘`total.pct`’, the times in seconds and percentages of the total time spent executing code in that function and code in that function or called from that function, respectively.

If `lines = "show"`, an additional component is added to the list:

|                      |                                                    |
|----------------------|----------------------------------------------------|
| <code>by.line</code> | A data frame of timings sorted by source location. |
|----------------------|----------------------------------------------------|

If `memory = "both"` the same list but with memory consumption in Mb in addition to the timings.

If `memory = "tseries"` a data frame giving memory statistics over time. Memory usage is in bytes.

If `memory = "stats"` a [by](#) object giving memory statistics by function. Memory usage is in bytes.

If no events were recorded, a zero-row data frame is returned.

## Memory profiling

Options other than `memory = "none"` apply only to files produced by `Rprof(memory.profiling = TRUE)`.

When called with `memory.profiling = TRUE`, the profiler writes information on three aspects of memory use: vector memory in small blocks on the R heap, vector memory in large blocks (from `malloc`), memory in nodes on the R heap. It also records the number of calls to the internal function `duplicate` in the time interval. `duplicate` is called by C code when arguments need to be copied. Note that the profiler does not track which function actually allocated the memory.

With `memory = "both"` the change in total memory (truncated at zero) is reported in addition to timing data.

With `memory = "tseries"` or `memory = "stats"` the `index` argument specifies how to summarize the stack trace. A positive number specifies that many calls from the bottom of the stack; a negative number specifies the number of calls from the top of the stack. With `memory = "tseries"` the `index` is used to construct labels and may be a vector to give multiple sets of labels. With `memory = "stats"` the `index` must be a single number and specifies how to aggregate the data to the maximum and average of the memory statistics. With both `memory = "tseries"` and `memory = "stats"` the argument `diff = TRUE` asks for summaries of the increase in memory use over the sampling interval and `diff = FALSE` asks for the memory use at the end of the interval.

## Line profiling

If the code being run has source reference information retained (via `keep.source = TRUE` in `source` or `KeepSource = TRUE` in a package ‘DESCRIPTION’ file or some other way), then information about the origin of lines is recorded during profiling. By default this is not displayed, but the `lines` parameter can enable the display.

If `lines = "show"`, line locations will be used in preference to the usual function name information, and the results will be displayed ordered by location in addition to the other orderings.

If `lines = "both"`, line locations will be mixed with function names in a combined display.

## See Also

The chapter on “Tidying and profiling R code” in “Writing R Extensions” (see the ‘doc/manual’ subdirectory of the R source tree).

`Rprof`

`tracemem` traces copying of an object via the C function `duplicate`.

`Rprofmem` is a non-sampling memory-use profiler.

<https://developer.r-project.org/memory-profiling.html>

## Examples

```
Not run:
Rprof() is not available on all platforms
Rprof(tmp <- tempfile())
example(glm)
Rprof()
summaryRprof(tmp)
unlink(tmp)

End(Not run)
```

## Description

`Sweave` provides a flexible framework for mixing text and R/S code for automatic report generation. The basic idea is to replace the code with its output, such that the final document only contains the text and the output of the statistical analysis; however, the source code can also be included.

## Usage

```
Sweave(file, driver = RweaveLatex(),
 syntax = getOption("SweaveSyntax"), encoding = "", ...)

Stangle(file, driver = Rtangle(),
 syntax = getOption("SweaveSyntax"), encoding = "", ...)
```

## Arguments

|                       |                                                                                                                                                                                                                                   |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>file</code>     | Path to Sweave source file. Note that this can be supplied without the extension, but the function will only proceed if there is exactly one Sweave file in the directory whose basename matches <code>file</code> .              |
| <code>driver</code>   | the actual workhorse, (a function returning) a named <a href="#">list</a> of five functions, see ‘Details’ or the Sweave manual vignette.                                                                                         |
| <code>syntax</code>   | NULL or an object of class <code>SweaveSyntax</code> or a character string with its name. See the section ‘Syntax Definition’.                                                                                                    |
| <code>encoding</code> | The default encoding to assume for <code>file</code> .                                                                                                                                                                            |
| <code>...</code>      | further arguments passed to the driver’s setup function: see section ‘Details’, or specifically the arguments of the <code>R...Setup()</code> function in <a href="#">RweaveLatex</a> and <a href="#">Rtangle</a> , respectively. |

## Details

Automatic generation of reports by mixing word processing markup (like latex) and S code. The S code gets replaced by its output (text or graphs) in the final markup file. This allows a report to be re-generated if the input data change and documents the code to reproduce the analysis in the same file that also produces the report.

`Sweave` combines the documentation and code chunks together (or their output) into a single document. `Stangle` extracts only the code from the Sweave file creating an S source file that can be run using [source](#). (Code inside `\Sexpr{}` statements is ignored by `Stangle`.)

`Stangle` is just a wrapper to `Sweave` specifying a different default driver. Alternative drivers can be used: the former CRAN package **cacheSweave** and the Bioconductor package **weaver** provide drivers based on the default driver [RweaveLatex](#) which incorporate ideas of *caching* the results of computations on code chunks.

Environment variable `SWEAVE_OPTIONS` can be used to override the initial options set by the driver: it should be a comma-separated set of `key=value` items, as would be used in a ‘`\SweaveOpts`’ statement in a document.

Non-ASCII source files must contain a line of the form

```
\usepackage[foo]{inputenc}
```

(where ‘foo’ is typically ‘latin1’, ‘latin2’, ‘utf8’ or ‘cp1252’ or ‘cp1250’) or they will give an error. Re-encoding can be turned off completely with argument `encoding = "bytes"`.

### Syntax Definition

Sweave allows a flexible syntax framework for marking documentation and text chunks. The default is a noweb-style syntax, as alternative a latex-style syntax can be used. (See the user manual for further details.)

If `syntax = NULL` (the default) then the available syntax objects are consulted in turn, and selected if their extension component matches (as a regexp) the file name. Objects `SweaveSyntaxNoweb` (with `extension = "[rsRS]nw$"`) and `SweaveSyntaxLatex` (with `extension = "[rsRS]tex$"`) are supplied, but users or packages can supply others with names matching the pattern `SweaveSyntax.*`.

Further Sweave drivers are in, for example, packages **R2HTML**, **ascii**, **odfWeave** (archived) and **pgfSweave** (archived).

Non-Sweave vignettes may be built with `tools::buildVignette`.

### Examples

```
testfile <- system.file("Sweave", "Sweave-test-1.Rnw", package = "utils")

enforce par(ask = FALSE)
options(device.ask.default = FALSE)

create a LaTeX file - in the current working directory, getwd():
Sweave(testfile)

This can be compiled to PDF by
tools::texi2pdf("Sweave-test-1.tex")

or outside R by
##
R CMD texi2pdf Sweave-test-1.tex
on Unix-alikes which sets the appropriate TEXINPUTS path.
```

```
##
On Windows,
Rcmd texify --pdf Sweave-test-1.tex
if MiKTeX is available.

create an R source file from the code chunks
Stangle(testfile)
which can be sourced, e.g.
source("Sweave-test-1.R")
```

|----------------|------------------------------|
| SweaveSyntConv | <i>Convert Sweave Syntax</i> |
|----------------|------------------------------|

---

## Description

This function converts the syntax of files in [Sweave](#) format to another Sweave syntax definition.

## Usage

```
SweaveSyntConv(file, syntax, output = NULL)
```

## Arguments

|                     |                                                                                                                                                                                                                                                                |
|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>file</code>   | Name of Sweave source file.                                                                                                                                                                                                                                    |
| <code>syntax</code> | An object of class <code>SweaveSyntax</code> or a character string with its name giving the target syntax to which the file is converted.                                                                                                                      |
| <code>output</code> | Name of output file, default is to remove the extension from the input file and to add the default extension of the target syntax. Any directory names in <code>file</code> are also removed such that the output is created in the current working directory. |

|     |                      |
|-----|----------------------|
| tar | Create a Tar Archive |
|-----|----------------------|

---

**Description**

Create a tar archive.

**Usage**

```
tar(tarfile, files = NULL,
 compression = c("none", "gzip", "bzip2", "xz"),
 compression_level = 6, tar = Sys.getenv("tar"),
 extra_flags = "")
```

**Arguments**

|                   |                                                                                                                                                                                                                                       |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| tarfile           | The pathname of the tar file: tilde expansion (see <a href="#">path.expand</a> ) will be performed. Alternatively, a <a href="#">connection</a> that can be used for binary writes.                                                   |
| files             | A character vector of filepaths to be archived: the default is to archive all files under the current directory.                                                                                                                      |
| compression       | character string giving the type of compression to be used (default none). Can be abbreviated.                                                                                                                                        |
| compression_level | integer: the level of compression. Only used for the internal method.                                                                                                                                                                 |
| tar               | character string: the path to the command to be used. If the command itself contains spaces it needs to be quoted (e.g., by <a href="#">shQuote</a> ) – but argument tar may also contain flags separated from the command by spaces. |
| extra_flags       | Any extra flags for an external tar.                                                                                                                                                                                                  |

**Details**

This is either a wrapper for a tar command or uses an internal implementation in R. The latter is used if tarfile is a connection or if the argument tar is "internal" or "" (the ‘factory-fresh’ default). Note that whereas Unix-alike versions of R set the environment variable TAR, its value is not the default for this function.

Argument extra\_flags is passed to an external tar and so is platform-dependent. Possibly useful values include ‘-h’ (follow symbolic links, also ‘-L’ on some platforms), ‘--acls’, ‘--exclude-backups’, ‘--exclude-vcs’ (and similar) and on Windows ‘--force-local’ (so drives can be included in filepaths: however, this is the default for the Rtools tar). For GNU tar, ‘--format=ustar’ forces a more portable format. (The default is set at compilation and will be shown at the end of the output from tar --help: for version 1.30 ‘out-of-the-box’ it is ‘--format=gnu’, but the manual says the intention is to change to ‘--format=posix’ which is the same as pax – it was never part of the POSIX standard for tar and should not be used.) For libarchive’s bsdtar, ‘--format=ustar’ is more portable than the default.

One issue which can cause an external command to fail is a command line too long for the system shell: as from R 3.5.0 this is worked around if the external command is detected to be GNU tar or libarchive tar (aka bsdtar).

Note that files = ' .' will usually not work with an external tar as that would expand the list of files after tarfile is created. (It does work with the default internal method.)

## Value

The return code from `system` or 0 for the internal version, invisibly.

## Portability

The ‘tar’ format no longer has an agreed standard! ‘Unix Standard Tar’ was part of POSIX 1003.1:1998 but has been removed in favour of `pax`, and in any case many common implementations diverged from the former standard.

Many R platforms use a version of GNU `tar` (including `Rtools` on Windows), but the behaviour seems to be changed with each version. macOS  $\geq$  10.6 and FreeBSD use `bsdtar` from the libarchive project (but for macOS, a version from 2010), and commercial Unixes will have their own versions. `bsdtar` is available for many other platforms: macOS up to at least 10.9 had GNU `tar` as `gnutar` and other platforms, e.g. Solaris, have it as `gtar`: on a Unix-alike `configure` will try `gnutar` and `gtar` before `tar`.

Known problems arise from

- The handling of file paths of more than 100 bytes. These were unsupported in early versions of `tar`, and supported in one way by POSIX `tar` and in another by GNU `tar` and yet another by the POSIX `pax` command which recent `tar` programs often support. The internal implementation warns on paths of more than 100 bytes, uses the ‘ustar’ way from the 1998 POSIX standard which supports up to 256 bytes (depending on the path: in particular the final component is limited to 100 bytes) if possible, otherwise the GNU way (which is widely supported, including by `untar`).

Most formats do not record the encoding of file paths.

- (File) links. `tar` was developed on an OS that used hard links, and physical files that were referred to more than once in the list of files to be included were included only once, the remaining instances being added as links. Later a means to include symbolic links was added. The internal implementation supports symbolic links (on OSes that support them), only. Of course, the question arises as to how links should be unpacked on OSes that do not support them: for regular files file copies can be used.

Names of links in the ‘ustar’ format are restricted to 100 bytes. There is an GNU extension for arbitrarily long link names, but `bsdtar` ignores it. The internal method uses the GNU extension, with a warning.

- Header fields, in particular the padding to be used when fields are not full or not used. POSIX did define the correct behaviour but commonly used implementations did (and still do) not comply.
- File sizes. The ‘ustar’ format is restricted to 8GB per (uncompressed) file.

For portability, avoid file paths of more than 100 bytes and all links (especially hard links and symbolic links to directories).

The internal implementation writes only the blocks of 512 bytes required (including trailing blocks of nuls), unlike GNU `tar` which by default pads with ‘nul’ to a multiple of 20 blocks (10KB). Implementations which pad differ on whether the block padding should occur before or after compression (or both): padding was designed for improved performance on physical tape drives.

The ‘ustar’ format records file modification times to a resolution of 1 second: on file systems with higher resolution it is conventional to discard fractional seconds.

## Compression

When an external `tar` command is used, compressing the tar archive requires that `tar` supports the ‘-z’, ‘-j’ or ‘-J’ flag, and may require the appropriate command (`gzip`, `bzip2` or `xz`) to be

available. For GNU `tar`, further compression programs can be specified by e.g. `extra_flags = "-I lz4"`. Some versions of `bsdtar` accept options such as `'--lz4'`, `'--lzop'` and `'--lrzip'` or an external compressor *via* `--use-compress-program lz4`: these could be supplied in `extra_flags`.

NetBSD prior to 8.0 used flag `'--xz'` rather than `'-J'`, so this should be used *via* `extra_flags = "--xz"` rather than `compression = "xz"`. The commands from OpenBSD and the Heirloom Toolchest are not documented to support `xz`.

The `tar` programs in commercial Unixen such as AIX and Solaris do not support compression.

### Note

For users of macOS (formerly OS X). Apple's HFS and HFS+ file systems have a legacy concept of 'resource forks' dating from classic Mac OS and rarely used nowadays. Apple's version of `tar` stores these as separate files in the tarball with names prefixed by `'._'`, and unpacks such files into resource forks (if possible): other ways of unpacking (including `untar` in R) unpack them as separate files.

When argument `tar` is set to the command `tar` on macOS, environment variable `COPYFILE_DISABLE=1` is set, which for the system version of `tar` prevents these separate files being included in the tarball.

[untar](#).

---

toLatex

*Converting R Objects to BibTeX or LaTeX*

---

### Description

These methods convert R objects to character vectors with BibTeX or LaTeX markup.

### Usage

```
toBibtex(object, ...)
toLatex(object, ...)
S3 method for class 'Bibtex'
print(x, prefix = "", ...)
S3 method for class 'Latex'
print(x, prefix = "", ...)
```

### Arguments

|                     |                                                                                                                      |
|---------------------|----------------------------------------------------------------------------------------------------------------------|
| <code>object</code> | object of a class for which a <code>toBibtex</code> or <code>toLatex</code> method exists.                           |
| <code>x</code>      | object of class <code>"Bibtex"</code> or <code>"Latex"</code> .                                                      |
| <code>prefix</code> | a character string which is printed at the beginning of each line, mostly used to insert whitespace for indentation. |
| <code>...</code>    | in the <code>print</code> methods, passed to <a href="#">writeLines</a> .                                            |

## Details

Objects of class "Bibtex" or "Latex" are simply character vectors where each element holds one line of the corresponding BibTeX or LaTeX file.

|----------------|--------------------------|
| txtProgressBar | <i>Text Progress Bar</i> |
|----------------|--------------------------|

---

## Description

Text progress bar in the R console.

## Usage

```
txtProgressBar(min = 0, max = 1, initial = 0, char = "=",
 width = NA, title, label, style = 1, file = "")

getTxtProgressBar(pb)
setTxtProgressBar(pb, value, title = NULL, label = NULL)
S3 method for class 'txtProgressBar'
close(con, ...)
```

## Arguments

|                |                                                                                                                                                                           |
|----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| min, max       | (finite) numeric values for the extremes of the progress bar. Must have min < max.                                                                                        |
| initial, value | initial or new value for the progress bar. See ‘Details’ for what happens with invalid values.                                                                            |
| char           | the character (or character string) to form the progress bar.                                                                                                             |
| width          | the width of the progress bar, as a multiple of the width of char. If NA, the default, the number of characters is that which fits into <code>getOption("width")</code> . |
| style          | the ‘style’ of the bar – see ‘Details’.                                                                                                                                   |
| file           | an open connection object or "" which indicates the console: <code>stderr()</code> might be useful here.                                                                  |
| pb, con        | an object of class "txtProgressBar".                                                                                                                                      |
| title, label   | ignored, for compatibility with other progress bars.                                                                                                                      |
| ...            | for consistency with the generic.                                                                                                                                         |

## Details

`txtProgressBar` will display a progress bar on the R console (or a connection) via a text representation.

`setTxtProgressbar` will update the value. Missing (NA) and out-of-range values of `value` will be (silently) ignored. (Such values of `initial` cause the progress bar not to be displayed until a valid value is set.)

The progress bar should be closed when finished with: this outputs the final newline character.

`style = 1` and `style = 2` just shows a line of `char`. They differ in that `style = 2` redraws the line each time, which is useful if other code might be writing to the R console. `style = 3` marks the end of the range by `|` and gives a percentage to the right of the bar.

## Value

For `txtProgressBar` an object of class "txtProgressBar".

For `getTxtProgressBar` and `setTxtProgressBar`, a length-one numeric vector giving the previous value (invisibly for `setTxtProgressBar`).

## Note

Using `style 2` or `3` or reducing the value with `style = 1` uses `'\r'` to return to the left margin – the interpretation of carriage return is up to the terminal or console in which R is running, and this is liable to produce ugly output on a connection other than a terminal, including when `stdout()` is redirected to a file.

## See Also

`winProgressBar` (Windows only), `tkProgressBar` (Unix-alike platforms).

## Examples

```
slow
testit <- function(x = sort(runif(20)), ...)
{
 pb <- txtProgressBar(...)
 for(i in c(0, x, 1)) {Sys.sleep(0.5); setTxtProgressBar(pb, i)}
 Sys.sleep(1)
 close(pb)
}
testit()
testit(runif(10))
testit(style = 3)
```

---

type.convert

*Convert Data to Appropriate Type*

---

## Description

Convert a data object to logical, integer, numeric, complex, character or factor as appropriate.

## Usage

```

type.convert(x, ...)
Default S3 method:
type.convert(x, na.strings = "NA", as.is = FALSE, dec = ".",
 numerals = c("allow.loss", "warn.loss", "no.loss"), ...)
S3 method for class 'data.frame'
type.convert(x, ...)
S3 method for class 'list'
type.convert(x, ...)

```

## Arguments

|                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>          | a vector, matrix, array, data frame, or list.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>na.strings</code> | a vector of strings which are to be interpreted as <a href="#">NA</a> values. Blank fields are also considered to be missing values in logical, integer, numeric or complex vectors.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <code>as.is</code>      | whether convert to <a href="#">factors</a> . When false (as by default currently, but planned <b>to be changed!</b> ), convert character vectors to factors. See ‘Details’.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>dec</code>        | the character to be assumed for decimal points.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <code>numerals</code>   | string indicating how to convert numbers whose conversion to double precision would lose accuracy, typically when <code>x</code> has more digits than can be stored in a <a href="#">double</a> . Can be abbreviated. Possible values are<br><br><code>numerals = "allow.loss"</code> , <b>default:</b> the conversion happens with some accuracy loss. This was the behavior of R versions 3.0.3 and earlier, and the default from 3.1.1 onwards.<br><code>numerals = "warn.loss"</code> : a <a href="#">warning</a> about accuracy loss is signalled and the conversion happens as with <code>numerals = "allow.loss"</code> .<br><code>numerals = "no.loss"</code> : <code>x</code> is <i>not</i> converted to a number, but to a <a href="#">factor</a> or character, depending on <code>as.is</code> . This was the behavior of R version 3.1.0. |
| <code>...</code>        | arguments to be passed to or from methods.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

## Details

This helper function is used by [read.table](#). When the data object `x` is a data frame or list, the function is called recursively for each column or list element.

Given a vector, the function attempts to convert it to logical, integer, numeric or complex, and failing that converts a character vector to [factor](#) unless `as.is = TRUE`. The first type that can accept all the non-missing values is chosen.

Vectors which are entirely missing values are converted to logical, since `NA` is primarily logical.

Vectors containing just `F`, `T`, `FALSE`, `TRUE` and values from `na.strings` are converted to logical. Vectors containing optional whitespace followed by decimal constants representable as R integers or values from `na.strings` are converted to integer. Other vectors containing optional whitespace followed by other decimal or hexadecimal constants (see [NumericConstants](#)), or `NaN`, `Inf` or `infinity` (ignoring case) or values from `na.strings` are converted to numeric. Where converting inputs to numeric or complex would result in loss of accuracy they can optionally be returned as strings (for `as.is = TRUE`) or factors.

Since this is a helper function, the caller should always pass an appropriate value of `as.is`.

**Value**

An object like `x` but using another storage mode when appropriate.

**Author(s)**

R Core, with a contribution by Arni Magnusson

**See Also**

`read.table`, `class`, `storage.mode`.

**Examples**

```
Numeric to integer
class(rivers)
x <- type.convert(rivers)
class(x)

Convert many columns
auto <- type.convert(mtcars)
str(mtcars)
str(auto)

Convert matrix
phones <- type.convert(WorldPhones)
storage.mode(WorldPhones)
storage.mode(phones)

Factor or character
chr <- c("A", "B", "B", "A")
fac <- factor(c("A", "B", "B", "A"))
type.convert(chr) # -> factor
type.convert(fac) # -> factor
type.convert(chr, as.is = TRUE) # -> character
type.convert(fac, as.is = TRUE) # -> character
```

---

untar

*Extract or List Tar Archives*

---

**Description**

Extract files from or list the contents of a tar archive.

**Usage**

```
untar(tarfile, files = NULL, list = FALSE, exdir = ".",
 compressed = NA, extras = NULL, verbose = FALSE,
 restore_times = TRUE,
 support_old_tars = Sys.getenv("R_SUPPORT_OLD_TARS", FALSE),
 tar = Sys.getenv("TAR"))
```

## Arguments

|                               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>tarfile</code>          | The pathname of the tar file: tilde expansion (see <code>path.expand</code> ) will be performed. Alternatively, a <code>connection</code> that can be used for binary reads. For a <i>compressed</i> tarfile, and if a connection is to be used, that should be created by <code>gzfile(.)</code> (or <code>gzcon(.)</code> which currently only works for "gzip", whereas <code>gzfile()</code> works for all compressions available in <code>tar()</code> ).                                                                         |
| <code>files</code>            | A character vector of recorded filepaths to be extracted: the default is to extract all files.                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>list</code>             | If TRUE, list the files (the equivalent of <code>tar -tf</code> ). Otherwise extract the files (the equivalent of <code>tar -xf</code> ).                                                                                                                                                                                                                                                                                                                                                                                              |
| <code>exdir</code>            | The directory to extract files to (the equivalent of <code>tar -C</code> ). It will be created if necessary.                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>compressed</code>       | (Deprecated in favour of auto-detection, used only for an external <code>tar</code> command.) Logical or character string. Values "gzip", "bzip2" and "xz" select that form of compression (and may be abbreviated to the first letter). TRUE indicates gzip compression, FALSE no known compression, and NA (the default) indicates that the type is to be inferred from the file header.<br>The external command may ignore the selected compression type but detect a type automatically.                                           |
| <code>extras</code>           | NULL or a character string: further command-line flags such as '-p' to be passed to an external <code>tar</code> program.                                                                                                                                                                                                                                                                                                                                                                                                              |
| <code>verbose</code>          | logical: if true echo the command used for an external <code>tar</code> program.                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <code>restore_times</code>    | logical. If true (default) restore file modification times. If false, the equivalent of the '-m' flag. Times in tarballs are supposed to be in UTC, but tarballs have been submitted to CRAN with times in the future or far past: this argument allows such times to be discarded.<br>Note that file times in a tarball are stored with a resolution of 1 second, and can only be restored to the resolution supported by the file system (which on a FAT system is 2 seconds).                                                       |
| <code>support_old_tars</code> | logical. If false (the default), the external <code>tar</code> command is assumed to be able handle compressed tarfiles and if <code>compressed</code> does not specify it, to automatically detect the type of compression. (The major implementations have done so since 2009; for GNU <code>tar</code> since version 1.22.)<br>If true, the R code calls an appropriate decompressor and pipes the output to <code>tar</code> , for <code>compressed = NA</code> examining the tarfile header to determine the type of compression. |
| <code>tar</code>              | character string: the path to the command to be used or "internal". If the command itself contains spaces it needs to be quoted – but <code>tar</code> can also contain flags separated from the command by spaces.                                                                                                                                                                                                                                                                                                                    |

## Details

This is either a wrapper for a `tar` command or for an internal implementation written in R. The latter is used if `tarfile` is a connection or if the argument `tar` is "internal" or "" (except on Windows, when `tar.exe` is tried first).

Unless otherwise stated three types of compression of the tar file are supported: gzip, bzip2 and xz.

What options are supported will depend on the `tar` implementation used: the "internal" one is intended to provide support for most in a platform-independent way.

**GNU tar:** Modern GNU `tar` versions support compressed archives and since 1.15 are able to detect the type of compression automatically: version 1.22 added support for `xz` compression. On a Unix-alike, `configure` will set environment variable `TAR`, preferring GNU `tar` if found.

**bsdtar:** macOS 10.6 and later (and FreeBSD and some other OSes) have a `tar` from the libarchive project which detects all three forms of compression automatically (even if undocumented in macOS).

**NetBSD:** It is undocumented if NetBSD's `tar` can detect compression automatically: for versions before 8 the flag for `xz` compression was `--xz` not `-J`. So `support_old_tars = TRUE` is recommended (or use `bsdtar` if installed).

**OpenBSD:** OpenBSD's `tar` does not detect compression automatically. It has no support for `xz` beyond reporting that the file is `xz`-compressed. So `support_old_tars = TRUE` is recommended.

**Heirloom Toolchest:** This `tar` does automatically detect `gzip` and `bzip2` compression (undocumented) but has no support for `xz` compression.

**Older support:** Environment variable `R_GZIPCMD` gives the command to decompress `gzip` files, and `R_BZIPCMD` for `bzip2` files. (On Unix-alikes these are set at installation if found.) `xz` is used if available: if not decompression is expected to fail.

Arguments `compressed`, `extras` and `verbose` are only used when an external `tar` is used.

Some external `tar` commands will detect some of `lrzip`, `lzma`, `lz4`, `lzop` and `zstd` compression in addition to `gzip`, `bzip2` and `xz`. (For some external `tar` commands, compressed tarfiles can only be read if the appropriate utility program is available.) For GNU `tar`, further (de)compression programs can be specified by e.g. `extras = "-I lz4"`. For `bsdtar` this could be `extras = "--use-compress-program lz4"`. Most commands will detect (the nowadays rarely seen) `.tar.Z` archives compressed by `compress`.

The internal implementation restores symbolic links as links on a Unix-alike, and as file copies on Windows (which works only for existing files, not for directories), and hard links as links. If the linking operation fails (as it may on a FAT file system), a file copy is tried. Since it uses `gzfile` to read a file it can handle files compressed by any of the methods that function can handle: at least `compress`, `gzip`, `bzip2` and `xz` compression, and some types of `lzma` compression. It does not guard against restoring absolute file paths, as some `tar` implementations do. It will create the parent directories for directories or files in the archive if necessary. It handles the USTAR/POSIX, GNU and `pax` ways of handling file paths of more than 100 bytes, and the GNU way of handling link targets of more than 100 bytes.

You may see warnings from the internal implementation such as

```
unsupported entry type 'x'
```

This often indicates an invalid archive: entry types "A-Z" are allowed as extensions, but other types are reserved. The only thing you can do with such an archive is to find a `tar` program that handles it, and look carefully at the resulting files. There may also be the warning

```
using pax extended headers
```

This indicates that additional information may have been discarded, such as ACLs, encodings ...

The former standards only supported ASCII filenames (indeed, only alphanumeric plus period, underscore and hyphen). `untar` makes no attempt to map filenames to those acceptable on the

current system, and treats the filenames in the archive as applicable without any re-encoding in the current locale.

The internal implementation does not special-case ‘resource forks’ in macOS: that system’s `tar` command does. This may lead to unexpected files with names with prefix ‘`._`’.

**Value**

If `list = TRUE`, a character vector of (relative or absolute) paths of files contained in the tar archive.

Otherwise the return code from `system` with an external `tar` or `0L`, invisibly.

**See Also**

`tar`, `unzip`.

---

|       |                                     |
|-------|-------------------------------------|
| unzip | <i>Extract or List Zip Archives</i> |
|-------|-------------------------------------|

---

**Description**

Extract files from or list a zip archive.

**Usage**

```
unzip(zipfile, files = NULL, list = FALSE, overwrite = TRUE,
 junkpaths = FALSE, exdir = ".", unzip = "internal",
 setTimes = FALSE)
```

**Arguments**

|           |                                                                                                                                                                     |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| zipfile   | The pathname of the zip file: tilde expansion (see <code>path.expand</code> ) will be performed.                                                                    |
| files     | A character vector of recorded filepaths to be extracted: the default is to extract all files.                                                                      |
| list      | If <code>TRUE</code> , list the files and extract none. The equivalent of <code>unzip -l</code> .                                                                   |
| overwrite | If <code>TRUE</code> , overwrite existing files (the equivalent of <code>unzip -o</code> ), otherwise ignore such files (the equivalent of <code>unzip -n</code> ). |
| junkpaths | If <code>TRUE</code> , use only the basename of the stored filepath when extracting. The equivalent of <code>unzip -j</code> .                                      |
| exdir     | The directory to extract files to (the equivalent of <code>unzip -d</code> ). It will be created if necessary.                                                      |
| unzip     | The method to be used. An alternative is to use <code>getOption("unzip")</code> , which on a Unix-alike may be set to the path to a <code>unzip</code> program.     |
| setTimes  | logical. For the internal method only, should the file times be set based on the times in the zip file? (NB: this applies to included files, not to directories.)   |

**Value**

If `list = TRUE`, a data frame with columns `Name` (character) `Length` (the size of the uncompressed file, numeric) and `Date` (of class `"POSIXct"`).

Otherwise for the `"internal"` method, a character vector of the filepaths extracted to, invisibly.

**Note**

The default internal method is a minimal implementation, principally designed for Windows' users to be able to unpack Windows binary packages without external software. It does not (for example) support Unicode filenames as introduced in `zip 3.0`: for that use `unzip = "unzip"` with `unzip 6.00` or later. It does have some support for `bzip2` compression and `> 2GB` zip files (but not `>= 4GB` files pre-compression contained in a zip file: like many builds of `unzip` it may truncate these, in R's case with a warning if possible).

If `unzip` specifies a program, the format of the dates listed with `list = TRUE` is unknown (on Windows it can even depend on the current locale) and the return values could be `NA` or expressed in the wrong time zone or misinterpreted (the latter being far less likely as from `unzip 6.00`).

File times in zip files are stored in the style of MS-DOS, as local times to an accuracy of 2 seconds. This is not very useful when transferring zip files between machines (even across continents), so we chose not to restore them by default.

**Source**

The internal C code uses `zlib` and is in particular based on the contributed 'minizip' application in the `zlib` sources (from <https://zlib.net/>) by Gilles Vollant.

**See Also**

`unz` to read a single component from a zip file.

`zip` for packing, i.e., the "inverse" of `unzip()`; further `untar` and `tar`, the corresponding pair for (un)packing tar archives ("tarballs") such as R source packages.

---

update.packages

*Compare Installed Packages with CRAN-like Repositories*

---

**Description**

`old.packages` indicates packages which have a (suitable) later version on the repositories whereas `update.packages` offers to download and install such packages.

`new.packages` looks for (suitable) packages on the repositories that are not already installed, and optionally offers them for installation.

**Usage**

```
update.packages(lib.loc = NULL, repos = getOption("repos"),
 contriburl = contrib.url(repos, type),
 method, instlib = NULL,
 ask = TRUE, available = NULL,
 oldPkgs = NULL, ..., checkBuilt = FALSE,
 type = getOption("pkgType"))
```

```

old.packages(lib.loc = NULL, repos = getOption("repos"),
 contriburl = contrib.url(repos, type),
 instPkgs = installed.packages(lib.loc = lib.loc, ...),
 method, available = NULL, checkBuilt = FALSE, ...,
 type = getOption("pkgType"))

new.packages(lib.loc = NULL, repos = getOption("repos"),
 contriburl = contrib.url(repos, type),
 instPkgs = installed.packages(lib.loc = lib.loc, ...),
 method, available = NULL, ask = FALSE, ...,
 type = getOption("pkgType"))

```

### Arguments

|                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>lib.loc</code>    | character vector describing the location of R library trees to search through (and update packages therein), or <code>NULL</code> for all known trees (see <a href="#">.libPaths</a> ).                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <code>repos</code>      | character vector, the base URL(s) of the repositories to use, e.g., the URL of a CRAN mirror such as <code>"https://cloud.r-project.org"</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>contriburl</code> | URL(s) of the contrib sections of the repositories. Use this argument if your repository is incomplete. Overrides argument <code>repos</code> . Incompatible with <code>type = "both"</code> .                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <code>method</code>     | Download method, see <a href="#">download.file</a> . Unused if a non- <code>NULL</code> <code>available</code> is supplied.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <code>instlib</code>    | character string giving the library directory where to install the packages.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>ask</code>        | logical indicating whether to ask the user to select packages before they are downloaded and installed, or the character string <code>"graphics"</code> , which brings up a widget to allow the user to (de-)select from the list of packages which could be updated. The latter value only works on systems with a GUI version of <a href="#">select.list</a> , and is otherwise equivalent to <code>ask = TRUE</code> . <code>ask</code> does not control questions asked before installing packages from source via <code>type = "both"</code> (see option <code>"install.packages.compile.from.source"</code> ). |
| <code>available</code>  | an object as returned by <a href="#">available.packages</a> listing packages available at the repositories, or <code>NULL</code> which makes an internal call to <a href="#">available.packages</a> . Incompatible with <code>type = "both"</code> .                                                                                                                                                                                                                                                                                                                                                                 |
| <code>checkBuilt</code> | If <code>TRUE</code> , a package built under an earlier major.minor version of R (e.g., 3.4) is considered to be 'old'.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <code>oldPkgs</code>    | if specified as non- <code>NULL</code> , <code>update.packages()</code> only considers these packages for updating. This may be a character vector of package names or a matrix as returned by <code>old.packages</code> .                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>instPkgs</code>   | by default all installed packages, <a href="#">installed.packages</a> ( <code>lib.loc = lib.loc</code> ). A subset can be specified; currently this must be in the same (character matrix) format as returned by <code>installed.packages()</code> .                                                                                                                                                                                                                                                                                                                                                                 |
| <code>...</code>        | Arguments such as <code>destdir</code> and <code>dependencies</code> to be passed to <a href="#">install.packages</a> and <code>ignore_repo_cache</code> , <code>max_repo_cache_age</code> and <code>noCache</code> to <a href="#">available.packages</a> or <a href="#">installed.packages</a> .                                                                                                                                                                                                                                                                                                                    |
| <code>type</code>       | character, indicating the type of package to download and install. See <a href="#">install.packages</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

## Details

`old.packages` compares the information from `available.packages` with that from `instPkgs` (computed by `installed.packages` by default) and reports installed packages that have newer versions on the repositories or, if `checkBuilt = TRUE`, that were built under an earlier minor version of R (for example built under 3.3.x when running R 3.4.0). (For binary package types there is no check that the version on the repository was built under the current minor version of R, but it is advertised as being suitable for this version.)

`new.packages` does the same comparison but reports uninstalled packages that are available at the repositories. If `ask != FALSE` it asks which packages should be installed in the first element of `lib.loc`.

The main function of the set is `update.packages`. First a list of all packages found in `lib.loc` is created and compared with those available at the repositories. If `ask = TRUE` (the default) packages with a newer version are reported and for each one the user can specify if it should be updated. If so the packages are downloaded from the repositories and installed in the respective library path (or `instlib` if specified).

For how the list of suitable available packages is determined see `available.packages`. `available = NULL` make a call to `available.packages(contriburl = contriburl, method = method)` and hence by default filters on R version, OS type and removes duplicates.

## Value

`update.packages` returns `NULL` invisibly.

For `old.packages`, `NULL` or a matrix with one row per package, row names the package names and column names "Package", "LibPath", "Installed" (the version), "Built" (the version built under), "ReposVer" and "Repository".

For `new.packages` a character vector of package names, *after* any selected *via* `ask` have been installed.

## Warning

Take care when using dependencies (passed to `install.packages`) with `update.packages`, for it is unclear where new dependencies should be installed. The current implementation will only allow it if all the packages to be updated are in a single library, when that library will be used.

---

|          |                           |
|----------|---------------------------|
| url.show | <i>Display a Text URL</i> |
|----------|---------------------------|

---

**Description**

Extension of [file.show](#) to display text files from a remote server.

**Usage**

```
url.show(url, title = url, file = tempfile(),
 delete.file = TRUE, method, ...)
```

**Arguments**

|             |                                                         |
|-------------|---------------------------------------------------------|
| url         | The URL to read from.                                   |
| title       | Title for the browser.                                  |
| file        | File to copy to.                                        |
| delete.file | Delete the file afterwards?                             |
| method      | File transfer method: see <a href="#">download.file</a> |
| ...         | Arguments to pass to <a href="#">file.show</a> .        |

**Note**

Since this is for text files, it will convert to CRLF line endings on Windows.

**See Also**

[url](#), [file.show](#), [download.file](#)

**Examples**

```
Not run: url.show("https://www.stats.ox.ac.uk/pub/datasets/csb/ch3a.txt")
```

---

|           |                                         |
|-----------|-----------------------------------------|
| URLencode | <i>Encode or Decode a (partial) URL</i> |
|-----------|-----------------------------------------|

---

**Description**

Functions to percent-encode or decode characters in URLs.

**Usage**

```
URLencode(URL, reserved = FALSE, repeated = FALSE)
URLdecode(URL)
```

**Arguments**

|          |                                                                   |
|----------|-------------------------------------------------------------------|
| URL      | a character string.                                               |
| reserved | logical: should 'reserved' characters be encoded? See 'Details'.  |
| repeated | logical: should apparently already-encoded URLs be encoded again? |

## Details

Characters in a URL other than the English alphanumeric characters and ‘\_ . ~’ should be encoded as % plus a two-digit hexadecimal representation, and any single-byte character can be so encoded. (Multi-byte characters are encoded byte-by-byte.) The standard refers to this as ‘percent-encoding’.

In addition, ‘! \$ & ' ( ) \* + , ; = : / ? @ # [ ]’ are reserved characters, and should be encoded unless used in their reserved sense, which is scheme specific. The default in `URLencode` is to leave them alone, which is appropriate for ‘file://’ URLs, but probably not for ‘http://’ ones.

An ‘apparently already-encoded URL’ is one containing %xx for two hexadecimal digits.

## Value

A character string.

## References

Internet STD 66 (formerly RFC 3986), <https://tools.ietf.org/html/std66>

## Examples

```
(y <- URLencode("a url with spaces and / and @"))
URLdecode(y)
(y <- URLencode("a url with spaces and / and @", reserved = TRUE))
URLdecode(y)

URLdecode(z <- "ab%20cd")
c(URLencode(z), URLencode(z, repeated = TRUE)) # first is usually wanted
```

---

utils-deprecated     *Deprecated Functions in Package **utils***

---

## Description

These functions are provided for compatibility with older versions of R only, and may be defunct as soon as of the next release.

## See Also

[Deprecated](#), [Defunct](#)

---

View*Invoke a Data Viewer*

---

## Description

Invoke a spreadsheet-style data viewer on a matrix-like R object.

## Usage

```
View(x, title)
```

## Arguments

|                    |                                                                                               |
|--------------------|-----------------------------------------------------------------------------------------------|
| <code>x</code>     | an R object which can be coerced to a data frame with non-zero numbers of rows and columns.   |
| <code>title</code> | title for viewer window. Defaults to name of <code>x</code> prefixed by <code>Data :</code> . |

## Details

Object `x` is coerced (if possible) to a data frame, then columns are converted to character using `format.data.frame`. The object is then viewed in a spreadsheet-like data viewer, a read-only version of `data.entry`.

If there are row names on the data frame that are not `1:nrow`, they are displayed in a separate first column called `row.names`.

Objects with zero columns or zero rows are not accepted.

**On Unix-alikes**, the array of cells can be navigated by the cursor keys and Home, End, Page Up and Page Down (where supported by X11) as well as Enter and Tab.

**On Windows**, the array of cells can be navigated *via* the scrollbars and by the cursor keys, Home, End, Page Up and Page Down.

On Windows, the initial size of the data viewer window is taken from the default dimensions of a pager (see `Rconsole`), but adjusted downwards to show a whole number of rows and columns.

## Value

Invisible `NULL`. The function puts up a window and returns immediately: the window can be closed via its controls or menus.

## See Also

`edit.data.frame`, `data.entry`.

vignette

*View, List or Get R Source of Package Vignettes***Description**

View a specified package vignette, or list the available ones; display it rendered in a viewer, and get or edit its R source file.

**Usage**

```
vignette(topic, package = NULL, lib.loc = NULL, all = TRUE)

S3 method for class 'vignette'
print(x, ...)
S3 method for class 'vignette'
edit(name, ...)
```

**Arguments**

|                      |                                                                                                                                                                                 |
|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>topic</code>   | a character string giving the (base) name of the vignette to view. If omitted, all vignettes from all installed packages are listed.                                            |
| <code>package</code> | a character vector with the names of packages to search through, or <code>NULL</code> in which ‘all’ packages (as defined by argument <code>all</code> ) are searched.          |
| <code>lib.loc</code> | a character vector of directory names of R libraries, or <code>NULL</code> . The default value of <code>NULL</code> corresponds to all libraries currently known.               |
| <code>all</code>     | logical; if <code>TRUE</code> search all available packages in the library trees specified by <code>lib.loc</code> , and if <code>FALSE</code> , search only attached packages. |
| <code>x, name</code> | object of class <code>vignette</code> .                                                                                                                                         |
| <code>...</code>     | ignored by the <code>print</code> method, passed on to <code>file.edit</code> by the <code>edit</code> method.                                                                  |

**Details**

Function `vignette` returns an object of the same class, the `print` method opens a viewer for it.

On Unix-alikes, The program specified by the `pdfviewer` option is used for viewing PDF versions of vignettes.

If several vignettes have PDF/HTML versions with base name identical to `topic`, the first one found is used.

If no topics are given, all available vignettes are listed. The corresponding information is returned in an object of class `"packageIQR"`.

**See Also**

[browseVignettes](#) for an HTML-based vignette browser; [RShowDoc](#)(`<basename>`, `package = "<pkg>"`) displays a “rendered” vignette (pdf or html).

## Examples

```
List vignettes from all *attached* packages
vignette(all = FALSE)

List vignettes from all *installed* packages (can take a long time!):
vignette(all = TRUE)

The grid intro vignette -- open it
Not run: vignette("grid") # calling print()
The same (conditional on existence of the vignette).
Note that 'package = *' is much faster in the case of many installed packages:
if(!is.null(v1 <- vignette("grid", package="grid"))) {
 ## Not run: v1 # calling print(.)
 str(v1)
 ## Now let us have a closer look at the code

 ## Not run: edit(v1) # e.g., to send lines ...
}# if(has vignette "installed")
A package can have more than one vignette (package grid has several):
vignette(package = "grid")
if(interactive()) {
 ## vignette("rotated")
 ## The same, but without searching for it:
 vignette("rotated", package = "grid")
}
```

---

warnErrList

---

*Collect and Summarize Errors From List*

---

## Description

Collect errors (class "error", typically from `tryCatch`) from a list `x` into a “summary warning”, by default produce a `warning` and keep that message as "warningMsg" attribute.

## Usage

```
warnErrList(x, warn = TRUE, errValue = NULL)
```

## Arguments

|                       |                                                                                                                                            |
|-----------------------|--------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>        | a <code>list</code> , typically from applying models to a list of data (sub)sets, e.g., using <code>tryCatch(*, error = identity)</code> . |
| <code>warn</code>     | logical indicating if <code>warning()</code> should be called.                                                                             |
| <code>errValue</code> | the value with which errors should be replaced.                                                                                            |

## Value

a `list` of the same length and names as the `x` argument, with the error components replaced by `errValue`, `NULL` by default, and summarized in the "warningMsg" attribute.

**See Also**

The `warnErrList()` utility has been used in `lmList()` and `nlsList()` in recommended package **nlme** forever.

**Examples**

```
Regression for each Chick:
ChWtgrps <- split(ChickWeight, ChickWeight[, "Chick"])
sapply(ChWtgrps, nrow) # typically 12 obs.
nlis1 <- lapply(ChWtgrps, function(DAT) tryCatch(error = identity,
 lm(weight ~ (Time + I(Time^2)) * Diet, data = DAT)))
nl1 <- warnErrList(nlis1) #-> warning :
50 times the same error (as Diet has only one level in each group)
stopifnot(sapply(nl1, is.null)) ## all errors --> all replaced by NULL
nlis2 <- lapply(ChWtgrps, function(DAT) tryCatch(error = identity,
 lm(weight ~ Time + I(Time^2), data = DAT)))
nl2 <- warnErrList(nlis2)
stopifnot(identical(nl2, nlis2)) # because there was *no* error at all
nlis3 <- lapply(ChWtgrps, function(DAT) tryCatch(error = identity,
 lm(weight ~ poly(Time, 3), data = DAT)))
nl3 <- warnErrList(nlis3) # 1 error caught:
stopifnot(inherits(nlis3[[1]], "error")
 , identical(nl3[-1], nlis3[-1])
 , is.null(nl3[[1]]))
)

With different error messages
if(requireNamespace("nlme")) { # almost always, as it is recommended
 data(Soybean, package="nlme")
 attr(Soybean, "formula") #-> weight ~ Time | Plot => split by "Plot":
 L <- lapply(split(Soybean, Soybean[, "Plot"]),
 function(DD) tryCatch(error = identity,
 nls(weight ~ SSlogis(Time, Asym, xmid, scal), data = DD)))
 Lw <- warnErrList(L)
} # if <nlme>
```

---

winDialog

---

*Dialog Boxes under Windows*

---

**Description**

On MS Windows only, put up a dialog box to communicate with the user. There are various types, either for the user to select from a set of buttons or to edit a string.

**Usage**

```
winDialog(type = c("ok", "okcancel", "yesno", "yesnocancel"),
 message)

winDialogString(message, default)
```

**Arguments**

|                      |                                                                                                      |
|----------------------|------------------------------------------------------------------------------------------------------|
| <code>type</code>    | character. The type of dialog box. It will have the buttons implied by its name.                     |
| <code>message</code> | character. The information field of the dialog box. Limited to 255 chars (by Windows, checked by R). |
| <code>default</code> | character. The default string.                                                                       |

**Value**

For `winDialog` a character string giving the name of the button pressed (in capitals) or `NULL` (invisibly) if the user had no choice.

For `winDialogString` a string giving the contents of the text box when `Ok` was pressed, or `NULL` if `Cancel` was pressed.

**Note**

The standard keyboard accelerators work with these dialog boxes: where appropriate `Return` accepts the default action, `Esc` cancels and the underlined initial letter (Y or N) can be used.

These functions are only available on Windows.

**See Also**

[winMenuAdd](#)  
[file.choose](#) to select a file  
 package `windlgs` in the package source distribution for ways to program dialogs in C in the `GraphApp` toolkit.

**Examples**

```
Not run: winDialog("yesno", "Is it OK to delete file blah")
```

---

winextras

*Get Windows Version*

---

**Description**

Get the self-reported Microsoft Windows version number.

**Usage**

```
win.version()
```

**Details**

`win.version` is an auxiliary function for [sessionInfo](#) and [bug.report](#).

**Value**

A character string describing the version of Windows reported to be in use.

**Note**

This function is only available on Microsoft Windows.

The result is based on the Windows `GetVersionEx` API function, which for recent versions of Windows reports the compatibility version, and not necessarily the actual version (hence 8.1 and 10 may be reported as 8). If the API call reports 8, this function returns `>= 8`.

**Examples**

```
if(.Platform$OS.type == "windows")
 print(win.version())
```

---

|          |                                           |
|----------|-------------------------------------------|
| winMenus | <i>User Menus under MS Windows (Rgui)</i> |
|----------|-------------------------------------------|

---

**Description**

Enables users to add, delete and program menus for the `Rgui` in MS Windows.

**Usage**

```
winMenuAdd(menuname)
winMenuAddItem(menuname, itemname, action)
winMenuDel(menuname)
winMenuDelItem(menuname, itemname)
winMenuNames()
winMenuItems(menuname)
```

**Arguments**

|                       |                                                                                                |
|-----------------------|------------------------------------------------------------------------------------------------|
| <code>menuname</code> | a character string naming a menu.                                                              |
| <code>itemname</code> | a character string naming a menu item on an existing menu.                                     |
| <code>action</code>   | a character string describing the action when that menu is selected, or "enable" or "disable". |

**Details**

User menus are added to the right of existing menus, and items are added at the bottom of the menu.

By default the action character string is treated as R input, being echoed on the command line and parsed and executed as usual.

If the `menuname` parameter of `winMenuAddItem` does not already exist, it will be created automatically.

Normally new submenus and menu items are added to the main console menu. They may be added elsewhere using the following special names:

```
$ConsoleMain The console menu (the default)
$ConsolePopup The console popup menu
$Graph<n>Main The menu for graphics window <n>
$Graph<n>Popup The popup menu for graphics window <n>
```

Specifying an existing item in `winMenuAddItem` enables the action to be changed.

Submenus can be specified by separating the elements in `menuname` by slashes: as a consequence menu names may not contain slashes.

If the `action` is specified as `"none"` no action is taken: this can be useful to reserve items for future expansion.

The function `winMenuNames` can be used to find out what menus have been created by the user and returns a vector of the existing menu names.

The `winMenuItems` function will take the name of a menu and return the items that exist in that menu. The return value is a named vector where the names correspond to the names of the items and the values of the vector are the corresponding actions.

The `winMenuDel` function will delete a menu and all of its items and submenus. `winMenuDelItem` just deletes one menu item.

The total path to an item (menu string plus item string) cannot exceed 1000 bytes, and the menu string cannot exceed 500 bytes.

## Value

NULL, invisibly. If an error occurs, an informative error message will be given.

## Note

These functions are only available on Windows and only when using the `Rgui`, hence not in `ESS` nor `RStudio`.

## See Also

`winDialog`

## Examples

```
Not run:
winMenuAdd("Testit")
winMenuAddItem("Testit", "one", "aaaa")
winMenuAddItem("Testit", "two", "bbbb")
winMenuAdd("Testit/extras")
winMenuAddItem("Testit", "-", "")
winMenuAddItem("Testit", "two", "disable")
winMenuAddItem("Testit", "three", "cccc")
winMenuAddItem("Testit/extras", "one more", "ddd")
winMenuAddItem("Testit/extras", "and another", "eee")
winMenuAdd("$ConsolePopup/Testit")
winMenuAddItem("$ConsolePopup/Testit", "six", "fff")
winMenuNames()
winMenuItems("Testit")

End(Not run)
```

winProgressBar

*Progress Bars under MS Windows***Description**

Put up a Windows progress bar widget, update and access it.

**Usage**

```
winProgressBar(title = "R progress bar", label = "",
 min = 0, max = 1, initial = 0, width = 300)

getWinProgressBar(pb)
setWinProgressBar(pb, value, title = NULL, label = NULL)
S3 method for class 'winProgressBar'
close(con, ...)
```

**Arguments**

|                             |                                                                                               |
|-----------------------------|-----------------------------------------------------------------------------------------------|
| <code>title, label</code>   | character strings, giving the window title and the label on the dialog box respectively.      |
| <code>min, max</code>       | (finite) numeric values for the extremes of the progress bar.                                 |
| <code>initial, value</code> | initial or new value for the progress bar.                                                    |
| <code>width</code>          | the width of the progress bar in pixels: the dialog box will be 40 pixels wider (plus frame). |
| <code>pb, con</code>        | an object of class "winProgressBar".                                                          |
| <code>...</code>            | for consistency with the generic.                                                             |

**Details**

`winProgressBar` will display a progress bar centred on the screen. Space will be allocated for the label only if it is non-empty.

`setWinProgressbar` will update the value and for non-NULL values, the title and label (provided there was one when the widget was created). Missing (NA) and out-of-range values of `value` will be (silently) ignored.

The progress bar should be `closed` when finished with, but it will be garbage-collected once no R object refers to it.

**Value**

For `winProgressBar` an object of class "winProgressBar".

For `getWinProgressBar` and `setWinProgressBar`, a length-one numeric vector giving the previous value (invisibly for `setWinProgressBar`).

**Note**

These functions are only available on Windows.

See Also

On all platforms, [txtProgressBar](#), [tkProgressBar](#)

Examples

```
pb <- winProgressBar("test progress bar", "Some information in %",
 0, 100, 50)

Sys.sleep(0.5)
u <- c(0, sort(runif(20, 0, 100)), 100)
for(i in u) {
 Sys.sleep(0.1)
 info <- sprintf("%d%% done", round(i))
 setWinProgressBar(pb, i, sprintf("test (%s)", info), info)
}
Sys.sleep(5)
close(pb)
```

---

|             |                    |
|-------------|--------------------|
| write.table | <i>Data Output</i> |
|-------------|--------------------|

---

Description

`write.table` prints its required argument `x` (after converting it to a data frame if it is not one nor a matrix) to a file or [connection](#).

Usage

```
write.table(x, file = "", append = FALSE, quote = TRUE, sep = " ",
 eol = "\n", na = "NA", dec = ".", row.names = TRUE,
 col.names = TRUE, qmethod = c("escape", "double"),
 fileEncoding = "")

write.csv(...)
write.csv2(...)
```

Arguments

- `x` the object to be written, preferably a matrix or data frame. If not, it is attempted to coerce `x` to a data frame.
- `file` either a character string naming a file or a [connection](#) open for writing. "" indicates output to the console.
- `append` logical. Only relevant if `file` is a character string. If `TRUE`, the output is appended to the file. If `FALSE`, any existing file of the name is destroyed.
- `quote` a logical value (`TRUE` or `FALSE`) or a numeric vector. If `TRUE`, any character or factor columns will be surrounded by double quotes. If a numeric vector, its elements are taken as the indices of columns to quote. In both cases, row and column names are quoted if they are written. If `FALSE`, nothing is quoted.
- `sep` the field separator string. Values within each row of `x` are separated by this string.

|                           |                                                                                                                                                                                                                                                                                                                                                                                                     |
|---------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>eol</code>          | the character(s) to print at the end of each line (row). For example, <code>eol = "\r\n"</code> will produce Windows' line endings on a Unix-alike OS, and <code>eol = "\r"</code> will produce files as expected by Excel:mac 2004.                                                                                                                                                                |
| <code>na</code>           | the string to use for missing values in the data.                                                                                                                                                                                                                                                                                                                                                   |
| <code>dec</code>          | the string to use for decimal points in numeric or complex columns: must be a single character.                                                                                                                                                                                                                                                                                                     |
| <code>row.names</code>    | either a logical value indicating whether the row names of <code>x</code> are to be written along with <code>x</code> , or a character vector of row names to be written.                                                                                                                                                                                                                           |
| <code>col.names</code>    | either a logical value indicating whether the column names of <code>x</code> are to be written along with <code>x</code> , or a character vector of column names to be written. See the section on 'CSV files' for the meaning of <code>col.names = NA</code> .                                                                                                                                     |
| <code>qmethod</code>      | a character string specifying how to deal with embedded double quote characters when quoting strings. Must be one of "escape" (default for <code>write.table</code> ), in which case the quote character is escaped in C style by a backslash, or "double" (default for <code>write.csv</code> and <code>write.csv2</code> ), in which case it is doubled. You can specify just the initial letter. |
| <code>fileEncoding</code> | character string: if non-empty declares the encoding to be used on a file (not a connection) so the character data can be re-encoded as they are written. See <a href="#">file</a> .                                                                                                                                                                                                                |
| <code>...</code>          | arguments to <code>write.table</code> : <code>append</code> , <code>col.names</code> , <code>sep</code> , <code>dec</code> and <code>qmethod</code> cannot be altered.                                                                                                                                                                                                                              |

## Details

If the table has no columns the rownames will be written only if `row.names = TRUE`, and *vice versa*.

Real and complex numbers are written to the maximal possible precision.

If a data frame has matrix-like columns these will be converted to multiple columns in the result (*via* [as.matrix](#)) and so a character `col.names` or a numeric `quote` should refer to the columns in the result, not the input. Such matrix-like columns are unquoted by default.

Any columns in a data frame which are lists or have a class (e.g., dates) will be converted by the appropriate `as.character` method: such columns are unquoted by default. On the other hand, any class information for a matrix is discarded and non-atomic (e.g., list) matrices are coerced to character.

Only columns which have been converted to character will be quoted if specified by `quote`.

The `dec` argument only applies to columns that are not subject to conversion to character because they have a class or are part of a matrix-like column (or matrix), in particular to columns protected by `I()`. Use `options("OutDec")` to control such conversions.

In almost all cases the conversion of numeric quantities is governed by the option "scipen" (see [options](#)), but with the internal equivalent of `digits = 15`. For finer control, use [format](#) to make a character matrix/data frame, and call `write.table` on that.

These functions check for a user interrupt every 1000 lines of output.

If `file` is a non-open connection, an attempt is made to open it and then close it after use.

To write a Unix-style file on Windows, use a binary connection e.g. `file = file("filename", "wb")`.

## CSV files

By default there is no column name for a column of row names. If `col.names = NA` and `row.names = TRUE` a blank column name is added, which is the convention used for CSV files to be read by spreadsheets. Note that such CSV files can be read in R by

```
read.csv(file = "<filename>", row.names = 1)
```

`write.csv` and `write.csv2` provide convenience wrappers for writing CSV files. They set `sep` and `dec` (see below), `qmethod = "double"`, and `col.names` to `NA` if `row.names = TRUE` (the default) and to `TRUE` otherwise.

`write.csv` uses `"."` for the decimal point and a comma for the separator.

`write.csv2` uses a comma for the decimal point and a semicolon for the separator, the Excel convention for CSV files in some Western European locales.

These wrappers are deliberately inflexible: they are designed to ensure that the correct conventions are used to write a valid file. Attempts to change `append`, `col.names`, `sep`, `dec` or `qmethod` are ignored, with a warning.

CSV files do not record an encoding, and this causes problems if they are not ASCII for many other applications. Windows Excel 2007/10 will open files (e.g., by the file association mechanism) correctly if they are ASCII or UTF-16 (use `fileEncoding = "UTF-16LE"`) or perhaps in the current Windows codepage (e.g., `"CP1252"`), but the 'Text Import Wizard' (from the 'Data' tab) allows far more choice of encodings. Excel:mac 2004/8 can *import* only 'Macintosh' (which seems to mean Mac Roman), 'Windows' (perhaps Latin-1) and 'PC-8' files. OpenOffice 3.x asks for the character set when opening the file.

There is an IETF RFC4180 (<https://tools.ietf.org/html/rfc4180>) for CSV files, which mandates comma as the separator and CRLF line endings. `write.csv` writes compliant files on Windows: use `eol = "\r\n"` on other platforms.

## Note

`write.table` can be slow for data frames with large numbers (hundreds or more) of columns: this is inevitable as each column could be of a different class and so must be handled separately. If they are all of the same class, consider using a matrix instead.

## See Also

The 'R Data Import/Export' manual.

`read.table`, `write`.

`write.matrix` in package **MASS**.

## Examples

```
Not run:
To write a CSV file for input to Excel one might use
x <- data.frame(a = I("a \" quote"), b = pi)
write.table(x, file = "foo.csv", sep = ",", col.names = NA,
 qmethod = "double")
and to read this file back into R one needs
read.table("foo.csv", header = TRUE, sep = ",", row.names = 1)
NB: you do need to specify a separator if qmethod = "double".

Alternatively
```

```

write.csv(x, file = "foo.csv")
read.csv("foo.csv", row.names = 1)
or without row names
write.csv(x, file = "foo.csv", row.names = FALSE)
read.csv("foo.csv")

To write a file in Mac Roman for simple use in Mac Excel 2004/8
write.csv(x, file = "foo.csv", fileEncoding = "macroman")
or for Windows Excel 2007/10
write.csv(x, file = "foo.csv", fileEncoding = "UTF-16LE")

End(Not run)

```

---

zip

---

Create Zip Archives

---

## Description

A wrapper for an external zip command to create zip archives.

## Usage

```

zip(zipfile, files, flags = "-r9X", extras = "",
 zip = Sys.getenv("R_ZIPCMD", "zip"))

```

## Arguments

|         |                                                                                                     |
|---------|-----------------------------------------------------------------------------------------------------|
| zipfile | The pathname of the zip file: tilde expansion (see <a href="#">path.expand</a> ) will be performed. |
| files   | A character vector of recorded filepaths to be included.                                            |
| flags   | A character string of flags to be passed to the command: see ‘Details’.                             |
| extras  | An optional character vector: see ‘Details’.                                                        |
| zip     | A character string specifying the external command to be used.                                      |

## Details

On a Unix-alike, the default for `zip` will by default use the value of `R_ZIPCMD`, which is set in ‘etc/Renviron’ if an `unzip` command was found during configuration. On Windows, the default relies on a `zip` program (for example that from Rtools) being in the path.

The default for `flags` is that appropriate for zipping up a directory tree in a portable way: see the system-specific help for the `zip` command for other possibilities.

Argument `extras` can be used to specify `-x` or `-i` followed by a list of filepaths to exclude or include. Since `extras` will be treated as if passed to [system](#), if the filepaths contain spaces they must be quoted e.g. by [shQuote](#).

## Value

The status value returned by the external command, invisibly.

## See Also

[unzip](#), [unz](#); further, [tar](#) and [untar](#) for (un)packing tar archives.

## **Part II**

## Chapter 15

# The KernSmooth package

---

bkde

*Compute a Binned Kernel Density Estimate*

---

### Description

Returns x and y coordinates of the binned kernel density estimate of the probability density of the data.

### Usage

```
bkde(x, kernel = "normal", canonical = FALSE, bandwidth,
 gridsize = 401L, range.x, truncate = TRUE)
```

### Arguments

|           |                                                                                                                                                                                                                                                                                                                                                                |
|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x         | numeric vector of observations from the distribution whose density is to be estimated. Missing values are not allowed.                                                                                                                                                                                                                                         |
| bandwidth | the kernel bandwidth smoothing parameter. Larger values of <code>bandwidth</code> make smoother estimates, smaller values of <code>bandwidth</code> make less smooth estimates. The default is a bandwidth computed from the variance of <code>x</code> , specifically the ‘oversmoothed bandwidth selector’ of Wand and Jones (1995, page 61).                |
| kernel    | character string which determines the smoothing kernel. <code>kernel</code> can be: "normal" - the Gaussian density function (the default). "box" - a rectangular box. "epanech" - the centred beta(2,2) density. "biweight" - the centred beta(3,3) density. "triweight" - the centred beta(4,4) density. This can be abbreviated to any unique abbreviation. |
| canonical | logical flag: if TRUE, canonically scaled kernels are used.                                                                                                                                                                                                                                                                                                    |
| gridsize  | the number of equally spaced points at which to estimate the density.                                                                                                                                                                                                                                                                                          |
| range.x   | vector containing the minimum and maximum values of <code>x</code> at which to compute the estimate. The default is the minimum and maximum data values, extended by the support of the kernel.                                                                                                                                                                |
| truncate  | logical flag: if TRUE, data with <code>x</code> values outside the range specified by <code>range.x</code> are ignored.                                                                                                                                                                                                                                        |

## Details

This is the binned approximation to the ordinary kernel density estimate. Linear binning is used to obtain the bin counts. For each  $x$  value in the sample, the kernel is centered on that  $x$  and the heights of the kernel at each datapoint are summed. This sum, after a normalization, is the corresponding  $y$  value in the output.

## Value

a list containing the following components:

|     |                                                                 |
|-----|-----------------------------------------------------------------|
| $x$ | vector of sorted $x$ values at which the estimate was computed. |
| $y$ | vector of density estimates at the corresponding $x$ .          |

## Background

Density estimation is a smoothing operation. Inevitably there is a trade-off between bias in the estimate and the estimate's variability: large bandwidths will produce smooth estimates that may hide local features of the density; small bandwidths may introduce spurious bumps into the estimate.

bkde2D

---

*Compute a 2D Binned Kernel Density Estimate*

---

## Description

Returns the set of grid points in each coordinate direction, and the matrix of density estimates over the mesh induced by the grid points. The kernel is the standard bivariate normal density.

## Usage

```
bkde2D(x, bandwidth, gridsize = c(51L, 51L), range.x, truncate = TRUE)
```

### Arguments

|                        |                                                                                                                                                                                                                                                                                                                                                                              |
|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>         | a two-column numeric matrix containing the observations from the distribution whose density is to be estimated. Missing values are not allowed.                                                                                                                                                                                                                              |
| <code>bandwidth</code> | numeric vector of length 2, containing the bandwidth to be used in each coordinate direction.                                                                                                                                                                                                                                                                                |
| <code>gridsize</code>  | vector containing the number of equally spaced points in each direction over which the density is to be estimated.                                                                                                                                                                                                                                                           |
| <code>range.x</code>   | a list containing two vectors, where each vector contains the minimum and maximum values of <code>x</code> at which to compute the estimate for each direction. The default minimum in each direction is minimum data value minus 1.5 times the bandwidth for that direction. The default maximum is the maximum data value plus 1.5 times the bandwidth for that direction. |
| <code>truncate</code>  | logical flag: if TRUE, data with <code>x</code> values outside the range specified by <code>range.x</code> are ignored.                                                                                                                                                                                                                                                      |

### Value

a list containing the following components:

|                   |                                                                                                            |
|-------------------|------------------------------------------------------------------------------------------------------------|
| <code>x1</code>   | vector of values of the grid points in the first coordinate direction at which the estimate was computed.  |
| <code>x2</code>   | vector of values of the grid points in the second coordinate direction at which the estimate was computed. |
| <code>fhat</code> | matrix of density estimates over the mesh induced by <code>x1</code> and <code>x2</code> .                 |

### Details

This is the binned approximation to the 2D kernel density estimate. Linear binning is used to obtain the bin counts and the Fast Fourier Transform is used to perform the discrete convolutions. For each `x1,x2` pair the bivariate Gaussian kernel is centered on that location and the heights of the kernel, scaled by the bandwidths, at each datapoint are summed. This sum, after a normalization, is the corresponding `fhat` value in the output.

bkfe

*Compute a Binned Kernel Functional Estimate***Description**

Returns an estimate of a binned approximation to the kernel estimate of the specified density functional. The kernel is the standard normal density.

**Usage**

```
bkfe(x, drv, bandwidth, gridsize = 401L, range.x, binned = FALSE,
 truncate = TRUE)
```

**Arguments**

|                        |                                                                                                                                                                                                 |
|------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>         | numeric vector of observations from the distribution whose density is to be estimated. Missing values are not allowed.                                                                          |
| <code>drv</code>       | order of derivative in the density functional. Must be a non-negative even integer.                                                                                                             |
| <code>bandwidth</code> | the kernel bandwidth smoothing parameter. Must be supplied.                                                                                                                                     |
| <code>gridsize</code>  | the number of equally-spaced points over which binning is performed.                                                                                                                            |
| <code>range.x</code>   | vector containing the minimum and maximum values of <code>x</code> at which to compute the estimate. The default is the minimum and maximum data values, extended by the support of the kernel. |
| <code>binned</code>    | logical flag: if <code>TRUE</code> , then <code>x</code> and <code>y</code> are taken to be grid counts rather than raw data.                                                                   |
| <code>truncate</code>  | logical flag: if <code>TRUE</code> , data with <code>x</code> values outside the range specified by <code>range.x</code> are ignored.                                                           |

**Details**

The density functional of order `drv` is the integral of the product of the density and its `drv`th derivative. The kernel estimates of such quantities are computed using a binned implementation, and the kernel is the standard normal density.

**Value**

the (scalar) estimated functional.

**Background**

Estimates of this type were proposed by Sheather and Jones (1991).

## Examples

```
data(geyser, package="MASS")
x <- geyser$duration
est <- bkfe(x, drv=4, bandwidth=0.3)
```

dpih

*Select a Histogram Bin Width*

## Description

Uses direct plug-in methodology to select the bin width of a histogram.

## Usage

```
dpih(x, scalest = "minim", level = 2L, gridsize = 401L,
 range.x = range(x), truncate = TRUE)
```

## Arguments

|                       |                                                                                                                                                                                                    |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>        | numeric vector containing the sample on which the histogram is to be constructed.                                                                                                                  |
| <code>scalest</code>  | estimate of scale.<br>"stdev" - standard deviation is used.<br>"iqr" - inter-quartile range divided by 1.349 is used.<br>"minim" - minimum of "stdev" and "iqr" is used.                           |
| <code>level</code>    | number of levels of functional estimation used in the plug-in rule.                                                                                                                                |
| <code>gridsize</code> | number of grid points used in the binned approximations to functional estimates.                                                                                                                   |
| <code>range.x</code>  | range over which functional estimates are obtained. The default is the minimum and maximum data values.                                                                                            |
| <code>truncate</code> | if <code>truncate</code> is <code>TRUE</code> then observations outside of the interval specified by <code>range.x</code> are omitted. Otherwise, they are used to weight the extreme grid points. |

## Details

The direct plug-in approach, where unknown functionals that appear in expressions for the asymptotically optimal bin width and bandwidths are replaced by kernel estimates, is used. The normal distribution is used to provide an initial estimate.

## Value

the selected bin width.

## Background

This method for selecting the bin width of a histogram is described in Wand (1995). It is an extension of the normal scale rule of Scott (1979) and uses plug-in ideas from bandwidth selection for kernel density estimation (e.g. Sheather and Jones, 1991).

*Select a Bandwidth for Kernel Density Estimation*

---

## Description

Use direct plug-in methodology to select the bandwidth of a kernel density estimate.

## Usage

```
dpik(x, scalest = "minim", level = 2L, kernel = "normal",
 canonical = FALSE, gridsize = 401L, range.x = range(x),
 truncate = TRUE)
```

## Arguments

|           |                                                                                                                                                                                                                                                                                                                                                   |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x         | numeric vector containing the sample on which the kernel density estimate is to be constructed.                                                                                                                                                                                                                                                   |
| scalest   | estimate of scale.<br>"stdev" - standard deviation is used.<br>"iqr" - inter-quartile range divided by 1.349 is used.<br>"minim" - minimum of "stdev" and "iqr" is used.                                                                                                                                                                          |
| level     | number of levels of functional estimation used in the plug-in rule.                                                                                                                                                                                                                                                                               |
| kernel    | character string which determines the smoothing kernel. kernel can be: "normal" - the Gaussian density function (the default). "box" - a rectangular box. "epanech" - the centred beta(2,2) density. "biweight" - the centred beta(3,3) density. "triweight" - the centred beta(4,4) density. This can be abbreviated to any unique abbreviation. |
| canonical | logical flag: if TRUE, canonically scaled kernels are used                                                                                                                                                                                                                                                                                        |
| gridsize  | the number of equally-spaced points over which binning is performed to obtain kernel functional approximation.                                                                                                                                                                                                                                    |

|                       |                                                                                                                                                          |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>range.x</code>  | vector containing the minimum and maximum values of <code>x</code> at which to compute the estimate. The default is the minimum and maximum data values. |
| <code>truncate</code> | logical flag: if <code>TRUE</code> , data with <code>x</code> values outside the range specified by <code>range.x</code> are ignored.                    |

### Details

The direct plug-in approach, where unknown functionals that appear in expressions for the asymptotically optimal bandwidths are replaced by kernel estimates, is used. The normal distribution is used to provide an initial estimate.

### Value

the selected bandwidth.

### Background

This method for selecting the bandwidth of a kernel density estimate was proposed by Sheather and Jones (1991) and is described in Section 3.6 of Wand and Jones (1995).

*Select a Bandwidth for Local Linear Regression*

---

### Description

Use direct plug-in methodology to select the bandwidth of a local linear Gaussian kernel regression estimate, as described by Ruppert, Sheather and Wand (1995).

### Usage

```
dpill(x, y, blockmax = 5, divisor = 20, trim = 0.01, proptrun = 0.05,
 gridsize = 401L, range.x, truncate = TRUE)
```

**Arguments**

|                       |                                                                                                                                                                                                                                                                                                      |
|-----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>        | numeric vector of <code>x</code> data. Missing values are not accepted.                                                                                                                                                                                                                              |
| <code>y</code>        | numeric vector of <code>y</code> data. This must be same length as <code>x</code> , and missing values are not accepted.                                                                                                                                                                             |
| <code>blockmax</code> | the maximum number of blocks of the data for construction of an initial parametric estimate.                                                                                                                                                                                                         |
| <code>divisor</code>  | the value that the sample size is divided by to determine a lower limit on the number of blocks of the data for construction of an initial parametric estimate.                                                                                                                                      |
| <code>trim</code>     | the proportion of the sample trimmed from each end in the <code>x</code> direction before application of the plug-in methodology.                                                                                                                                                                    |
| <code>proptrun</code> | the proportion of the range of <code>x</code> at each end truncated in the functional estimates.                                                                                                                                                                                                     |
| <code>gridsize</code> | number of equally-spaced grid points over which the function is to be estimated.                                                                                                                                                                                                                     |
| <code>range.x</code>  | vector containing the minimum and maximum values of <code>x</code> at which to compute the estimate. For density estimation the default is the minimum and maximum data values with 5% of the range added to each end. For regression estimation the default is the minimum and maximum data values. |
| <code>truncate</code> | logical flag: if TRUE, data with <code>x</code> values outside the range specified by <code>range.x</code> are ignored.                                                                                                                                                                              |

**Details**

The direct plug-in approach, where unknown functionals that appear in expressions for the asymptotically optimal bandwidths are replaced by kernel estimates, is used. The kernel is the standard normal density. Least squares quartic fits over blocks of data are used to obtain an initial estimate. Mallows's  $C_p$  is used to select the number of blocks.

**Value**

the selected bandwidth.

**Warning**

If there are severe irregularities (i.e. outliers, sparse regions) in the `x` values then the local polynomial smooths required for the bandwidth selection algorithm may become degenerate and the function will crash. Outliers in the `y` direction may lead to deterioration of the quality of the selected bandwidth.

fit <- locpoly(x, y, bandwidth = h)
lines(fit)
```

locpoly

*Estimate Functions Using Local Polynomials***Description**

Estimates a probability density function, regression function or their derivatives using local polynomials. A fast binned implementation over an equally-spaced grid is used.

**Usage**

```
locpoly(x, y, drv = 0L, degree, kernel = "normal",
 bandwidth, gridsize = 401L, bwdisc = 25,
 range.x, binned = FALSE, truncate = TRUE)
```

**Arguments**

|                        |                                                                                                                                                                                                     |
|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>         | numeric vector of x data. Missing values are not accepted.                                                                                                                                          |
| <code>bandwidth</code> | the kernel bandwidth smoothing parameter. It may be a single number or an array having length <code>gridsize</code> , representing a bandwidth that varies according to the location of estimation. |
| <code>y</code>         | vector of y data. This must be same length as <code>x</code> , and missing values are not accepted.                                                                                                 |
| <code>drv</code>       | order of derivative to be estimated.                                                                                                                                                                |
| <code>degree</code>    | degree of local polynomial used. Its value must be greater than or equal to the value of <code>drv</code> . The default value is of degree is <code>drv + 1</code> .                                |
| <code>kernel</code>    | "normal" - the Gaussian density function. Currently ignored.                                                                                                                                        |
| <code>gridsize</code>  | number of equally-spaced grid points over which the function is to be estimated.                                                                                                                    |
| <code>bwdisc</code>    | number of logarithmically-equally-spaced bandwidths on which <code>bandwidth</code> is discretised, to speed up computation.                                                                        |
| <code>range.x</code>   | vector containing the minimum and maximum values of <code>x</code> at which to compute the estimate.                                                                                                |
| <code>binned</code>    | logical flag: if <code>TRUE</code> , then <code>x</code> and <code>y</code> are taken to be grid counts rather than raw data.                                                                       |
| <code>truncate</code>  | logical flag: if <code>TRUE</code> , data with <code>x</code> values outside the range specified by <code>range.x</code> are ignored.                                                               |

**Value**

if `y` is specified, a local polynomial regression estimate of  $E[Y|X]$  (or its derivative) is computed. If `y` is missing, a local polynomial estimate of the density of `x` (or its derivative) is computed.

a list containing the following components:

|                |                                                                                                             |
|----------------|-------------------------------------------------------------------------------------------------------------|
| <code>x</code> | vector of sorted <code>x</code> values at which the estimate was computed.                                  |
| <code>y</code> | vector of smoothed estimates for either the density or the regression at the corresponding <code>x</code> . |

**Details**

Local polynomial fitting with a kernel weight is used to estimate either a density, regression function or their derivatives. In the case of density estimation, the data are binned and the local fitting procedure is applied to the bin counts. In either case, binned approximations over an equally-spaced grid is used for fast computation. The bandwidth may be either scalar or a vector of length `gridsize`.

```
data(geyser, package = "MASS")
local linear density estimate
x <- geyser$duration
est <- locpoly(x, bandwidth = 0.25)
plot(est, type = "l")

local linear regression estimate
y <- geyser$waiting
plot(x, y)
fit <- locpoly(x, y, bandwidth = 0.25)
lines(fit)
```

## Chapter 16

# The MASS package

---

abbey

*Determinations of Nickel Content*

---

### Description

A numeric vector of 31 determinations of nickel content (ppm) in a Canadian syenite rock.

### Usage

abbey

### Source

S. Abbey (1988) *Geostandards Newsletter* **12**, 241.

### References

Venables, W. N. and Ripley, B. D. (2002) *Modern Applied Statistics with S*. Fourth edition. Springer.

---

accdeaths

*Accidental Deaths in the US 1973-1978*

---

### Description

A regular time series giving the monthly totals of accidental deaths in the USA.

### Usage

accdeaths

### Details

The values for first six months of 1979 (p. 326) were 7798 7406 8363 8460 9217 9316.

---

addterm

---

Try All One-Term Additions to a Model

---

## Description

Try fitting all models that differ from the current model by adding a single term from those supplied, maintaining marginality.

This function is generic; there exist methods for classes `lm` and `glm` and the default method will work for many other classes.

## Usage

```
addterm(object, ...)

Default S3 method:
addterm(object, scope, scale = 0, test = c("none", "Chisq"),
 k = 2, sorted = FALSE, trace = FALSE, ...)
S3 method for class 'lm'
addterm(object, scope, scale = 0, test = c("none", "Chisq", "F"),
 k = 2, sorted = FALSE, ...)
S3 method for class 'glm'
addterm(object, scope, scale = 0, test = c("none", "Chisq", "F"),
 k = 2, sorted = FALSE, trace = FALSE, ...)
```

## Arguments

|                     |                                                                                                                                                                                                                                                                                                                                                             |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code> | An object fitted by some model-fitting function.                                                                                                                                                                                                                                                                                                            |
| <code>scope</code>  | a formula specifying a maximal model which should include the current one. All additional terms in the maximal model with all marginal terms in the original model are tried.                                                                                                                                                                               |
| <code>scale</code>  | used in the definition of the AIC statistic for selecting the models, currently only for <code>lm</code> , <code>aov</code> and <code>glm</code> models. Specifying <code>scale</code> asserts that the residual standard error or dispersion is known.                                                                                                     |
| <code>test</code>   | should the results include a test statistic relative to the original model? The F test is only appropriate for <code>lm</code> and <code>aov</code> models, and perhaps for some over-dispersed <code>glm</code> models. The Chisq test can be an exact test ( <code>lm</code> models with known scale) or a likelihood-ratio test depending on the method. |
| <code>k</code>      | the multiple of the number of degrees of freedom used for the penalty. Only <code>k=2</code> gives the genuine AIC: $k = \log(n)$ is sometimes referred to as BIC or SBC.                                                                                                                                                                                   |
| <code>sorted</code> | should the results be sorted on the value of AIC?                                                                                                                                                                                                                                                                                                           |
| <code>trace</code>  | if TRUE additional information may be given on the fits as they are tried.                                                                                                                                                                                                                                                                                  |
| <code>...</code>    | arguments passed to or from other methods.                                                                                                                                                                                                                                                                                                                  |

**Details**

The definition of AIC is only up to an additive constant: when appropriate (l<sub>m</sub> models with specified scale) the constant is taken to be that used in Mallows' Cp statistic and the results are labelled accordingly.

**Value**

A table of class "anova" containing at least columns for the change in degrees of freedom and AIC (or Cp) for the models. Some methods will give further information, for example sums of squares, deviances, log-likelihoods and test statistics.

```
quine.hi <- aov(log(Days + 2.5) ~ .^4, quine)
quine.lo <- aov(log(Days+2.5) ~ 1, quine)
addterm(quine.lo, quine.hi, test="F")

house.glm0 <- glm(Freq ~ Infl*Type*Cont + Sat, family=poisson,
 data=housing)
addterm(house.glm0, ~. + Sat:(Infl+Type+Cont), test="Chisq")
house.glm1 <- update(house.glm0, . ~ . + Sat*(Infl+Type+Cont))
addterm(house.glm1, ~. + Sat:(Infl+Type+Cont)^2, test = "Chisq")
```

Aids2

*Australian AIDS Survival Data***Description**

Data on patients diagnosed with AIDS in Australia before 1 July 1991.

**Usage**

```
Aids2
```

**Format**

This data frame contains 2843 rows and the following columns:

`state` Grouped state of origin: "NSW" includes ACT and "other" is WA, SA, NT and TAS.  
`sex` Sex of patient.  
`diag` (Julian) date of diagnosis.  
`death` (Julian) date of death or end of observation.  
`status` "A" (alive) or "D" (dead) at end of observation.  
`T.categ` Reported transmission category.  
`age` Age (years) at diagnosis.

**Note**

This data set has been slightly jittered as a condition of its release, to ensure patient confidentiality.

**Source**

`anorexia`*Anorexia Data on Weight Change*

---

**Description**

The `anorexia` data frame has 72 rows and 3 columns. Weight change data for young female anorexia patients.

**Usage**

```
anorexia
```

**Format**

This data frame contains the following columns:

`Treat` Factor of three levels: "Cont" (control), "CBT" (Cognitive Behavioural treatment) and "FT" (family treatment).

`Prewt` Weight of patient before study period, in lbs.

`Postwt` Weight of patient after study period, in lbs.

**Source**

---

`anova.negbin`*Likelihood Ratio Tests for Negative Binomial GLMs*

---

**Description**

Method function to perform sequential likelihood ratio tests for Negative Binomial generalized linear models.

**Usage**

```
S3 method for class 'negbin'
anova(object, ..., test = "Chisq")
```

**Arguments**

|                     |                                                                                                                                                                                                                                                       |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code> | Fitted model object of class <code>"negbin"</code> , inheriting from classes <code>"glm"</code> and <code>"lm"</code> , specifying a Negative Binomial fitted GLM. Typically the output of <code>glm.nb()</code> .                                    |
| <code>...</code>    | Zero or more additional fitted model objects of class <code>"negbin"</code> . They should form a nested sequence of models, but need not be specified in any particular order.                                                                        |
| <code>test</code>   | Argument to match the <code>test</code> argument of <code>anova.glm</code> . Ignored (with a warning if changed) if a sequence of two or more Negative Binomial fitted model objects is specified, but possibly used if only one object is specified. |

**Details**

This function is a method for the generic function `anova()` for class `"negbin"`. It can be invoked by calling `anova(x)` for an object `x` of the appropriate class, or directly by calling `anova.negbin(x)` regardless of the class of the object.

**Note**

If only one fitted model object is specified, a sequential analysis of deviance table is given for the fitted model. The `theta` parameter is kept fixed. If more than one fitted model object is specified they must all be of class `"negbin"` and likelihood ratio tests are done of each model within the next. In this case `theta` is assumed to have been re-estimated for each model.

**Examples**

```
m1 <- glm.nb(Days ~ Eth*Age*Lrn*Sex, quine, link = log)
m2 <- update(m1, . ~ . - Eth:Age:Lrn:Sex)
anova(m2, m1)
anova(m2)
```

---

area

*Adaptive Numerical Integration*

---

**Description**

Integrate a function of one variable over a finite range using a recursive adaptive method. This function is mainly for demonstration purposes.

**Usage**

```
area(f, a, b, ..., fa = f(a, ...), fb = f(b, ...),
 limit = 10, eps = 1e-05)
```

**Arguments**

|                    |                                                                                                |
|--------------------|------------------------------------------------------------------------------------------------|
| <code>f</code>     | The integrand as an S function object. The variable of integration must be the first argument. |
| <code>a</code>     | Lower limit of integration.                                                                    |
| <code>b</code>     | Upper limit of integration.                                                                    |
| <code>...</code>   | Additional arguments needed by the integrand.                                                  |
| <code>fa</code>    | Function value at the lower limit.                                                             |
| <code>fb</code>    | Function value at the upper limit.                                                             |
| <code>limit</code> | Limit on the depth to which recursion is allowed to go.                                        |
| <code>eps</code>   | Error tolerance to control the process.                                                        |

**Details**

The method divides the interval in two and compares the values given by Simpson's rule and the trapezium rule. If these are within `eps` of each other the Simpson's rule result is given, otherwise the process is applied separately to each half of the interval and the results added together.

**Value**

The integral from `a` to `b` of  $f(x)$ .

**References**

Venables, W. N. and Ripley, B. D. (1994) *Modern Applied Statistics with S-Plus*. Springer. pp. 105–110.

**Examples**

```
area(sin, 0, pi) # integrate the sin function from 0 to pi.
```

---

|          |                                                   |
|----------|---------------------------------------------------|
| bacteria | <i>Presence of Bacteria after Drug Treatments</i> |
|----------|---------------------------------------------------|

---

**Description**

Tests of the presence of the bacteria *H. influenzae* in children with otitis media in the Northern Territory of Australia.

**Usage**

```
bacteria
```

**Format**

This data frame has 220 rows and the following columns:

**y** presence or absence: a factor with levels `n` and `y`.

**ap** active/placebo: a factor with levels `a` and `p`.

**hilo** hi/low compliance: a factor with levels `hi` and `lo`.

**week** numeric: week of test.

**ID** subject ID: a factor.

**trt** a factor with levels `placebo`, `drug` and `drug+`, a re-coding of `ap` and `hilo`.

## Details

Dr A. Leach tested the effects of a drug on 50 children with a history of otitis media in the Northern Territory of Australia. The children were randomized to the drug or the a placebo, and also to receive active encouragement to comply with taking the drug.

The presence of *H. influenzae* was checked at weeks 0, 2, 4, 6 and 11: 30 of the checks were missing and are not included in this data frame.

---

bandwidth.nrd

*Bandwidth for density() via Normal Reference Distribution*

---

## Description

A well-supported rule-of-thumb for choosing the bandwidth of a Gaussian kernel density estimator.

## Usage

```
bandwidth.nrd(x)
```

**Arguments**

`x`                      A data vector.

**Value**

A bandwidth on a scale suitable for the `width` argument of `density`.

**References**

Venables, W. N. and Ripley, B. D. (2002) *Modern Applied Statistics with S*. Springer, equation (5.5) on page 130.

**Examples**

```
The function is currently defined as
function(x)
{
 r <- quantile(x, c(0.25, 0.75))
 h <- (r[2] - r[1])/1.34
 4 * 1.06 * min(sqrt(var(x)), h) * length(x)^(-1/5)
}
```

---

bcv

*Biased Cross-Validation for Bandwidth Selection*

---

**Description**

Uses biased cross-validation to select the bandwidth of a Gaussian kernel density estimator.

**Usage**

```
bcv(x, nb = 1000, lower, upper)
```

**Arguments**

`x`                      a numeric vector  
`nb`                     number of bins to use.  
`lower, upper`        Range over which to minimize. The default is almost always satisfactory.

**Value**

a bandwidth

`beav1`*Body Temperature Series of Beaver 1*

---

**Description**

Reynolds (1994) describes a small part of a study of the long-term temperature dynamics of beaver *Castor canadensis* in north-central Wisconsin. Body temperature was measured by telemetry every 10 minutes for four females, but data from a one period of less than a day for each of two animals is used there.

**Usage**

```
beav1
```

**Format**

The `beav1` data frame has 114 rows and 4 columns. This data frame contains the following columns:

`day` Day of observation (in days since the beginning of 1990), December 12–13.

`time` Time of observation, in the form 0330 for 3.30am.

`temp` Measured body temperature in degrees Celsius.

`activ` Indicator of activity outside the retreat.

**Note**

The observation at 22:20 is missing.

**Source**

P. S. Reynolds (1994) Time-series analyses of beaver body temperatures. Chapter 11 of Lange, N., Ryan, L., Billard, L., Brillinger, D., Conquest, L. and Greenhouse, J. eds (1994) *Case Studies in Biometry*. New York: John Wiley and Sons.

---

Belgian-phones

*Belgium Phone Calls 1950-1973*

---

## Description

A list object with the annual numbers of telephone calls, in Belgium. The components are:

`year` last two digits of the year.

`calls` number of telephone calls made (in millions of calls).

## Usage

`phones`

## Source

P. J. Rousseeuw and A. M. Leroy (1987) *Robust Regression & Outlier Detection*. Wiley.

## References

---

biopsy*Biopsy Data on Breast Cancer Patients*

---

**Description**

This breast cancer database was obtained from the University of Wisconsin Hospitals, Madison from Dr. William H. Wolberg. He assessed biopsies of breast tumours for 699 patients up to 15 July 1992; each of nine attributes has been scored on a scale of 1 to 10, and the outcome is also known. There are 699 rows and 11 columns.

**Usage**

biopsy

**Format**

This data frame contains the following columns:

ID sample code number (not unique).  
V1 clump thickness.  
V2 uniformity of cell size.  
V3 uniformity of cell shape.  
V4 marginal adhesion.  
V5 single epithelial cell size.  
V6 bare nuclei (16 values are missing).  
V7 bland chromatin.  
V8 normal nucleoli.  
V9 mitoses.  
class "benign" or "malignant".

birthwt

*Risk Factors Associated with Low Infant Birth Weight*

---

## Description

The `birthwt` data frame has 189 rows and 10 columns. The data were collected at Baystate Medical Center, Springfield, Mass during 1986.

## Usage

```
birthwt
```

## Format

This data frame contains the following columns:

`low` indicator of birth weight less than 2.5 kg.  
`age` mother's age in years.  
`lwt` mother's weight in pounds at last menstrual period.  
`race` mother's race (1 = white, 2 = black, 3 = other).  
`smoke` smoking status during pregnancy.  
`ptl` number of previous premature labours.  
`ht` history of hypertension.  
`ui` presence of uterine irritability.  
`ftv` number of physician visits during the first trimester.  
`bwt` birth weight in grams.

## Source

## References

Venables, W. N. and Ripley, B. D. (2002) *Modern Applied Statistics with S*. Fourth edition. Springer.

## Examples

```
bwt <- with(birthwt, {
 race <- factor(race, labels = c("white", "black", "other"))
 ptd <- factor(ptl > 0)
 ftv <- factor(ftv)
 levels(ftv)[-1:2] <- "2+"
 data.frame(low = factor(low), age, lwt, race, smoke = (smoke > 0),
 ptd, ht = (ht > 0), ui = (ui > 0), ftv)
})
options(contrasts = c("contr.treatment", "contr.poly"))
glm(low ~ ., binomial, bwt)
```

---

 Boston

*Housing Values in Suburbs of Boston*

---

### Description

The `Boston` data frame has 506 rows and 14 columns.

### Usage

`Boston`

### Format

This data frame contains the following columns:

`crim` per capita crime rate by town.

`zn` proportion of residential land zoned for lots over 25,000 sq.ft.

`indus` proportion of non-retail business acres per town.

`chas` Charles River dummy variable (= 1 if tract bounds river; 0 otherwise).

`nox` nitrogen oxides concentration (parts per 10 million).

`rm` average number of rooms per dwelling.

`age` proportion of owner-occupied units built prior to 1940.

`dis` weighted mean of distances to five Boston employment centres.

`rad` index of accessibility to radial highways.

`tax` full-value property-tax rate per \$10,000.

`ptratio` pupil-teacher ratio by town.

`black`  $1000(Bk - 0.63)^2$  where  $Bk$  is the proportion of blacks by town.

`lstat` lower status of the population (percent).

`medv` median value of owner-occupied homes in \$1000s.

boxcox

*Box-Cox Transformations for Linear Models***Description**

Computes and optionally plots profile log-likelihoods for the parameter of the Box-Cox power transformation.

**Usage**

```
boxcox(object, ...)
```

```
Default S3 method:
boxcox(object, lambda = seq(-2, 2, 1/10), plotit = TRUE,
 interp, eps = 1/50, xlab = expression(lambda),
 ylab = "log-Likelihood", ...)
```

```
S3 method for class 'formula'
boxcox(object, lambda = seq(-2, 2, 1/10), plotit = TRUE,
 interp, eps = 1/50, xlab = expression(lambda),
 ylab = "log-Likelihood", ...)
```

```
S3 method for class 'lm'
boxcox(object, lambda = seq(-2, 2, 1/10), plotit = TRUE,
 interp, eps = 1/50, xlab = expression(lambda),
 ylab = "log-Likelihood", ...)
```

**Arguments**

|                     |                                                                                                                                                         |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code> | a formula or fitted model object. Currently only <code>lm</code> and <code>aov</code> objects are handled.                                              |
| <code>lambda</code> | vector of values of <code>lambda</code> – default $(-2, 2)$ in steps of 0.1.                                                                            |
| <code>plotit</code> | logical which controls whether the result should be plotted.                                                                                            |
| <code>interp</code> | logical which controls whether spline interpolation is used. Default to <code>TRUE</code> if plotting with <code>lambda</code> of length less than 100. |
| <code>eps</code>    | Tolerance for <code>lambda = 0</code> ; defaults to 0.02.                                                                                               |
| <code>xlab</code>   | defaults to <code>"lambda"</code> .                                                                                                                     |
| <code>ylab</code>   | defaults to <code>"log-Likelihood"</code> .                                                                                                             |
| <code>...</code>    | additional parameters to be used in the model fitting.                                                                                                  |

**Value**

A list of the `lambda` vector and the computed profile log-likelihood vector, invisibly if the result is plotted.

**Side Effects**

If `plotit = TRUE` plots log-likelihood vs `lambda` and indicates a 95% confidence interval about the maximum observed value of `lambda`. If `interp = TRUE`, spline interpolation is used to give a smoother plot.

## Examples

```
boxcox(Volume ~ log(Height) + log(Girth), data = trees,
 lambda = seq(-0.25, 0.25, length = 10))

boxcox(Days+1 ~ Eth*Sex*Age*Lrn, data = quine,
 lambda = seq(-0.05, 0.45, len = 20))
```

---

cabbages

*Data from a cabbage field trial*

---

## Description

The cabbages data set has 60 observations and 4 variables

## Usage

```
cabbages
```

## Format

This data frame contains the following columns:

**Cult** Factor giving the cultivar of the cabbage, two levels: c39 and c52.

**Date** Factor specifying one of three planting dates: d16, d20 or d21.

**HeadWt** Weight of the cabbage head, presumably in kg.

**VitC** Ascorbic acid content, in undefined units.

caith

*Colours of Eyes and Hair of People in Caithness*

---

### Description

Data on the cross-classification of people in Caithness, Scotland, by eye and hair colour. The region of the UK is particularly interesting as there is a mixture of people of Nordic, Celtic and Anglo-Saxon origin.

### Usage

```
caith
```

### Format

A 4 by 5 table with rows the eye colours (blue, light, medium, dark) and columns the hair colours (fair, red, medium, dark, black).

### Source

Fisher, R.A. (1940) The precision of discriminant functions. *Annals of Eugenics (London)* **10**, 422–429.

dimnames(caith)[[2]] <- c("F", "R", "M", "D", "B")
par(mfcol=c(1,3))
plot(corresp(caith, nf=2)); title("symmetric")
plot(corresp(caith, nf=2), type="rows"); title("rows")
plot(corresp(caith, nf=2), type="col"); title("columns")
par(mfrow=c(1,1))
```

---

Cars93

*Data from 93 Cars on Sale in the USA in 1993*

---

### Description

The Cars93 data frame has 93 rows and 27 columns.

### Usage

```
Cars93
```

## Format

This data frame contains the following columns:

Manufacturer Manufacturer.

Model Model.

Type Type: a factor with levels "Small", "Sporty", "Compact", "Midsize", "Large" and "Van".

Min.Price Minimum Price (in \$1,000): price for a basic version.

Price Midrange Price (in \$1,000): average of Min.Price and Max.Price.

Max.Price Maximum Price (in \$1,000): price for "a premium version".

MPG.city City MPG (miles per US gallon by EPA rating).

MPG.highway Highway MPG.

AirBags Air Bags standard. Factor: none, driver only, or driver & passenger.

DriveTrain Drive train type: rear wheel, front wheel or 4WD; (factor).

Cylinders Number of cylinders (missing for Mazda RX-7, which has a rotary engine).

EngineSize Engine size (litres).

Horsepower Horsepower (maximum).

RPM RPM (revs per minute at maximum horsepower).

Rev.per.mile Engine revolutions per mile (in highest gear).

Man.trans.avail Is a manual transmission version available? (yes or no, Factor).

Fuel.tank.capacity Fuel tank capacity (US gallons).

Passengers Passenger capacity (persons)

Length Length (inches).

Wheelbase Wheelbase (inches).

Width Width (inches).

Turn.circle U-turn space (feet).

Rear.seat.room Rear seat room (inches) (missing for 2-seater vehicles).

Luggage.room Luggage capacity (cubic feet) (missing for vans).

Weight Weight (pounds).

Origin Of non-USA or USA company origins? (factor).

Make Combination of Manufacturer and Model (character).

## Details

Cars were selected at random from among 1993 passenger car models that were listed in both the *Consumer Reports* issue and the *PACE Buying Guide*. Pickup trucks and Sport/Utility vehicles were eliminated due to incomplete information in the *Consumer Reports* source. Duplicate models (e.g., Dodge Shadow and Plymouth Sundance) were listed at most once.

Further description can be found in Lock (1993).

cats

*Anatomical Data from Domestic Cats*

---

## Description

The heart and body weights of samples of male and female cats used for *digitalis* experiments. The cats were all adult, over 2 kg body weight.

## Usage

cats

## Format

This data frame contains the following columns:

Sex sex: Factor with levels "F" and "M".

Bwt body weight in kg.

Hwt heart weight in g.

cement

*Heat Evolved by Setting Cements*

---

## Description

Experiment on the heat evolved in the setting of each of 13 cements.

## Usage

cement

## Format

x1, x2, x3, x4 Proportions (%) of active ingredients.

y heat evolved in cal/gm.

**Details**

Thirteen samples of Portland cement were set. For each sample, the percentages of the four main chemical ingredients was accurately measured. While the cement was setting the amount of heat evolved was also measured.

**Source**

Woods, H., Steinour, H.H. and Starke, H.R. (1932) Effect of composition of Portland cement on heat evolved during hardening. *Industrial Engineering and Chemistry*, **24**, 1207–1214.

**References**

Hald, A. (1957) *Statistical Theory with Engineering Applications*. Wiley, New York.

**Examples**

```
lm(y ~ x1 + x2 + x3 + x4, cement)
```

---

chem

*Copper in Wholemeal Flour*

---

**Description**

A numeric vector of 24 determinations of copper in wholemeal flour, in parts per million.

**Usage**

```
chem
```

**Source**

Analytical Methods Committee (1989) Robust statistics – how not to reject outliers. *The Analyst* **114**, 1693–1702.

---

 con2tr

*Convert Lists to Data Frames for use by lattice*

---

### Description

Convert lists to data frames for use by lattice.

### Usage

```
con2tr(obj)
```

### Arguments

`obj` A list of components `x`, `y` and `z` as passed to `contour`.

### Details

`con2tr` repeats the `x` and `y` components suitably to match the vector `z`.

### Value

A data frame suitable for passing to lattice (formerly trellis) functions.

### References

Venables, W. N. and Ripley, B. D. (2002) *Modern Applied Statistics with S*. Fourth edition. Springer.

---

 confint-MASS

*Confidence Intervals for Model Parameters*

---

### Description

Computes confidence intervals for one or more parameters in a fitted model. Package **MASS** adds methods for `glm` and `nls` fits.

### Usage

```
S3 method for class 'glm'
confint(object, parm, level = 0.95, trace = FALSE, ...)

S3 method for class 'nls'
confint(object, parm, level = 0.95, ...)
```

## Arguments

|                     |                                                                                                                                                                       |
|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code> | a fitted model object. Methods currently exist for the classes "glm", "nls" and for profile objects from these classes.                                               |
| <code>parm</code>   | a specification of which parameters are to be given confidence intervals, either a vector of numbers or a vector of names. If missing, all parameters are considered. |
| <code>level</code>  | the confidence level required.                                                                                                                                        |
| <code>trace</code>  | logical. Should profiling be traced?                                                                                                                                  |
| <code>...</code>    | additional argument(s) for methods.                                                                                                                                   |

## Details

`confint` is a generic function in package `stats`.

These `confint` methods call the appropriate profile method, then find the confidence intervals by interpolation in the profile traces. If the profile object is already available it should be used as the main argument rather than the fitted model object itself.

## Value

A matrix (or vector) with columns giving lower and upper confidence limits for each parameter. These will be labelled as  $(1 - \text{level})/2$  and  $1 - (1 - \text{level})/2$  in % (by default 2.5% and 97.5%).

## References

Venables, W. N. and Ripley, B. D. (2002) *Modern Applied Statistics with S*. Fourth edition. Springer.

## See Also

`confint` (the generic and "lm" method), `profile`

## Examples

```
expn1 <- deriv(y ~ b0 + b1 * 2^(-x/th), c("b0", "b1", "th"),
 function(b0, b1, th, x) {})

wtloss.gr <- nls(Weight ~ expn1(b0, b1, th, Days),
 data = wtloss, start = c(b0=90, b1=95, th=120))

expn2 <- deriv(~b0 + b1*((w0 - b0)/b1)^(x/d0),
 c("b0", "b1", "d0"), function(b0, b1, d0, x, w0) {})

wtloss.init <- function(obj, w0) {
 p <- coef(obj)
 d0 <- - log((w0 - p["b0"])/p["b1"])/log(2) * p["th"]
 c(p[c("b0", "b1")], d0 = as.vector(d0))
}

out <- NULL
w0s <- c(110, 100, 90)
for(w0 in w0s) {
 fm <- nls(Weight ~ expn2(b0, b1, d0, Days, w0),
 wtloss, start = wtloss.init(wtloss.gr, w0))
 out <- rbind(out, c(coef(fm)["d0"], confint(fm, "d0")))
```

```

 }
 dimnames(out) <- list(paste(w0s, "kg:"), c("d0", "low", "high"))
 out

 ldose <- rep(0:5, 2)
 numdead <- c(1, 4, 9, 13, 18, 20, 0, 2, 6, 10, 12, 16)
 sex <- factor(rep(c("M", "F"), c(6, 6)))
 SF <- cbind(numdead, numalive = 20 - numdead)
 budworm.lg0 <- glm(SF ~ sex + ldose - 1, family = binomial)
 confint(budworm.lg0)
 confint(budworm.lg0, "ldose")

```

---

contr.sdif

---

*Successive Differences Contrast Coding*

---

## Description

A coding for factors based on successive differences.

## Usage

```
contr.sdif(n, contrasts = TRUE, sparse = FALSE)
```

## Arguments

|           |                                                                                                                          |
|-----------|--------------------------------------------------------------------------------------------------------------------------|
| n         | The number of levels required.                                                                                           |
| contrasts | logical: Should there be $n - 1$ columns orthogonal to the mean (the default) or $n$ columns spanning the space?         |
| sparse    | logical. If true and the result would be sparse (only true for <code>contrasts = FALSE</code> ), return a sparse matrix. |

## Details

The contrast coefficients are chosen so that the coded coefficients in a one-way layout are the differences between the means of the second and first levels, the third and second levels, and so on. This makes most sense for ordered factors, but does not assume that the levels are equally spaced.

## Value

If `contrasts` is `TRUE`, a matrix with  $n$  rows and  $n - 1$  columns, and the  $n$  by  $n$  identity matrix if `contrasts` is `FALSE`.

---

`corresp`*Simple Correspondence Analysis*

---

**Description**

Find the principal canonical correlation and corresponding row- and column-scores from a correspondence analysis of a two-way contingency table.

**Usage**

```
corresp(x, ...)

S3 method for class 'matrix'
corresp(x, nf = 1, ...)

S3 method for class 'factor'
corresp(x, y, ...)

S3 method for class 'data.frame'
corresp(x, ...)

S3 method for class 'xtabs'
corresp(x, ...)

S3 method for class 'formula'
corresp(formula, data, ...)
```

**Arguments**

|                         |                                                                                                                                                                                                                                                                                                                           |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x, formula</code> | The function is generic, accepting various forms of the principal argument for specifying a two-way frequency table. Currently accepted forms are matrices, data frames (coerced to frequency tables), objects of class " <code>xtabs</code> " and formulae of the form $\sim F1 + F2$ , where $F1$ and $F2$ are factors. |
| <code>nf</code>         | The number of factors to be computed. Note that although 1 is the most usual, one school of thought takes the first two singular vectors for a sort of biplot.                                                                                                                                                            |
| <code>y</code>          | a second factor for a cross-classification.                                                                                                                                                                                                                                                                               |
| <code>data</code>       | an optional data frame, list or environment against which to preferentially resolve variables in the formula.                                                                                                                                                                                                             |
| <code>...</code>        | If the principal argument is a formula, a data frame may be specified as well from which variables in the formula are preferentially satisfied.                                                                                                                                                                           |

**Details**

See Venables & Ripley (2002). The `plot` method produces a graphical representation of the table if `nf=1`, with the *areas* of circles representing the numbers of points. If `nf` is two or more the `biplot` method is called, which plots the second and third columns of the matrices  $A = D_r^{(-1/2)} U L$  and  $B = D_c^{(-1/2)} V L$  where the singular value decomposition is  $U L V$ . Thus the x-axis is the canonical correlation times the row and column scores. Although this is called a biplot, it does *not* have any useful inner product relationship between the row and column scores. Think of this as an equally-scaled plot with two unrelated sets of labels. The origin is marked on the plot with a cross. (For other versions of this plot see the book.)

**Value**

An list object of class "`correspondence`" for which `print`, `plot` and `biplot` methods are supplied. The main components are the canonical correlation(s) and the row and column scores.

plot(ct)

corresp(caith)
biplot(corresp(caith, nf = 2))
```

---

 cov.rob

---

*Resistant Estimation of Multivariate Location and Scatter*

---

**Description**

Compute a multivariate location and scale estimate with a high breakdown point – this can be thought of as estimating the mean and covariance of the good part of the data. `cov.mve` and `cov.mcd` are compatibility wrappers.

**Usage**

```
cov.rob(x, cor = FALSE, quantile.used = floor((n + p + 1)/2),
 method = c("mve", "mcd", "classical"),
 nsamp = "best", seed)

cov.mve(...)
cov.mcd(...)
```

**Arguments**

|                            |                                                                                                                                                                                                                                                                                        |
|----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>             | a matrix or data frame.                                                                                                                                                                                                                                                                |
| <code>cor</code>           | should the returned result include a correlation matrix?                                                                                                                                                                                                                               |
| <code>quantile.used</code> | the minimum number of the data points regarded as good points.                                                                                                                                                                                                                         |
| <code>method</code>        | the method to be used – minimum volume ellipsoid, minimum covariance determinant or classical product-moment. Using <code>cov.mve</code> or <code>cov.mcd</code> forces <code>mve</code> or <code>mcd</code> respectively.                                                             |
| <code>nsamp</code>         | the number of samples or "best" or "exact" or "sample". The limit If "sample" the number chosen is $\min(5 \cdot p, 3000)$ , taken from Rousseeuw and Hubert (1997). If "best" exhaustive enumeration is done up to 5000 samples: if "exact" exhaustive enumeration will be attempted. |
| <code>seed</code>          | the seed to be used for random sampling: see <a href="#">RNGkind</a> . The current value of <code>.Random.seed</code> will be preserved if it is set.                                                                                                                                  |
| <code>...</code>           | arguments to <code>cov.rob</code> other than <code>method</code> .                                                                                                                                                                                                                     |

## Details

For method "mve", an approximate search is made of a subset of size `quantile.used` with an enclosing ellipsoid of smallest volume; in method "mcd" it is the volume of the Gaussian confidence ellipsoid, equivalently the determinant of the classical covariance matrix, that is minimized. The mean of the subset provides a first estimate of the location, and the rescaled covariance matrix a first estimate of scatter. The Mahalanobis distances of all the points from the location estimate for this covariance matrix are calculated, and those points within the 97.5% point under Gaussian assumptions are declared to be `good`. The final estimates are the mean and rescaled covariance of the `good` points.

The rescaling is by the appropriate percentile under Gaussian data; in addition the first covariance matrix has an *ad hoc* finite-sample correction given by Marazzi.

For method "mve" the search is made over ellipsoids determined by the covariance matrix of `p` of the data points. For method "mcd" an additional improvement step suggested by Rousseeuw and van Driessen (1999) is used, in which once a subset of size `quantile.used` is selected, an ellipsoid based on its covariance is tested (as this will have no larger a determinant, and may be smaller).

There is a hard limit on the allowed number of samples,  $2^{31} - 1$ . However, practical limits are likely to be much lower and one might check the number of samples used for exhaustive enumeration, `combn(NROW(x), NCOL(x) + 1)`, before attempting it.

## Value

A list with components

|                     |                                                                                                                         |
|---------------------|-------------------------------------------------------------------------------------------------------------------------|
| <code>center</code> | the final estimate of location.                                                                                         |
| <code>cov</code>    | the final estimate of scatter.                                                                                          |
| <code>cor</code>    | (only is <code>cor = TRUE</code> ) the estimate of the correlation matrix.                                              |
| <code>sing</code>   | message giving number of singular samples out of total                                                                  |
| <code>crit</code>   | the value of the criterion on log scale. For MCD this is the determinant, and for MVE it is proportional to the volume. |
| <code>best</code>   | the subset used. For MVE the best sample, for MCD the best set of size <code>quantile.used</code> .                     |
| <code>n.obs</code>  | total number of observations.                                                                                           |

*Covariance Estimation for Multivariate t Distribution***Description**

Estimates a covariance or correlation matrix assuming the data came from a multivariate t distribution: this provides some degree of robustness to outlier without giving a high breakdown point.

**Usage**

```
cov.trob(x, wt = rep(1, n), cor = FALSE, center = TRUE, nu = 5,
 maxit = 25, tol = 0.01)
```

**Arguments**

|                     |                                                                                                                                                                                                                                    |
|---------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>      | data matrix. Missing values (NAs) are not allowed.                                                                                                                                                                                 |
| <code>wt</code>     | A vector of weights for each case: these are treated as if the case <code>i</code> actually occurred <code>wt[i]</code> times.                                                                                                     |
| <code>cor</code>    | Flag to choose between returning the correlation ( <code>cor = TRUE</code> ) or covariance ( <code>cor = FALSE</code> ) matrix.                                                                                                    |
| <code>center</code> | a logical value or a numeric vector providing the location about which the covariance is to be taken. If <code>center = FALSE</code> , no centering is done; if <code>center = TRUE</code> the MLE of the location vector is used. |
| <code>nu</code>     | 'degrees of freedom' for the multivariate t distribution. Must exceed 2 (so that the covariance matrix is finite).                                                                                                                 |
| <code>maxit</code>  | Maximum number of iterations in fitting.                                                                                                                                                                                           |
| <code>tol</code>    | Convergence tolerance for fitting.                                                                                                                                                                                                 |

**Value**

A list with the following components

|                     |                                                                                 |
|---------------------|---------------------------------------------------------------------------------|
| <code>cov</code>    | the fitted covariance matrix.                                                   |
| <code>center</code> | the estimated or specified location vector.                                     |
| <code>wt</code>     | the specified weights: only returned if the <code>wt</code> argument was given. |
| <code>n.obs</code>  | the number of cases used in the fitting.                                        |
| <code>cor</code>    | the fitted correlation matrix: only returned if <code>cor = TRUE</code> .       |
| <code>call</code>   | The matched call.                                                               |
| <code>iter</code>   | The number of iterations used.                                                  |

## Description

A relative performance measure and characteristics of 209 CPUs.

## Usage

```
cpus
```

## Format

The components are:

`name` manufacturer and model.

`syct` cycle time in nanoseconds.

`mmin` minimum main memory in kilobytes.

`mmax` maximum main memory in kilobytes.

`cach` cache size in kilobytes.

`chmin` minimum number of channels.

`chmax` maximum number of channels.

`perf` published performance on a benchmark mix relative to an IBM 370/158-3.

`estperf` estimated performance (by Ein-Dor & Feldmesser).

crabs

---

*Morphological Measurements on Leptograpsus Crabs*

---

**Description**

The `crabs` data frame has 200 rows and 8 columns, describing 5 morphological measurements on 50 crabs each of two colour forms and both sexes, of the species *Leptograpsus variegatus* collected at Fremantle, W. Australia.

**Usage**

```
crabs
```

**Format**

This data frame contains the following columns:

`sp` species - "B" or "O" for blue or orange.

`sex` as it says.

`index` index 1 : 50 within each of the four groups.

`FL` frontal lobe size (mm).

`RW` rear width (mm).

`CL` carapace length (mm).

`CW` carapace width (mm).

`BD` body depth (mm).

Cushings

---

*Diagnostic Tests on Patients with Cushing's Syndrome*

---

**Description**

Cushing's syndrome is a hypertensive disorder associated with over-secretion of cortisol by the adrenal gland. The observations are urinary excretion rates of two steroid metabolites.

**Usage**

```
Cushings
```

**Format**

The Cushings data frame has 27 rows and 3 columns:

Tetrahydrocortisone urinary excretion rate (mg/24hr) of Tetrahydrocortisone.

Pregnanetriol urinary excretion rate (mg/24hr) of Pregnanetriol.

Type underlying type of syndrome, coded a (adenoma) , b (bilateral hyperplasia), c (carcinoma) or u for unknown.

---

denumerate

---

*Transform an Allowable Formula for 'loglm' into one for 'terms'*

---

## Description

[loglm](#) allows dimension numbers to be used in place of names in the formula. `denumerate` modifies such a formula into one that [terms](#) can process.

## Usage

```
denumerate(x)
```

## Arguments

`x` A formula conforming to the conventions of [loglm](#), that is, it may allow dimension numbers to stand in for names when specifying a log-linear model.

## Details

The model fitting function [loglm](#) fits log-linear models to frequency data using iterative proportional scaling. To specify the model the user must nominate the margins in the data that remain fixed under the log-linear model. It is convenient to allow the user to use dimension numbers, 1, 2, 3, ... for the first, second, third, ..., margins in a similar way to variable names. As the model formula has to be parsed by [terms](#), which treats 1 in a special way and requires parseable variable names, these formulae have to be modified by giving genuine names for these margin, or dimension numbers. `denumerate` replaces these numbers with names of a special form, namely `n` is replaced by `.vn`. This allows [terms](#) to parse the formula in the usual way.

## Value

A linear model formula like that presented, except that where dimension numbers, say `n`, have been used to specify fixed margins these are replaced by names of the form `.vn` which may be processed by [terms](#).

## See Also

[renumerate](#)

## Examples

```
denumerate(~(1+2+3)^3 + a/b)
which gives ~ (.v1 + .v2 + .v3)^3 + a/b
```

---

dose.p

---

*Predict Doses for Binomial Assay model*

---

**Description**

Calibrate binomial assays, generalizing the calculation of LD50.

**Usage**

```
dose.p(obj, cf = 1:2, p = 0.5)
```

**Arguments**

|     |                                                                                        |
|-----|----------------------------------------------------------------------------------------|
| obj | A fitted model object of class inheriting from "glm".                                  |
| cf  | The terms in the coefficient vector giving the intercept and coefficient of (log-)dose |
| p   | Probabilities at which to predict the dose needed.                                     |

**Value**

An object of class "glm.dose" giving the prediction (attribute "p" and standard error (attribute "SE") at each response probability.

**References**

Venables, W. N. and Ripley, B. D. (2002) *Modern Applied Statistics with S*. Springer.

**Examples**

```
ldose <- rep(0:5, 2)
numdead <- c(1, 4, 9, 13, 18, 20, 0, 2, 6, 10, 12, 16)
sex <- factor(rep(c("M", "F"), c(6, 6)))
SF <- cbind(numdead, numalive = 20 - numdead)
budworm.lg0 <- glm(SF ~ sex + ldose - 1, family = binomial)

dose.p(budworm.lg0, cf = c(1,3), p = 1:3/4)
dose.p(update(budworm.lg0, family = binomial(link=probit)),
 cf = c(1,3), p = 1:3/4)
```

---

drivers

---

*Deaths of Car Drivers in Great Britain 1969-84*

---

**Description**

A regular time series giving the monthly totals of car drivers in Great Britain killed or seriously injured Jan 1969 to Dec 1984. Compulsory wearing of seat belts was introduced on 31 Jan 1983

**Usage**

```
drivers
```

**Source**

Harvey, A.C. (1989) *Forecasting, Structural Time Series Models and the Kalman Filter*. Cambridge University Press, pp. 519–523.

**References**

---

dropterm

---

*Try All One-Term Deletions from a Model*

---

**Description**

Try fitting all models that differ from the current model by dropping a single term, maintaining marginality.

This function is generic; there exist methods for classes `lm` and `glm` and the default method will work for many other classes.

**Usage**

```
dropterm (object, ...)

Default S3 method:
dropterm(object, scope, scale = 0, test = c("none", "Chisq"),
 k = 2, sorted = FALSE, trace = FALSE, ...)

S3 method for class 'lm'
dropterm(object, scope, scale = 0, test = c("none", "Chisq", "F"),
 k = 2, sorted = FALSE, ...)

S3 method for class 'glm'
dropterm(object, scope, scale = 0, test = c("none", "Chisq", "F"),
 k = 2, sorted = FALSE, trace = FALSE, ...)
```

**Arguments**

|                     |                                                                                                                                                                                                                                                                                                                                                            |
|---------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code> | A object fitted by some model-fitting function.                                                                                                                                                                                                                                                                                                            |
| <code>scope</code>  | a formula giving terms which might be dropped. By default, the model formula. Only terms that can be dropped and maintain marginality are actually tried.                                                                                                                                                                                                  |
| <code>scale</code>  | used in the definition of the AIC statistic for selecting the models, currently only for <code>lm</code> , <code>ao</code> and <code>glm</code> models. Specifying <code>scale</code> asserts that the residual standard error or dispersion is known.                                                                                                     |
| <code>test</code>   | should the results include a test statistic relative to the original model? The F test is only appropriate for <code>lm</code> and <code>ao</code> models, and perhaps for some over-dispersed <code>glm</code> models. The Chisq test can be an exact test ( <code>lm</code> models with known scale) or a likelihood-ratio test depending on the method. |
| <code>k</code>      | the multiple of the number of degrees of freedom used for the penalty. Only <code>k = 2</code> gives the genuine AIC: <code>k = log(n)</code> is sometimes referred to as BIC or SBC.                                                                                                                                                                      |

|        |                                                                            |
|--------|----------------------------------------------------------------------------|
| sorted | should the results be sorted on the value of AIC?                          |
| trace  | if TRUE additional information may be given on the fits as they are tried. |
| ...    | arguments passed to or from other methods.                                 |

### Details

The definition of AIC is only up to an additive constant: when appropriate (lm models with specified scale) the constant is taken to be that used in Mallows' Cp statistic and the results are labelled accordingly.

### Value

A table of class "anova" containing at least columns for the change in degrees of freedom and AIC (or Cp) for the models. Some methods will give further information, for example sums of squares, deviances, log-likelihoods and test statistics.

dropterm(house.glm1, test = "Chisq")
```

---

eagles

---

*Foraging Ecology of Bald Eagles*

---

### Description

Knight and Skagen collected during a field study on the foraging behaviour of wintering Bald Eagles in Washington State, USA data concerning 160 attempts by one (pirating) Bald Eagle to steal a chum salmon from another (feeding) Bald Eagle.

**Usage**

eagles

**Format**

The eagles data frame has 8 rows and 5 columns.

y Number of successful attempts.

n Total number of attempts.

P Size of pirating eagle (L = large, S = small).

A Age of pirating eagle (I = immature, A = adult).

V Size of victim eagle (L = large, S = small).

pairs(prof)
```

---

 epil

---

*Seizure Counts for Epileptics*

---

**Description**

Thall and Vail (1990) give a data set on two-week seizure counts for 59 epileptics. The number of seizures was recorded for a baseline period of 8 weeks, and then patients were randomly assigned to a treatment group or a control group. Counts were then recorded for four successive two-week periods. The subject's age is the only covariate.

**Usage**

epil

### Format

This data frame has 236 rows and the following 9 columns:

`y` the count for the 2-week period.  
`trt` treatment, "placebo" or "progabide".  
`base` the counts in the baseline 8-week period.  
`age` subject's age, in years.  
`V4` 0/1 indicator variable of period 4.  
`subject` subject number, 1 to 59.  
`period` period, 1 to 4.  
`lbase` log-counts for the baseline period, centred to have zero mean.  
`lage` log-ages, centred to have zero mean.

### Source

epil["time"] <- 1; epil2["time"] <- 4
epil2 <- rbind(epil, epil2)
epil2$pred <- unclass(epil2$trt) * (epil2$period > 0)
epil2$subject <- factor(epil2$subject)
epil3 <- aggregate(epil2, list(epil2$subject, epil2$period > 0),
 function(x) if(is.numeric(x)) sum(x) else x[1])
epil3$pred <- factor(epil3$pred,
 labels = c("base", "placebo", "drug"))

contrasts(epil3$pred) <- structure(contr.sdif(3),
 dimnames = list(NULL, c("placebo-base", "drug-placebo")))
IGNORE_RDIFF_BEGIN
summary(glm(y ~ pred + factor(subject) + offset(log(time)),
 family = poisson, data = epil3), cor = FALSE)
IGNORE_RDIFF_END

summary(glmmPQL(y ~ lbase*trt + lage + V4,
 random = ~ 1 | subject,
 family = poisson, data = epil))
summary(glmmPQL(y ~ pred, random = ~1 | subject,
 family = poisson, data = epil3))
```

---

eqsplot*Plots with Geometrically Equal Scales*

---

**Description**

Version of a scatterplot with scales chosen to be equal on both axes, that is 1cm represents the same units on each

**Usage**

```
eqsplot(x, y, ratio = 1, tol = 0.04, uin, ...)
```

**Arguments**

|                    |                                                                                                                                                                                                         |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>     | vector of x values, or a 2-column matrix, or a list with components <code>x</code> and <code>y</code>                                                                                                   |
| <code>y</code>     | vector of y values                                                                                                                                                                                      |
| <code>ratio</code> | desired ratio of units on the axes. Units on the y axis are drawn at <code>ratio</code> times the size of units on the x axis. Ignored if <code>uin</code> is specified and of length 2.                |
| <code>tol</code>   | proportion of white space at the margins of plot                                                                                                                                                        |
| <code>uin</code>   | desired values for the units-per-inch parameter. If of length 1, the desired units per inch on the x axis.                                                                                              |
| <code>...</code>   | further arguments for <code>plot</code> and graphical parameters. Note that <code>par(xaxs="i", yaxs="i")</code> is enforced, and <code>xlim</code> and <code>ylim</code> will be adjusted accordingly. |

**Details**

Limits for the x and y axes are chosen so that they include the data. One of the sets of limits is then stretched from the midpoint to make the units in the ratio given by `ratio`. Finally both are stretched by  $1 + \text{tol}$  to move points away from the axes, and the points plotted.

**Value**

invisibly, the values of `uin` used for the plot.

**Side Effects**

performs the plot.

**Note**

Arguments `ratio` and `uin` were suggested by Bill Dunlap.

farms

*Ecological Factors in Farm Management***Description**

The `farms` data frame has 20 rows and 4 columns. The rows are farms on the Dutch island of Terschelling and the columns are factors describing the management of grassland.

**Usage**

```
farms
```

**Format**

This data frame contains the following columns:

`Mois` Five levels of soil moisture – level 3 does not occur at these 20 farms.

`Manag` Grassland management type (SF = standard, BF = biological, HF = hobby farming, NM = nature conservation).

`Use` Grassland use (U1 = hay production, U2 = intermediate, U3 = grazing).

`Manure` Manure usage – classes C0 to C4.

text(farms.mca$cs, labels = dimnames(farms.mca$cs)[[1]], cex = 0.7)
```

fgl

*Measurements of Forensic Glass Fragments***Description**

The `fgl` data frame has 214 rows and 10 columns. It was collected by B. German on fragments of glass collected in forensic work.

**Usage**

```
fgl
```

**Format**

This data frame contains the following columns:

RI refractive index; more precisely the refractive index is 1.518xxxx.

The next 8 measurements are percentages by weight of oxides.

Na sodium.

Mg manganese.

Al aluminium.

Si silicon.

K potassium.

Ca calcium.

Ba barium.

Fe iron.

`type` The fragments were originally classed into seven types, one of which was absent in this dataset. The categories which occur are window float glass (`WinF`: 70), window non-float glass (`WinNF`: 76), vehicle window glass (`Veh`: 17), containers (`Con`: 13), tableware (`Tabl`: 9) and vehicle headlamps (`Head`: 29).

fitdistr

*Maximum-likelihood Fitting of Univariate Distributions***Description**

Maximum-likelihood fitting of univariate distributions, allowing parameters to be held fixed if desired.

**Usage**

```
fitdistr(x, densfun, start, ...)
```

## Arguments

|                      |                                                                                                                                                                                                                                                                                                                                                 |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>       | A numeric vector of length at least one containing only <a href="#">finite</a> values.                                                                                                                                                                                                                                                          |
| <code>densfun</code> | Either a character string or a function returning a density evaluated at its first argument.<br>Distributions "beta", "cauchy", "chi-squared", "exponential", "gamma", "geometric", "log-normal", "lognormal", "logistic", "negative binomial", "normal", "Poisson", "t" and "weibull" are recognised, case being ignored.                      |
| <code>start</code>   | A named list giving the parameters to be optimized with initial values. This can be omitted for some of the named distributions and must be for others (see Details).                                                                                                                                                                           |
| <code>...</code>     | Additional parameters, either for <code>densfun</code> or for <code>optim</code> . In particular, it can be used to specify bounds via <code>lower</code> or <code>upper</code> or both. If arguments of <code>densfun</code> (or the density function corresponding to a character-string specification) are included they will be held fixed. |

## Details

For the Normal, log-Normal, geometric, exponential and Poisson distributions the closed-form MLEs (and exact standard errors) are used, and `start` should not be supplied.

For all other distributions, direct optimization of the log-likelihood is performed using [optim](#). The estimated standard errors are taken from the observed information matrix, calculated by a numerical approximation. For one-dimensional problems the Nelder-Mead method is used and for multi-dimensional problems the BFGS method, unless arguments named `lower` or `upper` are supplied (when `L-BFGS-B` is used) or `method` is supplied explicitly.

For the "t" named distribution the density is taken to be the location-scale family with location `m` and scale `s`.

For the following named distributions, reasonable starting values will be computed if `start` is omitted or only partially specified: "cauchy", "gamma", "logistic", "negative binomial" (parametrized by `mu` and `size`), "t" and "weibull". Note that these starting values may not be good enough if the fit is poor: in particular they are not resistant to outliers unless the fitted distribution is long-tailed.

There are [print](#), [coef](#), [vcov](#) and [logLik](#) methods for class "fitdistr".

## Value

An object of class "fitdistr", a list with four components,

|                       |                                               |
|-----------------------|-----------------------------------------------|
| <code>estimate</code> | the parameter estimates,                      |
| <code>sd</code>       | the estimated standard errors,                |
| <code>vcov</code>     | the estimated variance-covariance matrix, and |
| <code>loglik</code>   | the log-likelihood.                           |

## Note

Numerical optimization cannot work miracles: please note the comments in [optim](#) on scaling data. If the fitted parameters are far away from one, consider re-fitting specifying the control parameter `parscale`.

## References

## Examples

```
avoid spurious accuracy
op <- options(digits = 3)
set.seed(123)
x <- rgamma(100, shape = 5, rate = 0.1)
fitdistr(x, "gamma")
now do this directly with more control.
fitdistr(x, dgamma, list(shape = 1, rate = 0.1), lower = 0.001)

set.seed(123)
x2 <- rt(250, df = 9)
fitdistr(x2, "t", df = 9)
allow df to vary: not a very good idea!
fitdistr(x2, "t")
now do fixed-df fit directly with more control.
mydt <- function(x, m, s, df) dt((x-m)/s, df)/s
fitdistr(x2, mydt, list(m = 0, s = 1), df = 9, lower = c(-Inf, 0))

set.seed(123)
x3 <- rweibull(100, shape = 4, scale = 100)
fitdistr(x3, "weibull")

set.seed(123)
x4 <- rnegbin(500, mu = 5, theta = 4)
fitdistr(x4, "Negative Binomial")
options(op)
```

fractions

*Rational Approximation***Description**

Find rational approximations to the components of a real numeric object using a standard continued fraction method.

**Usage**

```
fractions(x, cycles = 10, max.denominator = 2000, ...)
```

**Arguments**

|                              |                                                                                                                                             |
|------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>               | Any object of mode numeric. Missing values are now allowed.                                                                                 |
| <code>cycles</code>          | The maximum number of steps to be used in the continued fraction approximation process.                                                     |
| <code>max.denominator</code> | An early termination criterion. If any partial denominator exceeds <code>max.denominator</code> the continued fraction stops at that point. |
| <code>...</code>             | arguments passed to or from other methods.                                                                                                  |

**Details**

Each component is first expanded in a continued fraction of the form

$$x = \text{floor}(x) + 1 / (p_1 + 1 / (p_2 + \dots))$$

where  $p_1, p_2, \dots$  are positive integers, terminating either at `cycles` terms or when a  $p_j > \text{max.denominator}$ . The continued fraction is then re-arranged to retrieve the numerator and denominator as integers.

The numerators and denominators are then combined into a character vector that becomes the "fracs" attribute and used in printed representations.

Arithmetic operations on "fractions" objects have full floating point accuracy, but the character representation printed out may not.

**Value**

An object of class "fractions". A structure with `.Data` component the same as the input numeric `x`, but with the rational approximations held as a character vector attribute, "fracs". Arithmetic operations on "fractions" objects are possible.

**Examples**

```
X <- matrix(runif(25), 5, 5)
zapsmall(solve(X, X/5)) # print near-zeroes as zero
fractions(solve(X, X/5))
fractions(solve(X, X/5)) + 1
```

GAGurine

*Level of GAG in Urine of Children***Description**

Data were collected on the concentration of a chemical GAG in the urine of 314 children aged from zero to seventeen years. The aim of the study was to produce a chart to help a paediatrician to assess if a child's GAG concentration is 'normal'.

**Usage**

```
GAGurine
```

**Format**

This data frame contains the following columns:

Age age of child in years.

GAG concentration of GAG (the units have been lost).

**Source**

Mrs Susan Prosser, Paediatrics Department, University of Oxford, via Department of Statistics Consulting Service.

**References**

galaxies

*Velocities for 82 Galaxies***Description**

A numeric vector of velocities in km/sec of 82 galaxies from 6 well-separated conic sections of an unfilled survey of the Corona Borealis region. Multimodality in such surveys is evidence for voids and superclusters in the far universe.

**Usage**

```
galaxies
```

**Note**

There is an 83rd measurement of 5607 km/sec in the Postman *et al.* paper which is omitted in Roeder (1990) and from the dataset here.

There is also a typo: this dataset has 78th observation 26690 which should be 26960.

|------------------|-------------------------------------------------------------------------|
| gamma.dispersion | <i>Calculate the MLE of the Gamma Dispersion Parameter in a GLM Fit</i> |
|------------------|-------------------------------------------------------------------------|

---

**Description**

A front end to `gamma.shape` for convenience. Finds the reciprocal of the estimate of the shape parameter only.

**Usage**

```
gamma.dispersion(object, ...)
```

**Arguments**

|                     |                                                              |
|---------------------|--------------------------------------------------------------|
| <code>object</code> | Fitted model object giving the gamma fit.                    |
| <code>...</code>    | Additional arguments passed on to <code>gamma.shape</code> . |

**Value**

The MLE of the dispersion parameter of the gamma distribution.

**References**

---

|             |                                                                            |
|-------------|----------------------------------------------------------------------------|
| gamma.shape | <i>Estimate the Shape Parameter of the Gamma Distribution in a GLM Fit</i> |
|-------------|----------------------------------------------------------------------------|

---

**Description**

Find the maximum likelihood estimate of the shape parameter of the gamma distribution after fitting a Gamma generalized linear model.

**Usage**

```
S3 method for class 'glm'
gamma.shape(object, it.lim = 10,
 eps.max = .Machine$double.eps^0.25, verbose = FALSE, ...)
```

**Arguments**

|         |                                                                                                           |
|---------|-----------------------------------------------------------------------------------------------------------|
| object  | Fitted model object from a Gamma family or quasi family with <code>variance = "mu^2"</code> .             |
| it.lim  | Upper limit on the number of iterations.                                                                  |
| eps.max | Maximum discrepancy between approximations for the iteration process to continue.                         |
| verbose | If TRUE, causes successive iterations to be printed out. The initial estimate is taken from the deviance. |
| ...     | further arguments passed to or from other methods.                                                        |

**Details**

A glm fit for a Gamma family correctly calculates the maximum likelihood estimate of the mean parameters but provides only a crude estimate of the dispersion parameter. This function takes the results of the glm fit and solves the maximum likelihood equation for the reciprocal of the dispersion parameter, which is usually called the shape (or exponent) parameter.

**Value**

List of two components

|       |                                                                                                |
|-------|------------------------------------------------------------------------------------------------|
| alpha | the maximum likelihood estimate                                                                |
| SE    | the approximate standard error, the square-root of the reciprocal of the observed information. |

gehan

*Remission Times of Leukaemia Patients*

---

## Description

A data frame from a trial of 42 leukaemia patients. Some were treated with the drug *6-mercaptopurine* and the rest are controls. The trial was designed as matched pairs, both withdrawn from the trial when either came out of remission.

## Usage

gehan

## Format

This data frame contains the following columns:

`pair` label for pair.

`time` remission time in weeks.

`cens` censoring, 0/1.

`treat` treatment, control or 6-MP.

## Source

Cox, D. R. and Oakes, D. (1984) *Analysis of Survival Data*. Chapman & Hall, p. 7. Taken from

gehan.surv <- survfit(Surv(time, cens) ~ treat, data = gehan,
 conf.type = "log-log")
summary(gehan.surv)
survreg(Surv(time, cens) ~ factor(pair) + treat, gehan, dist = "exponential")
summary(survreg(Surv(time, cens) ~ treat, gehan, dist = "exponential"))
summary(survreg(Surv(time, cens) ~ treat, gehan))
gehan.cox <- coxph(Surv(time, cens) ~ treat, gehan)
summary(gehan.cox)
```

---

genotype

*Rat Genotype Data*

---

## Description

Data from a foster feeding experiment with rat mothers and litters of four different genotypes: A, B, I and J. Rat litters were separated from their natural mothers at birth and given to foster mothers to rear.

## Usage

```
genotype
```

## Format

The data frame has the following components:

`Litter` genotype of the litter.

`Mother` genotype of the foster mother.

`Wt` Litter average weight gain of the litter, in grams at age 28 days. (The source states that the within-litter variability is negligible.)

---

geyser

*Old Faithful Geyser Data*

---

## Description

A version of the eruptions data from the ‘Old Faithful’ geyser in Yellowstone National Park, Wyoming. This version comes from Azzalini and Bowman (1990) and is of continuous measurement from August 1 to August 15, 1985.

Some nocturnal duration measurements were coded as 2, 3 or 4 minutes, having originally been described as ‘short’, ‘medium’ or ‘long’.

## Usage

```
geyser
```

## Format

A data frame with 299 observations on 2 variables.

|          |         |                                |
|----------|---------|--------------------------------|
| duration | numeric | Eruption time in mins          |
| waiting  | numeric | Waiting time for this eruption |

## Note

The `waiting` time was incorrectly described as the time to the next eruption in the original files, and corrected for **MASS** version 7.3-30.

gilgais*Line Transect of Soil in Gilgai Territory*

---

**Description**

This dataset was collected on a line transect survey in gilgai territory in New South Wales, Australia. Gilgais are natural gentle depressions in otherwise flat land, and sometimes seem to be regularly distributed. The data collection was stimulated by the question: are these patterns reflected in soil properties? At each of 365 sampling locations on a linear grid of 4 meters spacing, samples were taken at depths 0–10 cm, 30–40 cm and 80–90 cm below the surface. pH, electrical conductivity and chloride content were measured on a 1:5 soil:water extract from each sample.

**Usage**

gilgais

**Format**

This data frame contains the following columns:

pH00 pH at depth 0–10 cm.  
pH30 pH at depth 30–40 cm.  
pH80 pH at depth 80–90 cm.  
e00 electrical conductivity in mS/cm (0–10 cm).  
e30 electrical conductivity in mS/cm (30–40 cm).  
e80 electrical conductivity in mS/cm (80–90 cm).  
c00 chloride content in ppm (0–10 cm).  
c30 chloride content in ppm (30–40 cm).  
c80 chloride content in ppm (80–90 cm).

ginv

*Generalized Inverse of a Matrix***Description**

Calculates the Moore-Penrose generalized inverse of a matrix X.

**Usage**

```
ginv(X, tol = sqrt(.Machine$double.eps))
```

**Arguments**

X                      Matrix for which the Moore-Penrose inverse is required.  
tol                     A relative tolerance to detect zero singular values.

**Value**

A MP generalized inverse matrix for X.

**References**

Venables, W. N. and Ripley, B. D. (1999) *Modern Applied Statistics with S-PLUS*. Third Edition. Springer. p.100.

**See Also**

glm.convert

*Change a Negative Binomial fit to a GLM fit***Description**

This function modifies an output object from `glm.nb()` to one that looks like the output from `glm()` with a negative binomial family. This allows it to be updated keeping the theta parameter fixed.

**Usage**

```
glm.convert(object)
```

**Arguments**

object                An object of class "negbin", typically the output from `glm.nb()`.

**Details**

Convenience function needed to effect some low level changes to the structure of the fitted model object.

**Value**

An object of class "glm" with negative binomial family. The theta parameter is then fixed at its present estimate.

**See Also**

[glm.nb](#), [negative.binomial](#), [glm](#)

**Examples**

```
quine.nbl <- glm.nb(Days ~ Sex/(Age + Eth*Lrn), data = quine)
quine.nbA <- glm.convert(quine.nbl)
quine.nbB <- update(quine.nbl, . ~ . + Sex:Age:Lrn)
anova(quine.nbA, quine.nbB)
```

---

|        |                                                         |
|--------|---------------------------------------------------------|
| glm.nb | <i>Fit a Negative Binomial Generalized Linear Model</i> |
|--------|---------------------------------------------------------|

---

**Description**

A modification of the system function [glm\(\)](#) to include estimation of the additional parameter, `theta`, for a Negative Binomial generalized linear model.

**Usage**

```
glm.nb(formula, data, weights, subset, na.action,
 start = NULL, etastart, mustart,
 control = glm.control(...), method = "glm.fit",
 model = TRUE, x = FALSE, y = TRUE, contrasts = NULL, ...,
 init.theta, link = log)
```

**Arguments**

`formula`, `data`, `weights`, `subset`, `na.action`, `start`, `etastart`, `mustart`, `control`, `method`,  
arguments for the [glm\(\)](#) function. Note that these exclude family and offset (but [offset\(\)](#) can be used).

`init.theta` Optional initial value for the theta parameter. If omitted a moment estimator after an initial fit using a Poisson GLM is used.

`link` The link function. Currently must be one of `log`, `sqrt` or `identity`.

**Details**

An alternating iteration process is used. For given `theta` the GLM is fitted using the same process as used by [glm\(\)](#). For fixed means the `theta` parameter is estimated using score and information iterations. The two are alternated until convergence of both. (The number of alternations and the number of iterations when estimating `theta` are controlled by the `maxit` parameter of [glm.control\(\)](#).)

Setting `trace > 0` traces the alternating iteration process. Setting `trace > 1` traces the [glm](#) fit, and setting `trace > 2` traces the estimation of `theta`.

**Value**

A fitted model object of class `negbin` inheriting from `glm` and `lm`. The object is like the output of `glm` but contains three additional components, namely `theta` for the ML estimate of  $\theta$ , `SE.theta` for its approximate standard error (using observed rather than expected information), and `twologlik` for twice the log-likelihood function.

There is a [simulate](#) method.

**Examples**

```
quine.nb1 <- glm.nb(Days ~ Sex/(Age + Eth*Ln), data = quine)
quine.nb2 <- update(quine.nb1, . ~ . + Sex:Age:Ln)
quine.nb3 <- update(quine.nb2, Days ~ .^4)
anova(quine.nb1, quine.nb2, quine.nb3)
```

---

glmmPQL

---

*Fit Generalized Linear Mixed Models via PQL*

---

**Description**

Fit a GLMM model with multivariate normal random effects, using Penalized Quasi-Likelihood.

**Usage**

```
glmmPQL(fixed, random, family, data, correlation, weights,
 control, niter = 10, verbose = TRUE, ...)
```

**Arguments**

|                          |                                                                                                                                                                                        |
|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>fixed</code>       | a two-sided linear formula giving fixed-effects part of the model.                                                                                                                     |
| <code>random</code>      | a formula or list of formulae describing the random effects.                                                                                                                           |
| <code>family</code>      | a GLM family.                                                                                                                                                                          |
| <code>data</code>        | an optional data frame, list or environment used as the first place to find variables in the formulae, <code>weights</code> and if present in <code>...</code> , <code>subset</code> . |
| <code>correlation</code> | an optional correlation structure.                                                                                                                                                     |
| <code>weights</code>     | optional case weights as in <code>glm</code> .                                                                                                                                         |
| <code>control</code>     | an optional argument to be passed to <code>lme</code> .                                                                                                                                |
| <code>niter</code>       | maximum number of iterations.                                                                                                                                                          |
| <code>verbose</code>     | logical: print out record of iterations?                                                                                                                                               |
| <code>...</code>         | Further arguments for <code>lme</code> .                                                                                                                                               |

## Details

glmmPQL works by repeated calls to [lme](#), so package nlme will be loaded at first use if necessary.

## Value

A object of class "lme": see [lmeObject](#).

hills

---

*Record Times in Scottish Hill Races*

---

## Description

The record times in 1984 for 35 Scottish hill races.

## Usage

```
hills
```

## Format

The components are:

`dist` distance in miles (on the map).

`climb` total height gained during the route, in feet.

`time` record time in minutes.

## Source

---

`hist.scott`*Plot a Histogram with Automatic Bin Width Selection*

---

## Description

Plot a histogram with automatic bin width selection, using the Scott or Freedman–Diaconis formulae.

## Usage

```
hist.scott(x, prob = TRUE, xlab = deparse(substitute(x)), ...)
hist.FD(x, prob = TRUE, xlab = deparse(substitute(x)), ...)
```

## Arguments

|                        |                                                           |
|------------------------|-----------------------------------------------------------|
| <code>x</code>         | A data vector                                             |
| <code>prob</code>      | Should the plot have unit area, so be a density estimate? |
| <code>xlab, ...</code> | Further arguments to <code>hist</code> .                  |

## Value

For the `nclass.*` functions, the suggested number of classes.

## Side Effects

Plot a histogram.

housing

*Frequency Table from a Copenhagen Housing Conditions Survey***Description**

The housing data frame has 72 rows and 5 variables.

**Usage**

```
housing
```

**Format**

Sat Satisfaction of householders with their present housing circumstances, (High, Medium or Low, ordered factor).

Infl Perceived degree of influence householders have on the management of the property (High, Medium, Low).

Type Type of rental accommodation, (Tower, Atrium, Apartment, Terrace).

Cont Contact residents are afforded with other residents, (Low, High).

Freq Frequencies: the numbers of residents in each class.

immer

*Yields from a Barley Field Trial*

---

**Description**

The `immer` data frame has 30 rows and 4 columns. Five varieties of barley were grown in six locations in each of 1931 and 1932.

**Usage**

```
immer
```

**Format**

This data frame contains the following columns:

`Loc` The location.

`Var` The variety of barley ("manchuria", "svansota", "velvet", "trebi" and "peatland").

`Y1` Yield in 1931.

`Y2` Yield in 1932.

immer.aov <- aov(cbind(Y1,Y2) ~ Loc + Var, data = immer)
summary(immer.aov)

immer.aov <- aov((Y1+Y2)/2 ~ Var + Loc, data = immer)
summary(immer.aov)
model.tables(immer.aov, type = "means", se = TRUE, cterms = "Var")
```

---

Insurance

*Numbers of Car Insurance claims*

---

## Description

The data given in data frame `Insurance` consist of the numbers of policyholders of an insurance company who were exposed to risk, and the numbers of car insurance claims made by those policyholders in the third quarter of 1973.

## Usage

`Insurance`

## Format

This data frame contains the following columns:

`District` factor: district of residence of policyholder (1 to 4): 4 is major cities.

`Group` an ordered factor: group of car with levels <1 litre, 1–1.5 litre, 1.5–2 litre, >2 litre.

`Age` an ordered factor: the age of the insured in 4 groups labelled <25, 25–29, 30–35, >35.

`Holders` numbers of policyholders.

`Claims` numbers of claims

glm(Claims ~ District + Group + Age + offset(log(Holders)),
 data = Insurance, family = poisson)

same via loglm
loglm(Claims ~ District + Group + Age + offset(log(Holders)),
 data = Insurance)
```

isoMDS

*Kruskal's Non-metric Multidimensional Scaling*

## Description

One form of non-metric multidimensional scaling

## Usage

```
isoMDS(d, y = cmdscale(d, k), k = 2, maxit = 50, trace = TRUE,
 tol = 1e-3, p = 2)
```

```
Shepard(d, x, p = 2)
```

## Arguments

|       |                                                                                                                                                                                                                                                        |
|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| d     | distance structure of the form returned by <code>dist</code> , or a full, symmetric matrix. Data are assumed to be dissimilarities or relative distances, but must be positive except for self-distance. Both missing and infinite values are allowed. |
| y     | An initial configuration. If none is supplied, <code>cmdscale</code> is used to provide the classical solution, unless there are missing or infinite dissimilarities.                                                                                  |
| k     | The desired dimension for the solution, passed to <code>cmdscale</code> .                                                                                                                                                                              |
| maxit | The maximum number of iterations.                                                                                                                                                                                                                      |
| trace | Logical for tracing optimization. Default <code>TRUE</code> .                                                                                                                                                                                          |
| tol   | convergence tolerance.                                                                                                                                                                                                                                 |
| p     | Power for Minkowski distance in the configuration space.                                                                                                                                                                                               |
| x     | A final configuration.                                                                                                                                                                                                                                 |

## Details

This chooses a  $k$ -dimensional (default  $k = 2$ ) configuration to minimize the stress, the square root of the ratio of the sum of squared differences between the input distances and those of the configuration to the sum of configuration distances squared. However, the input distances are allowed a monotonic transformation.

An iterative algorithm is used, which will usually converge in around 10 iterations. As this is necessarily an  $O(n^2)$  calculation, it is slow for large datasets. Further, since for the default  $p = 2$  the configuration is only determined up to rotations and reflections (by convention the centroid is at the origin), the result can vary considerably from machine to machine.

**Value**

Two components:

|                     |                                                |
|---------------------|------------------------------------------------|
| <code>points</code> | A k-column vector of the fitted configuration. |
| <code>stress</code> | The final stress achieved (in percent).        |

**Side Effects**

If `trace` is true, the initial stress and the current stress are printed out every 5 iterations.

kde2d

---

*Two-Dimensional Kernel Density Estimation*

---

**Description**

Two-dimensional kernel density estimation with an axis-aligned bivariate normal kernel, evaluated on a square grid.

**Usage**

```
kde2d(x, y, h, n = 25, lims = c(range(x), range(y)))
```

**Arguments**

|                   |                                                                                                                                                                                     |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>    | x coordinate of data                                                                                                                                                                |
| <code>y</code>    | y coordinate of data                                                                                                                                                                |
| <code>h</code>    | vector of bandwidths for x and y directions. Defaults to normal reference bandwidth (see <a href="#">bandwidth.nrd</a> ). A scalar value will be taken to apply to both directions. |
| <code>n</code>    | Number of grid points in each direction. Can be scalar or a length-2 integer vector.                                                                                                |
| <code>lims</code> | The limits of the rectangle covered by the grid as <code>c(xl, xu, yl, yu)</code> .                                                                                                 |

**Value**

A list of three components.

`x`, `y`            The x and y coordinates of the grid points, vectors of length `n`.

`z`                An `n[1]` by `n[2]` matrix of the estimated density: rows correspond to the value of `x`, columns to the value of `y`.

**References**

 lda

*Linear Discriminant Analysis*

---

**Description**

Linear discriminant analysis.

**Usage**

```
lda(x, ...)

S3 method for class 'formula'
lda(formula, data, ..., subset, na.action)

Default S3 method:
```

```
lda(x, grouping, prior = proportions, tol = 1.0e-4,
 method, CV = FALSE, nu, ...)

S3 method for class 'data.frame'
lda(x, ...)

S3 method for class 'matrix'
lda(x, grouping, ..., subset, na.action)
```

### Arguments

|                        |                                                                                                                                                                                                                                                                                         |
|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>formula</code>   | A formula of the form <code>groups ~ x1 + x2 + . . .</code> . That is, the response is the grouping factor and the right hand side specifies the (non-factor) discriminators.                                                                                                           |
| <code>data</code>      | An optional data frame, list or environment from which variables specified in <code>formula</code> are preferentially to be taken.                                                                                                                                                      |
| <code>x</code>         | (required if no formula is given as the principal argument.) a matrix or data frame or Matrix containing the explanatory variables.                                                                                                                                                     |
| <code>grouping</code>  | (required if no formula principal argument is given.) a factor specifying the class for each observation.                                                                                                                                                                               |
| <code>prior</code>     | the prior probabilities of class membership. If unspecified, the class proportions for the training set are used. If present, the probabilities should be specified in the order of the factor levels.                                                                                  |
| <code>tol</code>       | A tolerance to decide if a matrix is singular; it will reject variables and linear combinations of unit-variance variables whose variance is less than <code>tol^2</code> .                                                                                                             |
| <code>subset</code>    | An index vector specifying the cases to be used in the training sample. (NOTE: If given, this argument must be named.)                                                                                                                                                                  |
| <code>na.action</code> | A function to specify the action to be taken if NAs are found. The default action is for the procedure to fail. An alternative is <code>na.omit</code> , which leads to rejection of cases with missing values on any required variable. (NOTE: If given, this argument must be named.) |
| <code>method</code>    | "moment" for standard estimators of the mean and variance, "mle" for MLEs, "mve" to use <code>cov.mve</code> , or "t" for robust estimates based on a <i>t</i> distribution.                                                                                                            |
| <code>CV</code>        | If true, returns results (classes and posterior probabilities) for leave-one-out cross-validation. Note that if the prior is estimated, the proportions in the whole dataset are used.                                                                                                  |
| <code>nu</code>        | degrees of freedom for <code>method = "t"</code> .                                                                                                                                                                                                                                      |
| <code>. . .</code>     | arguments passed to or from other methods.                                                                                                                                                                                                                                              |

### Details

The function tries hard to detect if the within-class covariance matrix is singular. If any variable has within-group variance less than `tol^2` it will stop and report the variable as constant. This could result from poor scaling of the problem, but is more likely to result from constant variables.

Specifying the `prior` will affect the classification unless over-ridden in `predict.lda`. Unlike in most statistical packages, it will also affect the rotation of the linear discriminants within their space, as a weighted between-groups covariance matrix is used. Thus the first few linear discriminants emphasize the differences between groups with the weights given by the prior, which may differ from their prevalence in the dataset.

If one or more groups is missing in the supplied data, they are dropped with a warning, but the classifications produced are with respect to the original set of levels.

**Value**

If `CV = TRUE` the return value is a list with components `class`, the MAP classification (a factor), and `posterior`, posterior probabilities for the classes.

Otherwise it is an object of class `"lda"` containing the following components:

|                      |                                                                                                                                                                                    |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>prior</code>   | the prior probabilities used.                                                                                                                                                      |
| <code>means</code>   | the group means.                                                                                                                                                                   |
| <code>scaling</code> | a matrix which transforms observations to discriminant functions, normalized so that within groups covariance matrix is spherical.                                                 |
| <code>svd</code>     | the singular values, which give the ratio of the between- and within-group standard deviations on the linear discriminant variables. Their squares are the canonical F-statistics. |
| <code>N</code>       | The number of observations used.                                                                                                                                                   |
| <code>call</code>    | The (matched) function call.                                                                                                                                                       |

**Note**

This function may be called giving either a formula and optional data frame, or a matrix and grouping factor as the first two arguments. All other arguments are optional, but `subset=` and `na.action=`, if required, must be fully named.

If a formula is given as the principal argument the object may be modified using `update()` in the usual way.

ldahist

*Histograms or Density Plots of Multiple Groups***Description**

Plot histograms or density plots of data on a single Fisher linear discriminant.

**Usage**

```
ldahist(data, g, nbins = 25, h, x0 = - h/1000, breaks,
 xlim = range(breaks), ymax = 0, width,
 type = c("histogram", "density", "both"),
 sep = (type != "density"),
 col = 5, xlab = deparse(substitute(data)), bty = "n", ...)
```

**Arguments**

|        |                                                                                                             |
|--------|-------------------------------------------------------------------------------------------------------------|
| data   | vector of data. Missing values (NAs) are allowed and omitted.                                               |
| g      | factor or vector giving groups, of the same length as data.                                                 |
| nbins  | Suggested number of bins to cover the whole range of the data.                                              |
| h      | The bin width (takes precedence over nbins).                                                                |
| x0     | Shift for the bins - the breaks are at $x_0 + h * (\dots, -1, 0, 1, \dots)$                                 |
| breaks | The set of breakpoints to be used. (Usually omitted, takes precedence over h and nbins).                    |
| xlim   | The limits for the x-axis.                                                                                  |
| ymax   | The upper limit for the y-axis.                                                                             |
| width  | Bandwidth for density estimates. If missing, the Sheather-Jones selector is used for each group separately. |
| type   | Type of plot.                                                                                               |
| sep    | Whether there is a separate plot for each group, or one combined plot.                                      |
| col    | The colour number for the bar fill.                                                                         |
| xlab   | label for the plot x-axis. By default, this will be the name of data.                                       |
| bty    | The box type for the plot - defaults to none.                                                               |
| ...    | additional arguments to polygon.                                                                            |

**Side Effects**

Histogram and/or density plots are plotted on the current device.

leuk

---

*Survival Times and White Blood Counts for Leukaemia Patients*

---

**Description**

A data frame of data from 33 leukaemia patients.

**Usage**

leuk

**Format**

A data frame with columns:

wbc white blood count.

ag a test result, "present" or "absent".

time survival time in weeks.

**Details**

Survival times are given for 33 patients who died from acute myelogenous leukaemia. Also measured was the patient's white blood cell count at the time of diagnosis. The patients were also factored into 2 groups according to the presence or absence of a morphologic characteristic of white blood cells. Patients termed AG positive were identified by the presence of Auer rods and/or significant granulation of the leukaemic cells in the bone marrow at the time of diagnosis.

lm.gls

*Fit Linear Models by Generalized Least Squares***Description**

Fit linear models by Generalized Least Squares

**Usage**

```
lm.gls(formula, data, W, subset, na.action, inverse = FALSE,
 method = "qr", model = FALSE, x = FALSE, y = FALSE,
 contrasts = NULL, ...)
```

**Arguments**

|                        |                                                                                                                                                                  |
|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>formula</code>   | a formula expression as for regression models, of the form <code>response ~ predictors</code> . See the documentation of <code>formula</code> for other details. |
| <code>data</code>      | an optional data frame, list or environment in which to interpret the variables occurring in <code>formula</code> .                                              |
| <code>W</code>         | a weight matrix.                                                                                                                                                 |
| <code>subset</code>    | expression saying which subset of the rows of the data should be used in the fit. All observations are included by default.                                      |
| <code>na.action</code> | a function to filter missing data.                                                                                                                               |
| <code>inverse</code>   | logical: if true <code>W</code> specifies the inverse of the weight matrix: this is appropriate if a variance matrix is used.                                    |
| <code>method</code>    | method to be used by <code>lm.fit</code> .                                                                                                                       |
| <code>model</code>     | should the model frame be returned?                                                                                                                              |
| <code>x</code>         | should the design matrix be returned?                                                                                                                            |
| <code>y</code>         | should the response be returned?                                                                                                                                 |
| <code>contrasts</code> | a list of contrasts to be used for some or all of                                                                                                                |
| <code>...</code>       | additional arguments to <code>lm.fit</code> .                                                                                                                    |

**Details**

The problem is transformed to uncorrelated form and passed to `lm.fit`.

**Value**

An object of class `"lm.gls"`, which is similar to an `"lm"` object. There is no `"weights"` component, and only a few `"lm"` methods will work correctly. As from version 7.1-22 the residuals and fitted values refer to the untransformed problem.

**See Also**

|----------|-------------------------|
| lm.ridge | <i>Ridge Regression</i> |
|----------|-------------------------|

---

**Description**

Fit a linear model by ridge regression.

**Usage**

```
lm.ridge(formula, data, subset, na.action, lambda = 0, model = FALSE,
 x = FALSE, y = FALSE, contrasts = NULL, ...)
```

**Arguments**

|           |                                                                                                                                                                                                            |
|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| formula   | a formula expression as for regression models, of the form <code>response ~ predictors</code> . See the documentation of <code>formula</code> for other details. <a href="#">offset</a> terms are allowed. |
| data      | an optional data frame, list or environment in which to interpret the variables occurring in <code>formula</code> .                                                                                        |
| subset    | expression saying which subset of the rows of the data should be used in the fit. All observations are included by default.                                                                                |
| na.action | a function to filter missing data.                                                                                                                                                                         |
| lambda    | A scalar or vector of ridge constants.                                                                                                                                                                     |
| model     | should the model frame be returned? Not implemented.                                                                                                                                                       |
| x         | should the design matrix be returned? Not implemented.                                                                                                                                                     |
| y         | should the response be returned? Not implemented.                                                                                                                                                          |
| contrasts | a list of contrasts to be used for some or all of factor terms in the formula. See the <code>contrasts.arg</code> of <a href="#">model.matrix.default</a> .                                                |
| ...       | additional arguments to <a href="#">lm.fit</a> .                                                                                                                                                           |

**Details**

If an intercept is present in the model, its coefficient is not penalized. (If you want to penalize an intercept, put in your own constant term and remove the intercept.)

**Value**

A list with components

|        |                                                                                                                                                                           |
|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| coef   | matrix of coefficients, one row for each value of <code>lambda</code> . Note that these are not on the original scale and are for use by the <a href="#">coef</a> method. |
| scales | scalings used on the X matrix.                                                                                                                                            |
| Inter  | was intercept included?                                                                                                                                                   |
| lambda | vector of <code>lambda</code> values                                                                                                                                      |
| ym     | mean of y                                                                                                                                                                 |
| xm     | column means of x matrix                                                                                                                                                  |
| GCV    | vector of GCV values                                                                                                                                                      |
| kHKB   | HKB estimate of the ridge constant.                                                                                                                                       |
| kLW    | L-W estimate of the ridge constant.                                                                                                                                       |

*Fit Log-Linear Models by Iterative Proportional Scaling*

---

## Description

This function provides a front-end to the standard function, `loglin`, to allow log-linear models to be specified and fitted in a manner similar to that of other fitting functions, such as `glm`.

## Usage

```
loglm(formula, data, subset, na.action, ...)
```

## Arguments

|           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| formula   | <p>A linear model formula specifying the log-linear model.</p> <p>If the left-hand side is empty, the <code>data</code> argument is required and must be a (complete) array of frequencies. In this case the variables on the right-hand side may be the names of the <code>dimnames</code> attribute of the frequency array, or may be the positive integers: 1, 2, 3, ... used as alternative names for the 1st, 2nd, 3rd, ... dimension (classifying factor). If the left-hand side is not empty it specifies a vector of frequencies. In this case the <code>data</code> argument, if present, must be a data frame from which the left-hand side vector and the classifying factors on the right-hand side are (preferentially) obtained. The usual abbreviation of a <code>.</code> to stand for ‘all other variables in the data frame’ is allowed. Any non-factors on the right-hand side of the formula are coerced to factor.</p> |
| data      | <p>Numeric array or data frame (or list or environment). In the first case it specifies the array of frequencies; in the second it provides the data frame from which the variables occurring in the formula are preferentially obtained in the usual way.</p> <p>This argument may be the result of a call to <a href="#">xtabs</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| subset    | <p>Specifies a subset of the rows in the data frame to be used. The default is to take all rows.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| na.action | <p>Specifies a method for handling missing observations. The default is to fail if missing values are present.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| ...       | <p>May supply other arguments to the function <a href="#">loglm1</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

## Details

If the left-hand side of the formula is empty the `data` argument supplies the frequency array and the right-hand side of the formula is used to construct the list of fixed faces as required by `loglin`. Structural zeros may be specified by giving a `start` argument with those entries set to zero, as described in the help information for `loglin`.

If the left-hand side is not empty, all variables on the right-hand side are regarded as classifying factors and an array of frequencies is constructed. If some cells in the complete array are not specified they are treated as structural zeros. The right-hand side of the formula is again used to construct the list of faces on which the observed and fitted totals must agree, as required by `loglin`. Hence terms such as `a:b`, `a*b` and `a/b` are all equivalent.

## Value

An object of class "loglm" conveying the results of the fitted log-linear model. Methods exist for the generic functions `print`, `summary`, `deviance`, `fitted`, `coef`, `resid`, `anova` and `update`, which perform the expected tasks. Only log-likelihood ratio tests are allowed using `anova`.

The deviance is simply an alternative name for the log-likelihood ratio statistic for testing the current model within a saturated model, in accordance with standard usage in generalized linear models.

## Warning

If structural zeros are present, the calculation of degrees of freedom may not be correct. `loglin` itself takes no action to allow for structural zeros. `loglm` deducts one degree of freedom for each structural zero, but cannot make allowance for gains in error degrees of freedom due to loss of dimension in the model space. (This would require checking the rank of the model matrix, but since iterative proportional scaling methods are developed largely to avoid constructing the model matrix explicitly, the computation is at least difficult.)

When structural zeros (or zero fitted values) are present the estimated coefficients will not be available due to infinite estimates. The deviances will normally continue to be correct, though.

## Examples

```
The data frames Cars93, minn38 and quine are available
in the MASS package.

Case 1: frequencies specified as an array.
sapply(minn38, function(x) length(levels(x)))
hs phs fol sex f
3 4 7 2 0
##minn38a <- array(0, c(3,4,7,2), lapply(minn38[, -5], levels))
##minn38a[data.matrix(minn38[, -5])] <- minn38$f

or more simply
minn38a <- xtabs(f ~ ., minn38)
```

```

fm <- loglm(~ 1 + 2 + 3 + 4, minn38a) # numerals as names.
deviance(fm)
[1] 3711.9
fm1 <- update(fm, .~.^2)
fm2 <- update(fm, .~.^3, print = TRUE)
5 iterations: deviation 0.075
anova(fm, fm1, fm2)

Case 1. An array generated with xtabs.

loglm(~ Type + Origin, xtabs(~ Type + Origin, Cars93))

Case 2. Frequencies given as a vector in a data frame
names(quine)
[1] "Eth" "Sex" "Age" "Lrn" "Days"
fm <- loglm(Days ~ .^2, quine)
gm <- glm(Days ~ .^2, poisson, quine) # check glm.
c(deviance(fm), deviance(gm)) # deviances agree
[1] 1368.7 1368.7
c(fmdf, gmdf) # resid df do not!
c(fmdf, gmdf.residual) # resid df do not!
[1] 127 128
The loglm residual degrees of freedom is wrong because of
a non-detectable redundancy in the model matrix.

```

logtrans

*Estimate log Transformation Parameter***Description**

Find and optionally plot the marginal (profile) likelihood for alpha for a transformation model of the form  $\log(y + \alpha) \sim x_1 + x_2 + \dots$ .

**Usage**

```

logtrans(object, ...)

Default S3 method:
logtrans(object, ..., alpha = seq(0.5, 6, by = 0.25) - min(y),
 plotit = TRUE, interp =, xlab = "alpha",
 ylab = "log Likelihood")

S3 method for class 'formula'
logtrans(object, data, ...)

S3 method for class 'lm'
logtrans(object, ...)

```

**Arguments**

**object** Fitted linear model object, or formula defining the untransformed model that is  $y \sim x_1 + x_2 + \dots$ . The function is generic.

|        |                                                                                                                                                                                          |
|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ...    | If object is a formula, this argument may specify a data frame as for <code>lm</code> .                                                                                                  |
| alpha  | Set of values for the transformation parameter, <code>alpha</code> .                                                                                                                     |
| plotit | Should plotting be done?                                                                                                                                                                 |
| interp | Should the marginal log-likelihood be interpolated with a spline approximation? (Default is <code>TRUE</code> if plotting is to be done and the number of real points is less than 100.) |
| xlab   | as for <code>plot</code> .                                                                                                                                                               |
| ylab   | as for <code>plot</code> .                                                                                                                                                               |
| data   | optional data argument for <code>lm</code> fit.                                                                                                                                          |

Value

List with components `x` (for `alpha`) and `y` (for the marginal log-likelihood values).

Side Effects

A plot of the marginal log-likelihood is produced, if requested, together with an approximate mle and 95% confidence interval.

|-----|-----------------------------|
| lqs | <i>Resistant Regression</i> |
|-----|-----------------------------|

---

Description

Fit a regression to the *good* points in the dataset, thereby achieving a regression estimator with a high breakdown point. `lmsreg` and `ltsreg` are compatibility wrappers.

Usage

```
lqs(x, ...)

S3 method for class 'formula'
lqs(formula, data, ...,
 method = c("lts", "lqs", "lms", "S", "model.frame"),
 subset, na.action, model = TRUE,
 x.ret = FALSE, y.ret = FALSE, contrasts = NULL)
```

```
Default S3 method:
lqs(x, y, intercept = TRUE, method = c("lts", "lqs", "lms", "S"),
 quantile, control = lqs.control(...), k0 = 1.548, seed, ...)

lmsreg(...)
ltsreg(...)
```

## Arguments

|                                  |                                                                                                                                                                                                                                                                                                                            |
|----------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>formula</code>             | a formula of the form $y \sim x_1 + x_2 + \dots$                                                                                                                                                                                                                                                                           |
| <code>data</code>                | an optional data frame, list or environment from which variables specified in <code>formula</code> are preferentially to be taken.                                                                                                                                                                                         |
| <code>subset</code>              | an index vector specifying the cases to be used in fitting. (NOTE: If given, this argument must be named exactly.)                                                                                                                                                                                                         |
| <code>na.action</code>           | function to specify the action to be taken if NAs are found. The default action is for the procedure to fail. Alternatives include <code>na.omit</code> and <code>na.exclude</code> , which lead to omission of cases with missing values on any required variable. (NOTE: If given, this argument must be named exactly.) |
| <code>model, x.ret, y.ret</code> | logical. If TRUE the model frame, the model matrix and the response are returned, respectively.                                                                                                                                                                                                                            |
| <code>contrasts</code>           | an optional list. See the <code>contrasts.arg</code> of <code>model.matrix.default</code> .                                                                                                                                                                                                                                |
| <code>x</code>                   | a matrix or data frame containing the explanatory variables.                                                                                                                                                                                                                                                               |
| <code>y</code>                   | the response: a vector of length the number of rows of <code>x</code> .                                                                                                                                                                                                                                                    |
| <code>intercept</code>           | should the model include an intercept?                                                                                                                                                                                                                                                                                     |
| <code>method</code>              | the method to be used. <code>model.frame</code> returns the model frame: for the others see the Details section. Using <code>lmsreg</code> or <code>ltsreg</code> forces "lms" and "lts" respectively.                                                                                                                     |
| <code>quantile</code>            | the quantile to be used: see Details. This is over-ridden if <code>method = "lms"</code> .                                                                                                                                                                                                                                 |
| <code>control</code>             | additional control items: see Details.                                                                                                                                                                                                                                                                                     |
| <code>k0</code>                  | the cutoff / tuning constant used for $\chi()$ and $\psi()$ functions when <code>method = "S"</code> , currently corresponding to Tukey's 'biweight'.                                                                                                                                                                      |
| <code>seed</code>                | the seed to be used for random sampling: see <code>.Random.seed</code> . The current value of <code>.Random.seed</code> will be preserved if it is set..                                                                                                                                                                   |
| <code>...</code>                 | arguments to be passed to <code>lqs.default</code> or <code>lqs.control</code> , see <code>control</code> above and Details.                                                                                                                                                                                               |

## Details

Suppose there are  $n$  data points and  $p$  regressors, including any intercept.

The first three methods minimize some function of the sorted squared residuals. For methods "lqs" and "lms" is the quantile squared residual, and for "lts" it is the sum of the quantile smallest squared residuals. "lqs" and "lms" differ in the defaults for `quantile`, which are `floor((n+p+1)/2)` and `floor((n+1)/2)` respectively. For "lts" the default is `floor(n/2) + floor((p+1)/2)`.

The "S" estimation method solves for the scale  $s$  such that the average of a function  $\chi$  of the residuals divided by  $s$  is equal to a given constant.

The `control` argument is a list with components

`psamp`: the size of each sample. Defaults to `p`.  
`nsamp`: the number of samples or "best" (the default) or "exact" or "sample". If "sample" the number chosen is  $\min(5 \cdot p, 3000)$ , taken from Rousseeuw and Hubert (1997). If "best" exhaustive enumeration is done up to 5000 samples; if "exact" exhaustive enumeration will be attempted however many samples are needed.  
`adjust`: should the intercept be optimized for each sample? Defaults to `TRUE`.

### Value

An object of class "lqs". This is a list with components

|                            |                                                                                                                                                                                                                                                        |
|----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>crit</code>          | the value of the criterion for the best solution found, in the case of <code>method == "S"</code> before IWLS refinement.                                                                                                                              |
| <code>sing</code>          | character. A message about the number of samples which resulted in singular fits.                                                                                                                                                                      |
| <code>coefficients</code>  | of the fitted linear model                                                                                                                                                                                                                             |
| <code>bestone</code>       | the indices of those points fitted by the best sample found (prior to adjustment of the intercept, if requested).                                                                                                                                      |
| <code>fitted.values</code> | the fitted values.                                                                                                                                                                                                                                     |
| <code>residuals</code>     | the residuals.                                                                                                                                                                                                                                         |
| <code>scale</code>         | estimate(s) of the scale of the error. The first is based on the fit criterion. The second (not present for <code>method == "S"</code> ) is based on the variance of those residuals whose absolute value is less than 2.5 times the initial estimate. |

### Note

There seems no reason other than historical to use the `lms` and `lqs` options. LMS estimation is of low efficiency (converging at rate  $n^{-1/3}$ ) whereas LTS has the same asymptotic efficiency as an M estimator with trimming at the quartiles (Marazzi, 1993, p.201). LQS and LTS have the same maximal breakdown value of  $(\text{floor}((n-p)/2) + 1)/n$  attained if  $\text{floor}((n+p)/2) \leq \text{quantile} \leq \text{floor}((n+p+1)/2)$ . The only drawback mentioned of LTS is greater computation, as a sort was thought to be required (Marazzi, 1993, p.201) but this is not true as a partial sort can be used (and is used in this implementation).

Adjusting the intercept for each trial fit does need the residuals to be sorted, and may be significant extra computation if  $n$  is large and  $p$  small.

Opinions differ over the choice of `psamp`. Rousseeuw and Hubert (1997) only consider  $p$ ; Marazzi (1993) recommends  $p+1$  and suggests that more samples are better than adjustment for a given computational limit.

The computations are exact for a model with just an intercept and adjustment, and for LQS for a model with an intercept plus one regressor and exhaustive search with adjustment. For all other cases the minimization is only known to be approximate.

mca

---

## Multiple Correspondence Analysis

---

### Description

Computes a multiple correspondence analysis of a set of factors.

### Usage

```
mca(df, nf = 2, abbrev = FALSE)
```

### Arguments

|        |                                                                                                                                                                                                         |
|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| df     | A data frame containing only factors                                                                                                                                                                    |
| nf     | The number of dimensions for the MCA. Rarely 3 might be useful.                                                                                                                                         |
| abbrev | Should the vertex names be abbreviated? By default these are of the form ‘factor.level’ but if <code>abbrev = TRUE</code> they are just ‘level’ which will suffice if the factors have distinct levels. |

### Value

An object of class "mca", with components

|      |                                                                                            |
|------|--------------------------------------------------------------------------------------------|
| rs   | The coordinates of the rows, in <code>nf</code> dimensions.                                |
| cs   | The coordinates of the column vertices, one for each level of each factor.                 |
| fs   | Weights for each row, used to interpolate additional factors in <code>predict.mca</code> . |
| p    | The number of factors                                                                      |
| d    | The singular values for the <code>nf</code> dimensions.                                    |
| call | The matched call.                                                                          |

 binomial(link = probit), data = menarche)
```

michelson

*Michelson's Speed of Light Data***Description**

Measurements of the speed of light in air, made between 5th June and 2nd July, 1879. The data consists of five experiments, each consisting of 20 consecutive runs. The response is the speed of light in km/s, less 299000. The currently accepted value, on this scale of measurement, is 734.5.

**Usage**

michelson

**Format**

The data frame contains the following components:

`Expt` The experiment number, from 1 to 5.

`Run` The run number within each experiment.

`Speed` Speed-of-light measurement.

minn38

*Minnesota High School Graduates of 1938***Description**

The Minnesota high school graduates of 1938 were classified according to four factors, described below. The `minn38` data frame has 168 rows and 5 columns.

**Usage**

minn38

**Format**

This data frame contains the following columns:

`hs` high school rank: "L", "M" and "U" for lower, middle and upper third.

`phs` post high school status: Enrolled in college, ("C"), enrolled in non-collegiate school, ("N"), employed full-time, ("E") and other, ("O").

`fol` father's occupational level, (seven levels, "F1", "F2", ..., "F7").

`sex` sex: factor with levels "F" or "M".

`f` frequency.

`motors`*Accelerated Life Testing of Motorettes*

---

**Description**

The `motors` data frame has 40 rows and 3 columns. It describes an accelerated life test at each of four temperatures of 10 motorettes, and has rather discrete times.

**Usage**

```
motors
```

**Format**

This data frame contains the following columns:

`temp` the temperature (degrees C) of the test.

`time` the time in hours to failure or censoring at 8064 hours (= 336 days).

`cens` an indicator variable for death.

muscle

*Effect of Calcium Chloride on Muscle Contraction in Rat Hearts*

## Description

The purpose of this experiment was to assess the influence of calcium in solution on the contraction of heart muscle in rats. The left auricle of 21 rat hearts was isolated and on several occasions a constant-length strip of tissue was electrically stimulated and dipped into various concentrations of calcium chloride solution, after which the shortening of the strip was accurately measured as the response.

## Usage

```
muscle
```

## Format

This data frame contains the following columns:

Strip which heart muscle strip was used?

Conc concentration of calcium chloride solution, in multiples of 2.2 mM.

Length the change in length (shortening) of the strip, (allegedly) in mm.

(B <- coef(rats.nls1))

st <- list(alpha = B[2:22], beta = B[23], rho = B[1])
(rats.nls2 <- nls(log(Length) ~ alpha[Strip] + beta*rho^Conc,
 data = muscle, start = st))
IGNORE_RDIFF_END

Muscle <- with(muscle, {
Muscle <- expand.grid(Conc = sort(unique(Conc)), Strip = levels(Strip))
```

```

Muscle$Yhat <- predict(rats.nls2, Muscle)
Muscle <- cbind(Muscle, logLength = rep(as.numeric(NA), 126))
ind <- match(paste(Strip, Conc),
 paste(Muscle$Strip, Muscle$Conc))
Muscle$logLength[ind] <- log(Length)
Muscle))

lattice::xyplot(Yhat ~ Conc | Strip, Muscle, as.table = TRUE,
 ylim = range(c(Muscle$Yhat, Muscle$logLength), na.rm = TRUE),
 subscripts = TRUE, xlab = "Calcium Chloride concentration (mM)",
 ylab = "log(Length in mm)", panel =
 function(x, y, subscripts, ...) {
 panel.xyplot(x, Muscle$logLength[subscripts], ...)
 llines(spline(x, y))
 })

```

mvnorm

*Simulate from a Multivariate Normal Distribution***Description**

Produces one or more samples from the specified multivariate normal distribution.

**Usage**

```
mvnorm(n = 1, mu, Sigma, tol = 1e-6, empirical = FALSE, EISPACK = FALSE)
```

**Arguments**

|                        |                                                                                                                           |
|------------------------|---------------------------------------------------------------------------------------------------------------------------|
| <code>n</code>         | the number of samples required.                                                                                           |
| <code>mu</code>        | a vector giving the means of the variables.                                                                               |
| <code>Sigma</code>     | a positive-definite symmetric matrix specifying the covariance matrix of the variables.                                   |
| <code>tol</code>       | tolerance (relative to largest variance) for numerical lack of positive-definiteness in <code>Sigma</code> .              |
| <code>empirical</code> | logical. If true, <code>mu</code> and <code>Sigma</code> specify the empirical not population mean and covariance matrix. |
| <code>EISPACK</code>   | logical: values other than <code>FALSE</code> are an error.                                                               |

**Details**

The matrix decomposition is done via `eigen`; although a Choleski decomposition might be faster, the eigendecomposition is stabler.

**Value**

If `n = 1` a vector of the same length as `mu`, otherwise an `n` by `length(mu)` matrix with one sample in each row.

**Side Effects**

Causes creation of the dataset `.Random.seed` if it does not already exist, otherwise its value is updated.

negative.binomial    *Family function for Negative Binomial GLMs*

---

## Description

Specifies the information required to fit a Negative Binomial generalized linear model, with known `theta` parameter, using `glm()`.

## Usage

```
negative.binomial(theta = stop("'theta' must be specified"), link = "log")
```

## Arguments

|                    |                                                                                                                                                                                                                  |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>theta</code> | The known value of the additional parameter, <code>theta</code> .                                                                                                                                                |
| <code>link</code>  | The link function, as a character string, name or one-element character vector specifying one of <code>log</code> , <code>sqrt</code> or <code>identity</code> , or an object of class <code>"link-glm"</code> . |

## Value

An object of class `"family"`, a list of functions and expressions needed by `glm()` to fit a Negative Binomial generalized linear model.

## References

newcomb

*Newcomb's Measurements of the Passage Time of Light***Description**

A numeric vector giving the 'Third Series' of measurements of the passage time of light recorded by Newcomb in 1882. The given values divided by 1000 plus 24.8 give the time in millionths of a second for light to traverse a known distance. The 'true' value is now considered to be 33.02.

The dataset is given in the order in Staudte and Sheather. Stigler (1977, Table 5) gives the dataset as

```
28 26 33 24 34 -44 27 16 40 -2 29 22 24 21 25 30 23 29 31 19
24 20 36 32 36 28 25 21 28 29 37 25 28 26 30 32 36 26 30 22
36 23 27 27 28 27 31 27 26 33 26 32 32 24 39 28 24 25 32 25
29 27 28 29 16 23
```

However, order is not relevant to its use as an example of robust estimation. (Thanks to Anthony Unwin for bringing this difference to our attention.)

**Usage**

nlschools

*Eighth-Grade Pupils in the Netherlands***Description**

Snijders and Bosker (1999) use as a running example a study of 2287 eighth-grade pupils (aged about 11) in 132 classes in 131 schools in the Netherlands. Only the variables used in our examples are supplied.

**Usage**

nlschools

## Format

This data frame contains 2287 rows and the following columns:

lang language test score.

IQ verbal IQ.

class class ID.

GS class size: number of eighth-grade pupils recorded in the class (there may be others: see COMB, and some may have been omitted with missing values).

SES social-economic status of pupil's family.

COMB were the pupils taught in a multi-grade class (0/1)? Classes which contained pupils from grades 7 and 8 are coded 1, but only eighth-graders were tested.

npk

---

*Classical N, P, K Factorial Experiment*

---

## Description

A classical N, P, K (nitrogen, phosphate, potassium) factorial experiment on the growth of peas conducted on 6 blocks. Each half of a fractional factorial design confounding the NPK interaction was used on 3 of the plots.

## Usage

```
npk
```

**Format**

The npk data frame has 24 rows and 5 columns:

block which block (label 1 to 6).

N indicator (0/1) for the application of nitrogen.

P indicator (0/1) for the application of phosphate.

K indicator (0/1) for the application of potassium.

yield Yield of peas, in pounds/plot (the plots were (1/70) acre).

**Note**

This dataset is also contained in R 3.0.2 and later.

Null

Null Spaces of Matrices

---

**Description**

Given a matrix, `M`, find a matrix `N` giving a basis for the (left) null space. That is `crossprod(N, M) = t(N) %*% M` is an all-zero matrix and `N` has the maximum number of linearly independent columns.

**Usage**

```
Null(M)
```

**Arguments**

`M` Input matrix. A vector is coerced to a 1-column matrix.

**Details**

For a basis for the (right) null space  $\{x : Mx = 0\}$ , use `Null(t(M))`.

**Value**

The matrix `N` with the basis for the (left) null space, or a matrix with zero columns if the matrix `M` is square and of maximal rank.

**References**

oats

*Data from an Oats Field Trial*

## Description

The yield of oats from a split-plot field trial using three varieties and four levels of manurial treatment. The experiment was laid out in 6 blocks of 3 main plots, each split into 4 sub-plots. The varieties were applied to the main plots and the manurial treatments to the sub-plots.

## Usage

oats

## Format

This data frame contains the following columns:

B Blocks, levels I, II, III, IV, V and VI.

V Varieties, 3 levels.

N Nitrogen (manurial) treatment, levels 0.0cwt, 0.2cwt, 0.4cwt and 0.6cwt, showing the application in cwt/acre.

Y Yields in 1/4lbs per sub-plot, each of area 1/80 acre.

|     |                                                          |
|-----|----------------------------------------------------------|
| OME | <i>Tests of Auditory Perception in Children with OME</i> |
|-----|----------------------------------------------------------|

---

**Description**

Experiments were performed on children on their ability to differentiate a signal in broad-band noise. The noise was played from a pair of speakers and a signal was added to just one channel; the subject had to turn his/her head to the channel with the added signal. The signal was either coherent (the amplitude of the noise was increased for a period) or incoherent (independent noise was added for the same period to form the same increase in power).

The threshold used in the original analysis was the stimulus loudness needs to get 75% correct responses. Some of the children had suffered from otitis media with effusion (OME).

**Usage**

OME

**Format**

- The OME data frame has 1129 rows and 7 columns:
- ID Subject ID (1 to 99, with some IDs missing). A few subjects were measured at different ages.
- OME "low" or "high" or "N/A" (at ages other than 30 and 60 months).
- Age Age of the subject (months).
- Loud Loudness of stimulus, in decibels.
- Noise Whether the signal in the stimulus was "coherent" or "incoherent".
- Correct Number of correct responses from Trials trials.
- Trials Number of trials performed.

**Background**

The experiment was to study otitis media with effusion (OME), a very common childhood condition where the middle ear space, which is normally air-filled, becomes congested by a fluid. There is a concomitant fluctuating, conductive hearing loss which can result in various language, cognitive and social deficits. The term ‘binaural hearing’ is used to describe the listening conditions in which the brain is processing information from both ears at the same time. The brain computes differences in the intensity and/or timing of signals arriving at each ear which contributes to sound localisation and also to our ability to hear in background noise.

Some years ago, it was found that children of 7–8 years with a history of significant OME had significantly worse binaural hearing than children without such a history, despite having equivalent sensitivity. The question remained as to whether it was the timing, the duration, or the degree of

severity of the otitis media episodes during critical periods, which affected later binaural hearing. In an attempt to begin to answer this question, 95 children were monitored for the presence of effusion every month since birth. On the basis of OME experience in their first two years, the test population was split into one group of high OME prevalence and one of low prevalence.

```

**Description**

The subjective assessment, on a 0 to 20 integer scale, of 54 classical painters. The painters were assessed on four characteristics: composition, drawing, colour and expression. The data is due to the Eighteenth century art critic, de Piles.

**Usage**

```
painters
```

**Format**

The row names of the data frame are the painters. The components are:

Composition Composition score.

Drawing Drawing score.

Colour Colour score.

Expression Expression score.

School The school to which a painter belongs, as indicated by a factor level code as follows:  
 "A": Renaissance; "B": Mannerist; "C": Seicento; "D": Venetian; "E": Lombard; "F":  
 Sixteenth Century; "G": Seventeenth Century; "H": French.

pairs.lda
```

---

*Produce Pairwise Scatterplots from an 'lda' Fit*

---

**Description**

Pairwise scatterplot of the data on the linear discriminants.

**Usage**

```
S3 method for class 'lda'
pairs(x, labels = colnames(x), panel = panel.llda,
 dimen, abbrev = FALSE, ..., cex=0.7, type = c("std", "trellis"))
```

**Arguments**

|                     |                                                                                                                                                   |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>      | Object of class "lda".                                                                                                                            |
| <code>labels</code> | vector of character strings for labelling the variables.                                                                                          |
| <code>panel</code>  | panel function to plot the data in each panel.                                                                                                    |
| <code>dimen</code>  | The number of linear discriminants to be used for the plot; if this exceeds the number determined by <code>x</code> the smaller value is used.    |
| <code>abbrev</code> | whether the group labels are abbreviated on the plots. If <code>abbrev &gt; 0</code> this gives <code>minlength</code> in the call to abbreviate. |
| <code>...</code>    | additional arguments for <code>pairs.default</code> .                                                                                             |
| <code>cex</code>    | graphics parameter <code>cex</code> for labels on plots.                                                                                          |
| <code>type</code>   | type of plot. The default is in the style of <code>pairs.default</code> ; the style "trellis" uses the Trellis function <code>splom</code> .      |

**Details**

This function is a method for the generic function `pairs()` for class "lda". It can be invoked by calling `pairs(x)` for an object `x` of the appropriate class, or directly by calling `pairs.lda(x)` regardless of the class of the object.

parcoord

*Parallel Coordinates Plot*

---

**Description**

Parallel coordinates plot

**Usage**

```
parcoord(x, col = 1, lty = 1, var.label = FALSE, ...)
```

**Arguments**

|                        |                                                                                     |
|------------------------|-------------------------------------------------------------------------------------|
| <code>x</code>         | a matrix or data frame who columns represent variables. Missing values are allowed. |
| <code>col</code>       | A vector of colours, recycled as necessary for each observation.                    |
| <code>lty</code>       | A vector of line types, recycled as necessary for each observation.                 |
| <code>var.label</code> | If TRUE, each variable's axis is labelled with maximum and minimum values.          |
| <code>...</code>       | Further graphics parameters which are passed to <code>matplot</code> .              |

### Side Effects

a parallel coordinates plots is drawn.

### Author(s)

B. D. Ripley. Enhancements based on ideas and code by Fabian Scheipl.

### Examples

```
parcoord(state.x77[, c(7, 4, 6, 2, 5, 3)])

ir <- rbind(iris3[, , 1], iris3[, , 2], iris3[, , 3])
parcoord(log(ir)[, c(3, 4, 2, 1)], col = 1 + (0:149)%/%50)
```

---

petrol

*N. L. Prater's Petrol Refinery Data*

---

### Description

The yield of a petroleum refining process with four covariates. The crude oil appears to come from only 10 distinct samples.

These data were originally used by Prater (1956) to build an estimation equation for the yield of the refining process of crude oil to gasoline.

### Usage

```
petrol
```

### Format

The variables are as follows

No crude oil sample identification label. (Factor.)

SG specific gravity, degrees API. (Constant within sample.)

VP vapour pressure in pounds per square inch. (Constant within sample.)

V10 volatility of crude; ASTM 10% point. (Constant within sample.)

EP desired volatility of gasoline. (The end point. Varies within sample.)

Y yield as a percentage of crude.

### Source

Pima.tr

*Diabetes in Pima Indian Women*

---

## Description

A population of women who were at least 21 years old, of Pima Indian heritage and living near Phoenix, Arizona, was tested for diabetes according to World Health Organization criteria. The data were collected by the US National Institute of Diabetes and Digestive and Kidney Diseases. We used the 532 complete records after dropping the (mainly missing) data on serum insulin.

## Usage

```
Pima.tr
Pima.tr2
Pima.te
```

## Format

These data frames contains the following columns:

`npreg` number of pregnancies.  
`glu` plasma glucose concentration in an oral glucose tolerance test.  
`bp` diastolic blood pressure (mm Hg).  
`skin` triceps skin fold thickness (mm).  
`bmi` body mass index (weight in kg/(height in m)<sup>2</sup>).  
`ped` diabetes pedigree function.  
`age` age in years.  
`type` Yes or No, for diabetic according to WHO criteria.

## Details

The training set `Pima.tr` contains a randomly selected set of 200 subjects, and `Pima.te` contains the remaining 332 subjects. `Pima.tr2` contains `Pima.tr` plus 100 subjects with missing values in the explanatory variables.

plot.lda

---

*Plot Method for Class 'lda'*

---

## Description

Plots a set of data on one, two or more linear discriminants.

## Usage

```
S3 method for class 'lda'
plot(x, panel = panel.lda, ..., cex = 0.7, dimen,
 abbrev = FALSE, xlab = "LD1", ylab = "LD2")
```

## Arguments

|        |                                                                                                                                   |
|--------|-----------------------------------------------------------------------------------------------------------------------------------|
| x      | An object of class "lda".                                                                                                         |
| panel  | the panel function used to plot the data.                                                                                         |
| ...    | additional arguments to pairs, ldahist or eqscplot.                                                                               |
| cex    | graphics parameter cex for labels on plots.                                                                                       |
| dimen  | The number of linear discriminants to be used for the plot; if this exceeds the number determined by x the smaller value is used. |
| abbrev | whether the group labels are abbreviated on the plots. If abbrev > 0 this gives minlength in the call to abbreviate.              |
| xlab   | label for the x axis                                                                                                              |
| ylab   | label for the y axis                                                                                                              |

## Details

This function is a method for the generic function `plot()` for class "lda". It can be invoked by calling `plot(x)` for an object x of the appropriate class, or directly by calling `plot.lda(x)` regardless of the class of the object.

The behaviour is determined by the value of `dimen`. For `dimen > 2`, a `pairs` plot is used. For `dimen = 2`, an equiscaled scatter plot is drawn. For `dimen = 1`, a set of histograms or density plots are drawn. Use argument `type` to match "histogram" or "density" or "both".

S3 method for class 'profile'
plot(x, ...)
S3 method for class 'profile'
pairs(x, colours = 2:3, ...)
```

**Arguments**

|         |                                                                             |
|---------|-----------------------------------------------------------------------------|
| x       | an object inheriting from class "profile".                                  |
| colours | Colours to be used for the mean curves conditional on x and y respectively. |
| ...     | arguments passed to or from other methods.                                  |

## Details

This is the main `plot` method for objects created by `profile.glm`. It can also be called on objects created by `profile.nls`, but they have a specific method, `plot.profile.nls`.

The `pairs` method shows, for each pair of parameters  $x$  and  $y$ , two curves intersecting at the maximum likelihood estimate, which give the loci of the points at which the tangents to the contours of the bivariate profile likelihood become vertical and horizontal, respectively. In the case of an exactly bivariate normal profile likelihood, these two curves would be straight lines giving the conditional means of  $y|x$  and  $x|y$ , and the contours would be exactly elliptical.

## Author(s)

Originally, D. M. Bates and W. N. Venables. (For S in 1996.)

## See Also

`profile.glm`, `profile.nls`.

## Examples

```
see ?profile.glm for an example using glm fits.

a version of example(profile.nls) from R >= 2.8.0
fml <- nls(demand ~ SSasymptOrig(Time, A, lrc), data = BOD)
pr1 <- profile(fml, alpha = 0.1)
MASS::plot.profile(pr1)
pairs(pr1) # a little odd since the parameters are highly correlated

an example from ?nls
x <- -(1:100)/10
y <- 100 + 10 * exp(x / 2) + rnorm(x)/10
nlmod <- nls(y ~ Const + A * exp(B * x), start=list(Const=100, A=10, B=1))
pairs(profile(nlmod))
```

---

polr

*Ordered Logistic or Probit Regression*

---

## Description

Fits a logistic or probit regression model to an ordered factor response. The default logistic case is *proportional odds logistic regression*, after which the function is named.

## Usage

```
polr(formula, data, weights, start, ..., subset, na.action,
 contrasts = NULL, Hess = FALSE, model = TRUE,
 method = c("logistic", "probit", "loglog", "cloglog", "cauchit"))
```

## Arguments

|                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>formula</code>   | a formula expression as for regression models, of the form <code>response ~ predictors</code> . The response should be a factor (preferably an ordered factor), which will be interpreted as an ordinal response, with levels ordered as in the factor. The model must have an intercept: attempts to remove one will lead to a warning and be ignored. An offset may be used. See the documentation of <a href="#">formula</a> for other details. |
| <code>data</code>      | an optional data frame, list or environment in which to interpret the variables occurring in <code>formula</code> .                                                                                                                                                                                                                                                                                                                                |
| <code>weights</code>   | optional case weights in fitting. Default to 1.                                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>start</code>     | initial values for the parameters. This is in the format <code>c(coefficients, zeta)</code> : see the Values section.                                                                                                                                                                                                                                                                                                                              |
| <code>...</code>       | additional arguments to be passed to <a href="#">optim</a> , most often a <code>control</code> argument.                                                                                                                                                                                                                                                                                                                                           |
| <code>subset</code>    | expression saying which subset of the rows of the data should be used in the fit. All observations are included by default.                                                                                                                                                                                                                                                                                                                        |
| <code>na.action</code> | a function to filter missing data.                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <code>contrasts</code> | a list of contrasts to be used for some or all of the factors appearing as variables in the model formula.                                                                                                                                                                                                                                                                                                                                         |
| <code>Hess</code>      | logical for whether the Hessian (the observed information matrix) should be returned. Use this if you intend to call <code>summary</code> or <code>vcov</code> on the fit.                                                                                                                                                                                                                                                                         |
| <code>model</code>     | logical for whether the model matrix should be returned.                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>method</code>    | logistic or probit or (complementary) log-log or <code>cauchit</code> (corresponding to a Cauchy latent variable).                                                                                                                                                                                                                                                                                                                                 |

## Details

This model is what Agresti (2002) calls a *cumulative link* model. The basic interpretation is as a *coarsened* version of a latent variable  $Y_i$  which has a logistic or normal or extreme-value or Cauchy distribution with scale parameter one and a linear model for the mean. The ordered factor which is observed is which bin  $Y_i$  falls into with breakpoints

$$\zeta_0 = -\infty < \zeta_1 < \dots < \zeta_K = \infty$$

This leads to the model

$$\text{logit}P(Y \leq k|x) = \zeta_k - \eta$$

with *logit* replaced by *probit* for a normal latent variable, and  $\eta$  being the linear predictor, a linear function of the explanatory variables (with no intercept). Note that it is quite common for other software to use the opposite sign for  $\eta$  (and hence the coefficients `beta`).

In the logistic case, the left-hand side of the last display is the log odds of category  $k$  or less, and since these are log odds which differ only by a constant for different  $k$ , the odds are proportional. Hence the term *proportional odds logistic regression*.

The log-log and complementary log-log links are the increasing functions  $F^{-1}(p) = -\log(-\log(p))$  and  $F^{-1}(p) = \log(-\log(1 - p))$ ; some call the first the ‘negative log-log’ link. These correspond to a latent variable with the extreme-value distribution for the maximum and minimum respectively.

A *proportional hazards* model for grouped survival times can be obtained by using the complementary log-log link with grouping ordered by increasing times.

[predict](#), [summary](#), [vcov](#), [anova](#), [model.frame](#) and an `extractAIC` method for use with [stepAIC](#) (and [step](#)). There are also [profile](#) and [confint](#) methods.

**Value**

A object of class "polr". This has components

|                            |                                                                                                                                    |
|----------------------------|------------------------------------------------------------------------------------------------------------------------------------|
| <code>coefficients</code>  | the coefficients of the linear predictor, which has no intercept.                                                                  |
| <code>zeta</code>          | the intercepts for the class boundaries.                                                                                           |
| <code>deviance</code>      | the residual deviance.                                                                                                             |
| <code>fitted.values</code> | a matrix, with a column for each level of the response.                                                                            |
| <code>lev</code>           | the names of the response levels.                                                                                                  |
| <code>terms</code>         | the <code>terms</code> structure describing the model.                                                                             |
| <code>df.residual</code>   | the number of residual degrees of freedoms, calculated using the weights.                                                          |
| <code>edf</code>           | the (effective) number of degrees of freedom used by the model                                                                     |
| <code>n, nobs</code>       | the (effective) number of observations, calculated using the weights. ( <code>nobs</code> is for use by <a href="#">stepAIC</a> ). |
| <code>call</code>          | the matched call.                                                                                                                  |
| <code>method</code>        | the matched method used.                                                                                                           |
| <code>convergence</code>   | the convergence code returned by <code>optim</code> .                                                                              |
| <code>niter</code>         | the number of function and gradient evaluations used by <code>optim</code> .                                                       |
| <code>lp</code>            | the linear predictor (including any offset).                                                                                       |
| <code>Hessian</code>       | (if <code>Hess</code> is true). Note that this is a numerical approximation derived from the optimization proces.                  |
| <code>model</code>         | (if <code>model</code> is true).                                                                                                   |

**Note**

The [vcov](#) method uses the approximate Hessian: for reliable results the model matrix should be sensibly scaled with all columns having range the order of one.

Prior to version 7.3-32, `method = "cloglog"` confusingly gave the log-log link, implicitly assuming the first response level was the 'best'.

| predict.glmmPQL | <i>Predict Method for glmmPQL Fits</i> |
|-----------------|----------------------------------------|

---

## Description

Obtains predictions from a fitted generalized linear model with random effects.

## Usage

```
S3 method for class 'glmmPQL'
predict(object, newdata = NULL, type = c("link", "response"),
 level, na.action = na.pass, ...)
```

## Arguments

|                        |                                                                                                                                                                                                                                                                                                                                            |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code>    | a fitted object of class inheriting from "glmmPQL".                                                                                                                                                                                                                                                                                        |
| <code>newdata</code>   | optionally, a data frame in which to look for variables with which to predict.                                                                                                                                                                                                                                                             |
| <code>type</code>      | the type of prediction required. The default is on the scale of the linear predictors; the alternative "response" is on the scale of the response variable. Thus for a default binomial model the default predictions are of log-odds (probabilities on logit scale) and <code>type = "response"</code> gives the predicted probabilities. |
| <code>level</code>     | an optional integer vector giving the level(s) of grouping to be used in obtaining the predictions. Level values increase from outermost to innermost grouping, with level zero corresponding to the population predictions. Defaults to the highest or innermost level of grouping.                                                       |
| <code>na.action</code> | function determining what should be done with missing values in <code>newdata</code> . The default is to predict NA.                                                                                                                                                                                                                       |
| <code>...</code>       | further arguments passed to or from other methods.                                                                                                                                                                                                                                                                                         |

## Value

If `level` is a single integer, a vector otherwise a data frame.

## See Also

[glmmPQL](#), [predict.lme](#).

## Examples

```
fit <- glmmPQL(y ~ trt + I(week > 2), random = ~1 | ID,
 family = binomial, data = bacteria)
predict(fit, bacteria, level = 0, type="response")
predict(fit, bacteria, level = 1, type="response")
```

---

predict.lda

*Classify Multivariate Observations by Linear Discrimination*

---

## Description

Classify multivariate observations in conjunction with `lda`, and also project data onto the linear discriminants.

## Usage

```
S3 method for class 'lda'
predict(object, newdata, prior = object$prior, dimen,
 method = c("plug-in", "predictive", "debiased"), ...)
```

## Arguments

|                      |                                                                                                                                                                                                                                                                                                                                          |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code>  | object of class "lda"                                                                                                                                                                                                                                                                                                                    |
| <code>newdata</code> | data frame of cases to be classified or, if <code>object</code> has a formula, a data frame with columns of the same names as the variables used. A vector will be interpreted as a row vector. If <code>newdata</code> is missing, an attempt will be made to retrieve the data used to fit the <code>lda</code> object.                |
| <code>prior</code>   | The prior probabilities of the classes, by default the proportions in the training set or what was set in the call to <code>lda</code> .                                                                                                                                                                                                 |
| <code>dimen</code>   | the dimension of the space to be used. If this is less than <code>min(p, ng-1)</code> , only the first <code>dimen</code> discriminant components are used (except for <code>method="predictive"</code> ), and only those dimensions are returned in <code>x</code> .                                                                    |
| <code>method</code>  | This determines how the parameter estimation is handled. With "plug-in" (the default) the usual unbiased parameter estimates are used and assumed to be correct. With "debiased" an unbiased estimator of the log posterior probabilities is used, and with "predictive" the parameter estimates are integrated out using a vague prior. |
| <code>...</code>     | arguments based from or to other methods                                                                                                                                                                                                                                                                                                 |

## Details

This function is a method for the generic function `predict()` for class "lda". It can be invoked by calling `predict(x)` for an object `x` of the appropriate class, or directly by calling `predict.lda(x)` regardless of the class of the object.

Missing values in `newdata` are handled by returning `NA` if the linear discriminants cannot be evaluated. If `newdata` is omitted and the `na.action` of the fit omitted cases, these will be omitted on the prediction.

This version centres the linear discriminants so that the weighted mean (weighted by `prior`) of the group centroids is at the origin.

**Value**

a list with components

|           |                                                                             |
|-----------|-----------------------------------------------------------------------------|
| class     | The MAP classification (a factor)                                           |
| posterior | posterior probabilities for the classes                                     |
| x         | the scores of test cases on up to <code>dimen</code> discriminant variables |

|-------------|--------------------------------|
| predict.lqs | <i>Predict from an lqs Fit</i> |
|-------------|--------------------------------|

---

**Description**

Predict from an resistant regression fitted by `lqs`.

**Usage**

```
S3 method for class 'lqs'
predict(object, newdata, na.action = na.pass, ...)
```

**Arguments**

|           |                                                                                                                                                                                                                                                                                                                                    |
|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object    | object inheriting from class "lqs"                                                                                                                                                                                                                                                                                                 |
| newdata   | matrix or data frame of cases to be predicted or, if <code>object</code> has a formula, a data frame with columns of the same names as the variables used. A vector will be interpreted as a row vector. If <code>newdata</code> is missing, an attempt will be made to retrieve the data used to fit the <code>lqs</code> object. |
| na.action | function determining what should be done with missing values in <code>newdata</code> . The default is to predict NA.                                                                                                                                                                                                               |
| ...       | arguments to be passed from or to other methods.                                                                                                                                                                                                                                                                                   |

**Details**

This function is a method for the generic function `predict()` for class `lqs`. It can be invoked by calling `predict(x)` for an object `x` of the appropriate class, or directly by calling `predict.lqs(x)` regardless of the class of the object.

Missing values in `newdata` are handled by returning `NA` if the linear fit cannot be evaluated. If `newdata` is omitted and the `na.action` of the fit omitted cases, these will be omitted on the prediction.

predict.mca

*Predict Method for Class 'mca'*

---

**Description**

Used to compute coordinates for additional rows or additional factors in a multiple correspondence analysis.

**Usage**

```
S3 method for class 'mca'
predict(object, newdata, type = c("row", "factor"), ...)
```

**Arguments**

|                      |                                                                                                                                                                           |
|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code>  | An object of class <code>"mca"</code> , usually the result of a call to <code>mca</code> .                                                                                |
| <code>newdata</code> | A data frame containing <i>either</i> additional rows of the factors used to fit <code>object</code> <i>or</i> additional factors for the cases used in the original fit. |
| <code>type</code>    | Are predictions required for further rows or for new factors?                                                                                                             |
| <code>...</code>     | Additional arguments from <code>predict</code> : unused.                                                                                                                  |

**Value**

If `type = "row"`, the coordinates for the additional rows.

If `type = "factor"`, the coordinates of the column vertices for the levels of the new factors.

zq <- qda(train, cl)
predict(zq, test)$class
```

---

profile.glm

*Method for Profiling glm Objects*

---

**Description**

Investigates the profile log-likelihood function for a fitted model of class "glm".

**Usage**

```
S3 method for class 'glm'
profile(fitted, which = 1:p, alpha = 0.01, maxsteps = 10,
 del = zmax/5, trace = FALSE, ...)
```

**Arguments**

|          |                                                                                                                                             |
|----------|---------------------------------------------------------------------------------------------------------------------------------------------|
| fitted   | the original fitted model object.                                                                                                           |
| which    | the original model parameters which should be profiled. This can be a numeric or character vector. By default, all parameters are profiled. |
| alpha    | highest significance level allowed for the profile t-statistics.                                                                            |
| maxsteps | maximum number of points to be used for profiling each parameter.                                                                           |
| del      | suggested change on the scale of the profile t-statistics. Default value chosen to allow profiling at about 10 parameter values.            |
| trace    | logical: should the progress of profiling be reported?                                                                                      |
| ...      | further arguments passed to or from other methods.                                                                                          |

**Details**

The profile t-statistic is defined as the square root of change in sum-of-squares divided by residual standard error with an appropriate sign.

**Value**

A list of classes "profile.glm" and "profile" with an element for each parameter being profiled. The elements are data-frames with two variables

`par.vals`            a matrix of parameter values for each fitted model.  
`tau`                the profile t-statistics.

**Author(s)**

Originally, D. M. Bates and W. N. Venables. (For S in 1996.)

**Examples**

```
options(contrasts = c("contr.treatment", "contr.poly"))
ldose <- rep(0:5, 2)
numdead <- c(1, 4, 9, 13, 18, 20, 0, 2, 6, 10, 12, 16)
sex <- factor(rep(c("M", "F"), c(6, 6)))
SF <- cbind(numdead, numalive = 20 - numdead)
budworm.lg <- glm(SF ~ sex*ldose, family = binomial)
pr1 <- profile(budworm.lg)
plot(pr1)
pairs(pr1)
```

---

qda

---

*Quadratic Discriminant Analysis*

---

**Description**

Quadratic discriminant analysis.

**Usage**

```
qda(x, ...)

S3 method for class 'formula'
qda(formula, data, ..., subset, na.action)

Default S3 method:
qda(x, grouping, prior = proportions,
 method, CV = FALSE, nu, ...)

S3 method for class 'data.frame'
qda(x, ...)
```

```
S3 method for class 'matrix'
qda(x, grouping, ..., subset, na.action)
```

### Arguments

|                        |                                                                                                                                                                                                                                                                                         |
|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>formula</code>   | A formula of the form <code>groups ~ x1 + x2 + . . .</code> . That is, the response is the grouping factor and the right hand side specifies the (non-factor) discriminators.                                                                                                           |
| <code>data</code>      | An optional data frame, list or environment from which variables specified in <code>formula</code> are preferentially to be taken.                                                                                                                                                      |
| <code>x</code>         | (required if no formula is given as the principal argument.) a matrix or data frame or Matrix containing the explanatory variables.                                                                                                                                                     |
| <code>grouping</code>  | (required if no formula principal argument is given.) a factor specifying the class for each observation.                                                                                                                                                                               |
| <code>prior</code>     | the prior probabilities of class membership. If unspecified, the class proportions for the training set are used. If specified, the probabilities should be specified in the order of the factor levels.                                                                                |
| <code>subset</code>    | An index vector specifying the cases to be used in the training sample. (NOTE: If given, this argument must be named.)                                                                                                                                                                  |
| <code>na.action</code> | A function to specify the action to be taken if NAs are found. The default action is for the procedure to fail. An alternative is <code>na.omit</code> , which leads to rejection of cases with missing values on any required variable. (NOTE: If given, this argument must be named.) |
| <code>method</code>    | "moment" for standard estimators of the mean and variance, "mle" for MLEs, "mve" to use <code>cov.mve</code> , or "t" for robust estimates based on a t distribution.                                                                                                                   |
| <code>CV</code>        | If true, returns results (classes and posterior probabilities) for leave-out-out cross-validation. Note that if the prior is estimated, the proportions in the whole dataset are used.                                                                                                  |
| <code>nu</code>        | degrees of freedom for <code>method = "t"</code> .                                                                                                                                                                                                                                      |
| <code>...</code>       | arguments passed to or from other methods.                                                                                                                                                                                                                                              |

### Details

Uses a QR decomposition which will give an error message if the within-group variance is singular for any group.

### Value

an object of class "qda" containing the following components:

|                      |                                                                                                                                                             |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>prior</code>   | the prior probabilities used.                                                                                                                               |
| <code>means</code>   | the group means.                                                                                                                                            |
| <code>scaling</code> | for each group <code>i</code> , <code>scaling[, , i]</code> is an array which transforms observations so that within-groups covariance matrix is spherical. |
| <code>ldet</code>    | a vector of half log determinants of the dispersion matrix.                                                                                                 |
| <code>lev</code>     | the levels of the grouping factor.                                                                                                                          |
| <code>terms</code>   | (if formula is a formula) an object of mode expression and class term summarizing the formula.                                                              |

`call` the (matched) function call.

unless `CV=TRUE`, when the return value is a list with components:

`class` The MAP classification (a factor)  
`posterior` posterior probabilities for the classes

train <- rbind(iris3[tr,,1], iris3[tr,,2], iris3[tr,,3])
test <- rbind(iris3[-tr,,1], iris3[-tr,,2], iris3[-tr,,3])
cl <- factor(c(rep("s",25), rep("c",25), rep("v",25)))
z <- qda(train, cl)
predict(z, test)$class
```

---

quine

*Absenteeism from School in Rural New South Wales*

---

## Description

The quine data frame has 146 rows and 5 columns. Children from Walgett, New South Wales, Australia, were classified by Culture, Age, Sex and Learner status and the number of days absent from school in a particular school year was recorded.

## Usage

quine

## Format

This data frame contains the following columns:

`Eth` ethnic background: Aboriginal or Not, ("A" or "N").  
`Sex` sex: factor with levels ("F" or "M").  
`Age` age group: Primary ("F0"), or forms "F1", "F2" or "F3".  
`Lrn` learner status: factor with levels Average or Slow learner, ("AL" or "SL").  
`Days` days absent from school in the year.

Rabbit

*Blood Pressure in Rabbits*

---

## Description

Five rabbits were studied on two occasions, after treatment with saline (control) and after treatment with the  $5-HT_3$  antagonist MDL 72222. After each treatment ascending doses of phenylbiguanide were injected intravenously at 10 minute intervals and the responses of mean blood pressure measured. The goal was to test whether the cardiogenic chemoreflex elicited by phenylbiguanide depends on the activation of  $5-HT_3$  receptors.

## Usage

Rabbit

## Format

This data frame contains 60 rows and the following variables:

`BPchange` change in blood pressure relative to the start of the experiment.

`Dose` dose of Phenylbiguanide in micrograms.

`Run` label of run ("C1" to "C5", then "M1" to "M5").

`Treatment` placebo or the  $5-HT_3$  antagonist MDL 72222.

`Animal` label of animal used ("R1" to "R5").

---

rational*Rational Approximation*

---

### Description

Find rational approximations to the components of a real numeric object using a standard continued fraction method.

### Usage

```
rational(x, cycles = 10, max.denominator = 2000, ...)
```

### Arguments

|                              |                                                                                                                                             |
|------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>               | Any object of mode numeric. Missing values are now allowed.                                                                                 |
| <code>cycles</code>          | The maximum number of steps to be used in the continued fraction approximation process.                                                     |
| <code>max.denominator</code> | An early termination criterion. If any partial denominator exceeds <code>max.denominator</code> the continued fraction stops at that point. |
| <code>...</code>             | arguments passed to or from other methods.                                                                                                  |

### Details

Each component is first expanded in a continued fraction of the form

$$x = \text{floor}(x) + 1 / (p_1 + 1 / (p_2 + \dots))$$

where  $p_1, p_2, \dots$  are positive integers, terminating either at `cycles` terms or when a  $p_j > \text{max.denominator}$ . The continued fraction is then re-arranged to retrieve the numerator and denominator as integers and the ratio returned as the value.

### Value

A numeric object with the same attributes as `x` but with entries rational approximations to the values. This effectively rounds relative to the size of the object and replaces very small entries by zero.

### See Also

[fractions](#)

### Examples

```
X <- matrix(runif(25), 5, 5)
zapsmall(solve(X, X/5)) # print near-zeroes as zero
rational(solve(X, X/5))
```

---

renumerate

---

*Convert a Formula Transformed by 'denumerate'*

---

### Description

`denumerate` converts a formula written using the conventions of `loglm` into one that `terms` is able to process. `renumerate` converts it back again to a form like the original.

### Usage

```
renumerate(x)
```

### Arguments

`x`                      A formula, normally as modified by `denumerate`.

### Details

This is an inverse function to `denumerate`. It is only needed since `terms` returns an expanded form of the original formula where the non-marginal terms are exposed. This expanded form is mapped back into a form corresponding to the one that the user originally supplied.

### Value

A formula where all variables with names of the form `.vn`, where `n` is an integer, converted to numbers, `n`, as allowed by the formula conventions of `loglm`.

### See Also

`denumerate`

### Examples

```
denumerate(~(1+2+3)^3 + a/b)
~ (.v1 + .v2 + .v3)^3 + a/b
renumerate(.Last.value)
~ (1 + 2 + 3)^3 + a/b
```

---

rlm

---

*Robust Fitting of Linear Models*

---

### Description

Fit a linear model by robust regression using an M estimator.

**Usage**

```

rlm(x, ...)

S3 method for class 'formula'
rlm(formula, data, weights, ..., subset, na.action,
 method = c("M", "MM", "model.frame"),
 wt.method = c("inv.var", "case"),
 model = TRUE, x.ret = TRUE, y.ret = FALSE, contrasts = NULL)

Default S3 method:
rlm(x, y, weights, ..., w = rep(1, nrow(x)),
 init = "ls", psi = psi.huber,
 scale.est = c("MAD", "Huber", "proposal 2"), k2 = 1.345,
 method = c("M", "MM"), wt.method = c("inv.var", "case"),
 maxit = 20, acc = 1e-4, test.vec = "resid", lqs.control = NULL)

psi.huber(u, k = 1.345, deriv = 0)
psi.hampel(u, a = 2, b = 4, c = 8, deriv = 0)
psi.bisquare(u, c = 4.685, deriv = 0)

```

**Arguments**

|                        |                                                                                                                                                                                                                                                                                                                                                             |
|------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>formula</code>   | a formula of the form $y \sim x_1 + x_2 + \dots$                                                                                                                                                                                                                                                                                                            |
| <code>data</code>      | an optional data frame, list or environment from which variables specified in <code>formula</code> are preferentially to be taken.                                                                                                                                                                                                                          |
| <code>weights</code>   | a vector of prior weights for each case.                                                                                                                                                                                                                                                                                                                    |
| <code>subset</code>    | An index vector specifying the cases to be used in fitting.                                                                                                                                                                                                                                                                                                 |
| <code>na.action</code> | A function to specify the action to be taken if NAs are found. The ‘factory-fresh’ default action in R is <code>na.omit</code> , and can be changed by <code>options(na.action=)</code> .                                                                                                                                                                   |
| <code>x</code>         | a matrix or data frame containing the explanatory variables.                                                                                                                                                                                                                                                                                                |
| <code>y</code>         | the response: a vector of length the number of rows of <code>x</code> .                                                                                                                                                                                                                                                                                     |
| <code>method</code>    | currently either M-estimation or MM-estimation or (for the <code>formula</code> method only) find the model frame. MM-estimation is M-estimation with Tukey’s bi-weight initialized by a specific S-estimator. See the ‘Details’ section.                                                                                                                   |
| <code>wt.method</code> | are the weights case weights (giving the relative importance of case, so a weight of 2 means there are two of these) or the inverse of the variances, so a weight of two means this error is half as variable?                                                                                                                                              |
| <code>model</code>     | should the model frame be returned in the object?                                                                                                                                                                                                                                                                                                           |
| <code>x.ret</code>     | should the model matrix be returned in the object?                                                                                                                                                                                                                                                                                                          |
| <code>y.ret</code>     | should the response be returned in the object?                                                                                                                                                                                                                                                                                                              |
| <code>contrasts</code> | optional contrast specifications: see <code>lm</code> .                                                                                                                                                                                                                                                                                                     |
| <code>w</code>         | (optional) initial down-weighting for each case.                                                                                                                                                                                                                                                                                                            |
| <code>init</code>      | (optional) initial values for the coefficients OR a method to find initial values OR the result of a fit with a <code>coef</code> component. Known methods are <code>"ls"</code> (the default) for an initial least-squares fit using weights <code>w*weights</code> , and <code>"lts"</code> for an unweighted least-trimmed squares fit with 200 samples. |

|                          |                                                                                                                                                                                                                                                                                                                       |
|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>psi</code>         | the <code>psi</code> function is specified by this argument. It must give (possibly by name) a function <code>g(x, ..., deriv)</code> that for <code>deriv=0</code> returns <code>psi(x)/x</code> and for <code>deriv=1</code> returns <code>psi'(x)</code> . Tuning constants will be passed in via <code>...</code> |
| <code>scale.est</code>   | method of scale estimation: re-scaled MAD of the residuals (default) or Huber's proposal 2 (which can be selected by either <code>"Huber"</code> or <code>"proposal 2"</code> ).                                                                                                                                      |
| <code>k2</code>          | tuning constant used for Huber proposal 2 scale estimation.                                                                                                                                                                                                                                                           |
| <code>maxit</code>       | the limit on the number of IWLS iterations.                                                                                                                                                                                                                                                                           |
| <code>acc</code>         | the accuracy for the stopping criterion.                                                                                                                                                                                                                                                                              |
| <code>test.vec</code>    | the stopping criterion is based on changes in this vector.                                                                                                                                                                                                                                                            |
| <code>...</code>         | additional arguments to be passed to <code>rlm.default</code> or to the <code>psi</code> function.                                                                                                                                                                                                                    |
| <code>lqs.control</code> | An optional list of control values for <code>lqs</code> .                                                                                                                                                                                                                                                             |
| <code>u</code>           | numeric vector of evaluation points.                                                                                                                                                                                                                                                                                  |
| <code>k, a, b, c</code>  | tuning constants.                                                                                                                                                                                                                                                                                                     |
| <code>deriv</code>       | 0 or 1: compute values of the <code>psi</code> function or of its first derivative.                                                                                                                                                                                                                                   |

### Details

Fitting is done by iterated re-weighted least squares (IWLS).

`Psi` functions are supplied for the Huber, Hampel and Tukey bisquare proposals as `psi.huber`, `psi.hampel` and `psi.bisquare`. Huber's corresponds to a convex optimization problem and gives a unique solution (up to collinearity). The other two will have multiple local minima, and a good starting point is desirable.

Selecting `method = "MM"` selects a specific set of options which ensures that the estimator has a high breakdown point. The initial set of coefficients and the final scale are selected by an S-estimator with  $k_0 = 1.548$ ; this gives (for  $n \gg p$ ) breakdown point 0.5. The final estimator is an M-estimator with Tukey's biweight and fixed scale that will inherit this breakdown point provided  $c > k_0$ ; this is true for the default value of  $c$  that corresponds to 95% relative efficiency at the normal. Case weights are not supported for `method = "MM"`.

### Value

An object of class `"rlm"` inheriting from `"lm"`. Note that the `df.residual` component is deliberately set to NA to avoid inappropriate estimation of the residual scale from the residual mean square by `"lm"` methods.

The additional components not in an `lm` object are

|                        |                                                                       |
|------------------------|-----------------------------------------------------------------------|
| <code>s</code>         | the robust scale estimate used                                        |
| <code>w</code>         | the weights used in the IWLS process                                  |
| <code>psi</code>       | the <code>psi</code> function with parameters substituted             |
| <code>conv</code>      | the convergence criteria at each iteration                            |
| <code>converged</code> | did the IWLS converge?                                                |
| <code>wresid</code>    | a working residual, weighted for <code>"inv.var"</code> weights only. |

### Note

Prior to version 7.3-52, offset terms in `formula` were omitted from fitted and predicted values.

rms.curv

*Relative Curvature Measures for Non-Linear Regression*

---

## Description

Calculates the root mean square parameter effects and intrinsic relative curvatures,  $c^\theta$  and  $c^t$ , for a fitted nonlinear regression, as defined in Bates & Watts, section 7.3, p. 253ff

## Usage

```
rms.curv(obj)
```

## Arguments

|     |                                                                                           |
|-----|-------------------------------------------------------------------------------------------|
| obj | Fitted model object of class "nls". The model must be fitted using the default algorithm. |
|-----|-------------------------------------------------------------------------------------------|

## Details

The method of section 7.3.1 of Bates & Watts is implemented. The function `deriv3` should be used generate a model function with first derivative (gradient) matrix and second derivative (Hessian) array attributes. This function should then be used to fit the nonlinear regression model.

A print method, `print.rms.curv`, prints the `pc` and `ic` components only, suitably annotated.

If either `pc` or `ic` exceeds some threshold (0.3 has been suggested) the curvature is unacceptably high for the planar assumption.

## Value

A list of class `rms.curv` with components `pc` and `ic` for parameter effects and intrinsic relative curvatures multiplied by  $\sqrt{F}$ , `ct` and `ci` for  $c^\theta$  and  $c^t$  (unmultiplied), and `C` the C-array as used in section 7.3.1 of Bates & Watts.

(Purfit1 <- nls(rate ~ mmcurve(Vm, K, conc), data = Treated,
 start = list(Vm=200, K=0.1)))
rms.curv(Purfit1)
##Parameter effects: c^theta x sqrt(F) = 0.2121
Intrinsic: c^iota x sqrt(F) = 0.092
```

---

rnegbin

---

*Simulate Negative Binomial Variates*

---

## Description

Function to generate random outcomes from a Negative Binomial distribution, with mean  $\mu$  and variance  $\mu + \mu^2/\theta$ .

## Usage

```
rnegbin(n, mu = n, theta = stop("'theta' must be specified"))
```

## Arguments

|       |                                                                                                                                                                                                  |
|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| n     | If a scalar, the number of sample values required. If a vector, <code>length(n)</code> is the number required and <code>n</code> is used as the mean vector if <code>mu</code> is not specified. |
| mu    | The vector of means. Short vectors are recycled.                                                                                                                                                 |
| theta | Vector of values of the <code>theta</code> parameter. Short vectors are recycled.                                                                                                                |

## Details

The function uses the representation of the Negative Binomial distribution as a continuous mixture of Poisson distributions with Gamma distributed means. Unlike `rnbinom` the index can be arbitrary.

## Value

Vector of random Negative Binomial variate values.

## Side Effects

Changes `.Random.seed` in the usual way.

**Examples**

```
Negative Binomials with means fitted(fm) and theta = 4.5
fm <- glm.nb(Days ~ ., data = quine)
dummy <- rnegbin(fitted(fm), theta = 4.5)
```

---

|------|------------------------------------------|
| road | <i>Road Accident Deaths in US States</i> |
|------|------------------------------------------|

---

**Description**

A data frame with the annual deaths in road accidents for half the US states.

**Usage**

```
road
```

**Format**

Columns are:

state name.

deaths number of deaths.

drivers number of drivers (in 10,000s).

popden population density in people per square mile.

rural length of rural roads, in 1000s of miles.

temp average daily maximum temperature in January.

fuel fuel consumption in 10,000,000 US gallons per year.

|---------|---------------------------------------------|
| rotifer | <i>Numbers of Rotifers by Fluid Density</i> |
|---------|---------------------------------------------|

---

**Description**

The data give the numbers of rotifers falling out of suspension for different fluid densities. There are two species, `pm` *Polyartha major* and `kc`, *Keratella cochlearis* and for each species the number falling out and the total number are given.

**Usage**

```
rotifer
```

**Format**

density specific density of fluid.  
 pm.y number falling out for *P. major*.  
 pm.total total number of *P. major*.  
 kc.y number falling out for *K. cochlearis*.  
 kc.tot total number of *K. cochlearis*.

sammon

---

*Sammon's Non-Linear Mapping*

---

**Description**

One form of non-metric multidimensional scaling.

**Usage**

```

sammon(d, y = cmdscale(d, k), k = 2, niter = 100, trace = TRUE,
 magic = 0.2, tol = 1e-4)

```

**Arguments**

|       |                                                                                                                                                                                                                                             |
|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| d     | distance structure of the form returned by <code>dist</code> , or a full, symmetric matrix. Data are assumed to be dissimilarities or relative distances, but must be positive except for self-distance. This can contain missing values.   |
| y     | An initial configuration. If none is supplied, <code>cmdscale</code> is used to provide the classical solution. (If there are missing values in <code>d</code> , an initial configuration must be provided.) This must not have duplicates. |
| k     | The dimension of the configuration.                                                                                                                                                                                                         |
| niter | The maximum number of iterations.                                                                                                                                                                                                           |
| trace | Logical for tracing optimization. Default <code>TRUE</code> .                                                                                                                                                                               |
| magic | initial value of the step size constant in diagonal Newton method.                                                                                                                                                                          |
| tol   | Tolerance for stopping, in units of stress.                                                                                                                                                                                                 |

**Details**

This chooses a two-dimensional configuration to minimize the stress, the sum of squared differences between the input distances and those of the configuration, weighted by the distances, the whole sum being divided by the sum of input distances to make the stress scale-free.

An iterative algorithm is used, which will usually converge in around 50 iterations. As this is necessarily an  $O(n^2)$  calculation, it is slow for large datasets. Further, since the configuration is only determined up to rotations and reflections (by convention the centroid is at the origin), the result can vary considerably from machine to machine. In this release the algorithm has been modified by adding a step-length search (`magic`) to ensure that it always goes downhill.

**Value**

Two components:

|        |                                                  |
|--------|--------------------------------------------------|
| points | A two-column vector of the fitted configuration. |
| stress | The final stress achieved.                       |

**Side Effects**

If `trace` is true, the initial stress and the current stress are printed out every 10 iterations.

ships

*Ships Damage Data*

---

## Description

Data frame giving the number of damage incidents and aggregate months of service by ship type, year of construction, and period of operation.

## Usage

```
ships
```

## Format

`type` type: "A" to "E".

`year` year of construction: 1960–64, 65–69, 70–74, 75–79 (coded as "60", "65", "70", "75").

`period` period of operation : 1960–74, 75–79.

`service` aggregate months of service.

`incidents` number of damage incidents.

shuttle

*Space Shuttle Autolander Problem*

---

### Description

The `shuttle` data frame has 256 rows and 7 columns. The first six columns are categorical variables giving example conditions; the seventh is the decision. The first 253 rows are the training set, the last 3 the test conditions.

### Usage

```
shuttle
```

### Format

This data frame contains the following factor columns:

`stability` stable positioning or not (`stab` / `xstab`).

`error` size of error (`MM` / `SS` / `LX` / `XL`).

`sign` sign of error, positive or negative (`pp` / `nn`).

`wind` wind sign (`head` / `tail`).

`magn` wind strength (`Light` / `Medium` / `Strong` / `Out of Range`).

`vis` visibility (`yes` / `no`).

`use` use the autolander or not. (`auto` / `noauto`.)

snails

*Snail Mortality Data*

### Description

Groups of 20 snails were held for periods of 1, 2, 3 or 4 weeks in carefully controlled conditions of temperature and relative humidity. There were two species of snail, A and B, and the experiment was designed as a 4 by 3 by 4 by 2 completely randomized design. At the end of the exposure time the snails were tested to see if they had survived; the process itself is fatal for the animals. The object of the exercise was to model the probability of survival in terms of the stimulus variables, and in particular to test for differences between species.

The data are unusual in that in most cases fatalities during the experiment were fairly small.

### Usage

```
snails
```

### Format

The data frame contains the following components:

Species snail species A (1) or B (2).

Exposure exposure in weeks.

Rel.Hum relative humidity (4 levels).

Temp temperature, in degrees Celsius (3 levels).

Deaths number of deaths.

N number of snails exposed.

---

 stepAIC
 

---

---

*Choose a model by AIC in a Stepwise Algorithm*

---

**Description**

Performs stepwise model selection by AIC.

**Usage**

```
stepAIC(object, scope, scale = 0,
 direction = c("both", "backward", "forward"),
 trace = 1, keep = NULL, steps = 1000, use.start = FALSE,
 k = 2, ...)
```

**Arguments**

object an object representing a model of an appropriate class. This is used as the initial model in the stepwise search.

scope defines the range of models examined in the stepwise search. This should be either a single formula, or a list containing components upper and lower, both formulae. See the details for how to specify the formulae and how they are used.

|           |                                                                                                                                                                                                                                                                |
|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| scale     | used in the definition of the AIC statistic for selecting the models, currently only for <code>lm</code> and <code>aoV</code> models (see <code>extractAIC</code> for details).                                                                                |
| direction | the mode of stepwise search, can be one of "both", "backward", or "forward", with a default of "both". If the <code>scope</code> argument is missing the default for <code>direction</code> is "backward".                                                     |
| trace     | if positive, information is printed during the running of <code>stepAIC</code> . Larger values may give more information on the fitting process.                                                                                                               |
| keep      | a filter function whose input is a fitted model object and the associated AIC statistic, and whose output is arbitrary. Typically <code>keep</code> will select a subset of the components of the object and return them. The default is not to keep anything. |
| steps     | the maximum number of steps to be considered. The default is 1000 (essentially as many as required). It is typically used to stop the process early.                                                                                                           |
| use.start | if true the updated fits are done starting at the linear predictor for the currently selected model. This may speed up the iterative calculations for <code>glm</code> (and other fits), but it can also slow them down. <b>Not used in R.</b>                 |
| k         | the multiple of the number of degrees of freedom used for the penalty. Only $k = 2$ gives the genuine AIC: $k = \log(n)$ is sometimes referred to as BIC or SBC.                                                                                               |
| ...       | any additional arguments to <code>extractAIC</code> . (None are currently used.)                                                                                                                                                                               |

### Details

The set of models searched is determined by the `scope` argument. The right-hand-side of its `lower` component is always included in the model, and right-hand-side of the model is included in the upper component. If `scope` is a single formula, it specifies the upper component, and the lower model is empty. If `scope` is missing, the initial model is used as the upper model.

Models specified by `scope` can be templates to update `object` as used by `update.formula`.

There is a potential problem in using `glm` fits with a variable `scale`, as in that case the deviance is not simply related to the maximized log-likelihood. The `glm` method for `extractAIC` makes the appropriate adjustment for a gaussian family, but may need to be amended for other cases. (The `binomial` and `poisson` families have fixed `scale` by default and do not correspond to a particular maximum-likelihood problem for variable `scale`.)

Where a conventional deviance exists (e.g. for `lm`, `aoV` and `glm` fits) this is quoted in the analysis of variance table: it is the *unscaled* deviance.

### Value

the stepwise-selected model is returned, with up to two additional components. There is an "anova" component corresponding to the steps taken in the search, as well as a "keep" component if the `keep=` argument was supplied in the call. The "Resid. Dev" column of the analysis of deviance table refers to a constant minus twice the maximized log likelihood: it will be a deviance only in cases where a saturated model is well-defined (thus excluding `lm`, `aoV` and `survreg` fits, for example).

### Note

The model fitting must apply the models to the same dataset. This may be a problem if there are missing values and an `na.action` other than `na.fail` is used (as is the default in R). We suggest you remove the missing values first.

```

---

stormer

*The Stormer Viscometer Data*

---

## Description

The stormer viscometer measures the viscosity of a fluid by measuring the time taken for an inner cylinder in the mechanism to perform a fixed number of revolutions in response to an actuating weight. The viscometer is calibrated by measuring the time taken with varying weights while the mechanism is suspended in fluids of accurately known viscosity. The data comes from such a calibration, and theoretical considerations suggest a nonlinear relationship between time, weight and viscosity, of the form  $\text{Time} = (B1 \cdot \text{Viscosity}) / (\text{Weight} - B2) + E$  where  $B1$  and  $B2$  are unknown parameters to be estimated, and  $E$  is error.

## Usage

stormer

**Format**

The data frame contains the following components:

Viscosity viscosity of fluid.

Wt actuating weight.

Time time taken.

**Source**

E. J. Williams (1959) *Regression Analysis*. Wiley.

**References**

Venables, W. N. and Ripley, B. D. (2002) *Modern Applied Statistics with S*. Fourth edition. Springer.

---

studres

*Extract Studentized Residuals from a Linear Model*

---

**Description**

The Studentized residuals. Like standardized residuals, these are normalized to unit variance, but the Studentized version is fitted ignoring the current data point. (They are sometimes called jack-knifed residuals).

**Usage**

```
studres(object)
```

**Arguments**

object            any object representing a linear model.

**Value**

The vector of appropriately transformed residuals.

**References**

summary.loglm

*Summary Method Function for Objects of Class 'loglm'***Description**

Returns a summary list for log-linear models fitted by iterative proportional scaling using `loglm`.

**Usage**

```
S3 method for class 'loglm'
summary(object, fitted = FALSE, ...)
```

**Arguments**

|                     |                                                                                                                                                      |
|---------------------|------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code> | a fitted <code>loglm</code> model object.                                                                                                            |
| <code>fitted</code> | if <code>TRUE</code> return observed and expected frequencies in the result. Using <code>fitted = TRUE</code> may necessitate re-fitting the object. |
| <code>...</code>    | arguments to be passed to or from other methods.                                                                                                     |

**Details**

This function is a method for the generic function `summary()` for class `"loglm"`. It can be invoked by calling `summary(x)` for an object `x` of the appropriate class, or directly by calling `summary.loglm(x)` regardless of the class of the object.

**Value**

a list is returned for use by `print.summary.loglm`. This has components

|                      |                                                                                                                  |
|----------------------|------------------------------------------------------------------------------------------------------------------|
| <code>formula</code> | the formula used to produce <code>object</code>                                                                  |
| <code>tests</code>   | the table of test statistics (likelihood ratio, Pearson) for the fit.                                            |
| <code>oe</code>      | if <code>fitted = TRUE</code> , an array of the observed and expected frequencies, otherwise <code>NULL</code> . |

|                |                                                              |
|----------------|--------------------------------------------------------------|
| summary.negbin | <i>Summary Method Function for Objects of Class 'negbin'</i> |
|----------------|--------------------------------------------------------------|

---

## Description

Identical to `summary.glm`, but with three lines of additional output: the ML estimate of theta, its standard error, and twice the log-likelihood function.

## Usage

```
S3 method for class 'negbin'
summary(object, dispersion = 1, correlation = FALSE, ...)
```

## Arguments

|                          |                                                                                                                                                       |
|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code>      | fitted model object of class <code>negbin</code> inheriting from <code>glm</code> and <code>lm</code> . Typically the output of <code>glm.nb</code> . |
| <code>dispersion</code>  | as for <code>summary.glm</code> , with a default of 1.                                                                                                |
| <code>correlation</code> | as for <code>summary.glm</code> .                                                                                                                     |
| <code>...</code>         | arguments passed to or from other methods.                                                                                                            |

## Details

`summary.glm` is used to produce the majority of the output and supply the result. This function is a method for the generic function `summary()` for class "negbin". It can be invoked by calling `summary(x)` for an object `x` of the appropriate class, or directly by calling `summary.negbin(x)` regardless of the class of the object.

## Value

As for `summary.glm`; the additional lines of output are not included in the resultant object.

## Side Effects

A summary table is produced as for `summary.glm`, with the additional information described above.

## References

summary.rlm

*Summary Method for Robust Linear Models***Description**

summary method for objects of class "rlm"

**Usage**

```
S3 method for class 'rlm'
summary(object, method = c("XtX", "XtWX"), correlation = FALSE, ...)
```

**Arguments**

|             |                                                                                                                                                                                                                                   |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object      | the fitted model. This is assumed to be the result of some fit that produces an object inheriting from the class <code>rlm</code> , in the sense that the components returned by the <code>rlm</code> function will be available. |
| method      | Should the weighted (by the IWLS weights) or unweighted cross-products matrix be used?                                                                                                                                            |
| correlation | logical. Should correlations be computed (and printed)?                                                                                                                                                                           |
| ...         | arguments passed to or from other methods.                                                                                                                                                                                        |

**Details**

This function is a method for the generic function `summary()` for class "rlm". It can be invoked by calling `summary(x)` for an object `x` of the appropriate class, or directly by calling `summary.rlm(x)` regardless of the class of the object.

**Value**

If printing takes place, only a null value is returned. Otherwise, a list is returned with the following components. Printing always takes place if this function is invoked automatically as a method for the `summary` function.

|              |                                                                                                                                                                           |
|--------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| correlation  | The computed correlation coefficient matrix for the coefficients in the model.                                                                                            |
| cov.unscaled | The unscaled covariance matrix; i.e, a matrix such that multiplying it by an estimate of the error variance produces an estimated covariance matrix for the coefficients. |
| sigma        | The scale estimate.                                                                                                                                                       |
| stddev       | A scale estimate used for the standard errors.                                                                                                                            |
| df           | The number of degrees of freedom for the model and for residuals.                                                                                                         |
| coefficients | A matrix with three columns, containing the coefficients, their standard errors and the corresponding t statistic.                                                        |
| terms        | The terms object used in fitting this model.                                                                                                                              |

survey

*Student Survey Data*

---

**Description**

This data frame contains the responses of 237 Statistics I students at the University of Adelaide to a number of questions.

**Usage**

```
survey
```

**Format**

The components of the data frame are:

Sex The sex of the student. (Factor with levels "Male" and "Female".)

Wr.Hnd span (distance from tip of thumb to tip of little finger of spread hand) of writing hand, in centimetres.

NW.Hnd span of non-writing hand.

W.Hnd writing hand of student. (Factor, with levels "Left" and "Right".)

Fold "Fold your arms! Which is on top" (Factor, with levels "R on L", "L on R", "Neither".)

Pulse pulse rate of student (beats per minute).

Clap 'Clap your hands! Which hand is on top?' (Factor, with levels "Right", "Left", "Neither".)

Exer how often the student exercises. (Factor, with levels "Freq" (frequently), "Some", "None".)

Smoke how much the student smokes. (Factor, levels "Heavy", "Regul" (regularly), "Occas" (occasionally), "Never".)

Height height of the student in centimetres.

M.I whether the student expressed height in imperial (feet/inches) or metric (centimetres/metres) units. (Factor, levels "Metric", "Imperial".)

Age age of the student in years.

synth.tr

*Synthetic Classification Problem***Description**

The `synth.tr` data frame has 250 rows and 3 columns. The `synth.te` data frame has 100 rows and 3 columns. It is intended that `synth.tr` be used from training and `synth.te` for testing.

**Usage**

```
synth.tr
synth.te
```

**Format**

These data frames contains the following columns:

```
xs x-coordinate
ys y-coordinate
yc class, coded as 0 or 1.
```

**Source**

theta.md

*Estimate theta of the Negative Binomial***Description**

Given the estimated mean vector, estimate `theta` of the Negative Binomial Distribution.

**Usage**

```
theta.md(y, mu, dfr, weights, limit = 20, eps = .Machine$double.eps^0.25)

theta.ml(y, mu, n, weights, limit = 10, eps = .Machine$double.eps^0.25,
 trace = FALSE)

theta.mm(y, mu, dfr, weights, limit = 10, eps = .Machine$double.eps^0.25)
```

## Arguments

|                      |                                                                                                                                                           |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>y</code>       | Vector of observed values from the Negative Binomial.                                                                                                     |
| <code>mu</code>      | Estimated mean vector.                                                                                                                                    |
| <code>n</code>       | Number of data points (defaults to the sum of <code>weights</code> )                                                                                      |
| <code>dfr</code>     | Residual degrees of freedom (assuming <code>theta</code> known). For a weighted fit this is the sum of the weights minus the number of fitted parameters. |
| <code>weights</code> | Case weights. If missing, taken as 1.                                                                                                                     |
| <code>limit</code>   | Limit on the number of iterations.                                                                                                                        |
| <code>eps</code>     | Tolerance to determine convergence.                                                                                                                       |
| <code>trace</code>   | logical: should iteration progress be printed?                                                                                                            |

## Details

`theta.md` estimates by equating the deviance to the residual degrees of freedom, an analogue of a moment estimator.

`theta.ml` uses maximum likelihood.

`theta.mm` calculates the moment estimator of `theta` by equating the Pearson chi-square  $\sum (y - \mu)^2 / (\mu + \mu^2 / \theta)$  to the residual degrees of freedom.

## Value

The required estimate of `theta`, as a scalar. For `theta.ml`, the standard error is given as attribute "SE".

Traffic

*Effect of Swedish Speed Limits on Accidents*

---

### Description

An experiment was performed in Sweden in 1961–2 to assess the effect of a speed limit on the motorway accident rate. The experiment was conducted on 92 days in each year, matched so that day `j` in 1962 was comparable to day `j` in 1961. On some days the speed limit was in effect and enforced, while on other days there was no speed limit and cars tended to be driven faster. The speed limit days tended to be in contiguous blocks.

### Usage

```
Traffic
```

### Format

This data frame contains the following columns:

`year` 1961 or 1962.

`day` of year.

`limit` was there a speed limit?

`y` traffic accident count for that day.

|----------|-------------------------|
| truehist | <i>Plot a Histogram</i> |
|----------|-------------------------|

---

## Description

Creates a histogram on the current graphics device.

## Usage

```
truehist(data, nbins = "Scott", h, x0 = -h/1000,
 breaks, prob = TRUE, xlim = range(breaks),
 ymax = max(est), col = "cyan",
 xlab = deparse(substitute(data)), bty = "n", ...)
```

## Arguments

|        |                                                                                                                                                                                                                                                                                                                                                                            |
|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| data   | numeric vector of data for histogram. Missing values (NAs) are allowed and omitted.                                                                                                                                                                                                                                                                                        |
| nbins  | The suggested number of bins. Either a positive integer, or a character string naming a rule: "Scott" or "Freedman-Diaconis" or "FD". (Case is ignored.)                                                                                                                                                                                                                   |
| h      | The bin width, a strictly positive number (takes precedence over nbins).                                                                                                                                                                                                                                                                                                   |
| x0     | Shift for the bins - the breaks are at $x_0 + h * (\dots, -1, 0, 1, \dots)$                                                                                                                                                                                                                                                                                                |
| breaks | The set of breakpoints to be used. (Usually omitted, takes precedence over h and nbins).                                                                                                                                                                                                                                                                                   |
| prob   | If true (the default) plot a true histogram. The vertical axis has a <i>relative frequency density</i> scale, so the product of the dimensions of any panel gives the relative frequency. Hence the total area under the histogram is 1 and it is directly comparable with most other estimates of the probability density function. If false plot the counts in the bins. |
| xlim   | The limits for the x-axis.                                                                                                                                                                                                                                                                                                                                                 |
| ymax   | The upper limit for the y-axis.                                                                                                                                                                                                                                                                                                                                            |
| col    | The colour for the bar fill: the default is colour 5 in the default R palette.                                                                                                                                                                                                                                                                                             |
| xlab   | label for the plot x-axis. By default, this will be the name of data.                                                                                                                                                                                                                                                                                                      |
| bty    | The box type for the plot - defaults to none.                                                                                                                                                                                                                                                                                                                              |
| ...    | additional arguments to <a href="#">rect</a> or <a href="#">plot</a> .                                                                                                                                                                                                                                                                                                     |

## Details

This plots a true histogram, a density estimate of total area 1. If `breaks` is specified, those break-points are used. Otherwise if `h` is specified, a regular grid of bins is used with width `h`. If neither `breaks` nor `h` is specified, `nbins` is used to select a suitable `h`.

## Side Effects

A histogram is plotted on the current device.

---

*Unbiased Cross-Validation for Bandwidth Selection*

---

## Description

Uses unbiased cross-validation to select the bandwidth of a Gaussian kernel density estimator.

## Usage

```
ucv(x, nb = 1000, lower, upper)
```

## Arguments

|                           |                                                                          |
|---------------------------|--------------------------------------------------------------------------|
| <code>x</code>            | a numeric vector                                                         |
| <code>nb</code>           | number of bins to use.                                                   |
| <code>lower, upper</code> | Range over which to minimize. The default is almost always satisfactory. |

## Value

a bandwidth.

UScereal

*Nutritional and Marketing Information on US Cereals***Description**

The UScereal data frame has 65 rows and 11 columns. The data come from the 1993 ASA Statistical Graphics Exposition, and are taken from the mandatory F&DA food label. The data have been normalized here to a portion of one American cup.

**Usage**

UScereal

**Format**

This data frame contains the following columns:

mfr Manufacturer, represented by its first initial: G=General Mills, K=Kelloggs, N=Nabisco, P=Post, Q=Quaker Oats, R=Ralston Purina.

calories number of calories in one portion.

protein grams of protein in one portion.

fat grams of fat in one portion.

sodium milligrams of sodium in one portion.

fibre grams of dietary fibre in one portion.

carbo grams of complex carbohydrates in one portion.

sugars grams of sugars in one portion.

shelf display shelf (1, 2, or 3, counting from the floor).

potassium grams of potassium.

vitamins vitamins and minerals (none, enriched, or 100%).

**Source**

The original data are available at <http://lib.stat.cmu.edu/datasets/1993.expo/>.

**References**

UScrime

*The Effect of Punishment Regimes on Crime Rates***Description**

Criminologists are interested in the effect of punishment regimes on crime rates. This has been studied using aggregate data on 47 states of the USA for 1960 given in this data frame. The variables seem to have been re-scaled to convenient numbers.

**Usage**

UScrime

**Format**

This data frame contains the following columns:

M percentage of males aged 14–24.  
 So indicator variable for a Southern state.  
 Ed mean years of schooling.  
 Po1 police expenditure in 1960.  
 Po2 police expenditure in 1959.  
 LF labour force participation rate.  
 M.F number of males per 1000 females.  
 Pop state population.  
 NW number of non-whites per 1000 people.  
 U1 unemployment rate of urban males 14–24.  
 U2 unemployment rate of urban males 35–39.  
 GDP gross domestic product per head.  
 Ineq income inequality.  
 Prob probability of imprisonment.  
 Time average time served in state prisons.  
 y rate of crimes in a particular category per head of population.

---

VA

---

*Veteran's Administration Lung Cancer Trial*

---

### Description

Veteran's Administration lung cancer trial from Kalbfleisch & Prentice.

### Usage

VA

### Format

A data frame with columns:

`stime` survival or follow-up time in days.

`status` dead or censored.

`treat` treatment: standard or test.

`age` patient's age in years.

`Karn` Karnofsky score of patient's performance on a scale of 0 to 100.

`diag.time` times since diagnosis in months at entry to trial.

`cell` one of four cell types.

`prior` prior therapy?

---

waders

---

*Counts of Waders at 15 Sites in South Africa*

---

### Description

The `waders` data frame has 15 rows and 19 columns. The entries are counts of waders in summer.

### Usage

`waders`

**Format**

This data frame contains the following columns (species)

S1 Oystercatcher  
 S2 White-fronted Plover  
 S3 Kitt Lutz's Plover  
 S4 Three-banded Plover  
 S5 Grey Plover  
 S6 Ringed Plover  
 S7 Bar-tailed Godwit  
 S8 Whimbrel  
 S9 Marsh Sandpiper  
 S10 Greenshank  
 S11 Common Sandpiper  
 S12 Turnstone  
 S13 Knot  
 S14 Sanderling  
 S15 Little Stint  
 S16 Curlew Sandpiper  
 S17 Ruff  
 S18 Avocet  
 S19 Black-winged Stilt

The rows are the sites:

A = Namibia North coast  
 B = Namibia North wetland  
 C = Namibia South coast  
 D = Namibia South wetland  
 E = Cape North coast  
 F = Cape North wetland  
 G = Cape West coast  
 H = Cape West wetland  
 I = Cape South coast  
 J = Cape South wetland  
 K = Cape East coast  
 L = Cape East wetland  
 M = Transkei coast  
 N = Natal coast  
 O = Natal wetland

**Examples**

```
plot(corresp(waders, nf=2))
```

whiteside

*House Insulation: Whiteside's Data***Description**

Mr Derek Whiteside of the UK Building Research Station recorded the weekly gas consumption and average external temperature at his own house in south-east England for two heating seasons, one of 26 weeks before, and one of 30 weeks after cavity-wall insulation was installed. The object of the exercise was to assess the effect of the insulation on gas consumption.

**Usage**

whiteside

**Format**

The whiteside data frame has 56 rows and 3 columns.:

Insul A factor, before or after insulation.

Temp Purportedly the average outside temperature in degrees Celsius. (These values is far too low for any 56-week period in the 1960s in South-East England. It might be the weekly average of daily minima.)

Gas The weekly gas consumption in 1000s of cubic feet.

**Source**

A data set collected in the 1960s by Mr Derek Whiteside of the UK Building Research Station. Reported by

Hand, D. J., Daly, F., McConway, K., Lunn, D. and Ostrowski, E. eds (1993) *A Handbook of Small Data Sets*. Chapman & Hall, p. 69.

**References**

Venables, W. N. and Ripley, B. D. (2002) *Modern Applied Statistics with S*. Fourth edition. Springer.

**Examples**

```
require(lattice)
xyplot(Gas ~ Temp | Insul, whiteside, panel =
 function(x, y, ...) {
 panel.xyplot(x, y, ...)
 panel.lmline(x, y, ...)
 }, xlab = "Average external temperature (deg. C)",
 ylab = "Gas consumption (1000 cubic feet)", aspect = "xy",
 strip = function(...) strip.default(..., style = 1))

gasB <- lm(Gas ~ Temp, whiteside, subset = Insul=="Before")
gasA <- update(gasB, subset = Insul=="After")
summary(gasB)
summary(gasA)
gasBA <- lm(Gas ~ Insul/Temp - 1, whiteside)
summary(gasBA)
```

```
gasQ <- lm(Gas ~ Insul/(Temp + I(Temp^2)) - 1, whiteside)
coef(summary(gasQ))

gasPR <- lm(Gas ~ Insul + Temp, whiteside)
anova(gasPR, gasBA)
options(contrasts = c("contr.treatment", "contr.poly"))
gasBA1 <- lm(Gas ~ Insul*Temp, whiteside)
coef(summary(gasBA1))
```

width.SJ

*Bandwidth Selection by Pilot Estimation of Derivatives***Description**

Uses the method of Sheather & Jones (1991) to select the bandwidth of a Gaussian kernel density estimator.

**Usage**

```
width.SJ(x, nb = 1000, lower, upper, method = c("ste", "dpi"))
```

**Arguments**

|              |                                                                  |
|--------------|------------------------------------------------------------------|
| x            | a numeric vector                                                 |
| nb           | number of bins to use.                                           |
| upper, lower | range over which to search for solution if method = "ste".       |
| method       | Either "ste" ("solve-the-equation") or "dpi" ("direct plug-in"). |

**Value**

a bandwidth.

**Note**

A faster version for large n (thousands) is available in  $R \geq 3.4.0$  as part of [bw.SJ](#): quadruple its value for comparability with this version.

width.SJ(galaxies)
```

---

write.matrix

---

*Write a Matrix or Data Frame*

---

**Description**

Writes a matrix or data frame to a file or the console, using column labels and a layout respecting columns.

**Usage**

```
write.matrix(x, file = "", sep = " ", blocksize)
```

**Arguments**

|           |                                                                                                                                                                       |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x         | matrix or data frame.                                                                                                                                                 |
| file      | name of output file. The default ("") is the console.                                                                                                                 |
| sep       | The separator between columns.                                                                                                                                        |
| blocksize | If supplied and positive, the output is written in blocks of <code>blocksize</code> rows. Choose as large as possible consistent with the amount of memory available. |

**Details**

If `x` is a matrix, supplying `blocksize` is more memory-efficient and enables larger matrices to be written, but each block of rows might be formatted slightly differently.

If `x` is a data frame, the conversion to a matrix may negate the memory saving.

**Side Effects**

A formatted file is produced, with column headings (if `x` has them) and columns of data.

wtloss

---

*Weight Loss Data from an Obese Patient*

---

**Description**

The data frame gives the weight, in kilograms, of an obese patient at 52 time points over an 8 month period of a weight rehabilitation programme.

**Usage**

```
wtloss
```

**Format**

This data frame contains the following columns:

`Days` time in days since the start of the programme.

`Weight` weight in kilograms of the patient.

**Source**

Dr T. Davies, Adelaide.

**References**

Venables, W. N. and Ripley, B. D. (2002) *Modern Applied Statistics with S*. Fourth edition. Springer.

**Examples**

```
IGNORE_RDIFF_BEGIN
wtloss.fm <- nls(Weight ~ b0 + b1*2^(-Days/th),
 data = wtloss, start = list(b0=90, b1=95, th=120))
wtloss.fm
IGNORE_RDIFF_END
plot(wtloss)
with(wtloss, lines(Days, fitted(wtloss.fm)))
```

## Chapter 17

# The `Matrix` package

---

`abIndex-class`

*Class "abIndex" of Abstract Index Vectors*

---

### Description

The `"abIndex"` [class](#), short for “Abstract Index Vector”, is used for dealing with large index vectors more efficiently, than using integer (or [numeric](#)) vectors of the kind `2:1000000` or `c(0:1e5, 1000:1e6)`.

Note that the current implementation details are subject to change, and if you consider working with these classes, please contact the package maintainers (`packageDescription("Matrix")$Maintainer`).

### Objects from the Class

Objects can be created by calls of the form `new("abIndex", ...)`, but more easily and typically either by `as(x, "abIndex")` where `x` is an integer (valued) vector, or directly by `abIseq()` and combination `c(...)` of such.

### Slots

**kind:** a [character](#) string, one of `("int32", "double", "rleDiff")`, denoting the internal structure of the `abIndex` object.

**x:** Object of class `"numLike"`; is used (i.e., not of length 0) only iff the object is *not* compressed, i.e., currently exactly when `kind != "rleDiff"`.

**rleD:** object of class `"rleDiff"`, used for compression via [rle](#).

### Methods

**as.numeric, as.integer, as.vector** `signature(x = "abIndex"): ...`

**[** `signature(x = "abIndex", i = "index", j = "ANY", drop = "ANY"): ...`

**coerce** `signature(from = "numeric", to = "abIndex"): ...`

**coerce** `signature(from = "abIndex", to = "numeric"): ...`

**coerce** `signature(from = "abIndex", to = "integer"): ...`

**length** `signature(x = "abIndex"): ...`

**Ops** signature(e1 = "numeric", e2 = "abIndex"): These and the following arithmetic and logic operations are **not yet implemented**; see [Ops](#) for a list of these (S4) group methods.

**Ops** signature(e1 = "abIndex", e2 = "abIndex"): ...

**Ops** signature(e1 = "abIndex", e2 = "numeric"): ...

**Summary** signature(x = "abIndex"): ...

**show** ("abIndex"): simple [show](#) method, building on `show(<rlDiff>)`.

**is.na** ("abIndex"): works analogously to regular vectors.

**is.finite, is.infinite** ("abIndex"): ditto.

## Note

This is currently experimental and not yet used for our own code. Please contact us (`packageDescription("Matrix")$Maintainer`), if you plan to make use of this class.

Partly builds on ideas and code from Jens Oehlschlaegel, as implemented (around 2008, in the GPL'ed part of) package **ff**.

## See Also

[rle](#) (base) which is used here; [numeric](#)

## Examples

```
showClass("abIndex")
ii <- c(-3:40, 20:70)
str(ai <- as(ii, "abIndex"))# note
ai # -> show() method

stopifnot(identical(-3:20,
 as(abIseq1(-3,20), "vector")))
```

---

abIseq

*Sequence Generation of "abIndex", Abstract Index Vectors*

---

## Description

Generation of abstract index vectors, i.e., objects of class "[abIndex](#)".

`abIseq()` is designed to work entirely like [seq](#), but producing "abIndex" vectors.

`abIseq1()` is its basic building block, where `abIseq1(n,m)` corresponds to `n:m`.

`c(x, ...)` will return an "abIndex" vector, when `x` is one.

## Usage

```
abIseq1(from = 1, to = 1)
abIseq (from = 1, to = 1, by = ((to - from)/(length.out - 1)),
 length.out = NULL, along.with = NULL)

S3 method for class 'abIndex'
c(...)
```

**Arguments**

|                         |                                                                                                                                                                                     |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>from, to</code>   | the starting and (maximal) end value of the sequence.                                                                                                                               |
| <code>by</code>         | number: increment of the sequence.                                                                                                                                                  |
| <code>length.out</code> | desired length of the sequence. A non-negative number, which for <code>seq</code> and <code>seq.int</code> will be rounded up if fractional.                                        |
| <code>along.with</code> | take the length from the length of this argument.                                                                                                                                   |
| <code>...</code>        | in general an arbitrary number of R objects; here, when the first is an <code>"abIndex"</code> vector, these arguments will be concatenated to a new <code>"abIndex"</code> object. |

**Value**

An abstract index vector, i.e., object of class `"abIndex"`.

**See Also**

the class `abIndex` documentation; `rep2abI()` for another constructor; `rle` (**base**).

**Examples**

```
stopifnot(identical(-3:20,
 as(abIseq1(-3,20), "vector")))

try(## (arithmetic) not yet implemented
abIseq(1, 50, by = 3)
)
```

---

all-methods

---

*"Matrix" Methods for Functions all() and any()*

---

**Description**

The basic R functions `all` and `any` now have methods for `Matrix` objects and should behave as for `matrix` ones.

**Methods**

```
all signature(x = "Matrix", ..., na.rm = FALSE): ...
any signature(x = "Matrix", ..., na.rm = FALSE): ...
all signature(x = "ldenseMatrix", ..., na.rm = FALSE): ...
all signature(x = "lsparseMatrix", ..., na.rm = FALSE): ...
```

### Examples

```
M <- Matrix(1:12 + 0, 3, 4)
all(M >= 1) # TRUE
any(M < 0) # FALSE
MN <- M; MN[2,3] <- NA; MN
all(MN >= 0) # NA
any(MN < 0) # NA
any(MN < 0, na.rm = TRUE) # -> FALSE
```

---

all.equal-methods    *Matrix Package Methods for Function all.equal()*

---

### Description

Methods for function `all.equal()` (from R package **base**) are defined for all `Matrix` classes.

### Methods

**target = "Matrix", current = "Matrix" \**  
**target = "ANY", current = "Matrix" \**  
**target = "Matrix", current = "ANY"** these three methods are simply using `all.equal.numeric` directly and work via `as.vector()`.  
 There are more methods, notably also for `"sparseVector"`'s, see `showMethods("all.equal")`.

### Examples

```
showMethods("all.equal")

(A <- spMatrix(3,3, i= c(1:3,2:1), j=c(3:1,1:2), x = 1:5))
ex <- expand(lu. <- lu(A))
stopifnot(all.equal(as(A[lu.@p + 1L, lu.@q + 1L], "CsparseMatrix"),
 lu.@L %*% lu.@U),
 with(ex, all.equal(as(P %*% A %*% Q, "CsparseMatrix"),
 L %*% U)),
 with(ex, all.equal(as(A, "CsparseMatrix"),
 t(P) %*% L %*% U %*% t(Q))))
```

---

atomicVector-class    *Virtual Class "atomicVector" of Atomic Vectors*

---

### Description

The `class` `"atomicVector"` is a *virtual* class containing all atomic vector classes of base R, as also implicitly defined via `is.atomic`.

### Objects from the Class

A virtual Class: No objects may be created from it.

## Methods

In the **Matrix** package, the "atomicVector" is used in signatures where typically “old-style” "matrix" objects can be used and can be substituted by simple vectors.

## Extends

The atomic classes "logical", "integer", "double", "numeric", "complex", "raw" and "character" are extended directly. Note that "numeric" already contains "integer" and "double", but we want all of them to be direct subclasses of "atomicVector".

## Author(s)

Martin Maechler

## See Also

`is.atomic`, `integer`, `numeric`, `complex`, etc.

## Examples

```
showClass("atomicVector")
```

---

band

---

*Extract bands of a matrix*

---

## Description

Returns a new matrix formed by extracting the lower triangle (`tril`) or the upper triangle (`triu`) or a general band relative to the diagonal (`band`), and setting other elements to zero. The general forms of these functions include integer arguments to specify how many diagonal bands above or below the main diagonal are not set to zero.

## Usage

```
band(x, k1, k2, ...)
tril(x, k = 0, ...)
triu(x, k = 0, ...)
```

## Arguments

|                        |                                                                                                                                                                                                                                                                                                    |
|------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>         | a matrix-like object                                                                                                                                                                                                                                                                               |
| <code>k, k1, k2</code> | integers specifying the diagonal bands that will not be set to zero. These are given relative to the main diagonal, which is <code>k=0</code> . A negative value of <code>k</code> indicates a diagonal below the main diagonal and a positive value indicates a diagonal above the main diagonal. |
| <code>...</code>       | Optional arguments used by specific methods. (None used at present.)                                                                                                                                                                                                                               |

## Value

An object of an appropriate matrix class. The class of the value of `tril` or `triu` inherits from `triangularMatrix` when appropriate. Note that the result is of class `sparseMatrix` only if `x` is.

**Methods**

**x = "CsparseMatrix"** method for compressed, sparse, column-oriented matrices.

**x = "TsparseMatrix"** method for sparse matrices in triplet format.

**x = "RsparseMatrix"** method for compressed, sparse, row-oriented matrices.

**x = "ddenseMatrix"** method for dense numeric matrices, including packed numeric matrices.

**See Also**

[bandSparse](#) for the *construction* of a banded sparse matrix directly from its non-zero diagonals.

**Examples**

```
A random sparse matrix :
set.seed(7)
m <- matrix(0, 5, 5)
m[sample(length(m), size = 14)] <- rep(1:9, length=14)
(mm <- as(m, "CsparseMatrix"))

tril(mm) # lower triangle
tril(mm, -1) # strict lower triangle
triu(mm, 1) # strict upper triangle
band(mm, -1, 2) # general band
(m5 <- Matrix(rnorm(25), nc = 5))
tril(m5) # lower triangle
tril(m5, -1) # strict lower triangle
triu(m5, 1) # strict upper triangle
band(m5, -1, 2) # general band
(m65 <- Matrix(rnorm(30), nc = 5)) # not square
triu(m65) # result in not dtrMatrix unless square
(sm5 <- crossprod(m65)) # symmetric
 band(sm5, -1, 1) # symmetric band preserves symmetry property
as(band(sm5, -1, 1), "sparseMatrix") # often preferable
```

---

bandSparse

---

*Construct Sparse Banded Matrix from (Sup-/Super-) Diagonals*

---

**Description**

Construct a sparse banded matrix by specifying its non-zero sup- and super-diagonals.

**Usage**

```
bandSparse(n, m = n, k, diagonals, symmetric = FALSE,
 repr = "C", giveCsparse = (repr == "C"))
```

**Arguments**

|                          |                                                                                                                                                                                                                                                                                                                                                                                                                   |
|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>n, m</code>        | the matrix dimension $(n, m) = (nrow, ncol)$ .                                                                                                                                                                                                                                                                                                                                                                    |
| <code>k</code>           | integer vector of “diagonal numbers”, with identical meaning as in <code>band(*, k)</code> , i.e., relative to the main diagonal, which is $k=0$ .                                                                                                                                                                                                                                                                |
| <code>diagonals</code>   | optional list of sub-/super- diagonals; if missing, the result will be a pattern matrix, i.e., inheriting from class <code>nMatrix</code> .<br>diagonals can also be $n' \times d$ matrix, where $d < \text{length}(k)$ and $n' \geq \min(n, m)$ . In that case, the sub-/super- diagonals are taken from the columns of diagonals, where only the first several rows will be used (typically) for off-diagonals. |
| <code>symmetric</code>   | logical; if true the result will be symmetric (inheriting from class <code>symmetricMatrix</code> ) and only the upper or lower triangle must be specified (via <code>k</code> and <code>diagonals</code> ).                                                                                                                                                                                                      |
| <code>repr</code>        | character string, one of "C", "T", or "R", specifying the sparse representation to be used for the result, i.e., one from the super classes <code>CsparseMatrix</code> , <code>TsparseMatrix</code> , or <code>RsparseMatrix</code> .                                                                                                                                                                             |
| <code>giveCsparse</code> | <b>(deprecated, replaced with repr)</b> : logical indicating if the result should be a <code>CsparseMatrix</code> or a <code>TsparseMatrix</code> , where the default was TRUE, and now is determined from <code>repr</code> ; very often Csparse matrices are more efficient subsequently, but not always.                                                                                                       |

**Value**

a sparse matrix (of class `CsparseMatrix`) of dimension  $n \times m$  with diagonal “bands” as specified.

**See Also**

`band`, for extraction of matrix bands; `bdiag`, `diag`, `sparseMatrix`, `Matrix`.

**Examples**

```
diags <- list(1:30, 10*(1:20), 100*(1:20))
s1 <- bandSparse(13, k = -c(0:2, 6), diag = c(diags, diags[2]), symm=TRUE)
s1
s2 <- bandSparse(13, k = c(0:2, 6), diag = c(diags, diags[2]), symm=TRUE)
stopifnot(identical(s1, t(s2)), is(s1, "dsCMatrix"))

a pattern Matrix of *full* (sub-)diagonals:
bk <- c(0:4, 7, 9)
(s3 <- bandSparse(30, k = bk, symm = TRUE))

If you want a pattern matrix, but with "sparse"-diagonals,
you currently need to go via logical sparse:
lLis <- lapply(list(rpois(20, 2), rpois(20, 1), rpois(20, 3))[c(1:3, 2:3, 3:2)],
 as.logical)
(s4 <- bandSparse(20, k = bk, symm = TRUE, diag = lLis))
(s4. <- as(drop0(s4), "nsparsedMatrix"))

n <- 1e4
bk <- c(0:5, 7, 11)
bMat <- matrix(1:8, n, 8, byrow=TRUE)
bLis <- as.data.frame(bMat)
```

```

B <- bandSparse(n, k = bk, diag = bLis)
Bs <- bandSparse(n, k = bk, diag = bLis, symmetric=TRUE)
B [1:15, 1:30]
Bs[1:15, 1:30]
can use a list *or* a matrix for specifying the diagonals:
stopifnot(identical(B, bandSparse(n, k = bk, diag = bMat)),
 identical(Bs, bandSparse(n, k = bk, diag = bMat, symmetric=TRUE))
 , inherits(B, "dtCMatrix") # triangular!
)

```

bdiag

*Construct a Block Diagonal Matrix***Description**

Build a block diagonal matrix given several building block matrices.

**Usage**

```

bdiag(...)
.bdiag(lst)

```

**Arguments**

... individual matrices or a [list](#) of matrices.  
 lst non-empty [list](#) of matrices.

**Details**

For non-trivial argument list, `bdiag()` calls `.bdiag()`. The latter maybe useful to programmers.

**Value**

A *sparse* matrix obtained by combining the arguments into a block diagonal matrix.

The value of `bdiag()` inheris from class [CsparseMatrix](#), whereas `.bdiag()` returns a [TsparseMatrix](#).

**Note**

This function has been written and is efficient for the case of relatively few block matrices which are typically sparse themselves.

It is currently *inefficient* for the case of many small dense block matrices. For the case of *many* dense  $k \times k$  matrices, the `bdiag_m()` function in the ‘Examples’ is an order of magnitude faster.

**Author(s)**

Martin Maechler, built on a version posted by Berton Gunter to R-help; earlier versions have been posted by other authors, notably Scott Chasalow to S-news. Doug Bates’s faster implementation builds on [TsparseMatrix](#) objects.

## See Also

[Diagonal](#) for constructing matrices of class [diagonalMatrix](#), or [kronecker](#) which also works for "Matrix" inheriting matrices.

[bandSparse](#) constructs a *banded* sparse matrix from its non-zero sub-/super - diagonals.

Note that other CRAN R packages have own versions of `bdiag()` which return traditional matrices.

## Examples

```
bdiag(matrix(1:4, 2), diag(3))
combine "Matrix" class and traditional matrices:
bdiag(Diagonal(2), matrix(1:3, 3,4), diag(3:2))

mlist <- list(1, 2:3, diag(x=5:3), 27, cbind(1,3:6), 100:101)
bdiag(mlist)
stopifnot(identical(bdiag(mlist),
 bdiag(lapply(mlist, as.matrix))))

ml <- c(as(matrix((1:24)%% 11 == 0, 6,4),"nMatrix"),
 rep(list(Diagonal(2, x=TRUE)), 3))
mln <- c(ml, Diagonal(x = 1:3))
stopifnot(is(bdiag(ml), "lsparseMatrix"),
 is(bdiag(mln), "dsparseMatrix"))

random (diagonal-)block-triangular matrices:
rblockTri <- function(nb, max.ni, lambda = 3) {
 .bdiag(replicate(nb, {
 n <- sample.int(max.ni, 1)
 tril(Matrix(rpois(n*n, lambda=lambda), n,n)) }))
}

(T4 <- rblockTri(4, 10, lambda = 1))
image(T1 <- rblockTri(12, 20))

##' Fast version of Matrix :: .bdiag() -- for the case of *many* (k x k) matrices:
##' @param lmat list(<mat1>, <mat2>,, <mat_N>) where each mat_j is a k x k 'matrix'
##' @return a sparse (N*k x N*k) matrix of class \code{"\linkS4class{dgCMatrix}"}.
bdiag_m <- function(lmat) {
 ## Copyright (C) 2016 Martin Maechler, ETH Zurich
 if(!length(lmat)) return(new("dgCMatrix"))
 stopifnot(is.list(lmat), is.matrix(lmat[[1]]),
 (k <- (d <- dim(lmat[[1]]))[1]) == d[2], # k x k
 all(vapply(lmat, dim, integer(2)) == k)) # all of them
 N <- length(lmat)
 if(N * k > .Machine$integer.max)
 stop("resulting matrix too large; would be M x M, with M=", N*k)
 M <- as.integer(N * k)
 ## result: an M x M matrix
 new("dgCMatrix", Dim = c(M,M),
 ## 'i :' maybe there's a faster way (w/o matrix indexing), but elegant?
 i = as.vector(matrix(0L:(M-1L), nrow=k)[, rep(seq_len(N), each=k)]),
 p = k * 0L:M,
 x = as.double(unlist(lmat, recursive=FALSE, use.names=FALSE)))
}
```

```
l12 <- replicate(12, matrix(rpois(16, lambda = 6.4), 4,4), simplify=FALSE)
dim(T12 <- bdiag_m(l12))# 48 x 48
T12[1:20, 1:20]
```

---

BunchKaufman-methods

### *Bunch-Kaufman Decomposition Methods*

---

## Description

The Bunch-Kaufman Decomposition of a square symmetric matrix  $A$  is  $A = PLDL'P'$  where  $P$  is a permutation matrix,  $L$  is *unit*-lower triangular and  $D$  is *block*-diagonal with blocks of dimension  $1 \times 1$  or  $2 \times 2$ .

This is generalization of a pivoting  $LDL'$  Cholesky decomposition.

## Usage

```
S4 method for signature 'dsyMatrix'
BunchKaufman(x, ...)
S4 method for signature 'dspMatrix'
BunchKaufman(x, ...)
S4 method for signature 'matrix'
BunchKaufman(x, uplo = NULL, ...)
```

## Arguments

|                   |                                                                                                                                                                                                                                                                                                            |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>    | a symmetric square matrix.                                                                                                                                                                                                                                                                                 |
| <code>uplo</code> | optional string, "U" or "L" indicating which "triangle" half of <code>x</code> should determine the result. The default is "U" unless <code>x</code> has a <code>uplo</code> slot which is the case for those inheriting from class <code>symmetricMatrix</code> , where <code>x@uplo</code> will be used. |
| <code>...</code>  | potentially further arguments passed to methods.                                                                                                                                                                                                                                                           |

## Details

FIXME: We really need an `expand()` method in order to *work* with the result!

## Value

an object of class `BunchKaufman`, which can also be used as a (triangular) matrix directly. Somewhat amazingly, it inherits its `uplo` slot from `x`.

## Methods

Currently, only methods for **dense** numeric symmetric matrices are implemented. To compute the Bunch-Kaufman decomposition, the methods use either one of two Lapack routines:

```
x = "dspMatrix" routine dsptrf(); whereas
x = "dsyMatrix" , and
x = "matrix" use dsytrf().
```

## References

The original LAPACK source code, including documentation; <https://www.netlib.org/lapack/double/dsytrf.f> and <https://www.netlib.org/lapack/double/dsptrf.f>

## See Also

The resulting class, [BunchKaufman](#). Related decompositions are the LU, [lu](#), and the Cholesky, [chol](#) (and for *sparse* matrices, [Cholesky](#)).

## Examples

```
data(CAex)
dim(CAex)
isSymmetric(CAex) # TRUE
CAs <- as(CAex, "symmetricMatrix")
if(FALSE) # no method defined yet for *sparse* :
 bk. <- BunchKaufman(CAs)
does apply to *dense* symmetric matrices:
bkCA <- BunchKaufman(as(CAs, "denseMatrix"))
bkCA

image(bkCA) # shows how sparse it is, too
str(R.CA <- as(bkCA, "sparseMatrix"))
an upper triangular 72x72 matrix with only 144 non-zero entries
```

---

CAex

*Albers' example Matrix with "Difficult" Eigen Factorization*

---

## Description

An example of a sparse matrix for which [eigen\(\)](#) seemed to be difficult, an unscaled version of this has been posted to the web, accompanying an E-mail to R-help (<https://stat.ethz.ch/mailman/listinfo/r-help>), by Casper J Albers, Open University, UK.

## Usage

```
data(CAex)
```

## Format

This is a  $72 \times 72$  symmetric matrix with 216 non-zero entries in five bands, stored as sparse matrix of class [dgCMatrix](#).

## Details

Historical note (2006-03-30): In earlier versions of R, [eigen](#)(CAex) fell into an infinite loop whereas [eigen](#)(CAex, EISPACK=TRUE) had been okay.

## Examples

```
data(CAex)
str(CAex) # of class "dgCMatrix"

image(CAex) # -> it's a simple band matrix with 5 bands
and the eigen values are basically 1 (42 times) and 0 (30 x):
zapsmall(ev <- eigen(CAex, only.values=TRUE)$values)
i.e., the matrix is symmetric, hence
sCA <- as(CAex, "symmetricMatrix")
and
stopifnot(class(sCA) == "dsCMatrix",
 as(sCA, "matrix") == as(CAex, "matrix"))
```

---

cBind

---

*Versions of 'cbind' and 'rbind' recursively built on cbind2/rbind2*

---

## Description

The base functions `cbind` and `rbind` are defined for an arbitrary number of arguments and hence have the first formal argument `...`. For that reason, in the past S4 methods could easily be defined for binding together matrices inheriting from `Matrix`.

For that reason, `cbind2` and `rbind2` have been provided for binding together *two* matrices, and we have defined methods for these and the `'Matrix'`-matrices.

Before R version 3.2.0 (April 2015), we have needed a substitute for *S4-enabled* versions of `cbind` and `rbind`, and provided `cBind` and `rBind` with identical syntax and semantic in order to bind together multiple matrices (`"matrix"` or `"Matrix"` and vectors. With R version 3.2.0 and newer, `cBind` and `rBind` are *deprecated* and produce a deprecation warning (via `.Deprecated`), and your code should start using `cbind()` and `rbind()` instead.

## Usage

```
cBind(..., deparse.level = 1)
rBind(..., deparse.level = 1)
```

## Arguments

`...` matrix-like R objects to be bound together, see `cbind` and `rbind`.  
`deparse.level` integer determining under which circumstances column and row names are built from the actual arguments' 'expression', see `cbind`.

## Details

The implementation of these is *recursive*, calling `cbind2` or `rbind2` respectively, where these have methods defined and so should dispatch appropriately.

## Value

typically a 'matrix-like' object of a similar `class` as the first argument in `...`

Note that sometimes by default, the result is a `sparseMatrix` if one of the arguments is (even in the case where this is not efficient). In other cases, the result is chosen to be sparse when there are more zero entries than non-zero ones (as the default `sparse` in `Matrix()`).

**Author(s)**

Martin Maechler

**See Also**[cbind2](#), [cbind](#), Documentation in base R's **methods** package .**Examples**

```
(a <- matrix(c(2:1,1:2), 2,2))
D <- Diagonal(2)
if(getRversion() < "3.2.0") {
 M1 <- cbind(0, rBind(a, 7))
 print(M1) # remains traditional matrix

 M2 <- cBind(4, a, D, -1, D, 0) # a sparse Matrix
 print(M2)

} else { ## newer versions of R do not need cBind / rBind:

 M1 <- cbind(0, suppressWarnings(rBind(a, 7)))
 print(M1) # remains traditional matrix

 M2 <- suppressWarnings(cBind(4, a, D, -1, D, 0)) # a sparse Matrix
 print(M2)

 stopifnot(identical(M1, cbind(0, rbind(a, 7))),
 identical(M2, cbind(4, a, D, -1, D, 0)))
}# R >= 3.2.0
```

CHMfactor-class

*CHOLMOD-based Cholesky Factorizations***Description**

The virtual class "CHMfactor" is a class of CHOLMOD-based Cholesky factorizations of symmetric, sparse, compressed, column-oriented matrices. Such a factorization is simplicial (virtual class "CHMsimpl") or supernodal (virtual class "CHMsuper"). Objects that inherit from these classes are either numeric factorizations (classes "dCHMsimpl" and "dCHMsuper") or symbolic factorizations (classes "nCHMsimpl" and "nCHMsuper").

**Usage**

```
isLDL(x)

S4 method for signature 'CHMfactor'
update(object, parent, mult = 0, ...)
.updateCHMfactor(object, parent, mult)

and many more methods, notably,
solve(a, b, system = c("A", "LDLt", "LD", "DLt", "L", "Lt", "D", "P", "Pt"), ...)
----- see below
```

## Arguments

|                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|---------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x, object, a</code> | a "CHMfactor" object (almost always the result of <code>Cholesky()</code> ).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>parent</code>       | a "dsCMatrix" or "dgCMatrix" matrix object with the same nonzero pattern as the matrix that generated object. If <code>parent</code> is symmetric, of class "dsCMatrix", then object should be a decomposition of a matrix with the same nonzero pattern as <code>parent</code> . If <code>parent</code> is not symmetric then object should be the decomposition of a matrix with the same nonzero pattern as <code>tcrossprod(parent)</code> .<br>Since Matrix version 1.0-8, other "sparseMatrix" matrices are coerced to <code>dsparseMatrix</code> and <code>CsparseMatrix</code> if needed. |
| <code>mult</code>         | a numeric scalar (default 0). <code>mult</code> times the identity matrix is (implicitly) added to <code>parent</code> or <code>tcrossprod(parent)</code> before updating the decomposition object.                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>...</code>          | potentially further arguments to the methods.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

## Objects from the Class

Objects can be created by calls of the form `new("dCHMsuper", ...)` but are more commonly created via `Cholesky()`, applied to `dsCMatrix` or `lsCMatrix` objects.

For an introduction, it may be helpful to look at the `expand()` method and examples below.

## Slots

of "CHMfactor" and all classes inheriting from it:

**perm:** An integer vector giving the 0-based permutation of the rows and columns chosen to reduce fill-in and for post-ordering.

**colcount:** Object of class "integer" ....

**type:** Object of class "integer" ....

Slots of the non virtual classes "[dl]CHM(superlsimpl)":

**p:** Object of class "integer" of pointers, one for each column, to the initial (zero-based) index of elements in the column. Only present in classes that contain "CHMsimpl".

**i:** Object of class "integer" of length `nnzero` (number of non-zero elements). These are the row numbers for each non-zero element in the matrix. Only present in classes that contain "CHMsimpl".

**x:** For the "d\*" classes: "numeric" - the non-zero elements of the matrix.

## Methods

**isLDL** (`x`) returns a **logical** indicating if `x` is an  $LDL'$  decomposition or (when `FALSE`) an  $LL'$  one.

**coerce** signature(`from` = "CHMfactor", `to` = "sparseMatrix") (or equivalently, `to` = "Matrix" or `to` = "triangularMatrix")

`as(*, "sparseMatrix")` returns the lower triangular factor  $L$  from the  $LL'$  form of the Cholesky factorization. Note that (currently) the factor from the  $LL'$  form is always returned, even if the "CHMfactor" object represents an  $LDL'$  decomposition. Furthermore, this is the factor after any fill-reducing permutation has been applied. See the `expand` method for obtaining both the permutation matrix,  $P$ , and the lower Cholesky factor,  $L$ .

**coerce** signature (from = "CHMfactor", to = "pMatrix") returns the permutation matrix  $P$ , representing the fill-reducing permutation used in the decomposition.

**expand** signature (x = "CHMfactor") returns a list with components  $P$ , the matrix representing the fill-reducing permutation, and  $L$ , the lower triangular Cholesky factor. The original positive-definite matrix  $A$  corresponds to the product  $A = P'LL'P$ . Because of fill-in during the decomposition the product may apparently have more non-zeros than the original matrix, even after applying `drop0` to it. However, the extra "non-zeros" should be very small in magnitude.

**image** signature (x = "CHMfactor") : Plot the image of the lower triangular factor,  $L$ , from the decomposition. This method is equivalent to `image(as(x, "sparseMatrix"))` so the comments in the above description of the `coerce` method apply here too.

**solve** signature (a = "CHMfactor", b = "ddenseMatrix"), system = \*:

The `solve` methods for a "CHMfactor" object take an optional third argument `system` whose value can be one of the character strings "A", "LDLt", "LD", "DLt", "L", "Lt", "D", "P" or "Pt". This argument describes the system to be solved. The default, "A", is to solve  $Ax = b$  for  $x$  where  $A$  is the sparse, positive-definite matrix that was factored to produce  $a$ . Analogously, `system = "L"` returns the solution  $x$ , of  $Lx = b$ . Similarly, for all system codes but "P" and "Pt" where, e.g., `x <- solve(a, b, system = "P")` is equivalent to `x <- P %*% b`.

See also [solve-methods](#).

**determinant** signature (x = "CHMfactor", logarithm = "logical") returns the determinant (or the logarithm of the determinant, if `logarithm = TRUE`, the default) of the factor  $L$  from the  $LL'$  decomposition (even if the decomposition represented by  $x$  is of the  $LDL'$  form (!)). This is the square root of the determinant (half the logarithm of the determinant when `logarithm = TRUE`) of the positive-definite matrix that was decomposed.

**update** signature (object = "CHMfactor"), parent. The `update` method requires an additional argument `parent`, which is either a "dsCMatrix" object, say  $A$ , (with the same structure of nonzeros as the matrix that was decomposed to produce `object`) or a general "dgCMatrix", say  $M$ , where  $A := MM'$  ( $= \text{tcrossprod}(\text{parent})$ ) is used for  $A$ . Further it provides an optional argument `mult`, a numeric scalar. This method updates the numeric values in `object` to the decomposition of  $A + mI$  where  $A$  is the matrix above (either the `parent` or  $MM'$ ) and  $m$  is the scalar `mult`. Because only the numeric values are updated this method should be faster than creating and decomposing  $A + mI$ . It is not uncommon to want, say, the determinant of  $A + mI$  for many different values of  $m$ . This method would be the preferred approach in such cases.

## Examples

```
An example for the expand() method
n <- 1000; m <- 200; nnz <- 2000
set.seed(1)
M1 <- spMatrix(n, m,
 i = sample(n, nnz, replace = TRUE),
 j = sample(m, nnz, replace = TRUE),
 x = round(rnorm(nnz), 1))
XX <- crossprod(M1) ## = M1'M1 = M M' where M <- t(M1)
CX <- Cholesky(XX)
isLDL(CX)
```

```

str(CX) ## a "dCHMsimpl" object
r <- expand(CX)
L.P <- with(r, crossprod(L,P)) ## == L'P
PLLP <- crossprod(L.P) ## == (L'P)' L'P == P'LL'P = XX = M M'
b <- sample(m)
stopifnot(all.equal(PLLP, XX),
 all(as.vector(solve(CX, b, system="P")) == r$P %*% b),
 all(as.vector(solve(CX, b, system="Pt")) == t(r$P) %*% b))

u1 <- update(CX, XX, mult=pi)
u2 <- update(CX, t(M1), mult=pi) # with the original M, where XX = M M'
stopifnot(all.equal(u1,u2, tol=1e-14))

[See help(Cholesky) for more examples]

```

chol

*Choleski Decomposition - 'Matrix' S4 Generic and Methods*

## Description

Compute the Choleski factorization of a real symmetric positive-definite square matrix.

## Usage

```

chol(x, ...)
S4 method for signature 'dsCMatrix'
chol(x, pivot = FALSE, ...)
S4 method for signature 'dsparseMatrix'
chol(x, pivot = FALSE, cache = TRUE, ...)

```

## Arguments

|                    |                                                                                                                                                                    |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>     | a (sparse or dense) square matrix, here inheriting from class <code>Matrix</code> ; if <code>x</code> is not positive definite, an error is signalled.             |
| <code>pivot</code> | logical indicating if pivoting is to be used. Currently, this is <i>not</i> made use of for dense matrices.                                                        |
| <code>cache</code> | logical indicating if the result should be cached in <code>x@factors</code> ; note that this argument is experimental and only available for some sparse matrices. |
| <code>...</code>   | potentially further arguments passed to methods.                                                                                                                   |

## Details

Note that these Cholesky factorizations are typically *cached* with `x` currently, and these caches are available in `x@factors`, which may be useful for the sparse case when `pivot = TRUE`, where the permutation can be retrieved; see also the examples.

However, this should not be considered part of the API and made use of. Rather consider `Cholesky()` in such situations, since `chol(x, pivot=TRUE)` uses the same algorithm (but not the same return value!) as `Cholesky(x, LDL=FALSE)` and `chol(x)` corresponds to `Cholesky(x, perm=FALSE, LDL=FALSE)`.

**Value**

a matrix of class `Cholesky`, i.e., upper triangular:  $R$  such that  $R'R = x$  (if `pivot=FALSE`) or  $P'R'RP = x$  (if `pivot=TRUE` and  $P$  is the corresponding permutation matrix).

**Methods**

Use `showMethods(chol)` to see all; some are worth mentioning here:

**chol** signature (`x = "dgeMatrix"`): works via `"dpoMatrix"`, see class `dpoMatrix`.

**chol** signature (`x = "dpoMatrix"`): Returns (and stores) the Cholesky decomposition of `x`, via LAPACK routines `dlacpy` and `dpotrf`.

**chol** signature (`x = "dppMatrix"`): Returns (and stores) the Cholesky decomposition via LAPACK routine `dpptf`.

**chol** signature (`x = "dsCMatrix", pivot = "logical"`): Returns (and stores) the Cholesky decomposition of `x`. If `pivot` is true, the Approximate Minimal Degree (AMD) algorithm is used to create a reordering of the rows and columns of `x` so as to reduce fill-in.

**References**

Timothy A. Davis (2006) *Direct Methods for Sparse Linear Systems*, SIAM Series “Fundamentals of Algorithms”.

Tim Davis (1996), An approximate minimal degree ordering algorithm, *SIAM J. Matrix Analysis and Applications*, **17**, 4, 886–905.

**See Also**

The default from `base`, `chol`; for more flexibility (but not returning a matrix!) `Cholesky`.

**Examples**

```
showMethods(chol, inherited = FALSE) # show different methods

sy2 <- new("dsyMatrix", Dim = as.integer(c(2,2)), x = c(14, NA, 32, 77))
(c2 <- chol(sy2))#-> "Cholesky" matrix
stopifnot(all.equal(c2, chol(as(sy2, "dpoMatrix")), tolerance= 1e-13))
str(c2)

An example where chol() can't work
(sy3 <- new("dsyMatrix", Dim = as.integer(c(2,2)), x = c(14, -1, 2, -7)))
try(chol(sy3)) # error, since it is not positive definite

A sparse example --- exemplifying 'pivot'
(mm <- toeplitz(as(c(10, 0, 1, 0, 3), "sparseVector")))) # 5 x 5
(R <- chol(mm)) ## default: pivot = FALSE
R2 <- chol(mm, pivot=FALSE)
stopifnot(identical(R, R2), all.equal(crossprod(R), mm))
(R. <- chol(mm, pivot=TRUE))# nice band structure,
but of course crossprod(R.) is *NOT* equal to mm
--> see Cholesky() and its examples, for the pivot structure & factorization
stopifnot(all.equal(sqrt(det(mm)), det(R)),
 all.equal(prod(diag(R)), det(R)),
 all.equal(prod(diag(R.)), det(R)))

a second, even sparser example:
```

```

(M2 <- toeplitz(as(c(1,.5, rep(0,12), -.1), "sparseVector")))
c2 <- chol(M2)
C2 <- chol(M2, pivot=TRUE)
For the experts, check the caching of the factorizations:
ff <- M2@factors[["spdCholesky"]]
FF <- M2@factors[["sPdCholesky"]]
L1 <- as(ff, "Matrix") # pivot=FALSE: no perm.
L2 <- as(FF, "Matrix"); P2 <- as(FF, "pMatrix")
stopifnot(identical(t(L1), c2),
 all.equal(t(L2), C2, tolerance=0), #-- why not identical()?
 all.equal(M2, tcrossprod(L1)), # M = LL'
 all.equal(M2, crossprod(crossprod(L2, P2))) # M = P'L L'P
)

```

---

chol2inv-methods      *Inverse from Choleski or QR Decomposition – Matrix Methods*

---

## Description

Invert a symmetric, positive definite square matrix from its Choleski decomposition. Equivalently, compute  $(X'X)^{-1}$  from the ( $R$  part) of the QR decomposition of  $X$ .  
 Even more generally, given an upper triangular matrix  $R$ , compute  $(R'R)^{-1}$ .

## Methods

- x = "ANY"** the default method from **base**, see `chol2inv`, for traditional matrices.
- x = "dtrMatrix"** method for the numeric triangular matrices, built on the same LAPACK DPOTRI function as the base method.
- x = "denseMatrix"** if  $x$  is coercable to a `triangularMatrix`, call the "dtrMatrix" method above.
- x = "sparseMatrix"** if  $x$  is coercable to a `triangularMatrix`, use `solve()` currently.

## See Also

`chol` (for `Matrix` objects); further, `chol2inv` (from the **base** package), `solve`.

## Examples

```

(M <- Matrix(cbind(1, 1:3, c(1,3,7))))
(cM <- chol(M)) # a "Cholesky" object, inheriting from "dtrMatrix"
chol2inv(cM) %**% M # the identity
stopifnot(all(chol2inv(cM) %**% M - Diagonal(nrow(M))) < 1e-10)

```

## Description

Computes the Cholesky (aka “Choleski”) decomposition of a sparse, symmetric, positive-definite matrix. However, typically `chol()` should rather be used unless you are interested in the different kinds of sparse Cholesky decompositions.

## Usage

```
Cholesky(A, perm = TRUE, LDL = !super, super = FALSE, Imult = 0, ...)
```

## Arguments

|                    |                                                                                                                                                                                                                                                                                                                                                                               |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>A</code>     | sparse symmetric matrix. No missing values or IEEE special values are allowed.                                                                                                                                                                                                                                                                                                |
| <code>perm</code>  | logical scalar indicating if a fill-reducing permutation should be computed and applied to the rows and columns of <code>A</code> . Default is <code>TRUE</code> .                                                                                                                                                                                                            |
| <code>LDL</code>   | logical scalar indicating if the decomposition should be computed as <code>LDL'</code> where <code>L</code> is a unit lower triangular matrix. The alternative is <code>LL'</code> where <code>L</code> is lower triangular with arbitrary diagonal elements. Default is <code>TRUE</code> . Setting it to <code>NA</code> leaves the choice to a CHOLMOD-internal heuristic. |
| <code>super</code> | logical scalar indicating if a supernodal decomposition should be created. The alternative is a simplicial decomposition. Default is <code>FALSE</code> . Setting it to <code>NA</code> leaves the choice to a CHOLMOD-internal heuristic.                                                                                                                                    |
| <code>Imult</code> | numeric scalar which defaults to zero. The matrix that is decomposed is $A + m \cdot I$ where $m$ is the value of <code>Imult</code> and <code>I</code> is the identity matrix of order <code>ncol(A)</code> .                                                                                                                                                                |
| <code>...</code>   | further arguments passed to or from other methods.                                                                                                                                                                                                                                                                                                                            |

## Details

This is a generic function with special methods for different types of matrices. Use `showMethods("Cholesky")` to list all the methods for the `Cholesky` generic.

The method for class `dsCMatrix` of sparse matrices — the only one available currently — is based on functions from the CHOLMOD library.

Again: If you just want the Cholesky decomposition of a matrix in a straightforward way, you should probably rather use `chol()`.

Note that if `perm=TRUE` (default), the decomposition is

$$A = P' \tilde{L} D \tilde{L}' P = P' L L' P,$$

where  $L$  can be extracted by `as(*, "Matrix")`,  $P$  by `as(*, "pMatrix")` and both by `expand(*)`, see the class `CHMfactor` documentation.

Note that consequently, you cannot easily get the “traditional” cholesky factor  $R$ , from this decomposition, as

$$R' R = A = P' L L' P = P' \tilde{R} \tilde{R} P = (\tilde{R} P)' (\tilde{R} P),$$

but  $\tilde{R} P$  is *not* triangular even though  $\tilde{R}$  is.

## Value

an object inheriting from either "`CHMsuper`", or "`CHMsimpl`", depending on the `super` argument; both classes extend "`CHMfactor`" which extends "`MatrixFactorization`".

In other words, the result of `Cholesky()` is *not* a matrix, and if you want one, you should probably rather use `chol()`, see Details.

## See Also

Class definitions `CHMfactor` and `dsCMatrix` and function `expand`. Note the extra `solve(*, system = .)` options in `CHMfactor`.

Note that `chol()` returns matrices (inheriting from "`Matrix`") whereas `Cholesky()` returns a "`CHMfactor`" object, and hence a typical user will rather use `chol(A)`.

## Examples

```
data(KNex)
mtm <- with(KNex, crossprod(mm))
str(mtm@factors) # empty list()
(C1 <- Cholesky(mtm)) # uses show(<MatrixFactorization>)
str(mtm@factors) # 'SPDCholesky' (simpl)
(Cm <- Cholesky(mtm, super = TRUE))
c(C1 = isLDL(C1), Cm = isLDL(Cm))
str(mtm@factors) # 'SPDCholesky' *and* 'SPdCholesky'
str(cml <- as(C1, "sparseMatrix"))
str(cmat <- as(Cm, "sparseMatrix")) # hmm: super is *less* sparse here
cml[1:20, 1:20]

b <- matrix(c(rep(0, 711), 1), nc = 1)
solve(Cm, b) by default solves Ax = b, where A = Cm'Cm (= mtm)!
hence, the identical() check *should* work, but fails on some GOTObas:
x <- solve(Cm, b)
stopifnot(identical(x, solve(Cm, b, system = "A")),
 all.equal(x, solve(mtm, b)))

Cn <- Cholesky(mtm, perm = FALSE) # no permutation -- much worse:
sizes <- c(simple = object.size(C1),
 super = object.size(Cm),
 noPerm = object.size(Cn))
simple is 100, super= 137, noPerm= 812 :
noquote(cbind(format(100 * sizes / sizes[1], digits=4)))

Visualize the sparseness:
dq <- function(ch) paste('"' , ch, '"' , sep="") ## dQuote(<UTF-8>) gives bad plots
image(mtm, main=paste("crossprod(mm) : Sparse", dq(class(mtm))))
image(cml, main= paste("as(Cholesky(crossprod(mm)), \"sparseMatrix\") : ",
```

```

dq(class(cm1)))

Smaller example, with same matrix as in help(chol) :
(mm <- Matrix(toeplitz(c(10, 0, 1, 0, 3)), sparse = TRUE)) # 5 x 5
(opts <- expand.grid(perm = c(TRUE,FALSE), LDL = c(TRUE,FALSE), super = c(FALSE,TRUE)))
rr <- lapply(seq_len(nrow(opts)), function(i)
 do.call(Cholesky, c(list(A = mm), opts[i,])))
nn <- do.call(expand.grid, c(attr(opts, "out.attr")$dimnames,
 stringsAsFactors=FALSE,KEEP.OUT.ATTRS=FALSE))
names(rr) <- apply(nn, 1, function(r)
 paste(sub("(=.) .*", "\\1", r), collapse=","))
str(rr, max=1)

str(re <- lapply(rr, expand), max=2) ## each has a 'P' and a 'L' matrix

R0 <- chol(mm, pivot=FALSE)
R1 <- chol(mm, pivot=TRUE)
stopifnot(all.equal(t(R1), re[[1]]$L),
 all.equal(t(R0), re[[2]]$L),
 identical(as(1:5, "pMatrix"), re[[2]]$P), # no pivoting
TRUE)

Version of the underlying SuiteSparse library by Tim Davis :
.SuiteSparse_version()

```

Cholesky-class

*Cholesky and Bunch-Kaufman Decompositions*

## Description

The "Cholesky" class is the class of Cholesky decompositions of positive-semidefinite, real dense matrices. The "BunchKaufman" class is the class of Bunch-Kaufman decompositions of symmetric, real matrices. The "pCholesky" and "pBunchKaufman" classes are their *packed* storage versions.

## Objects from the Class

Objects can be created by calls of the form `new("Cholesky",...)` or `new("BunchKaufman",...)`, etc, or rather by calls of the form `chol(pm)` or `BunchKaufman(pm)` where `pm` inherits from the "`dpoMatrix`" or "`dsyMatrix`" class or as a side-effect of other functions applied to "`dpoMatrix`" objects (see `dpoMatrix`).

## Slots

A Cholesky decomposition extends class `MatrixFactorization` but is basically a triangular matrix extending the "`dtrMatrix`" class.

**uplo:** inherited from the "`dtrMatrix`" class.

**diag:** inherited from the "`dtrMatrix`" class.

**x:** inherited from the "`dtrMatrix`" class.

**Description**

Form row and column sums and means for objects, for `sparseMatrix` the result may optionally be sparse (`sparseVector`), too. Row or column names are kept respectively as for **base** matrices and `colSums` methods, when the result is `numeric` vector.

**Usage**

```
colSums(x, na.rm = FALSE, dims = 1, ...)
rowSums(x, na.rm = FALSE, dims = 1, ...)
colMeans(x, na.rm = FALSE, dims = 1, ...)
rowMeans(x, na.rm = FALSE, dims = 1, ...)

S4 method for signature 'CsparseMatrix'
colSums(x, na.rm = FALSE,
 dims = 1, sparseResult = FALSE)
S4 method for signature 'CsparseMatrix'
rowSums(x, na.rm = FALSE,
 dims = 1, sparseResult = FALSE)
S4 method for signature 'CsparseMatrix'
colMeans(x, na.rm = FALSE,
 dims = 1, sparseResult = FALSE)
S4 method for signature 'CsparseMatrix'
rowMeans(x, na.rm = FALSE,
 dims = 1, sparseResult = FALSE)
```

**Arguments**

|                           |                                                                                                                                                                                                      |
|---------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>            | a Matrix, i.e., inheriting from <code>Matrix</code> .                                                                                                                                                |
| <code>na.rm</code>        | logical. Should missing values (including NaN) be omitted from the calculations?                                                                                                                     |
| <code>dims</code>         | completely ignored by the <code>Matrix</code> methods.                                                                                                                                               |
| <code>...</code>          | potentially further arguments, for method <code>&lt;-&gt;</code> generic compatibility.                                                                                                              |
| <code>sparseResult</code> | logical indicating if the result should be sparse, i.e., inheriting from class <code>sparseVector</code> . Only applicable when <code>x</code> is inheriting from a <code>sparseMatrix</code> class. |

**Value**

returns a numeric vector if `sparseResult` is `FALSE` as per default. Otherwise, returns a `sparseVector`.

`dimnames(x)` are only kept (as `names(v)`) when the resulting `v` is `numeric`, since `sparseVectors` do not have names.

**See Also**

`colSums` and the `sparseVector` classes.

## Examples

```
(M <- bdiag(Diagonal(2), matrix(1:3, 3,4), diag(3:2))) # 7 x 8
colSums(M)
d <- Diagonal(10, c(0,0,10,0,2,rep(0,5)))
MM <- kronecker(d, M)
dim(MM) # 70 80
length(MM@x) # 160, but many are '0' ; drop those:
MM <- drop0(MM)
length(MM@x) # 32
cm <- colSums(MM)
(scm <- colSums(MM, sparseResult = TRUE))
stopifnot(is(scm, "sparseVector"),
 identical(cm, as.numeric(scm)))
rowSums(MM, sparseResult = TRUE) # 14 of 70 are not zero
colMeans(MM, sparseResult = TRUE) # 16 of 80 are not zero
Since we have no 'NA's, these two are equivalent :
stopifnot(identical(rowMeans(MM, sparseResult = TRUE),
 rowMeans(MM, sparseResult = TRUE, na.rm = TRUE)),
 rowMeans(Diagonal(16)) == 1/16,
 colSums(Diagonal(7)) == 1)

dimnames(x) --> names(<value>) :
dimnames(M) <- list(paste0("r", 1:7), paste0("V",1:8))
M
colSums(M)
rowMeans(M)
Assertions :
stopifnot(all.equal(colSums(M),
 setNames(c(1,1,6,6,6,6,3,2), colnames(M))),
 all.equal(rowMeans(M), structure(c(1,1,4,8,12,3,2) / 8,
 .Names = paste0("r", 1:7))))
```

---

compMatrix-class      *Class "compMatrix" of Composite (Factorizable) Matrices*

---

## Description

Virtual class of *composite* matrices; i.e., matrices that can be *factorized*, typically as a product of simpler matrices.

## Objects from the Class

A virtual Class: No objects may be created from it.

## Slots

**factors:** Object of class "list" - a list of factorizations of the matrix. Note that this is typically empty, i.e., `list()`, initially and is *updated **automagically*** whenever a matrix factorization is computed.

**Dim, Dimnames:** inherited from the [Matrix](#) class, see there.

## Extends

Class "Matrix", directly.

## Methods

**dimnames<-** signature(x = "compMatrix", value = "list"): set the dimnames to a [list](#) of length 2, see [dimnames<-](#). The factors slot is currently reset to empty, as the factorization dimnames would have to be adapted, too.

## See Also

The matrix factorization classes "[MatrixFactorization](#)" and their generators, [lu\(\)](#), [qr\(\)](#), [chol\(\)](#) and [Cholesky\(\)](#), [BunchKaufman\(\)](#), [Schur\(\)](#).

---

|         |                                                                            |
|---------|----------------------------------------------------------------------------|
| condest | <i>Compute Approximate CONDition number and 1-Norm of (Large) Matrices</i> |
|---------|----------------------------------------------------------------------------|

---

## Description

“Estimate”, i.e. compute approximately the CONDition number of a (potentially large, often sparse) matrix A. It works by apply a fast *randomized* approximation of the 1-norm, [norm\(A, "1"\)](#), through [onenormest\(\)](#).

## Usage

```
condest(A, t = min(n, 5), normA = norm(A, "1"),
 silent = FALSE, quiet = TRUE)

onenormest(A, t = min(n, 5), A.x, At.x, n,
 silent = FALSE, quiet = silent,
 iter.max = 10, eps = 4 * .Machine$double.eps)
```

## Arguments

|           |                                                                                                                            |
|-----------|----------------------------------------------------------------------------------------------------------------------------|
| A         | a square matrix, optional for <a href="#">onenormest()</a> , where instead of A, A.x and At.x can be specified, see there. |
| t         | number of columns to use in the iterations.                                                                                |
| normA     | number; (an estimate of) the 1-norm of A, by default <a href="#">norm(A, "1")</a> ; may be replaced by an estimate.        |
| silent    | logical indicating if warning and (by default) convergence messages should be displayed.                                   |
| quiet     | logical indicating if convergence messages should be displayed.                                                            |
| A.x, At.x | when A is missing, these two must be given as functions which compute A %% x, or t(A) %% x, respectively.                  |
| n         | == nrow(A), only needed when A is not specified.                                                                           |
| iter.max  | maximal number of iterations for the 1-norm estimator.                                                                     |
| eps       | the relative change that is deemed irrelevant.                                                                             |

## Details

`condest()` calls `lu(A)`, and subsequently `onenormest(A.x = , At.x =)` to compute an approximate norm of the *inverse* of  $A$ ,  $A^{-1}$ , in a way which keeps using sparse matrices efficiently when  $A$  is sparse.

Note that `onenormest()` uses random vectors and hence *both* functions' results are random, i.e., depend on the random seed, see, e.g., `set.seed()`.

## Value

Both functions return a `list`; `condest()` with components,

`est`            a number  $> 0$ , the estimated (1-norm) condition number  $\hat{\kappa}$ ; when  $r := \text{rcond}(A)$ ,  $1/\hat{\kappa} \approx r$ .

`v`              the maximal  $Ax$  column, scaled to  $\text{norm}(v) = 1$ . Consequently,  $\text{norm}(Av) = \text{norm}(A)/\text{est}$ ; when `est` is large, `v` is an approximate null vector.

The function `onenormest()` returns a list with components,

`est`            a number  $> 0$ , the estimated  $\text{norm}(A, "1")$ .

`v`              0-1 integer vector length  $n$ , with an 1 at the index  $j$  with maximal column  $A[, j]$  in  $A$ .

`w`              numeric vector, the largest  $Ax$  found.

`iter`          the number of iterations used.

## Author(s)

This is based on octave's `condest()` and `onenormest()` implementations with original author Jason Riedy, U Berkeley; translation to R and adaption by Martin Maechler.

---

CsparseMatrix-class

*Class "CsparseMatrix" of Sparse Matrices in Column-compressed Form*

---

## Description

The "CsparseMatrix" class is the virtual class of all sparse matrices coded in sorted compressed column-oriented form. Since it is a virtual class, no objects may be created from it. See `showClass("CsparseMatrix")` for its subclasses.

## Slots

**i:** Object of class "integer" of length `nnzero` (number of non-zero elements). These are the *0-based* row numbers for each non-zero element in the matrix, i.e., `i` must be in `0:(nrow(.)-1)`.

**p:** integer vector for providing pointers, one for each column, to the initial (zero-based) index of elements in the column. `.@p` is of length `ncol(.) + 1`, with `p[1] == 0` and `p[length(p)] == nnzero`, such that in fact, `diff(.@p)` are the number of non-zero elements for each column.

In other words, `m@p[1:ncol(m)]` contains the indices of those elements in `m@x` that are the first elements in the respective column of `m`.

**Dim, Dimnames:** inherited from the superclass, see the `sparseMatrix` class.

## Extends

Class "sparseMatrix", directly. Class "Matrix", by class "sparseMatrix".

## Methods

matrix products `%*%`, `crossprod()` and `tcrossprod()`, several `solve` methods, and other matrix methods available:

`signature(e1 = "CsparseMatrix", e2 = "numeric"): ...`

**Arith** `signature(e1 = "numeric", e2 = "CsparseMatrix"): ...`

**Math** `signature(x = "CsparseMatrix"): ...`

**band** `signature(x = "CsparseMatrix"): ...`

- `signature(e1 = "CsparseMatrix", e2 = "numeric"): ...`

- `signature(e1 = "numeric", e2 = "CsparseMatrix"): ...`

+ `signature(e1 = "CsparseMatrix", e2 = "numeric"): ...`

+ `signature(e1 = "numeric", e2 = "CsparseMatrix"): ...`

**coerce** `signature(from = "CsparseMatrix", to = "TsparseMatrix"): ...`

```

coerce signature(from = "CsparseMatrix",to = "denseMatrix"): ...
coerce signature(from = "CsparseMatrix",to = "matrix"): ...
coerce signature(from = "CsparseMatrix",to = "lsparseMatrix"): ...
coerce signature(from = "CsparseMatrix",to = "nsparseMatrix"): ...
coerce signature(from = "TsparseMatrix",to = "CsparseMatrix"): ...
coerce signature(from = "denseMatrix",to = "CsparseMatrix"): ...
diag signature(x = "CsparseMatrix"): ...
gamma signature(x = "CsparseMatrix"): ...
lgamma signature(x = "CsparseMatrix"): ...
log signature(x = "CsparseMatrix"): ...
t signature(x = "CsparseMatrix"): ...
tril signature(x = "CsparseMatrix"): ...
triu signature(x = "CsparseMatrix"): ...

```

### Note

All classes extending `CsparseMatrix` have a common validity (see `validObject`) check function. That function additionally checks the `i` slot for each column to contain increasing row numbers.

In earlier versions of **Matrix** ( $\leq 0.999375-16$ ), `validObject` automatically re-sorted the entries when necessary, and hence `new()` calls with somewhat permuted `i` and `x` slots worked, as `new(...)` (with slot arguments) automatically checks the validity.

Now, you have to use `sparseMatrix` to achieve the same functionality or know how to use `.validateCsparse()` to do so.

### See Also

`colSums`, `kronecker`, and other such methods with own help pages.

Further, the super class of `CsparseMatrix`, `sparseMatrix`, and, e.g., class `dgCMatrix` for the links to other classes.

### Examples

```

getClass("CsparseMatrix")

The common validity check function (based on C code):
getValidity(getClass("CsparseMatrix"))

```

---

ddenseMatrix-class *Virtual Class "ddenseMatrix" of Numeric Dense Matrices*

---

### Description

This is the virtual class of all dense numeric (i.e., **double**, hence “*ddense*”) S4 matrices.

Its most important subclass is the `dgeMatrix` class.

**Extends**

Class "dMatrix" directly; class "Matrix", by the above.

**Slots**

the same slots at its subclass [dgeMatrix](#), see there.

**Methods**

Most methods are implemented via `as(*, "dgeMatrix")` and are mainly used as “fallbacks” when the subclass doesn’t need its own specialized method.

Use `showMethods(class = "ddenseMatrix", where = "package:Matrix")` for an overview.

**See Also**

The virtual classes [Matrix](#), [dMatrix](#), and [dsparseMatrix](#).

**Examples**

```
showClass("ddenseMatrix")

showMethods(class = "ddenseMatrix", where = "package:Matrix")
```

---

|                 |                                                       |
|-----------------|-------------------------------------------------------|
| ddiMatrix-class | <i>Class "ddiMatrix" of Diagonal Numeric Matrices</i> |
|-----------------|-------------------------------------------------------|

---

**Description**

The class "ddiMatrix" of numerical diagonal matrices.

Note that diagonal matrices now extend `sparseMatrix`, whereas they did extend dense matrices earlier.

**Objects from the Class**

Objects can be created by calls of the form `new("ddiMatrix", ...)` but typically rather via [Diagonal](#).

**Slots**

**x:** numeric vector. For an  $n \times n$  matrix, the x slot is of length  $n$  or 0, depending on the diag slot:  
**diag:** "character" string, either "U" or "N" where "U" denotes unit-diagonal, i.e., identity matrices.

**Dim,Dimnames:** matrix dimension and `dimnames`, see the [Matrix](#) class description.

**Extends**

Class "[diagonalMatrix](#)", directly. Class "[dMatrix](#)", directly. Class "[sparseMatrix](#)", indirectly, see `showClass("ddiMatrix")`.

**Methods**

```
%*% signature(x = "ddiMatrix", y = "ddiMatrix"): ...
```

**See Also**

Class [diagonalMatrix](#) and function [Diagonal](#).

**Examples**

```
(d2 <- Diagonal(x = c(10,1)))
str(d2)
slightly larger in internal size:
str(as(d2, "sparseMatrix"))

M <- Matrix(cbind(1,2:4))
M %*% d2 #> `fast' multiplication

chol(d2) # trivial
stopifnot(is(cd2 <- chol(d2), "ddiMatrix"),
 all.equal(cd2@x, c(sqrt(10),1)))
```

---

denseMatrix-class    *Virtual Class "denseMatrix" of All Dense Matrices*

---

**Description**

This is the virtual class of all dense (S4) matrices. It is the direct superclass of [ddenseMatrix](#), [ldenseMatrix](#)

**Extends**

class "Matrix" directly.

**Slots**

exactly those of its superclass "[Matrix](#)".

**Methods**

Use [showMethods](#)(class = "denseMatrix", where = "package:Matrix") for an overview of methods.

Extraction ("[" ) methods, see [\[-methods](#).

**See Also**

[colSums](#), [kronecker](#), and other such methods with own help pages.

Its superclass [Matrix](#), and main subclasses, [ddenseMatrix](#) and [sparseMatrix](#).

**Examples**

```
showClass("denseMatrix")
```

---

dgCMatrix-class      *Compressed, sparse, column-oriented numeric matrices*

---

## Description

The `dgCMatrix` class is a class of sparse numeric matrices in the compressed, sparse, column-oriented format. In this implementation the non-zero elements in the columns are sorted into increasing row order. `dgCMatrix` is the “*standard*” class for sparse numeric matrices in the **Matrix** package.

## Objects from the Class

Objects can be created by calls of the form `new("dgCMatrix", ...)`, more typically via `as(*, "CsparseMatrix")` or similar. Often however, more easily via `Matrix(*, sparse = TRUE)`, or most efficiently via `sparseMatrix()`.

## Slots

`x`: Object of class "numeric" - the non-zero elements of the matrix.

... all other slots are inherited from the superclass "`CsparseMatrix`".

## Methods

Matrix products (e.g., [crossprod-methods](#)), and (among other)

**coerce** signature(`from` = "matrix", `to` = "dgCMatrix")

**coerce** signature(`from` = "dgCMatrix", `to` = "matrix")

**coerce** signature(`from` = "dgCMatrix", `to` = "dgTMatrix")

**diag** signature(`x` = "dgCMatrix"): returns the diagonal of `x`

**dim** signature(`x` = "dgCMatrix"): returns the dimensions of `x`

**image** signature(`x` = "dgCMatrix"): plots an image of `x` using the [levelplot](#) function

**solve** signature(`a` = "dgCMatrix", `b` = "..."): see [solve-methods](#), notably the extra argument `sparse`.

**lu** signature(`x` = "dgCMatrix"): computes the LU decomposition of a square `dgCMatrix` object

## See Also

Classes [dsCMatrix](#), [dtCMatrix](#), [lu](#)

## Examples

```
(m <- Matrix(c(0,0,2:0), 3,5))
str(m)
m[,1]
```

---

dgeMatrix-class      *Class "dgeMatrix" of Dense Numeric (S4 Class) Matrices*

---

## Description

A general numeric dense matrix in the S4 Matrix representation. `dgeMatrix` is the “*standard*” class for dense numeric matrices in the **Matrix** package.

## Objects from the Class

Objects can be created by calls of the form `new("dgeMatrix", ...)` or, more commonly, by coercion from the `Matrix` class (see [Matrix](#)) or by `Matrix(...)`.

## Slots

**x:** Object of class "numeric" - the numeric values contained in the matrix, in column-major order.

**Dim:** Object of class "integer" - the dimensions of the matrix - must be an integer vector with exactly two non-negative values.

**Dimnames:** a list of length two - inherited from class [Matrix](#).

**factors:** Object of class "list" - a list of factorizations of the matrix.

## Methods

There are group methods (see, e.g., [Arith](#))

**Arith** signature(`e1` = "dgeMatrix", `e2` = "dgeMatrix"): ...

**Arith** signature(`e1` = "dgeMatrix", `e2` = "numeric"): ...

**Arith** signature(`e1` = "numeric", `e2` = "dgeMatrix"): ...

**Math** signature(`x` = "dgeMatrix"): ...

**Math2** signature(`x` = "dgeMatrix", `digits` = "numeric"): ...

matrix products `%*%`, `crossprod()` and `tcrossprod()`, several [solve](#) methods, and other matrix methods available:

**Schur** signature(`x` = "dgeMatrix", `vectors` = "logical"): ...

**Schur** signature(`x` = "dgeMatrix", `vectors` = "missing"): ...

**chol** signature(`x` = "dgeMatrix"): see [chol](#).

**coerce** signature(`from` = "dgeMatrix", `to` = "lgeMatrix"): ...

**coerce** signature(`from` = "dgeMatrix", `to` = "matrix"): ...

**coerce** signature(`from` = "matrix", `to` = "dgeMatrix"): ...

**colMeans** signature(`x` = "dgeMatrix"): columnwise means (averages)

**colSums** signature(`x` = "dgeMatrix"): columnwise sums

**diag** signature(`x` = "dgeMatrix"): ...

**dim** signature(`x` = "dgeMatrix"): ...

**dimnames** signature(`x` = "dgeMatrix"): ...

**eigen** signature(`x` = "dgeMatrix", `only.values` = "logical"): ...

**eigen** signature(x = "dgeMatrix", only.values = "missing"): ...  
**norm** signature(x = "dgeMatrix", type = "character"): ...  
**norm** signature(x = "dgeMatrix", type = "missing"): ...  
**rcond** signature(x = "dgeMatrix", norm = "character") or norm = "missing":  
the reciprocal condition number, [rcond\(\)](#).  
**rowMeans** signature(x = "dgeMatrix"): rowwise means (averages)  
**rowSums** signature(x = "dgeMatrix"): rowwise sums  
**t** signature(x = "dgeMatrix"): matrix transpose

---

|                 |                                                         |
|-----------------|---------------------------------------------------------|
| dgRMatrix-class | <i>Sparse Compressed, Row-oriented Numeric Matrices</i> |
|-----------------|---------------------------------------------------------|

---

### Description

The `dgRMatrix` class is a class of sparse numeric matrices in the compressed, sparse, row-oriented format. In this implementation the non-zero elements in the rows are sorted into increasing column order.

**Note:** The column-oriented sparse classes, e.g., [dgCMatrix](#), are preferred and better supported in the **Matrix** package.

### Objects from the Class

Objects can be created by calls of the form `new("dgRMatrix", ...)`.

### Slots

**j:** Object of class "integer" of length `nnzero` (number of non-zero elements). These are the column numbers for each non-zero element in the matrix.  
**p:** Object of class "integer" of pointers, one for each row, to the initial (zero-based) index of elements in the row.  
**x:** Object of class "numeric" - the non-zero elements of the matrix.  
**Dim:** Object of class "integer" - the dimensions of the matrix.

### Methods

**coerce** signature(from = "matrix", to = "dgRMatrix")  
**coerce** signature(from = "dgRMatrix", to = "matrix")  
**coerce** signature(from = "dgRMatrix", to = "dgTMatrix")  
**diag** signature(x = "dgRMatrix"): returns the diagonal of x  
**dim** signature(x = "dgRMatrix"): returns the dimensions of x  
**image** signature(x = "dgRMatrix"): plots an image of x using the [levelplot](#) function

### See Also

the [RsparseMatrix](#) class, the virtual class of all sparse compressed row-oriented matrices, with its methods. The [dgCMatrix](#) class (column compressed sparse) is really preferred.

---

 dgTMatrix-class      *Sparse matrices in triplet form*

---

## Description

The "dgTMatrix" class is the class of sparse matrices stored as (possibly redundant) triplets. The internal representation is not at all unique, contrary to the one for class [dgCMatrix](#).

## Objects from the Class

Objects can be created by calls of the form `new("dgTMatrix", ...)`, but more typically via `as(*, "dgTMatrix")`, `spMatrix()`, or `sparseMatrix(*, repr = "T")`.

## Slots

- i:** [integer](#) row indices of non-zero entries *in 0-base*, i.e., must be in `0:(nrow(.)-1)`.
- j:** [integer](#) column indices of non-zero entries. Must be the same length as slot **i** and *0-based* as well, i.e., in `0:(ncol(.)-1)`.
- x:** [numeric](#) vector - the (non-zero) entry at position `(i, j)`. Must be the same length as slot **i**. If an index pair occurs more than once, the corresponding values of slot **x** are added to form the element of the matrix.
- Dim:** Object of class "integer" of length 2 - the dimensions of the matrix.

## Methods

- +** `signature(e1 = "dgTMatrix", e2 = "dgTMatrix")`
- coerce** `signature(from = "dgTMatrix", to = "dgCMatrix")`
- coerce** `signature(from = "dgTMatrix", to = "dgeMatrix")`
- coerce** `signature(from = "dgTMatrix", to = "matrix")`, and typically coercion methods for more specific signatures, we are not mentioning here.  
Note that these are not guaranteed to continue to exist, but rather you should use calls like `as(x, "CsparseMatrix")`, `as(x, "generalMatrix")`, `as(x, "dMatrix")`, i.e. coercion to higher level virtual classes.
- coerce** `signature(from = "matrix", to = "dgTMatrix")`, (direct coercion from tradition matrix).
- image** `signature(x = "dgTMatrix")`: plots an image of **x** using the [levelplot](#) function
- t** `signature(x = "dgTMatrix")`: returns the transpose of **x**

## Note

Triplet matrices are a convenient form in which to construct sparse matrices after which they can be coerced to [dgCMatrix](#) objects.

Note that both `new(.)` and [spMatrix](#) constructors for "dgTMatrix" (and other "[TsparseMatrix](#)" classes) implicitly add  $x_k$ 's that belong to identical  $(i_k, j_k)$  pairs.

However this means that a matrix typically can be stored in more than one possible "[TsparseMatrix](#)" representations. Use [uniqTsparse\(\)](#) in order to ensure uniqueness of the internal representation of such a matrix.

**See Also**

Class `dgCMatrix` or the superclasses `dsparseMatrix` and `TsparseMatrix`; `uniqTsparse`.

**Examples**

```
m <- Matrix(0+1:28, nrow = 4)
m[-3,c(2,4:5,7)] <- m[3, 1:4] <- m[1:3, 6] <- 0
(mT <- as(m, "dgTMatrix"))
str(mT)
mT[1,]
mT[4, drop = FALSE]
stopifnot(identical(mT[lower.tri(mT)],
 m [lower.tri(m)]))
mT[lower.tri(mT,diag=TRUE)] <- 0
mT

Triplet representation with repeated (i,j) entries
adds the corresponding x's:
T2 <- new("dgTMatrix",
 i = as.integer(c(1,1,0,3,3)),
 j = as.integer(c(2,2,4,0,0)), x=10*1:5, Dim=4:5)
str(T2) # contains (i,j,x) slots exactly as above, but
T2 ## has only three non-zero entries, as for repeated (i,j)'s,
 ## the corresponding x's are "implicitly" added
stopifnot(nnzero(T2) == 3)
```

---

Diagonal

---

*Create Diagonal Matrix Object*

---

**Description**

Create a diagonal matrix object, i.e., an object inheriting from `diagonalMatrix` (or a “standard” `CsparseMatrix` diagonal matrix in cases that is preferred).

**Usage**

```
Diagonal(n, x = NULL)

.symDiagonal(n, x = rep.int(1,n), uplo = "U", kind)
.trDiagonal(n, x = 1, uplo = "U", unitri=TRUE, kind)
.sparseDiagonal(n, x = 1, uplo = "U",
 shape = if(missing(cols)) "t" else "g",
 unitri, kind, cols = if(n) 0:(n - 1L) else integer(0))
```

**Arguments**

**n** integer specifying the dimension of the (square) matrix. If missing, `length(x)` is used.

**x** numeric or logical; if missing, a *unit* diagonal  $n \times n$  matrix is created.

|        |                                                                                                                                                                                                                                                                                               |
|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| uplo   | for <code>.symDiagonal</code> ( <code>.trDiagonal</code> ), the resulting sparse <code>symmetricMatrix</code> (or <code>triangularMatrix</code> ) will have slot <code>uplo</code> set from this argument, either "U" or "L". Only rarely will it make sense to change this from the default. |
| shape  | string of 1 character, one of <code>c("t", "s", "g")</code> , to choose a triangular, symmetric or general result matrix.                                                                                                                                                                     |
| unitri | optional logical indicating if a triangular result should be “unit-triangular”, i.e., with <code>diag = "U"</code> slot, if possible. The default, <code>missing</code> , is the same as <code>TRUE</code> .                                                                                  |
| kind   | string of 1 character, one of <code>c("d", "l", "n")</code> , to choose the storage mode of the result, from classes <code>dsparseMatrix</code> , <code>lsparseMatrix</code> , or <code>nsparseMatrix</code> , respectively.                                                                  |
| cols   | integer vector with values from <code>0:(n-1)</code> , denoting the <i>columns</i> to subselect conceptually, i.e., get the equivalent of <code>Diagonal(n, *)[, cols + 1]</code> .                                                                                                           |

### Value

`Diagonal()` returns an object of class `ddiMatrix` or `ldiMatrix` (with “superclass” `diagonalMatrix`).

`.symDiagonal()` returns an object of class `dsCMatrix` or `lsCMatrix`, i.e., a *sparse symmetric* matrix. Analogously, `.triDiagonal` gives a sparse `triangularMatrix`. This can be more efficient than `Diagonal(n)` when the result is combined with further symmetric (sparse) matrices, e.g., in `kronecker`, however *not* for matrix multiplications where `Diagonal()` is clearly preferred.

`.sparseDiagonal()`, the workhorse of `.symDiagonal` and `.trDiagonal` returns a `CsparseMatrix` (the resulting class depending on `shape` and `kind`) representation of `Diagonal(n)`, or, when `cols` are specified, of `Diagonal(n)[, cols+1]`.

### Author(s)

Martin Maechler

### See Also

the generic function `diag` for *extraction* of the diagonal from a matrix works for all “Matrices”.

`bandSparse` constructs a *banded* sparse matrix from its non-zero sub-/super - diagonals. `band(A)` returns a band matrix containing some sub-/super - diagonals of `A`.

`Matrix` for general matrix construction; further, class `diagonalMatrix`.

### Examples

```
Diagonal(3)
Diagonal(x = 10^(3:1))
Diagonal(x = (1:4) >= 2) #-> "ldiMatrix"

Use Diagonal() + kronecker() for "repeated-block" matrices:
M1 <- Matrix(0+0:5, 2, 3)
(M <- kronecker(Diagonal(3), M1))

(S <- crossprod(Matrix(rbinom(60, size=1, prob=0.1), 10, 6)))
(SI <- S + 10*.symDiagonal(6)) # sparse symmetric still
stopifnot(is(SI, "dsCMatrix"))
(I4 <- .sparseDiagonal(4, shape="t")) # now (2012-10) unittriangular
```

```
stopifnot(I4@diag == "U", all(I4 == diag(4)))
```

---

diagonalMatrix-class

*Class "diagonalMatrix" of Diagonal Matrices*

---

## Description

Class "diagonalMatrix" is the virtual class of all diagonal matrices.

## Objects from the Class

A virtual Class: No objects may be created from it.

## Slots

**diag:** code"character" string, either "U" or "N", where "U" means ‘unit-diagonal’.

**Dim:** matrix dimension, and

**Dimnames:** the [dimnames](#), a [list](#), see the [Matrix](#) class description. Typically `list(NULL, NULL)` for diagonal matrices.

## Extends

Class "[sparseMatrix](#)", directly.

## Methods

These are just a subset of the signature for which defined methods. Currently, there are (too) many explicit methods defined in order to ensure efficient methods for diagonal matrices.

**coerce** signature(from = "matrix", to = "diagonalMatrix"): ...

**coerce** signature(from = "Matrix", to = "diagonalMatrix"): ...

**coerce** signature(from = "diagonalMatrix", to = "generalMatrix"): ...

**coerce** signature(from = "diagonalMatrix", to = "triangularMatrix"): ...

**coerce** signature(from = "diagonalMatrix", to = "nMatrix"): ...

**coerce** signature(from = "diagonalMatrix", to = "matrix"): ...

**coerce** signature(from = "diagonalMatrix", to = "sparseVector"): ...

**t** signature(x = "diagonalMatrix"): ...

and many more methods

**solve** signature(a = "diagonalMatrix", b, ...): is trivially implemented, of course; see also [solve-methods](#).

**which** signature(x = "nMatrix"), semantically equivalent to **base** function [which](#)(x, arr.ind).

**"Math"** signature(x = "diagonalMatrix"): all these group methods return a "diagonalMatrix", apart from [cumsum](#)() etc which return a *vector* also for **base** [matrix](#).

```
* signature(e1 = "ddiMatrix", e2 = "denseMatrix"): arithmetic and other operators
 from the Ops group have a few dozen explicit method definitions, in order to keep the results
 diagonal in many cases, including the following:

/ signature(e1 = "ddiMatrix", e2 = "denseMatrix"): the result is from class
 ddiMatrix which is typically very desirable. Note that when e2 contains off-diagonal
 zeros or NAs, we implicitly use $0/x = 0$, hence differing from traditional R arithmetic (where
 $0/0 \mapsto \text{NaN}$), in order to preserve sparsity.

summary (object = "diagonalMatrix"): Returns an object of S3 class
 "diagSummary" which is the summary of the vector object@x plus a simple heading,
 and an appropriate print method.
```

### See Also

`Diagonal()` as constructor of these matrices, and `isDiagonal`. `ddiMatrix` and `ldiMatrix` are “actual” classes extending “diagonalMatrix”.

### Examples

```
I5 <- Diagonal(5)
D5 <- Diagonal(x = 10*(1:5))
trivial (but explicitly defined) methods:
stopifnot(identical(crossprod(I5), I5),
 identical(tcrossprod(I5), I5),
 identical(crossprod(I5, D5), D5),
 identical(tcrossprod(D5, I5), D5),
 identical(solve(D5), solve(D5, I5)),
 all.equal(D5, solve(solve(D5)), tolerance = 1e-12)
)
solve(D5) # efficient as is diagonal

an unusual way to construct a band matrix:
rbind2(cbind2(I5, D5),
 cbind2(D5, I5))
```

---

diagU2N

*Transform Triangular Matrices from Unit Triangular to General Triangular and Back*

---

### Description

Transform a triangular matrix `x`, i.e., of class “`triangularMatrix`”, from (internally!) unit triangular (“unitriangular”) to “general” triangular (`diagU2N(x)`) or back (`diagN2U(x)`). Note that the latter, `diagN2U(x)`, also sets the diagonal to one in cases where `diag(x)` was not all one.

`.diagU2N(x)` assumes but does *not* check that `x` is a `triangularMatrix` with `diag` slot “U”, and should hence be used with care.

### Usage

```
diagN2U(x, cl = getClassDef(class(x)), checkDense = FALSE)

diagU2N(x, cl = getClassDef(class(x)), checkDense = FALSE)
.diagU2N(x, cl, checkDense = FALSE)
```

**Arguments**

|                         |                                                                                                                                                                                                  |
|-------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>          | a <code>triangularMatrix</code> , often sparse.                                                                                                                                                  |
| <code>cl</code>         | (optional, for speedup only:) class (definition) of <code>x</code> .                                                                                                                             |
| <code>checkDense</code> | logical indicating if dense (see <code>denseMatrix</code> ) matrices should be considered at all; i.e., when false, as per default, the result will be sparse even when <code>x</code> is dense. |

**Details**

The concept of unit triangular matrices with a `diag` slot of "U" stems from LAPACK.

**Value**

a triangular matrix of the same `class` but with a different `diag` slot. For `diagU2N` (semantically) with identical entries as `x`, whereas in `diagN2U(x)`, the off-diagonal entries are unchanged and the diagonal is set to all 1 even if it was not previously.

**Note**

Such internal storage details should rarely be of relevance to the user. Hence, these functions really are rather *internal* utilities.

**See Also**

"`triangularMatrix`", "`dtCMatrix`".

**Examples**

```
(T <- Diagonal(7) + triu(Matrix(rpois(49, 1/4), 7,7), k = 1))
(uT <- diagN2U(T)) # "unittriangular"
(t.u <- diagN2U(10*T)) # changes the diagonal!
stopifnot(all(T == uT), diag(t.u) == 1,
 identical(T, diagU2N(uT)))
T[upper.tri(T)] <- 5
T <- diagN2U(as(T, "triangularMatrix"))
stopifnot(T@diag == "U")
dT <- as(T, "denseMatrix")
dt. <- diagN2U(dT)
dtU <- diagN2U(dT, checkDense=TRUE)
stopifnot(is(dtU, "denseMatrix"), is(dt., "sparseMatrix"),
 all(dT == dt.), all(dT == dtU),
 dt.@diag == "U", dtU@diag == "U")
```

---

dMatrix-class

(Virtual) Class "dMatrix" of "double" Matrices

---

**Description**

The `dMatrix` class is a virtual class contained by all actual classes of numeric matrices in the **Matrix** package. Similarly, all the actual classes of logical matrices inherit from the `lMatrix` class.

## Slots

Common to *all* matrix object in the package:

**Dim:** Object of class "integer" - the dimensions of the matrix - must be an integer vector with exactly two non-negative values.

**Dimnames:** list of length two; each component containing NULL or a [character](#) vector length equal the corresponding Dim element.

## Methods

There are (relatively simple) group methods (see, e.g., [Arith](#))

**Arith** signature(e1 = "dMatrix", e2 = "dMatrix"): ...

**Arith** signature(e1 = "dMatrix", e2 = "numeric"): ...

**Arith** signature(e1 = "numeric", e2 = "dMatrix"): ...

**Math** signature(x = "dMatrix"): ...

**Math2** signature(x = "dMatrix", digits = "numeric"): this group contains [round\(\)](#) and [signif\(\)](#).

**Compare** signature(e1 = "numeric", e2 = "dMatrix"): ...

**Compare** signature(e1 = "dMatrix", e2 = "numeric"): ...

**Compare** signature(e1 = "dMatrix", e2 = "dMatrix"): ...

**Summary** signature(x = "dMatrix"): The "Summary" group contains the seven functions [max\(\)](#), [min\(\)](#), [range\(\)](#), [prod\(\)](#), [sum\(\)](#), [any\(\)](#), and [all\(\)](#).

The following methods are also defined for all double matrices:

**coerce** signature(from = "dMatrix", to = "matrix"): ...

**expm** signature(x = "dMatrix"): computes the "*Matrix Exponential*", see [expm](#).

**zapsmall** signature(x = "dMatrix"): ...

The following methods are defined for all logical matrices:

**which** signature(x = "lsparseMatrix") and many other subclasses of "lMatrix": as the **base** function [which](#)(x, arr.ind) returns the indices of the [TRUE](#) entries in x; if arr.ind is true, as a 2-column matrix of row and column indices. Since **Matrix** version 1.2-9, if useNames is true, as by default, with [dimnames](#), the same as `base::which`.

## See Also

The nonzero-pattern matrix class [nMatrix](#), which can be used to store non-NA [logical](#) matrices even more compactly.

The numeric matrix classes [dgeMatrix](#), [dgCMatrix](#), and [Matrix](#).

[drop0](#)(x, tol=1e-10) is sometimes preferable to (and more efficient than) [zapsmall](#)(x, digits=10).

## Examples

```
showClass("dMatrix")

set.seed(101)
round(Matrix(rnorm(28), 4, 7), 2)
M <- Matrix(rlnorm(56, sd=10), 4, 14)
(M. <- zapsmall(M))
table(as.logical(M. == 0))
```

---

|                 |                                                                            |
|-----------------|----------------------------------------------------------------------------|
| dpoMatrix-class | <i>Positive Semi-definite Dense (Packed   Non-packed) Numeric Matrices</i> |
|-----------------|----------------------------------------------------------------------------|

---

## Description

- The "dpoMatrix" class is the class of positive-semidefinite symmetric matrices in non-packed storage.
- The "dppMatrix" class is the same except in packed storage. Only the upper triangle or the lower triangle is required to be available.
- The "corMatrix" class of correlation matrices extends "dpoMatrix" with a slot `sd`, which allows to restore the original covariance matrix.

## Objects from the Class

Objects can be created by calls of the form `new("dpoMatrix", ...)` or from `crossprod` applied to an "dgeMatrix" object.

## Slots

**uplo:** Object of class "character". Must be either "U", for upper triangular, and "L", for lower triangular.

**x:** Object of class "numeric". The numeric values that constitute the matrix, stored in column-major order.

**Dim:** Object of class "integer". The dimensions of the matrix which must be a two-element vector of non-negative integers.

**Dimnames:** inherited from class "Matrix"

**factors:** Object of class "list". A named list of factorizations that have been computed for the matrix.

**sd:** (for "corMatrix") a [numeric](#) vector of length `n` containing the (original)  $\sqrt{\text{var}(\cdot)}$  entries which allow reconstruction of a covariance matrix from the correlation matrix.

## Extends

Class "dsyMatrix", directly.  
 Classes "dgeMatrix", "symmetricMatrix", and many more by class "dsyMatrix".

## Methods

**chol** signature (x = "dpoMatrix"): Returns (and stores) the Cholesky decomposition of x, see [chol](#).

**determinant** signature (x = "dpoMatrix"): Returns the [determinant](#) of x, via `chol(x)`, see above.

**rcond** signature (x = "dpoMatrix", norm = "character"): Returns (and stores) the reciprocal of the condition number of x. The norm can be "O" for the one-norm (the default) or "I" for the infinity-norm. For symmetric matrices the result does not depend on the norm.

**solve** signature (a = "dpoMatrix", b = "..."), and

**solve** signature (a = "dppMatrix", b = "...") work via the Cholesky composition, see also the Matrix [solve-methods](#).

**Arith** signature (e1 = "dpoMatrix", e2 = "numeric") (and quite a few other signatures): The result of ("elementwise" defined) arithmetic operations is typically *not* positive-definite anymore. The only exceptions, currently, are multiplications, divisions or additions with *positive* `length(.) == 1` numbers (or [logicals](#)).

## See Also

Classes [dsyMatrix](#) and [dgeMatrix](#); further, [Matrix](#), [rcond](#), [chol](#), [solve](#), [crossprod](#).

## Examples

```
h6 <- Hilbert(6)
rcond(h6)
str(h6)
h6 * 27720 # is ``integer``
solve(h6)
str(hp6 <- as(h6, "dppMatrix"))

Note that as(*, "corMatrix") *scales* the matrix
(ch6 <- as(h6, "corMatrix"))
stopifnot(all.equal(h6 * 27720, round(27720 * h6), tolerance = 1e-14),
 all.equal(ch6@sd^(-2), 2*(1:6)-1, tolerance= 1e-12))
chch <- chol(ch6)
stopifnot(identical(chch, ch6@factors$Cholesky),
 all(abs(crossprod(chch) - ch6) < 1e-10))
```

---

drop0

*Drop "Explicit Zeroes" from a Sparse Matrix*

---

## Description

Returns a sparse matrix with no "explicit zeroes", i.e., all zero or FALSE entries are dropped from the explicitly indexed matrix entries.

## Usage

```
drop0(x, tol = 0, is.Csparse = NA)
```

**Arguments**

|                         |                                                                                                                              |
|-------------------------|------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>          | a Matrix, typically sparse, i.e., inheriting from <code>sparseMatrix</code> .                                                |
| <code>tol</code>        | non-negative number to be used as tolerance for checking if an entry $x_{i,j}$ should be considered to be zero.              |
| <code>is.Csparse</code> | logical indicating prior knowledge about the “Cspareness” of <code>x</code> . This exists for possible speedup reasons only. |

**Value**

a Matrix like `x` but with no explicit zeros, i.e., `!any(x@x == 0)`, always inheriting from `CsparseMatrix`.

**Note**

When a sparse matrix is the result of matrix multiplications, you may want to consider combining `drop0()` with `zapsmall()`, see the example.

**See Also**

`spMatrix`, class `sparseMatrix`; `nnzero`

**Examples**

```
m <- spMatrix(10,20, i= 1:8, j=2:9, x = c(0:2,3:-1))
m
drop0(m)

A larger example:
t5 <- new("dtCMatrix", Dim = c(5L, 5L), uplo = "L",
 x = c(10, 1, 3, 10, 1, 10, 1, 10, 10),
 i = c(0L,2L,4L, 1L, 3L,2L,4L, 3L, 4L),
 p = c(0L, 3L, 5L, 7:9))
TT <- kronecker(t5, kronecker(kronecker(t5,t5), t5))
IT <- solve(TT)
I. <- TT %*% IT ; nnzero(I.) # 697 (= 625 + 72)
I.0 <- drop0(zapsmall(I.))
which actually can be more efficiently achieved by
I.. <- drop0(I., tol = 1e-15)
stopifnot(all(I.0 == Diagonal(625)),
 nnzero(I..) == 625)
```

---

dsCMatrix-class

*Numeric Symmetric Sparse (column compressed) Matrices*

---

**Description**

The `dsCMatrix` class is a class of symmetric, sparse numeric matrices in the compressed, column-oriented format. In this implementation the non-zero elements in the columns are sorted into increasing row order.

The `dsTMatrix` class is the class of symmetric, sparse numeric matrices in triplet format.

## Objects from the Class

Objects can be created by calls of the form `new("dsCMatrix",...)` or `new("dsTMatrix",...)`, or automatically via e.g., `as(*,"symmetricMatrix")`, or (for `dsCMatrix`) also from `Matrix(.)`.

Creation “from scratch” most efficiently happens via `sparseMatrix(*, symmetric=TRUE)`.

## Slots

**uplo:** A character object indicating if the upper triangle ("U") or the lower triangle ("L") is stored.

**i:** Object of class "integer" of length `nnZ` (*half* number of non-zero elements). These are the row numbers for each non-zero element in the lower triangle of the matrix.

**p:** (only in class "dsCMatrix":) an `integer` vector for providing pointers, one for each column, see the detailed description in `CsparseMatrix`.

**j:** (only in class "dsTMatrix":) Object of class "integer" of length `nnZ` (as `i`). These are the column numbers for each non-zero element in the lower triangle of the matrix.

**x:** Object of class "numeric" of length `nnZ` – the non-zero elements of the matrix (to be duplicated for full matrix).

**factors:** Object of class "list" - a list of factorizations of the matrix.

**Dim:** Object of class "integer" - the dimensions of the matrix - must be an integer vector with exactly two non-negative values.

## Extends

Both classes extend classes `symmetricMatrix` `dsparseMatrix` directly; `dsCMatrix` further directly extends `CsparseMatrix`, where `dsTMatrix` does `TsparseMatrix`.

## Methods

**solve** signature(`a` = "dsCMatrix", `b` = "..."): `x <- solve(a,b)` solves  $Ax = b$  for `x`; see `solve-methods`.

**chol** signature(`x` = "dsCMatrix", `pivot` = "logical"): Returns (and stores) the Cholesky decomposition of `x`, see `chol`.

**Cholesky** signature(`A` = "dsCMatrix", ...): Computes more flexibly Cholesky decompositions, see `Cholesky`.

**determinant** signature(`x` = "dsCMatrix", `logarithm` = "missing"): Evaluate the determinant of `x` on the logarithm scale. This creates and stores the Cholesky factorization.

**determinant** signature(`x` = "dsCMatrix", `logarithm` = "logical"): Evaluate the determinant of `x` on the logarithm scale or not, according to the `logarithm` argument. This creates and stores the Cholesky factorization.

**t** signature(`x` = "dsCMatrix"): Transpose. As for all symmetric matrices, a matrix for which the upper triangle is stored produces a matrix for which the lower triangle is stored and vice versa, i.e., the `uplo` slot is swapped, and the row and column indices are interchanged.

**t** signature(`x` = "dsTMatrix"): Transpose. The `uplo` slot is swapped from "U" to "L" or vice versa, as for a "dsCMatrix", see above.

**coerce** signature(`from` = "dsCMatrix", `to` = "dgTMatrix")

**coerce** signature(`from` = "dsCMatrix", `to` = "dgeMatrix")

**coerce** signature(`from` = "dsCMatrix", `to` = "matrix")

```

coerce signature(from = "dsTMatrix",to = "dgeMatrix")
coerce signature(from = "dsTMatrix",to = "dsCMatrix")
coerce signature(from = "dsTMatrix",to = "dsyMatrix")
coerce signature(from = "dsTMatrix",to = "matrix")

```

### See Also

Classes [dgCMatrix](#), [dgTMatrix](#), [dgeMatrix](#) and those mentioned above.

### Examples

```

mm <- Matrix(toeplitz(c(10, 0, 1, 0, 3)), sparse = TRUE)
mm # automatically dsCMatrix
str(mm)

how would we go from a manually constructed Tsparse* :
mT <- as(mm, "dgTMatrix")

Either
(symM <- as(mT, "symmetricMatrix"))# dsT
(symC <- as(symM, "CsparseMatrix"))# dsC
or
sC <- Matrix(mT, sparse=TRUE, forceCheck=TRUE)

sym2 <- as(symC, "TsparseMatrix")
--> the same as 'symM', a "dsTMatrix"

```

---

dsparseMatrix-class

*Virtual Class "dsparseMatrix" of Numeric Sparse Matrices*

---

### Description

The Class "dsparseMatrix" is the virtual (super) class of all numeric sparse matrices.

### Slots

**Dim:** the matrix dimension, see class "[Matrix](#)".  
**Dimnames:** see the "Matrix" class.  
**x:** a [numeric](#) vector containing the (non-zero) matrix entries.

### Extends

Class "dMatrix" and "sparseMatrix", directly.  
 Class "Matrix", by the above classes.

### See Also

the documentation of the (non virtual) sub classes, see `showClass("dsparseMatrix")`; in particular, [dgTMatrix](#), [dgCMatrix](#), and [dgRMatrix](#).

**Examples**

```
showClass("dsparseMatrix")
```

---

|                 |                                                 |
|-----------------|-------------------------------------------------|
| dsRMatrix-class | <i>Symmetric Sparse Compressed Row Matrices</i> |
|-----------------|-------------------------------------------------|

---

**Description**

The `dsRMatrix` class is a class of symmetric, sparse matrices in the compressed, row-oriented format. In this implementation the non-zero elements in the rows are sorted into increasing column order.

**Objects from the Class**

These `"...RMatrix"` classes are currently still mostly unimplemented!

Objects can be created by calls of the form `new("dsRMatrix", ...)`.

**Slots**

**uplo:** A character object indicating if the upper triangle ("U") or the lower triangle ("L") is stored. At present only the lower triangle form is allowed.

**j:** Object of class `"integer"` of length `nnzero` (number of non-zero elements). These are the row numbers for each non-zero element in the matrix.

**p:** Object of class `"integer"` of pointers, one for each row, to the initial (zero-based) index of elements in the row.

**factors:** Object of class `"list"` - a list of factorizations of the matrix.

**x:** Object of class `"numeric"` - the non-zero elements of the matrix.

**Dim:** Object of class `"integer"` - the dimensions of the matrix - must be an integer vector with exactly two non-negative values.

**Dimnames:** List of length two, see [Matrix](#).

**Extends**

Classes [RsparseMatrix](#), [dsparseMatrix](#) and [symmetricMatrix](#), directly.

Class `"dMatrix"`, by class `"dsparseMatrix"`, class `"sparseMatrix"`, by class `"dsparseMatrix"` or `"RsparseMatrix"`; class `"compMatrix"` by class `"symmetricMatrix"` and of course, class `"Matrix"`.

**Methods**

**forceSymmetric** signature (`x = "dsRMatrix"`, `uplo = "missing"`): a trivial method just returning `x`

**forceSymmetric** signature (`x = "dsRMatrix"`, `uplo = "character"`): if `uplo == x@uplo`, this trivially returns `x`; otherwise `t(x)`.

**coerce** signature (`from = "dsCMatrix"`, `to = "dsRMatrix"`)

**See Also**

the classes [dgCMatrix](#), [dgTMatrix](#), and [dgeMatrix](#).

**Examples**

```

(m0 <- new("dsRMatrix"))
m2 <- new("dsRMatrix", Dim = c(2L,2L),
 x = c(3,1), j = c(1L,1L), p = 0:2)
m2
stopifnot(colSums(as(m2, "TsparseMatrix")) == 3:4)
str(m2)
(ds2 <- forceSymmetric(diag(2))) # dsy*
dR <- as(ds2, "RsparseMatrix")
dR # dsRMatrix

```

|                 |                                                               |
|-----------------|---------------------------------------------------------------|
| dsyMatrix-class | <i>Symmetric Dense (Packed   Non-packed) Numeric Matrices</i> |
|-----------------|---------------------------------------------------------------|

---

**Description**

- The "dsyMatrix" class is the class of symmetric, dense matrices in *non-packed* storage and
- "dspMatrix" is the class of symmetric dense matrices in *packed* storage. Only the upper triangle or the lower triangle is stored.

**Objects from the Class**

Objects can be created by calls of the form `new("dsyMatrix",...)` or `new("dspMatrix",...)`, respectively.

**Slots**

**uplo:** Object of class "character". Must be either "U", for upper triangular, and "L", for lower triangular.

**x:** Object of class "numeric". The numeric values that constitute the matrix, stored in column-major order.

**Dim,Dimnames:** The dimension (a length-2 "integer") and corresponding names (or NULL), see the [Matrix](#).

**factors:** Object of class "list". A named list of factorizations that have been computed for the matrix.

**Extends**

"dsyMatrix" extends class "dgeMatrix", directly, whereas

"dspMatrix" extends class "ddenseMatrix", directly.

Both extend class "symmetricMatrix", directly, and class "Matrix" and others, *indirectly*, use `showClass("dsyMatrix")`, e.g., for details.

**Methods**

**coerce** signature(from = "ddenseMatrix", to = "dgeMatrix")

**coerce** signature(from = "dspMatrix", to = "matrix")

**coerce** signature(from = "dsyMatrix", to = "matrix")

**coerce** signature (from = "dsyMatrix", to = "dspMatrix")

**coerce** signature (from = "dspMatrix", to = "dsyMatrix")

**norm** signature (x = "dspMatrix", type = "character"), or x = "dsyMatrix" or type = "missing": Computes the matrix norm of the desired type, see, [norm](#).

**rcond** signature (x = "dspMatrix", type = "character"), or x = "dsyMatrix" or type = "missing": Computes the reciprocal condition number, [rcond\(\)](#).

**solve** signature (a = "dspMatrix", b = "..."), and

**solve** signature (a = "dsyMatrix", b = "..."):  $x \leftarrow \text{solve}(a, b)$  solves  $Ax = b$  for  $x$ ; see [solve-methods](#).

**t** signature (x = "dsyMatrix"): Transpose; swaps from upper triangular to lower triangular storage, i.e., the uplo slot from "U" to "L" or vice versa, the same as for all symmetric matrices.

### See Also

The *positive (Semi-)definite* dense (packed or non-packed numeric matrix classes [dpoMatrix](#), [dppMatrix](#) and [corMatrix](#),

Classes [dgeMatrix](#) and [Matrix](#); [solve](#), [norm](#), [rcond](#), [t](#)

### Examples

```
Only upper triangular part matters (when uplo == "U" as per default)
(sy2 <- new("dsyMatrix", Dim = as.integer(c(2,2)), x = c(14, NA, 32, 77)))
str(t(sy2)) # uplo = "L", and the lower tri. (i.e. NA is replaced).

chol(sy2) #-> "Cholesky" matrix
(sp2 <- pack(sy2)) # a "dspMatrix"

Coercing to dpoMatrix gives invalid object:
sy3 <- new("dsyMatrix", Dim = as.integer(c(2,2)), x = c(14, -1, 2, -7))
try(as(sy3, "dpoMatrix")) # -> error: not positive definite
```

|                 |                                                        |
|-----------------|--------------------------------------------------------|
| dtCMatrix-class | <i>Triangular, (compressed) sparse column matrices</i> |
|-----------------|--------------------------------------------------------|

---

### Description

The "dtCMatrix" class is a class of triangular, sparse matrices in the compressed, column-oriented format. In this implementation the non-zero elements in the columns are sorted into increasing row order.

The "dtTMatrix" class is a class of triangular, sparse matrices in triplet format.

### Objects from the Class

Objects can be created by calls of the form `new("dtCMatrix", ...)` or calls of the form `new("dtTMatrix", ...)`, but more typically automatically via [Matrix\(\)](#) or coercion such as `as(x, "triangularMatrix")`, or `as(x, "dtCMatrix")`.

## Slots

- uplo:** Object of class "character". Must be either "U", for upper triangular, and "L", for lower triangular.
- diag:** Object of class "character". Must be either "U", for unit triangular (diagonal is all ones), or "N"; see [triangularMatrix](#).
- p:** (only present in "dtCMatrix":) an [integer](#) vector for providing pointers, one for each column, see the detailed description in [CsparseMatrix](#).
- i:** Object of class "integer" of length nnzero (number of non-zero elements). These are the row numbers for each non-zero element in the matrix.
- j:** Object of class "integer" of length nnzero (number of non-zero elements). These are the column numbers for each non-zero element in the matrix. (Only present in the [dtTMatrix](#) class.)
- x:** Object of class "numeric" - the non-zero elements of the matrix.
- Dim,Dimnames:** The dimension (a length-2 "integer") and corresponding names (or NULL), inherited from the [Matrix](#), see there.

## Extends

Class "dgCMatrix", directly. Class "triangularMatrix", directly. Class "dMatrix", "sparseMatrix", and more by class "dgCMatrix" etc, see the examples.

## Methods

- coerce** signature(from = "dtCMatrix",to = "dgTMatrix")
- coerce** signature(from = "dtCMatrix",to = "dgeMatrix")
- coerce** signature(from = "dtTMatrix",to = "dgeMatrix")
- coerce** signature(from = "dtTMatrix",to = "dtrMatrix")
- coerce** signature(from = "dtTMatrix",to = "matrix")
- solve** signature(a = "dtCMatrix",b = "..."): sparse triangular solve (aka "back-solve" or "forwardsolve"), see [solve-methods](#).
- t** signature(x = "dtCMatrix"): returns the transpose of x
- t** signature(x = "dtTMatrix"): returns the transpose of x

## See Also

Classes [dgCMatrix](#), [dgTMatrix](#), [dgeMatrix](#), and [dtrMatrix](#).

## Examples

```
showClass("dtCMatrix")

showClass("dtTMatrix")
t1 <- new("dtTMatrix", x= c(3,7), i= 0:1, j=3:2, Dim= as.integer(c(4,4)))
t1
from 0-diagonal to unit-diagonal {low-level step}:
tu <- t1 ; tu@diag <- "U"
tu
(cu <- as(tu, "dtCMatrix"))
str(cu)# only two entries in @i and @x
stopifnot(cu@i == 1:0,
```

```

all(2 * symmpart(cu) == Diagonal(4) + forceSymmetric(cu))

t1[1,2:3] <- -1:-2
diag(t1) <- 10*c(1:2,3:2)
t1 # still triangular
(it1 <- solve(t1))
t1. <- solve(it1)
all(abs(t1 - t1.) < 10 * .Machine$double.eps)

2nd example
U5 <- new("dtCMatrix", i= c(1L, 0:3), p=c(0L,0L,0:2, 5L), Dim = c(5L, 5L),
 x = rep(1, 5), diag = "U")
U5
(iu <- solve(U5)) # contains one '0'
validObject(iu2 <- solve(U5, Diagonal(5)))# failed in earlier versions

I5 <- iu %*% U5 # should equal the identity matrix
i5 <- iu2 %*% U5
m53 <- matrix(1:15, 5,3, dimnames=list(NULL,letters[1:3]))
asDiag <- function(M) as(drop0(M), "diagonalMatrix")
stopifnot(
 all.equal(Diagonal(5), asDiag(I5), tolerance=1e-14) ,
 all.equal(Diagonal(5), asDiag(i5), tolerance=1e-14) ,
 identical(list(NULL, dimnames(m53)[[2]]), dimnames(solve(U5, m53)))
)

```

dtpMatrix-class

*Packed Triangular Dense Matrices - "dtpMatrix"*

## Description

The "dtpMatrix" class is the class of triangular, dense, numeric matrices in packed storage. The "dtrMatrix" class is the same except in nonpacked storage.

## Objects from the Class

Objects can be created by calls of the form `new("dtpMatrix", ...)` or by coercion from other classes of matrices.

## Slots

**uplo:** Object of class "character". Must be either "U", for upper triangular, and "L", for lower triangular.

**diag:** Object of class "character". Must be either "U", for unit triangular (diagonal is all ones), or "N"; see [triangularMatrix](#).

**x:** Object of class "numeric". The numeric values that constitute the matrix, stored in column-major order. For a packed square matrix of dimension  $d \times d$ , `length(x)` is of length  $d(d+1)/2$  (also when `diag == "U"`!).

**Dim,Dimnames:** The dimension (a length-2 "integer") and corresponding names (or NULL), inherited from the [Matrix](#), see there.

## Extends

Class "ddenseMatrix", directly. Class "triangularMatrix", directly. Class "dMatrix" and more by class "ddenseMatrix" etc, see the examples.

## Methods

```
%% signature(x = "dtpMatrix", y = "dgeMatrix"): Matrix multiplication;
ditto for several other signature combinations, see showMethods("%*%", class =
"dtpMatrix").

coerce signature(from = "dtpMatrix", to = "dtrMatrix")

coerce signature(from = "dtpMatrix", to = "matrix")

determinant signature(x = "dtpMatrix", logarithm = "logical"): the
determinant(x) trivially is prod(diag(x)), but computed on log scale to pre-
vent over- and underflow.

diag signature(x = "dtpMatrix"): ...

norm signature(x = "dtpMatrix", type = "character"): ...

rcond signature(x = "dtpMatrix", norm = "character"): ...

solve signature(a = "dtpMatrix", b = "..."): efficiently using internal backsolve or
forwardsolve, see solve-methods.

t signature(x = "dtpMatrix"): t(x) remains a "dtpMatrix", lower triangular if x is
upper triangular, and vice versa.
```

## See Also

Class [dtrMatrix](#)

## Examples

```
showClass("dtrMatrix")

example("dtrMatrix-class", echo=FALSE)
(p1 <- as(T2, "dtpMatrix"))
str(p1)
(pp <- as(T, "dtpMatrix"))
ip1 <- solve(p1)
stopifnot(length(p1@x) == 3, length(pp@x) == 3,
 p1 @ uplo == T2 @ uplo, pp @ uplo == T @ uplo,
 identical(t(pp), p1), identical(t(p1), pp),
 all((l.d <- p1 - T2) == 0), is(l.d, "dtpMatrix"),
 all((u.d <- pp - T) == 0), is(u.d, "dtpMatrix"),
 l.d@uplo == T2@uplo, u.d@uplo == T@uplo,
 identical(t(ip1), solve(pp)), is(ip1, "dtpMatrix"),
 all.equal(as(solve(p1,p1), "diagonalMatrix"), Diagonal(2)))
```

---

dtRMatrix-class      *Triangular Sparse Compressed Row Matrices*

---

## Description

The `dtRMatrix` class is a class of triangular, sparse matrices in the compressed, row-oriented format. In this implementation the non-zero elements in the rows are sorted into increasing columnnd order.

## Objects from the Class

This class is currently still mostly unimplemented!

Objects can be created by calls of the form `new("dtRMatrix", ...)`.

## Slots

**uplo:** Object of class "character". Must be either "U", for upper triangular, and "L", for lower triangular. At present only the lower triangle form is allowed.

**diag:** Object of class "character". Must be either "U", for unit triangular (diagonal is all ones), or "N"; see [triangularMatrix](#).

**j:** Object of class "integer" of length `nnzero(.)` (number of non-zero elements). These are the row numbers for each non-zero element in the matrix.

**p:** Object of class "integer" of pointers, one for each row, to the initial (zero-based) index of elements in the row. (Only present in the `dsRMatrix` class.)

**x:** Object of class "numeric" - the non-zero elements of the matrix.

**Dim:** The dimension (a length-2 "integer")

**Dimnames:** corresponding names (or NULL), inherited from the [Matrix](#), see there.

## Extends

Class "dgRMatrix", directly. Class "dsparseMatrix", by class "dgRMatrix". Class "dMatrix", by class "dgRMatrix". Class "sparseMatrix", by class "dgRMatrix". Class "Matrix", by class "dgRMatrix".

## Methods

No methods currently with class "dsRMatrix" in the signature.

## See Also

Classes [dgCMatrix](#), [dgTMatrix](#), [dgeMatrix](#)

## Examples

```
(m0 <- new("dtRMatrix"))
(m2 <- new("dtRMatrix", Dim = c(2L,2L),
 x = c(5, 1:2), p = c(0L,2:3), j= c(0:1,1L)))
str(m2)
(m3 <- as(Diagonal(2), "RsparseMatrix"))# --> dtRMatrix
```

---

|                 |                                            |
|-----------------|--------------------------------------------|
| dtrMatrix-class | <i>Triangular, dense, numeric matrices</i> |
|-----------------|--------------------------------------------|

---

## Description

The "dtrMatrix" class is the class of triangular, dense, numeric matrices in nonpacked storage. The "dtpMatrix" class is the same except in packed storage.

## Objects from the Class

Objects can be created by calls of the form `new("dtrMatrix", ...)`.

## Slots

**uplo:** Object of class "character". Must be either "U", for upper triangular, and "L", for lower triangular.

**diag:** Object of class "character". Must be either "U", for unit triangular (diagonal is all ones), or "N"; see [triangularMatrix](#).

**x:** Object of class "numeric". The numeric values that constitute the matrix, stored in column-major order.

**Dim:** Object of class "integer". The dimensions of the matrix which must be a two-element vector of non-negative integers.

## Extends

Class "ddenseMatrix", directly. Class "triangularMatrix", directly. Class "Matrix" and others, by class "ddenseMatrix".

## Methods

Among others (such as matrix products, e.g. [?crossprod-methods](#)),

**coerce** signature (from = "dgeMatrix", to = "dtrMatrix")

**coerce** signature (from = "dtrMatrix", to = "matrix")

**coerce** signature (from = "dtrMatrix", to = "ltrMatrix")

**coerce** signature (from = "dtrMatrix", to = "matrix")

**coerce** signature (from = "matrix", to = "dtrMatrix")

**norm** signature (x = "dtrMatrix", type = "character")

**rcond** signature (x = "dtrMatrix", norm = "character")

**solve** signature (a = "dtrMatrix", b = "...") efficiently use a "forwardsolve" or backsolve for a lower or upper triangular matrix, respectively, see also [solve-methods](#).

**+, -, \*, ..., ==, >=, ...** all the [Ops](#) group methods are available. When applied to two triangular matrices, these return a triangular matrix when easily possible.

## See Also

Classes [ddenseMatrix](#), [dtpMatrix](#), [triangularMatrix](#)

**Examples**

```
(m <- rbind(2:3, 0:-1))
(M <- as(m, "dgeMatrix"))

(T <- as(M, "dtrMatrix")) ## upper triangular is default
(T2 <- as(t(M), "dtrMatrix"))
stopifnot(T@uplo == "U", T2@uplo == "L", identical(T2, t(T)))
```

expand

*Expand a (Matrix) Decomposition into Factors***Description**

Expands decompositions stored in compact form into factors.

**Usage**

```
expand(x, ...)
```

**Arguments**

`x` a matrix decomposition.  
`...` further arguments passed to or from other methods.

**Details**

This is a generic function with special methods for different types of decompositions, see [showMethods](#) (`expand`) to list them all.

**Value**

The expanded decomposition, typically a list of matrix factors.

**Note**

Factors for decompositions such as `lu` and `qr` can be stored in a compact form. The function `expand` allows all factors to be fully expanded.

**See Also**

The LU [lu](#), and the [Cholesky](#) decompositions which have `expand` methods; [facmul](#).

**Examples**

```
(x <- Matrix(round(rnorm(9), 2), 3, 3))
(ex <- expand(lux <- lu(x)))
```

---

expm*Matrix Exponential*

---

## Description

Compute the exponential of a matrix.

## Usage

```
expm(x)
```

## Arguments

`x` a matrix, typically inheriting from the `dMatrix` class.

## Details

The exponential of a matrix is defined as the infinite Taylor series  $\text{expm}(A) = I + A + A^2/2! + A^3/3! + \dots$  (although this is definitely not the way to compute it). The method for the `dgeMatrix` class uses Ward's diagonal Pade' approximation with three step preconditioning.

## Value

The matrix exponential of `x`.

## Note

The **expm** package contains newer (partly faster and more accurate) algorithms for `expm()` and includes `logm` and `sqrtm`.

## Author(s)

This is a translation of the implementation of the corresponding Octave function contributed to the Octave project by A. Scottedward Hodel <A.S.Hodel@Eng.Auburn.EDU>. A bug in there has been fixed by Martin Maechler.

## See Also

`Schur`; additionally, `expm`, `logm`, etc in package **expm**.

## Examples

```
(m1 <- Matrix(c(1,0,1,1), nc = 2))
(e1 <- expm(m1)) ; e <- exp(1)
stopifnot(all.equal(e1@x, c(e,0,e,e), tolerance = 1e-15))
(m2 <- Matrix(c(-49, -64, 24, 31), nc = 2))
(e2 <- expm(m2))
(m3 <- Matrix(cbind(0, rbind(6*diag(3), 0)))) # sparse!
(e3 <- expm(m3)) # upper triangular
```

externalFormats

*Read and write external matrix formats*

## Description

Read matrices stored in the Harwell-Boeing or MatrixMarket formats or write `sparseMatrix` objects to one of these formats.

## Usage

```
readHB(file)
readMM(file)
writeMM(obj, file, ...)
```

## Arguments

|                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>obj</code>  | a real sparse matrix                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <code>file</code> | for <code>writeMM</code> - the name of the file to be written. For <code>readHB</code> and <code>readMM</code> the name of the file to read, as a character scalar. The names of files storing matrices in the Harwell-Boeing format usually end in <code>".rua"</code> or <code>".rsa"</code> . Those storing matrices in the MatrixMarket format usually end in <code>".mtx"</code> . Alternatively, <code>readHB</code> and <code>readMM</code> accept connection objects. |
| <code>...</code>  | optional additional arguments. Currently none are used in any methods.                                                                                                                                                                                                                                                                                                                                                                                                        |

## Value

The `readHB` and `readMM` functions return an object that inherits from the `"Matrix"` class. Methods for the `writeMM` generic functions usually return `NULL` and, as a side effect, the matrix `obj` is written to `file` in the MatrixMarket format (`writeMM`).

## Note

The Harwell-Boeing format is older and less flexible than the MatrixMarket format. The function `writeHB` was deprecated and has now been removed. Please use `writeMM` instead.

A very simple way to export small sparse matrices `S`, is to use `summary(S)` which returns a `data.frame` with columns `i`, `j`, and possibly `x`, see `summary` in `sparseMatrix-class`, and an example below.

## References

<https://math.nist.gov/MatrixMarket/>  
<https://sparse.tamu.edu/>

## Examples

```
str(pores <- readMM(system.file("external/pores_1.mtx",
 package = "Matrix")))
str(utm <- readHB(system.file("external/utm300.rua",
 package = "Matrix")))
str(lundA <- readMM(system.file("external/lund_a.mtx",
 package = "Matrix")))
str(lundA <- readHB(system.file("external/lund_a.rsa",
 package = "Matrix")))

Not run:
NOTE: The following examples take quite some time
---- even on a fast internet connection:
if(FALSE) # the URL has been corrected, but we need an un-tar step!
str(sm <-
 readHB(gzcon(url("https://www.cise.ufl.edu/research/sparse/RB/Boeing/msc00726.tar.gz"))))

str(jgl009 <-
 readMM(gzcon(url("ftp://math.nist.gov/pub/MatrixMarket2/Harwell-Boeing/counterx/jgl009.mtx.gz"))))

End(Not run)
data(KNex)
Store as MatrixMarket (".mtx") file, here inside temporary dir./folder:
(MMfile <- file.path(tempdir(), "mmMM.mtx"))
writeMM(KNex$mm, file=MMfile)
file.info(MMfile)[,c("size", "ctime")] # (some confirmation of the file's)

very simple export - in triplet format - to text file:
data(CAex)
s.CA <- summary(CAex)
s.CA # shows (i, j, x) [columns of a data frame]
message("writing to ", outf <- tempfile())
write.table(s.CA, file = outf, row.names=FALSE)
and read it back -- showing off sparseMatrix():
str(dd <- read.table(outf, header=TRUE))
has columns (i, j, x) -> we can use via do.call() as arguments to sparseMatrix():
mm <- do.call(sparseMatrix, dd)
stopifnot(all.equal(mm, CAex, tolerance=1e-15))
```

---

 facmul

---

*Multiplication by Decomposition Factors*

---

## Description

Performs multiplication by factors for certain decompositions (and allows explicit formation of those factors).

## Usage

```
facmul(x, factor, y, transpose, left, ...)
```

## Arguments

**x** a matrix decomposition. No missing values or IEEE special values are allowed.

|           |                                                                                                                                |
|-----------|--------------------------------------------------------------------------------------------------------------------------------|
| factor    | an indicator for selecting a particular factor for multiplication.                                                             |
| y         | a matrix or vector to be multiplied by the factor or its transpose. No missing values or IEEE special values are allowed.      |
| transpose | a logical value. When FALSE (the default) the factor is applied. When TRUE the transpose of the factor is applied.             |
| left      | a logical value. When TRUE (the default) the factor is applied from the left. When FALSE the factor is applied from the right. |
| ...       | the method for "qr.Matrix" has additional arguments.                                                                           |

### Value

the product of the selected factor (or its transpose) and y

### NOTE

Factors for decompositions such as `lu` and `qr` can be stored in a compact form. The function `facmul` allows multiplication without explicit formation of the factors, saving both storage and operations.

### References

Golub, G., and Van Loan, C. F. (1989). *Matrix Computations*, 2nd edition, Johns Hopkins, Baltimore.

### Examples

```
library(Matrix)
x <- Matrix(rnorm(9), 3, 3)
Not run:
qrx <- qr(x) # QR factorization of x
y <- rnorm(3)
facmul(qr(x), factor = "Q", y) # form Q y

End(Not run)
```

---

forceSymmetric

*Force a Matrix to 'symmetricMatrix' Without Symmetry Checks*

---

### Description

Force a square matrix x to a [symmetricMatrix](#), **without** a symmetry check as it would be applied for `as(x, "symmetricMatrix")`.

### Usage

```
forceSymmetric(x, uplo)
```

**Arguments**

|                   |                                                                                                                                                                                                                                                                                                                                      |
|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>    | any square matrix (of numbers), either “traditional” ( <a href="#">matrix</a> ) or inheriting from <a href="#">Matrix</a> .                                                                                                                                                                                                          |
| <code>uplo</code> | optional string, "U" or "L" indicating which “triangle” half of <code>x</code> should determine the result. The default is "U" unless <code>x</code> already has a <code>uplo</code> slot (i.e., when it is <a href="#">symmetricMatrix</a> , or <a href="#">triangularMatrix</a> ), where the default will be <code>x@uplo</code> . |

**Value**

a square matrix inheriting from class [symmetricMatrix](#).

**See Also**

[symmpart](#) for the symmetric part of a matrix, or the coercions `as(x, <symmetricMatrix class>)`.

**Examples**

```
Hilbert matrix
i <- 1:6
h6 <- 1/outer(i - 1L, i, "+")
sd <- sqrt(diag(h6))
hh <- t(h6/sd)/sd # theoretically symmetric
isSymmetric(hh, tol=0) # FALSE; hence
try(as(hh, "symmetricMatrix")) # fails, but this works fine:
H6 <- forceSymmetric(hh)

result can be pretty surprising:
(M <- Matrix(1:36, 6))
forceSymmetric(M) # symmetric, hence very different in lower triangle
(tm <- tril(M))
forceSymmetric(tm)
```

**Description**

Utilities for formatting sparse numeric matrices in a flexible way. These functions are used by the [format](#) and [print](#) methods for sparse matrices and can be applied as well to standard R matrices. Note that *all* arguments but the first are optional.

`formatSparseM()` is the main “workhorse” of [formatSpMatrix](#), the `format` method for sparse matrices.

`.formatSparseSimple()` is a simple helper function, also dealing with (short/empty) column names construction.

**Usage**

```
formatSparseM(x, zero.print = ".", align = c("fancy", "right"),
 m = as(x, "matrix"), asLogical=NULL, uniDiag=NULL,
 digits=NULL, cx, iN0, dn = dimnames(m))

.formatSparseSimple(m, asLogical=FALSE, digits=NULL,
 col.names, note.dropping.colnames = TRUE,
 dn=dimnames(m))
```

**Arguments**

|                                                |                                                                                                                                                                                                             |
|------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>                                 | an R object inheriting from class <code>sparseMatrix</code> .                                                                                                                                               |
| <code>zero.print</code>                        | character which should be used for <i>structural</i> zeroes. The default "." may occasionally be replaced by " " (blank); using "0" would look almost like <code>print()</code> ing of non-sparse matrices. |
| <code>align</code>                             | a string specifying how the <code>zero.print</code> codes should be aligned, see <code>formatSpMatrix</code> .                                                                                              |
| <code>m</code>                                 | (optional) a (standard R) <code>matrix</code> version of <code>x</code> .                                                                                                                                   |
| <code>asLogical</code>                         | should the matrix be formatted as a logical matrix (or rather as a numeric one); mostly for <code>formatSparseM()</code> .                                                                                  |
| <code>uniDiag</code>                           | logical indicating if the diagonal entries of a sparse unit triangular or unit-diagonal matrix should be formatted as "I" instead of "1" (to emphasize that the 1's are "structural").                      |
| <code>digits</code>                            | significant digits to use for printing, see <code>print.default</code> .                                                                                                                                    |
| <code>cx</code>                                | (optional) character matrix; a formatted version of <code>x</code> , still with strings such as "0.00" for the zeros.                                                                                       |
| <code>iN0</code>                               | (optional) integer vector, specifying the location of the <i>non</i> -zeroes of <code>x</code> .                                                                                                            |
| <code>col.names, note.dropping.colnames</code> | see <code>formatSpMatrix</code> .                                                                                                                                                                           |
| <code>dn</code>                                | <code>dimnames</code> to be used; a list (of length two) with row and column names (or <code>NULL</code> ).                                                                                                 |

**Value**

a character matrix like `cx`, where the zeros have been replaced with (padded versions of) `zero.print`. As this is a *dense* matrix, do not use these functions for really large (really) sparse matrices!

**Author(s)**

Martin Maechler

**See Also**

`formatSpMatrix` which calls `formatSparseM()` and is the `format` method for sparse matrices.  
`printSpMatrix` which is used by the (typically implicitly called) `show` and `print` methods for sparse matrices.

**Examples**

```

m <- suppressWarnings(matrix(c(0, 3.2, 0, 0, 11, 0, 0, 0, 0, -7, 0), 4, 9))
fm <- formatSparseM(m)
noquote(fm)
nice, but this is nicer {with "units" vertically aligned}:
print(fm, quote=FALSE, right=TRUE)
and "the same" as :
Matrix(m)

align = "right" is cheaper --> the "." are not aligned:
noquote(f2 <- formatSparseM(m, align="r"))
stopifnot(f2 == fm | m == 0, dim(f2) == dim(m),
 (f2 == ".") == (m == 0))

```

---

generalMatrix-class

*Class "generalMatrix" of General Matrices*

---

**Description**

Virtual class of “general” matrices; i.e., matrices that do not have a known property such as symmetric, triangular, or diagonal.

**Objects from the Class**

A virtual Class: No objects may be created from it.

**Slots**

factors ,

Dim ,

Dimnames: all slots inherited from [compMatrix](#); see its description.

**Extends**

Class "compMatrix", directly. Class "Matrix", by class "compMatrix".

**See Also**

Classes [compMatrix](#), and the non-general virtual classes: [symmetricMatrix](#), [triangularMatrix](#), [diagonalMatrix](#).

---

graph-sparseMatrix *Conversions "graph" <-> (sparse) Matrix*

---

## Description

The **Matrix** package has supported conversion from and to "graph" objects from (Bioconductor) package **graph** since summer 2005, via the usual `as(., "<class>")` coercion,

```
as(from, Class)
```

Since 2013, this functionality is further exposed as the `graph2T()` and `T2graph()` functions (with further arguments than just `from`), which convert graphs to and from the triplet form of sparse matrices (of class "`TsparseMatrix`").

## Usage

```
graph2T(from, use.weights =)
T2graph(from, need.uniq = is_not_uniqT(from), edgemode = NULL)
```

## Arguments

|                          |                                                                                                                                                                                                                                                                                                                                                             |
|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>from</code>        | for <code>graph2T()</code> , an R object of class "graph";<br>for <code>T2graph()</code> , a sparse matrix inheriting from " <code>TsparseMatrix</code> ".                                                                                                                                                                                                  |
| <code>use.weights</code> | logical indicating if weights should be used, i.e., equivalently the result will be numeric, i.e. of class <code>dgTMatrix</code> ; otherwise the result will be <code>ngTMatrix</code> or <code>nsTMatrix</code> , the latter if the graph is undirected. The default looks if there are weights in the graph, and if any differ from 1, weights are used. |
| <code>need.uniq</code>   | a logical indicating if <code>from</code> may need to be internally "uniquified"; do not set this and hence rather use the default, unless you know what you are doing!                                                                                                                                                                                     |
| <code>edgemode</code>    | one of <code>NULL</code> , "directed", or "undirected". The default <code>NULL</code> looks if the matrix is symmetric and assumes "undirected" in that case.                                                                                                                                                                                               |

## Value

For `graph2T()`, a sparse matrix inheriting from "`TsparseMatrix`".

For `T2graph()` an R object of class "graph".

## See Also

Note that the CRAN package **igraph** also provides conversions from and to sparse matrices (of package **Matrix**) via its `graph.adjacency()` and `get.adjacency()`.

## Examples

```
if(isTRUE(try(require(graph)))) { ## super careful .. for "checking reasons"
 n4 <- LETTERS[1:4]; dns <- list(n4,n4)
 show(a1 <- sparseMatrix(i= c(1:4), j=c(2:4,1), x = 2, dimnames=dns))
 show(g1 <- as(a1, "graph")) # directed
 unlist(edgeWeights(g1)) # all '2'

 show(a2 <- sparseMatrix(i= c(1:4,4), j=c(2:4,1:2), x = TRUE, dimnames=dns))
```

```

show(g2 <- as(a2, "graph")) # directed
now if you want it undirected:
show(g3 <- T2graph(as(a2, "TsparseMatrix"), edgemode="undirected"))
show(m3 <- as(g3, "Matrix"))
show(graph2T(g3)) # a "pattern Matrix" (nsTMatrix)

a. <- sparseMatrix(i= 4:1, j=1:4, dimnames=list(n4,n4), giveC=FALSE) # no 'x'
show(a.) # "ngTMatrix"
show(g. <- as(a., "graph"))

}

```

Hilbert

*Generate a Hilbert matrix***Description**

Generate the  $n$  by  $n$  symmetric Hilbert matrix. Because these matrices are ill-conditioned for moderate to large  $n$ , they are often used for testing numerical linear algebra code.

**Usage**

```
Hilbert(n)
```

**Arguments**

$n$  a non-negative integer.

**Value**

the  $n$  by  $n$  symmetric Hilbert matrix as a "dpoMatrix" object.

**See Also**

the class [dpoMatrix](#)

**Examples**

```
Hilbert(6)
```

image-methods

*Methods for image() in Package 'Matrix'***Description**

Methods for function [image](#) in package **Matrix**. An image of a matrix simply color codes all matrix entries and draws the  $n \times m$  matrix using an  $n \times m$  grid of (colored) rectangles.

The **Matrix** package image methods are based on [levelplot\(\)](#) from package **lattice**; hence these methods return an “object” of class "trellis", producing a graphic when (auto-) [print\(\)](#) ed.

## Usage

```
S4 method for signature 'dgTMatrix'
image(x,
 xlim = c(1, di[2]),
 ylim = c(di[1], 1), aspect = "iso",
 sub = sprintf("Dimensions: %d x %d", di[1], di[2]),
 xlab = "Column", ylab = "Row", cuts = 15,
 useRaster = FALSE,
 useAbs = NULL, colorkey = !useAbs,
 col.regions = NULL,
 lwd = NULL, border.col = NULL, ...)
```

## Arguments

|                              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>               | a Matrix object, i.e., fulfilling <code>is(x, "Matrix")</code> .                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>xlim, ylim</code>      | x- and y-axis limits; may be used to “zoom into” matrix. Note that <i>x, y</i> “feel reversed”: <code>ylim</code> is for the rows (= 1st index) and <code>xlim</code> for the columns (= 2nd index). For convenience, when the limits are integer valued, they are both extended by 0.5; also, <code>ylim</code> is always used decreasingly.                                                                                                                            |
| <code>aspect</code>          | aspect ratio specified as number ( <i>y/x</i> ) or string; see <code>levelplot</code> .                                                                                                                                                                                                                                                                                                                                                                                  |
| <code>sub, xlab, ylab</code> | axis annotation with sensible defaults; see <code>plot.default</code> .                                                                                                                                                                                                                                                                                                                                                                                                  |
| <code>cuts</code>            | number of levels the range of matrix values would be divided into.                                                                                                                                                                                                                                                                                                                                                                                                       |
| <code>useRaster</code>       | logical indicating if raster graphics should be used (instead of the tradition rectangle vector drawing). If true, <code>panel.levelplot.raster</code> (from <b>lattice</b> package) is used, and the colorkey is also done via rasters, see also <code>levelplot</code> and possibly <code>grid.raster</code> .<br><br>Note that using raster graphics may often be faster, but can be slower, depending on the matrix dimensions and the graphics device (dimensions). |
| <code>useAbs</code>          | logical indicating if <code>abs(x)</code> should be shown; if TRUE, the former (implicit) default, the default <code>col.regions</code> will be <code>grey</code> colors (and no colorkey drawn). The default is FALSE unless the matrix has no negative entries.                                                                                                                                                                                                        |
| <code>colorkey</code>        | logical indicating if a color key aka ‘legend’ should be produced. Default is to draw one, unless <code>useAbs</code> is true. You can also specify a <code>list</code> , see <code>levelplot</code> , such as <code>list(raster=TRUE)</code> in the case of rastering.                                                                                                                                                                                                  |
| <code>col.regions</code>     | vector of gradually varying colors; see <code>levelplot</code> .                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>lwd</code>             | (only used when <code>useRaster</code> is false:) non-negative number or NULL (default), specifying the line-width of the rectangles of each non-zero matrix entry (drawn by <code>grid.rect</code> ). The default depends on the matrix dimension and the device size.                                                                                                                                                                                                  |
| <code>border.col</code>      | color for the border of each rectangle. NA means no border is drawn. When NULL as by default, <code>border.col &lt;- if (lwd &lt; .01) NA else NULL</code> is used. Consider using an opaque color instead of NULL which corresponds to <code>grid::get.gpar("col")</code> .                                                                                                                                                                                             |
| <code>...</code>             | further arguments passed to methods and <code>levelplot</code> , notably at for specifying (possibly non equidistant) cut values for dividing the matrix values (superseeding <code>cuts</code> above).                                                                                                                                                                                                                                                                  |

**Value**

as all **lattice** graphics functions, `image(<Matrix>)` returns a "trellis" object, effectively the result of `levelplot()`.

**Methods**

All methods currently end up calling the method for the `dgTMatrix` class. Use `showMethods(image)` to list them all.

**See Also**

`levelplot`, and `print.trellis` from package **lattice**.

**Examples**

```
showMethods(image)
If you want to see all the methods' implementations:
showMethods(image, incl=TRUE, inherit=FALSE)

data(CAex)
image(CAex, main = "image(CAex)")
image(CAex, useAbs=TRUE, main = "image(CAex, useAbs=TRUE)")

cCA <- Cholesky(crossprod(CAex), Imult = .01)
See ?print.trellis --- place two image() plots side by side:
print(image(cCA, main="Cholesky(crossprod(CAex), Imult = .01)",
 split=c(x=1,y=1,nx=2, ny=1), more=TRUE)
print(image(cCA, useAbs=TRUE),
 split=c(x=2,y=1,nx=2,ny=1))

data(USCounties)
image(USCounties)# huge
image(sign(USCounties))## just the pattern
how the result looks, may depend heavily on
the device, screen resolution, antialiasing etc
e.g. x11(type="Xlib") may show very differently than cairo-based

Drawing borders around each rectangle;
again, viewing depends very much on the device:
image(USCounties[1:400,1:200], lwd=.1)
Using (xlim,ylim) has advantage : matrix dimension and (col/row) indices:
image(USCounties, c(1,200), c(1,400), lwd=.1)
image(USCounties, c(1,300), c(1,200), lwd=.5)
image(USCounties, c(1,300), c(1,200), lwd=.01)
These 3 are all equivalent :
(I1 <- image(USCounties, c(1,100), c(1,100), useAbs=FALSE))
I2 <- image(USCounties, c(1,100), c(1,100), useAbs=FALSE, border.col=NA)
I3 <- image(USCounties, c(1,100), c(1,100), useAbs=FALSE, lwd=2, border.col=NA)
stopifnot(all.equal(I1, I2, check.environment=FALSE),
 all.equal(I2, I3, check.environment=FALSE))
using an opaque border color
image(USCounties, c(1,100), c(1,100), useAbs=FALSE, lwd=3, border.col = adjustcolor("skyb

if(doExtras <- interactive() || nzchar(Sys.getenv("R_MATRIX_CHECK_EXTRA"))) ||
 identical("true", unname(Sys.getenv("R_PKG_CHECKING_doExtras")))) {
Using raster graphics: For PDF this would give a 77 MB file,
```

```
however, for such a large matrix, this is typically considerably
slower (than vector graphics rectangles) in most cases :
if(doPNG <- !dev.interactive())
 png("image-USCounties-raster.png", width=3200, height=3200)
image(USCounties, useRaster = TRUE) # should not suffer from anti-aliasing
if(doPNG)
 dev.off()
 ## and now look at the *.png image in a viewer you can easily zoom in and out
}#only if(doExtras)
```

index-class

---

*Virtual Class "index" - Simple Class for Matrix Indices*

---

### Description

The class "index" is a virtual class used for indices (in signatures) for matrix indexing and sub-assignment of **Matrix** matrices.

In fact, it is currently implemented as a simple class union ([setClassUnion](#)) of "numeric", "logical" and "character".

### Objects from the Class

Since it is a virtual Class, no objects may be created from it.
